

# AURIX™ TC3xx

## About this document

### Scope and purpose

This User's Manual describes the Infineon AURIX™ TC3xx Platform family, a range of 32-bit multicore microcontrollers based on the Infineon TriCore™ Architecture.

This family document covers the superset functionality. It is supplemented by a separate device specific document "Appendix" that covers differences of a particular device to this family superset.

### Attention

For the devices TC39x-B, TC38x, TC37x, TC37xEXT, TC36x, TC35x, TC3Ex, TC33x/TC32x and TC33xEXT this set of documentation was released as User's Manual V1.5.0.

For the device TC3Ax this set of documentation qualifies only as Target Specification.

## Table of Contents

<b>About this document.....</b>	<b>Preface-1</b>
<b>Table of Contents .....</b>	<b>TOC-1</b>
<b>1 Introduction .....</b>	<b>1-1</b>
1.1 About this Document .....	1-1
1.1.1 Related Documentations .....	1-1
1.1.2 Text Conventions .....	1-1
1.1.3 Family Specification and Appendix .....	1-2
1.1.4 Register and Memory Address Documentation .....	1-2
1.1.5 Reserved, Undefined, and Unimplemented Terminology .....	1-3
1.1.6 Register Access Modes .....	1-3
1.1.7 Register Reset Documentation .....	1-5
1.1.8 Abbreviations and Acronyms .....	1-7
1.2 System Architecture of the AURIX™ TC3xx Platform .....	1-10
1.2.1 AURIX™ TC3xx Platform High End – TC39x .....	1-11
1.2.2 AURIX™ TC3xx Platform - Family Overview .....	1-12
1.2.2.1 TC38x Block Diagram .....	1-20
1.2.2.2 TC37xEXT Block Diagram .....	1-21
1.2.2.3 TC37x Block Diagram .....	1-22
1.2.2.4 TC36x Block Diagram .....	1-23
1.2.2.5 TC35x Block Diagram .....	1-24
1.2.2.6 TC33xEXT Block Diagram .....	1-25
1.2.2.7 TC33x Block Diagram .....	1-26
1.2.2.8 TC3Ex Block Diagram .....	1-27
1.2.2.9 TC3Ax Block Diagram .....	1-28
1.2.3 Variants .....	1-29
1.2.3.1 Encoding of the Product Name .....	1-29
1.2.3.2 Emulation Devices .....	1-31
1.2.3.3 TC32x .....	1-31
1.2.3.4 TC39x With Feature Package “P” .....	1-32
1.2.4 Revision History .....	1-32
1.3 On-Chip Debug Support (OCDS) .....	1-35
1.3.1 Introduction .....	1-35
1.3.2 Feature List .....	1-36
1.3.3 Family Overview .....	1-39
1.3.4 Tool Interface Recommendations .....	1-39
1.3.5 Debug Access Server (DAS) .....	1-40
1.3.6 Revision History .....	1-40
1.4 Emulation Device (ED) .....	1-41
1.4.1 Block Diagram .....	1-42
1.4.2 Feature List .....	1-44
1.4.3 Comparison to AURIX Emulation Devices .....	1-46
1.4.4 Trace Source Multiplexer .....	1-47
1.4.4.1 TMUX Setting Options .....	1-47
1.4.4.2 Trace Source Multiplexer in CPU Subsystem (TCMUX) .....	1-48
1.4.4.3 Parallel Trace Use Cases .....	1-49
1.4.5 DAP ED Interface (DAPE) .....	1-50
1.4.6 Revision History .....	1-51

1.5	Software over the Air (SOTA) .....	1-52
1.5.1	Overview .....	1-52
1.5.2	Functional Description .....	1-52
1.5.2.1	Performance considerations .....	1-52
1.5.2.2	Configuring for SOTA .....	1-52
1.5.2.2.1	Configuration parameters .....	1-53
1.5.2.2.2	Initial device configuration for SOTA .....	1-53
1.5.2.2.3	Runtime SWAP configuration .....	1-54
1.5.3	Safety .....	1-57
1.5.4	Security .....	1-57
1.5.5	Revision History .....	1-57
<b>2</b>	<b>Memory Maps (MEMMAP)</b> .....	<b>2-1</b>
2.1	Feature List .....	2-1
2.2	Overview .....	2-1
2.3	Functional Description .....	2-2
2.3.1	Segments .....	2-2
2.3.2	Address Map of the On Chip Bus System .....	2-3
2.3.2.1	Segments 0 to 14 .....	2-3
2.3.2.2	Segment 15 .....	2-14
2.3.3	Memory Accesses .....	2-22
2.4	Revision History .....	2-23
<b>3</b>	<b>AURIX™ TC3xx Platform Firmware</b> .....	<b>3-1</b>
3.1	Functional description .....	3-1
3.1.1	Startup Software .....	3-1
3.1.1.1	Events triggering SSW execution .....	3-1
3.1.1.1.1	Cold (initial) power-on reset .....	3-1
3.1.1.1.2	System reset .....	3-2
3.1.1.1.3	Application reset .....	3-2
3.1.1.2	Clock system during start-up .....	3-2
3.1.1.3	RAM overwrite during start-up .....	3-3
3.1.1.4	Stand-by controller handling during start-up .....	3-3
3.1.1.5	Boot Options Summary .....	3-3
3.1.1.6	Boot Mode evaluation sequence .....	3-4
3.1.1.6.1	Evaluation of Boot Mode Headers .....	3-4
3.1.1.6.2	Alternate Boot Mode evaluation .....	3-9
3.1.1.6.3	Processing in case no valid BMHD found .....	3-11
3.1.1.6.4	Processing in case no Boot Mode configured by SSW .....	3-12
3.1.1.7	Startup Software Main Flow .....	3-14
3.1.1.7.1	Flash ramp-up .....	3-15
3.1.1.7.2	Device Configuration .....	3-15
3.1.1.7.3	RAM Initialization .....	3-15
3.1.1.7.4	Select and execute Startup Modes .....	3-15
3.1.1.7.5	LBIST execution .....	3-15
3.1.1.7.6	Lockstep configuration .....	3-16
3.1.1.7.7	Debug System handling .....	3-16
3.1.1.7.8	ESR0 pin handling .....	3-17
3.1.1.7.9	Ending the SSW and Starting the User Code .....	3-17
3.1.2	Checker Software .....	3-19
3.1.2.1	CHSW execution flow .....	3-19

3.1.2.2	Checks performed by CHSW and exit information .....	3-20
3.1.2.3	Checker Software exit information for ALL CHECKS PASSED .....	3-22
3.1.3	Bootstrap Loaders .....	3-23
3.1.3.1	ASC Bootstrap loader .....	3-23
3.1.3.2	CAN Bootstrap loader .....	3-24
3.1.3.2.1	CAN BSL summary .....	3-24
3.1.3.2.2	Clock system during CAN BSL .....	3-24
3.1.3.2.3	CAN BSL usage after application reset .....	3-25
3.1.3.2.4	Supported CAN features .....	3-25
3.1.3.2.5	CAN BSL flow .....	3-26
3.1.4	Support for Software over the Air (SOTA) .....	3-30
3.1.5	Shutdown request handler .....	3-30
3.1.6	Power Supply Friendly Debug Monitor .....	3-31
3.2	Registers .....	3-32
3.2.1	Firmware specific usage of device registers .....	3-32
3.2.1.1	Registers providing information on the boot selections .....	3-32
3.2.1.2	Registers providing information on the Checker Software activity .....	3-34
3.3	Revision History .....	3-43
<b>4</b>	<b>On-Chip System Connectivity {and Bridges} .....</b>	<b>4-1</b>
4.1	Feature List .....	4-2
4.1.1	What is new in the SRI Fabric .....	4-2
4.2	Overview .....	4-2
4.3	Functional Description .....	4-5
4.3.1	Operational Overview .....	4-5
4.3.1.1	Master Connection Interface (MCI) .....	4-6
4.3.1.2	Slave Connection Interface (SCI) .....	4-6
4.3.1.3	Slave Arbiter .....	4-6
4.3.1.4	Default Slave .....	4-7
4.3.1.5	OnLine Data Acquisition (OLDA) .....	4-7
4.3.1.6	Control and Status Register Access Protection .....	4-8
4.3.2	Arbitration Details .....	4-8
4.3.2.1	Master Request Arbitration .....	4-8
4.3.3	SRI Errors .....	4-11
4.3.3.1	SRI Protocol Errors .....	4-11
4.3.3.2	SRI Transaction ID Errors .....	4-11
4.3.3.3	SRI EDC Errors .....	4-12
4.3.3.4	Error Handling .....	4-12
4.3.3.5	Error Tracking Capability .....	4-13
4.3.3.6	Indication Event Interactions .....	4-14
4.3.3.7	Releasing the lock from registers ERR and ERRADD .....	4-14
4.3.4	Implementation of the SRI Fabric .....	4-14
4.3.4.1	Mapping of SRI Masters to Domain 0 Master Interfaces .....	4-15
4.3.4.2	Mapping of SRI Slaves to Domain 0 Slave Interfaces .....	4-16
4.3.4.3	Mapping of SRI Masters to Domain 1 Master Interfaces .....	4-17
4.3.4.4	Mapping of SRI Slaves to Domain 1 Slave Interfaces .....	4-17
4.3.4.5	Mapping of SRI Masters to Domain 2 Master Interfaces .....	4-17
4.3.4.6	Mapping of SRI Slaves to Domain 2 Slave Interfaces .....	4-18
4.4	Registers .....	4-18
4.4.1	Domain Common Registers .....	4-20

4.4.2	SCI Control Registers .....	4-25
4.5	S2S Bridge .....	4-29
4.5.1	EDC Errors .....	4-29
4.5.2	Protocol Errors .....	4-29
4.5.3	Transaction ID Errors .....	4-29
4.5.4	Transaction Errors for Writes via S2S Bridge .....	4-29
4.6	SFI_F2S Bridge .....	4-30
4.6.1	Functional Overview .....	4-30
4.7	SFI_S2F Bridge .....	4-31
4.7.1	Functional Overview .....	4-31
4.8	Resource Access Times .....	4-31
4.9	Revision History .....	4-34
4.10	FPI Interconnect .....	4-35
4.10.1	Feature List .....	4-35
4.10.1.1	Delta to TC2xx .....	4-36
4.10.2	Overview .....	4-36
4.10.2.1	Bus Transaction Types .....	4-36
4.10.2.2	Reaction of a Busy Slave .....	4-37
4.10.2.3	Address Alignment Rules .....	4-37
4.10.2.4	FPI Bus Basic Operations .....	4-37
4.10.3	Functional Description (SBCU, EBCU) .....	4-38
4.10.3.1	FPI Bus Arbitration .....	4-38
4.10.3.1.1	Arbitration on the System Peripheral Bus .....	4-39
4.10.3.1.2	Default Master .....	4-39
4.10.3.1.3	Arbitration Algorithms .....	4-39
4.10.3.2	FPI Bus Error Handling .....	4-40
4.10.4	FPI Bus Integrity Support .....	4-41
4.10.4.1	Safety Support .....	4-43
4.10.4.2	FPI EDC Overview .....	4-45
4.10.4.3	Error Injection .....	4-46
4.10.4.4	SPB: Mapping of ALARM signals to SBCU_ALSTATx and SBCU_ALCLRx registers .....	4-46
4.10.4.5	BBB: Mapping of ALARM signals to EBCU_ALSTATx and EBCU_ALCLRx registers .....	4-49
4.10.5	Debug .....	4-51
4.10.5.1	Address Trigger .....	4-51
4.10.5.2	Signal Status Trigger .....	4-52
4.10.5.3	Grant Trigger .....	4-53
4.10.5.4	Combination of Trigger Events .....	4-54
4.10.5.5	BCU Breakpoint Generation Examples .....	4-54
4.10.6	Registers .....	4-56
4.10.6.1	Registers Description .....	4-57
4.10.6.2	System Registers .....	4-73
4.10.6.3	Register Access Protection (ACCEN1/0) .....	4-74
4.10.6.4	Kernel Reset Registers (KRST1/0, KRSTCLR) .....	4-75
4.10.6.5	Clock Control Register (CLC) .....	4-75
4.10.6.6	OCDS Control and Status Register (OCS) .....	4-75
4.10.7	On Chip Bus Master TAG Assignments .....	4-75
4.10.8	Revision History .....	4-77
<b>5</b>	<b>CPU Subsystem .....</b>	<b>5-1</b>
5.1	Feature List .....	5-2

5.2	Overview .....	5-4
5.2.1	CPU Diagram .....	5-5
5.2.2	Instruction Fetch Unit .....	5-5
5.2.3	Execution Unit .....	5-6
5.2.4	General Purpose Register File .....	5-7
5.3	Functional Description .....	5-7
5.3.1	Summary of functional changes from AURIX .....	5-7
5.3.2	Summary of changes from TC39x A-Step .....	5-8
5.3.3	AURIX™ Family CPU configurations .....	5-9
5.3.4	CPU Implementation-Specific Features .....	5-12
5.3.4.1	Context Save Areas / Context Operations .....	5-12
5.3.4.2	Program Counter (PC) Register .....	5-12
5.3.4.3	Store Buffers .....	5-12
5.3.4.4	Interrupt System .....	5-14
5.3.4.5	Trap System .....	5-14
5.3.4.6	WAIT Instruction .....	5-15

11.5.1	Changes from AURIX 2G PMS V2.2.19 onwards .....	11-200

<b>12</b>	<b>Power Management System for Low-End (PMSLE) .....</b>	<b>12-1</b>
12.1	Overview .....	12-2
12.2	Functional Description .....	12-2
12.2.1	Power Supply Infrastructure and Supply Start-up .....	12-2
12.2.1.1	Supply Mode Selection .....	12-2
12.2.1.2	Supply Ramp-up and Ramp-down Behavior .....	12-9
12.2.1.2.1	Single Supply mode (a) .....	12-9
12.2.1.2.2	Single Supply mode (e) .....	12-11
12.2.1.2.3	External Supply mode (d) .....	12-13
12.2.1.2.4	External Supply mode (h) .....	12-15
12.2.1.2.5	EVRC, VCAPx behavior during Start-up .....	12-17
12.2.1.3	PMS Infrastructure Components .....	12-18
12.2.1.3.1	Independent VEVRSB & VDDPD Supply domain and EVR Pre-Regulator (EVRPR) .....	12-18
12.2.1.3.2	Reference Voltage Generation : Secondary Bandgap Reference (SHPBG) .....	12-18
12.2.1.3.3	100 MHz Back-up Clock Source (fBACK) .....	12-18
12.2.1.4	Die Temperature Measurement .....	12-20
12.2.2	Power Supply Generation and Monitoring .....	12-21
12.2.2.1	Linear Regulator Mode (EVR33) .....	12-21
12.2.2.2	Switch Capacitor Regulator (EVRC) .....	12-22
12.2.2.2.1	EVRC Supply Pins .....	12-26
12.2.2.2.2	VDD Connectivity .....	12-28
12.2.2.2.3	EVRC Frequency and Phase Synchronization to CCU6/GTM Input .....	12-29
12.2.2.3	Components and Layout .....	12-32
12.2.2.4	External Supply Modes .....	12-33
12.2.2.5	Supply Voltage Monitoring .....	12-35
12.2.2.5.1	Primary under-voltage monitors and Cold PORST .....	12-36
12.2.2.5.2	Secondary over- and under-voltage monitors and alarm generation .....	12-38
12.2.2.5.3	Power Built In Self Test at Start-up (PBIST) .....	12-44
12.2.2.5.4	Secondary Monitor and Standby SMU Built in Self Test (MONBIST) .....	12-44
12.2.2.6	Interrupts .....	12-46
12.2.2.7	OCDS Trigger Bus (OTGB) Interface .....	12-47
12.2.2.7.1	ADC Monitor and Voltage Trigger Sets .....	12-47
12.2.2.7.2	EVR Control output Trigger Sets .....	12-48
12.2.3	Power Management .....	12-49
12.2.3.1	Power Management Overview .....	12-49
12.2.3.2	Idle Mode .....	12-53
12.2.3.2.1	Entering Idle Mode: .....	12-53
12.2.3.2.2	State during Idle mode .....	12-53
12.2.3.2.3	Exiting Idle mode .....	12-54
12.2.3.3	Sleep Mode .....	12-54
12.2.3.3.1	Entering Sleep Mode .....	12-54
12.2.3.3.2	State during Sleep Mode .....	12-55
12.2.3.3.3	Exiting Sleep Mode .....	12-57
12.2.3.4	Standby Mode .....	12-59
12.2.3.4.1	Standby Mode with only VEVRSB domain supplied and VEXT domain switched off .....	12-59
12.2.3.4.2	Standby Mode with both VEXT and VEVRSB supplied via common supply rail. ....	12-60
12.2.3.4.3	Standby RAM .....	12-61
12.2.3.4.4	VEXT Supply Monitor .....	12-61
12.2.3.4.5	Pin Wake-up Unit .....	12-61
12.2.3.4.6	Standby ContolleR (SCR) Interface .....	12-62

12.2.3.4.7	Wake-up Timer (WUT) .....	12-63
12.2.3.4.8	Entering Standby Mode (only VEVRSB domain supplied) .....	12-66
12.2.3.4.9	Entering Standby Mode (both VEVRSB and VEXT domain supplied) .....	12-69
12.2.3.4.10	State during Standby Mode .....	12-70
12.2.3.4.11	Exiting Standby Mode - Wake-up event .....	12-70
12.2.3.4.12	Exiting Standby Mode - Power Fail or Reset event .....	12-73
12.2.3.5	Load Jump Sequencing and Voltage Droop .....	12-74
12.2.3.6	Core Die Temperature Sensor (DTSC) .....	12-77
12.3	Registers .....	12-78
12.3.1	Register Access Modes .....	12-78
12.3.2	Power Management Control Registers (PMS) .....	12-80
12.3.2.1	Safety Flip-Flops .....	12-82
12.3.2.2	Power Supply Generation and Monitoring Control Registers .....	12-83
12.3.2.3	Die Temperature Sensor Registers .....	12-146
12.3.2.4	Standby and Wake-up Control Registers .....	12-149
12.3.2.5	OCDS Trigger Bus Configuration Registers (OTGB) .....	12-169
12.3.2.6	SMU Registers .....	12-174
12.3.3	Power Management Control Registers (SCU) .....	12-175
12.3.3.1	Power Management Control and Status Registers .....	12-175
12.4	IO Interfaces .....	12-193
12.5	Revision History .....	12-195
12.5.1	Changes from AURIX TC33x PMS V1.0.1 Onwards .....	12-195
<b>13</b>	<b>Memory Test Unit (MTU)</b> .....	<b>13-1</b>
13.1	Feature List .....	13-1
13.2	Overview .....	13-1
13.3	Functional Description .....	13-2
13.3.1	Major Functional Changes from TC39xA-Step to TC39XB-Step / TC38XA-Step .....	13-2
13.3.2	SRAM Support Hardware (SSH) .....	13-3
13.3.3	Control and Status Interfaces .....	13-3
13.3.3.1	Interface to the CPU .....	13-3
13.3.4	Enabling the SRAM Support Hardware (SSH) .....	13-4
13.3.4.1	Security-Sensitive Memories and AutoInitialization .....	13-4
13.3.4.1.1	Security Applications .....	13-5
13.3.4.1.2	Non-Security Applications .....	13-5
13.3.4.2	Memory Map selection .....	13-5
13.3.5	SRAM Support Hardware (SSH) Operation .....	13-5
13.3.5.1	Memory Testing and Initialization .....	13-6
13.3.5.1.1	Starting a Memory Test Sequence .....	13-6
13.3.5.1.2	Memory Test Done Interrupt .....	13-6
13.3.5.1.3	Getting Detailed Memory Test Results .....	13-6
13.3.5.1.4	Filling a Memory with Defined Contents .....	13-7
13.3.5.1.5	Initializing SRAMs .....	13-7
13.3.5.1.6	Reading a Single Memory Location .....	13-9
13.3.5.1.7	Writing to a Single Memory Location .....	13-9
13.3.6	Resets and Clocks in the MTU, SSH & SRAM .....	13-9
13.3.6.1	Clock Domains .....	13-9
13.3.6.2	Reset Domains .....	13-10
13.3.6.2.1	Alarm Handling after Reset .....	13-10
13.3.7	SRAM Addressing and Scrambling .....	13-11

13.3.8	MBIST Algorithms .....	13-11
13.3.8.1	Non-Destructive Test (NDT) .....	13-11
13.4	Registers .....	13-14
13.4.1	Registers Overview .....	13-16
13.4.2	Register Description .....	13-18
13.4.2.1	System Registers .....	13-18
13.4.2.2	MTU Configuration Registers .....	13-20
13.4.2.3	SRAM Support Hardware (SSH) Registers .....	13-24
13.5	Safety Measures .....	13-41
13.5.1	Safety Features .....	13-41
13.5.1.1	SRAM Error Detection & Correction (EDC/ECC) .....	13-41
13.5.1.2	Address Error Monitor .....	13-42
13.5.1.3	SRAM Mux Factor .....	13-42
13.5.1.4	Error Tracking Registers .....	13-42
13.5.1.5	Safety Flip-Flops .....	13-43
13.5.2	Safety Notifications .....	13-43
13.5.2.1	Alarm Handling .....	13-45
13.5.2.1.1	Alarms after startup .....	13-46
13.5.2.1.2	Diagnostics .....	13-46
13.5.2.1.3	Error Mapping .....	13-47
13.5.2.1.4	Error Injection and Alarm Triggering .....	13-48
13.6	Revision History .....	13-49
<b>14</b>	<b>General Purpose I/O Ports and Peripheral I/O Lines (Ports) .....</b>	<b>14-1</b>
14.1	Feature List .....	14-1
14.2	Overview .....	14-1
14.3	Functional Description .....	14-3
14.3.1	System Connectivity of Ports .....	14-3
14.4	Registers .....	14-5
14.4.1	Module Identification Register .....	14-7
14.4.2	Port Input/Output Control Registers .....	14-8
14.4.3	Pad Driver Mode Register .....	14-12
14.4.4	LVDS Pad Control Register .....	14-15
14.4.5	Pin Function Decision Control Register .....	14-18
14.4.6	Pin Controller Select Register .....	14-19
14.4.7	Port Output Register .....	14-20
14.4.8	Port Output Modification Register .....	14-21
14.4.9	Port Output Modification Set Register .....	14-22
14.4.10	Port Output Modification Set Registers .....	14-23
14.4.11	Port Output Modification Clear Register .....	14-26
14.4.12	Port Output Modification Clear Registers .....	14-27
14.4.13	Emergency Stop Register .....	14-30
14.4.14	Port Input Register .....	14-31
14.4.15	Access Protection Registers .....	14-32
14.5	Revision History .....	14-34
<b>15</b>	<b>Safety Management Unit (SMU) .....</b>	<b>15-1</b>
15.1	Feature List .....	15-2
15.2	Overview .....	15-2
15.2.1	Architecture .....	15-4
15.2.2	SMU_core .....	15-5

15.2.3	SMU_stdby .....	15-5

## Introduction

# 1 Introduction

This User's Manual describes the Infineon AURIX™ TC3xx Platform, a range of 32-bit multicore microcontrollers based on the Infineon TriCore Architecture.

## 1.1 About this Document

This document is designed to be read primarily by potential users of a AURIX™ TC3xx Platform product who need a detailed description of the products and their functional units.

### 1.1.1 Related Documentations

A complete description of the TriCore architecture is found in the document entitled “TriCore Architecture Manual”. The architecture of the TriCore is described separately this way because of the configurable nature of the TriCore specification: different versions of the architecture may contain a different mix of systems components. The TriCore architecture, however, remains constant across all derivative designs in order to preserve compatibility.

This User's Manual should be read in conjunction with the “TriCore Architecture Manual”.

### 1.1.2 Text Conventions

This document uses the following text conventions for named components:

- Functional units are given in plain UPPER CASE. For example: “The QSPI supports full-duplex and half-duplex synchronous communication”.
- Pins using negative logic are indicated by an overline. For example: “The external reset pin, ESR0, has a dual function”.
- Bit fields and bits in registers are in general referenced as “Module\_Register name.Bit field” or “Module\_Register name.Bit”. For example: “The Current CPU Priority Number bit field CPU\_ICR.CCPN is cleared”. Most of the register names contain a module name prefix, separated by an underscore character “\_” from the actual register name (for example, “QSPI0\_GLOBALCON”, where “QSPI0” is the module name prefix, and “GLOBALCON” is the kernel register name). In chapters describing the kernels of the peripheral modules, the registers are mainly referenced with their kernel register names. The peripheral module implementation sections mainly refer to the actual register names with module prefixes.
- Variables used to describe sets of processing units or registers appear in mixed upper and lower cases. For example, register name “MOFCRn” refers to multiple “MOFCR” registers with variable n. The bounds of the variables are always given where the register expression is first used (for example, “n = 0-255”), and are repeated as needed in the rest of the text.
- The default radix is decimal. Hexadecimal constants are suffixed with a subscript letter “H”, as in: 100<sub>H</sub>. Binary constants are suffixed with a subscript letter “B”, as in: 111<sub>B</sub>.
- When the extent of register fields, groups register bits, or groups of pins are collectively named in the body of the document, they are represented as “NAME[A:B]”, which defines a range for the named group from A to B. Individual bits, signals, or pins are given as “NAME[C]” where the range of the variable C is given in the text. For example: CFG[2:0] and SRPN[0].
- Units are abbreviated as follows:
  - **MHz** = Megahertz
  - **µs** = Microseconds
  - **kBaud, kbit/s** = 1000 characters/bits per second
  - **MBaud, Mbit/s** = 1000000 characters/bits per second
  - **Kbyte, KB** = 1024 bytes of memory

## Introduction

- **Mbyte**, MB= 1048576 bytes of memory  
In general, the k prefix scales a unit by 1000 whereas the K prefix scales a unit by 1024. Hence, the Kbyte unit scales the expression preceding it by 1024. The kBaud unit scales the expression preceding it by 1000. The M prefix scales by 1000000 or 1048576, and  $\mu$  scales by .000001. For example, 1 Kbyte is 1024 bytes, 1 Mbyte is  $1024 \times 1024$  bytes, 1 kBaud/kbit are 1000 characters/bits per second, 1 MBaud/Mbit are 1000000 characters/bits per second, and 1 MHz is 1000000 Hz.
- Data format quantities are defined as follows:
  - **Byte** = 8-bit quantity
  - **Half-word** = 16-bit quantity
  - **Word** = 32-bit quantity
  - **Double-word** = 64-bit quantity

### 1.1.3 Family Specification and Appendix

The User's Manual is split into a "Family" part (named "AURIXTC3XX\_\*) and an "Appendix" per silicon.

The Family part describes each module used in this family of devices. It is intended as reference for the human reader to understand functionality and register set of these modules. Additionally it contains a family wide address map, a feature set table and all block diagrams.

The Appendix describes differences of a module implementation for a certain device series. Its content is usually supplied by tools (e.g. compiler, debugger, configuration tools). These differences are usually device connectivity (connections to pins or other modules), the Register Address Space (i.e. a list of implemented modules and their address ranges) and specific register implementations like bit fields that are only functional in certain devices. Registers that are identical to the Family part contain a cross reference to the Family documentation.

When bus interfaces are shared between modules (e.g. for SCU, CCU, PMS) the Appendix is also shared to allow an accurate listing of all registers in a certain address range.

### 1.1.4 Register and Memory Address Documentation

Some modules enable through their bus interface access to memory ranges and registers. In these cases the "Register Address Space" table shows memories differently, for example:

**Table 1 Register Address Space - LMU\_DAM**

Module	Base Address	End Address	Note
(DAM0)	90400000 <sub>H</sub>	9040FFFF <sub>H</sub>	DAM RAM Access cached address space
	B0400000 <sub>H</sub>	B040FFFF <sub>H</sub>	DAM RAM Access non-cached address space
DAM0	F8500000 <sub>H</sub>	F8507FFF <sub>H</sub>	Special Function Register Address Space

In this example "LMU\_DAM" notifies the module name. In the first column "(DAM0)" and all following rows with empty Module field contain memory ranges accessible by this module instance DAM0. The row showing "DAM0" in the first column contains the address range definition of the DAM0 registers.

The following "Register Overview" table lists all registers with offset addresses based on the row containing "DAM0".

If the LMU\_DAM has multiple instances (e.g. DAM0, DAM1) then the table has further rows with "(DAM1)" for memories and "DAM1" as base address for the registers.

## Introduction

### 1.1.5 Reserved, Undefined, and Unimplemented Terminology

In tables where register bit fields are defined, the following conventions are used to indicate undefined and unimplemented function. Furthermore, types of bits and bit fields are defined using the abbreviations as shown in [Table 2](#).

**Table 2 Bit Function Terminology**

Function of Bits	Description
<b>Unimplemented, Reserved</b>	Register bit fields named <b>0</b> indicate unimplemented functions with the following behavior: <ul style="list-style-type: none"><li>• Reading these bit fields returns 0.</li><li>• These bit fields should be written with 0 if the bit field is defined as <b>r</b> or <b>rh</b>.</li><li>• These bit fields have to be written with 0 if the bit field is defined as <b>rw</b>.</li></ul> These bit fields are reserved. The detailed description of these bit fields can be found in the register descriptions.
<b>rw</b>	The bit or bit field can be read and written.
<b>rwh</b>	As <b>rw</b> , but bit or bit field can be also set or reset by hardware.
<b>r</b>	The bit or bit field can only be read (read-only).
<b>w, wX</b>	The bit or bit field can only be written (write-only). A read of this register will always give a default value back that is described in the register documentation.
<b>w0, w1</b>	The bit or bit field can only be written (write-only). A read of this register will always give the value 0 or 1 back.
<b>r0, r1</b>	The bit or bit field can only be read. The read value is 0 or 1.
<b>rh</b>	This bit or bit field can be modified by hardware (read-hardware, typical example: status flags). A read of this bit or bit field give the actual status of this bit or bit field back. Writing to this bit or bit field has no effect on the setting of this bit or bit field.
<b>s</b>	Bits with this attribute are “sticky” in one direction. If their reset value is once overwritten by software, they can be switched again into their reset state only by a reset operation. Software cannot switch this type of bit into its reset state by writing the register. This attribute can be combined to “rws” or “rwhs”.
<b>f</b>	Bits with this attribute are readable only when they are accessed by an instruction fetch. Normal data read operations will return other values.

### 1.1.6 Register Access Modes

Read and write access to registers and memory locations are sometimes restricted. In memory and register access tables, the terms as defined in [Table 3](#) are used.

In general, if an access type is not permitted under these rules (e.g. attempted write to R, attempted user mode access to SV, attempted access to E without Endinit, etc.) then a **Bus Error** will result, unless the access is also marked as nBE (or otherwise stated in the specific module chapter).

Other special access restrictions may apply in some modules. These will be described within the module chapters.

## Introduction

**Table 3 Access Terms**

Symbol	Description
BE	Always returns Bus Error (e.g. used on Write Access to indicate a read-only register)
CPUx	Access only by CPUx (identified by its bus master id).
CEy	Access only when CPUy ENDINIT is not active (SCU_WDTCPUyCON0.ENDINIT = 0)
E	Access only when any CEx is inactive (SCU_WDTCPUxCON0.ENDINIT = 0 for any CPUx), or SCU_EICON0.ENDINIT = 0
H	Access only from HSM Master (and Cerberus, if HSM Debug is enabled) when DFLASH1 is HSM Exclusive (DMU_SP_PROCONHSMCFG.HSMDX is set)
M	Marks module specific access condition which is described in the module's chapter
OEN	Access only when OCDS is enabled
P	Access only from Master x (when MOD_ACCEN0.ENx = 1)
P0	Access only from Master x (when MOD_ACCEN00.ENx = 1) <sup>1)</sup>
P1	Access only from Master x (when MOD_ACCEN10.ENx = 1) <sup>1)</sup>
Pr	Access only from Master x (when MOD_ACCENr0.ENx or MOD_ACCENr1.ENx = 1) <sup>2)</sup>
P00/P01	Access only from Master x (when MOD_ACCEN0/01.ENx = 1, i.e. r=0) <sup>2)</sup>
PW	Access only when correct Password
SE	Access only when Safety Endinit is inactive (SCU_WDTSCON0.ENDINIT = 0 or SCU_SEICON.ENDINIT = 0)
ST	Access only when startup (SSW) executes
SV	Access only for when Supervisor Mode is active on the bus.
TM	Access only when SCU test mode
U	Access only when User Mode is active on the bus.
32	Access only when 32-bit width
32,64	Access only when 32-bit or 64-bit width

1) Different definition in IR module, also defining "P1" and "P2".

2) Definitions used in DMA module to separate resource partitions "r".

**Table 4 Combined Access Conditions**

Symbol	Description
U, SV	U or SV
P, U, SV	P and (U or SV)
P, SV, E	P and SV and E
SV, SE	SV and SE
TM, ST	TM or ST

More complicated Access Conditions (e.g. write access depending on value of other register) described in text or separate "Access Mode Restrictions" tables.

**Introduction****Table 5 Other Register Annotations**

<b>Symbol</b>	<b>Description</b>
nBE	Indicates that no Bus Error is generated when accessing this address range, even though it is either an access to an undefined address or the access does not follow the given rules.
nE	Indicates that no Error is generated when accessing this address or address range, even though the access is to an undefined address or address range. True for CPU accesses (MTCR/MFCR) to undefined addresses in the CSFR range.

**1.1.7 Register Reset Documentation**

From application point of view the register reset value is the initial content of the register upon application start. In addition to the documented hardware reset types (see headline “Reset Types” in chapter “Reset Control Unit (RCU)”) also the Startup Software can affect the initial content. Finally the resulting content may depend on conditions. Reset tables linked to the register definition convey this information.

In the following example “LVD Reset” and “Cold PORST” are hardware reset types and “After SSW execution” shows that the SSW overwrites this register with a different value:

**Table 6 Reset Values of <Name of Register>**

<b>Reset Type</b>	<b>Reset Value</b>	<b>Note</b>
LVD Reset	0059 7F4A <sub>H</sub>	
Cold PORST	0059 7F4A <sub>H</sub>	
After SSW execution	005C 834A <sub>H</sub>	

The following Reset Type definitions can be found in this documentation:

**Table 7 Defined Reset Types**

<b>Reset Type</b>	<b>Description</b>
Application Reset	see RCU chapter
PowerOn Reset	see RCU chapter
System Reset	see RCU chapter
Cold PowerOn Reset	see RCU chapter. Also abbreviated “Cold PORST”.
Warm PowerOn Reset	see RCU chapter. Also abbreviated “Warm PORST”.
Debug Reset	see RCU chapter. Also name “Debug Clear”.
LVD Reset	Low Voltage Detector reset, see PMS chapter.
Kernel Reset	Module internal hardware reset triggered with KRST0 and KRST1 registers. Also named “Module Reset”.
other name	Module specific reset type described in respective chapter usually, among them: <ul style="list-style-type: none"> <li>• IOClient Reset (OCDS)</li> <li>• MCDS Reset (MiniMCDS)</li> <li>• DPLL_RAM_INI.INIT... (GTM)</li> <li>• Generated Reset (SCR)</li> </ul>

---

## Introduction

**Table 7    Defined Reset Types (cont'd)**

<b>Reset Type</b>	<b>Description</b>
CFS Value	Indicating that CFS or UCB contain a reference value for this register. This value can be copied automatically by hardware or SSW into the register or application software has to perform the copying. Details are described in the respective chapter.
Default Flash	Indicating values in a Flash location (UCB or CFS) that are contained at delivery time.
After SSW execution	Register overwritten by SSW.

The “Reset Value” column may contain letter “-” and “X” to indicate bits or nibbles that are either not affected by this reset type or are changed to a value not known at design time (e.g. trimming value).

The “Note” column may describe further conditions when this particular value is applied.

---

## Introduction

### 1.1.8 Abbreviations and Acronyms

The following acronyms and terms are used in this document:

**Table 8 Abbreviations and Acronyms**

Acronym	Description
ADAS	Advanced Driver Assistance System
ADC	Analog-to-Digital Converter
ALU	Arithmetic and Logic Unit
ASCLIN	Asynchronous/Synchronous Serial Controller with LIN
BBB	Back Bone Bus
BCU	Bus Control Unit
BROM	Boot ROM & Test ROM
CAN	Controller Area Network
CIF	Camera (and ADC) Interface
CCU	Clock Control Unit
CPU	Central Processing Unit
CRC	Cyclic Redundancy Code
CSA	Context Save Area
CSFR	Core Special Function Register
CCU6	Capture Compare Unit 6
DAM	Default Application Memory
DAP	Device Access Port
DAS	Device Access Server
DPI	Direct Processor Interface (to Local Flash Bank)
DCACHE	Data Cache
DFLASH (or DF)	Data Flash Memory
DLMU	Direct-connected Local Memory Unit
DMA	Direct Memory Access
DMBI	Data Memory Bus Interface
DMI	Data Memory Interface
DMU	Data Memory Unit
DRLB	Data Read Line Buffer
DSPR	Data Scratchpad RAM
EBU	External Bus Interface
ECC	Error Correction Code
ED	Emulation Device
EDSADC	Enhanced Delta-Sigma Analog to Digital Converter
EVADC	Enhanced Versatile Analog-to-Digital Converter
EMI	Electro-Magnetic Interference
ERAY	Flexray Controller

---

## Introduction

**Table 8 Abbreviations and Acronyms (cont'd)**

<b>Acronym</b>	<b>Description</b>
EtherMAC	Ethernet Media Access Controller
EVR	Embedded Voltage Regulator
FCE	Flexible CRC Engine
FCOMP	Fast Comparator
FM-PLL	PLL with Frequency Modulation support
FPI	Flexible Peripheral Interconnect (Bus protocol)
FPU	Floating Point Unit
FSM	Finite State Machine
GPIO	General Purpose Input/Output
GPT12	General Purpose Timer 12
GTM	Generic Timer Module
HSM	Hardware Security Module
HSPDM	High Speed Pulse Density Modulator
HSSL	High Speed Serial Link
I2C	Inter-Integrated Circuit Controller
I/O	Input / Output
IOM	I/O Monitor Unit
IR	Interrupt Router
JTAG	Joint Test Action Group = IEEE1149.1
LMU	Local Bus Memory Unit
MBIST	Memory Build In Self Test
MMU	Memory Management Unit
MSB	Most Significant Bit
MSC	Micro Second Channel
MTU	Memory Test Unit
MCMCAN	CAN controller
NC	Not Connected
NMI	Non-Maskable Interrupt
NVM	Non Volatile Memory
OCDS	On-Chip Debug Support
OVRAM	Overlay Memory
PLL	Phase Locked Loop
PCACHE	Program Cache
PD	Production Device
PFI	Program Flash Interface
PFLASH (or PF)	Program Flash Memory
PMBI	Program Memory Bus Interface
PMI	Program Memory Interface

---

## Introduction

**Table 8 Abbreviations and Acronyms (cont'd)**

<b>Acronym</b>	<b>Description</b>
PMS	Power Management System
PSI5	Peripheral Sensor Interface
PSI5-S	Peripheral Sensor Interface with Serial Interface to Phy
PSPR	Program Scratchpad RAM
QSPI	Queued SPI Controller
RAM	Random Access Memory
RCU	Reset Control Unit
RIF	Radar Interface
RISC	Reduced Instruction Set Computing
SBCU	System Peripheral Bus Control Unit
SCU	System Control Unit
SCR	Standby Controller
SENT	Single Edge Nibble Transmission
SFR	Special Function Register
SMU	Safety Management Unit
SPB	System Peripheral Bus (based on FPI protocol)
SPU	Signal Processing Unit
SPD	Single Pin DAP
SPI	Synchronous Serial Controller
SRI	Shared Resource Interconnect
SRAM	Static Data Memory
SRN	Service Request Node
STM	System Timer
SWD	Supply Watchdog
TC1.6.2P	TriCore CPU TC1.6.2P
UCB	User Configuration Block
WDT	Watchdog Timer
XBar, XBar_SRI	Cross Bar Interconnect, based on the Shared Resource Interconnect protocol

---

## Introduction

### 1.2 System Architecture of the AURIX™ TC3xx Platform

The AURIX™ TC3xx Platform is a family of high-performance microcontrollers with multiple TriCore CPUs, program and data memories, buses, bus arbitration, interrupt system, DMA controller, and a powerful set of on-chip peripherals. The AURIX™ TC3xx Platform is designed to meet the needs of the most demanding embedded control systems applications where the competing issues of price/performance, real-time responsiveness, computational power, data bandwidth, and power consumption are key design elements.

The AURIX™ TC3xx Platform offers several versatile on-chip peripheral units such as serial controllers, timer units, and analog-to-digital converters. Within the AURIX™ TC3xx Platform, all these peripheral units are connected to the TriCore CPUs / system via a System Peripheral Bus (SPB) and a Shared Resource Interconnect (SRI). A number of I/O lines on the AURIX™ TC3xx Platform ports are reserved for these peripheral units to communicate with the external world.

The TriCore processor architecture combines three powerful technologies within one processing unit, achieving new levels of power, speed, and economy for embedded applications:

- Reduced Instruction Set Computing (RISC) processor architecture
- Digital Signal Processing (DSP) operations and addressing modes
- On-chip memories and peripherals

DSP operations and addressing modes provide the computational power necessary to efficiently analyse complex real-world signals. The RISC load/store architecture provides high computational bandwidth with low system cost. On-chip memory and peripherals are designed to support even the most demanding high-bandwidth real-time embedded control-systems tasks.

Additional high-level features of the AURIX™ TC3xx Platform products include:

- Multicore Architecture
- Efficient memory organization: instruction and data scratch memories, caches, and local flash banks
- Serial communication interfaces – flexible synchronous and asynchronous modes
- Multiple channel DMA Controller – DMA operations and interrupt servicing
- Flexible interrupt system – configurable interrupt priorities and targets
- Hardware Security Module
- Flexible CRC Engine
- General-purpose timers
- High-performance on-chip buses
- On-chip debugging and emulation facilities
- Flexible interconnections to external components
- Flexible power-management

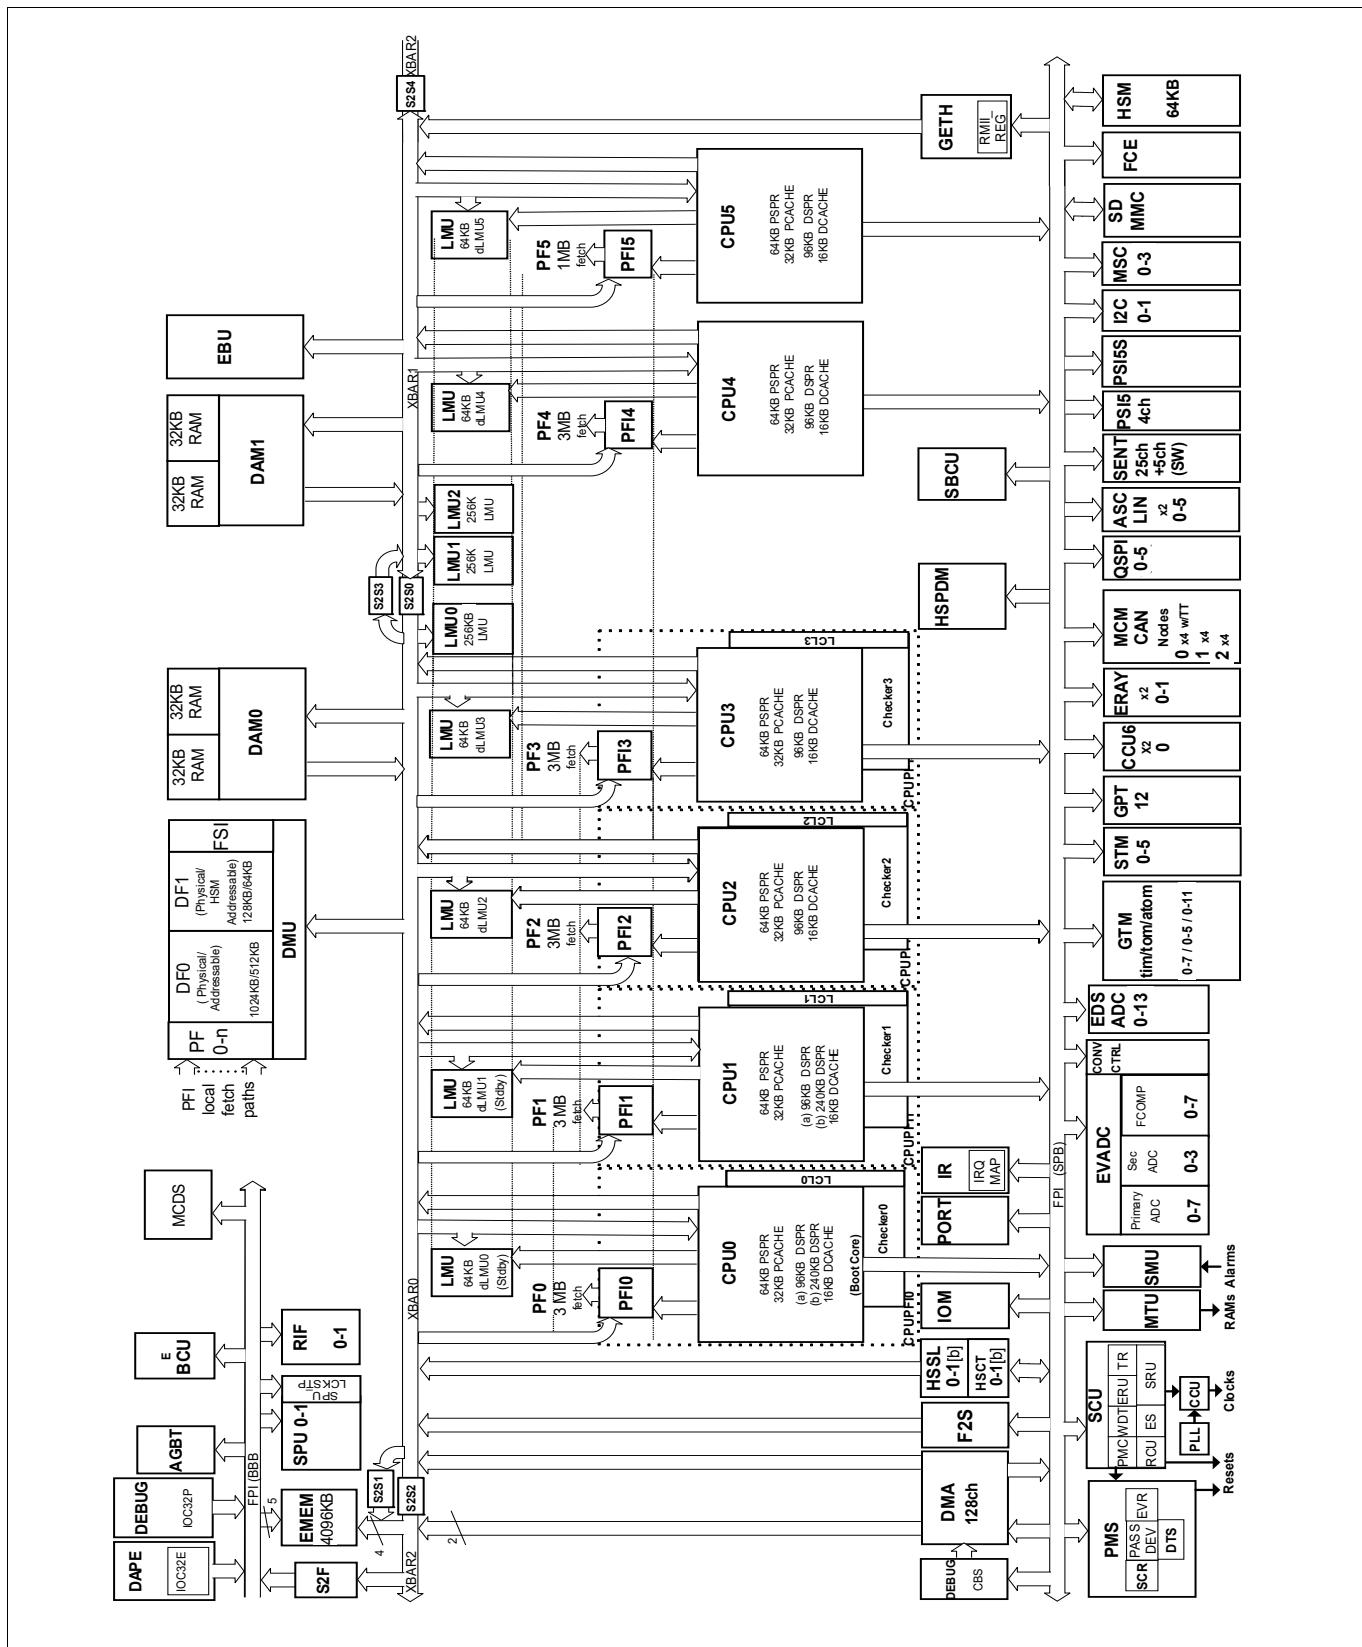

In addition, the following Advanced Driver Assistance System or Extended features are available in some products:

- Camera Interface
- Radar Interface
- Extended Memory
- ADAS Signal Processing Unit

## Introduction

## **1.2.1 AURIX™ TC3xx Platform High End – TC39x**

**Figure 1** shows the block diagram of the TC39x lead device.

**Figure 1** Block Diagram of TC39x

## Introduction

### 1.2.2 AURIX™ TC3xx Platform - Family Overview

The following pages show the block diagrams of the main platform devices which are based upon the TC3xx architecture.

The devices are:

- TC39x: Infineon internal name used in some tools and documentation “TC39xED”
- TC38x
- TC3Ex
- TC37xEXT: Infineon internal name used in some tools and documentation “TC37xED”
- TC37x
- TC36x
- TC35x
- TC3Ax
- TC33xEXT: Infineon internal name used in some tools and documentation “TC33xED”
- TC33x

For each of these devices an Appendix document is supplied. Devices of the same series might share one Datasheet.

The [Table 9](#) shows a feature overview of the AURIX™ TC3xx Platform family.

Due to pin limitations the usable functionality depends on the pinning of a certain package.

Note further that derivative products called “variants” are created from above device list with a reduced feature set, see [Section 1.2.3](#).

- 1) In TC3Ex due to pinning constraints only 5 primary groups are usable.
- 2) In TC3Ex due to pinning constraints only 6 channels are usable.
- 3) TBU3 has special purpose as angle clock.
- 4) ASCLIN instances ASCLIN12 to ASCLIN23 are usable only for LIN and UART communication. SPI is not usable as this function is not connected to pads.
- 5) In TC3Ex due to pinning constraints only 20 channels are usable.
- 6) In TC3Ex due to pinning constraints only MSC0 and MSC1 are usable.
- 7) Note: depending on the package not all pins for 1Gbit might be available.

---

## Introduction

- 8) In TC3Ax, SPU2 is used.
- 9) In TC3Ax, 600 Mbps / Lane is implemented.
- 10) Only in feature package “E”, i.e. designated emulation devices and some feature package “T” devices for development. And in certain feature package “A” devices for tracing in laboratory. Not available in productive devices. Availability depends also on the package.
- 11) Power Management System for Low-End.
- 12) For TC37xEXT and TC39x only available for Feature package “E” devices, i.e. designated Emulation devices. For these bare die is available but only in VEES (Very Early Engineering Sample) quality.
- 13) Only for Feature package “E” devices, i.e. designated Emulation devices. For these this package is available but not qualified.

## Introduction

### 1.2.3 Variants

From the devices described in [Chapter 1.2.1](#) and [Chapter 1.2.2](#) “Variants” are created with reduced feature set. This reduction of features is realized by switching functionality off or by documentation only.

#### 1.2.3.1 Encoding of the Product Name

The product name of a variant (e.g. SAK-TC375SB-128F200W AA) supplies the following information:

**Figure 11 Example for Orderable Part Number**

#### Temperature Range

- K :  $T_{\text{ambient}}$  temperature range from  $-40^{\circ}\text{C}$  up to  $+125^{\circ}\text{C}$
- L :  $T_{\text{ambient}}$  temperature range from  $-40^{\circ}\text{C}$  up to  $+150^{\circ}\text{C}$  in packaged devices

#### Architecture

The architecture (= device family) is identified by the “3” in TC3xy.

In AURIX™ TC3xx Platform the SCU\_CHIPID field CHTEC encodes the devices series. Encoding is defined in the User’s Manual.

#### Device Series

The series (e.g. TC39x, TC38x, TC37x, TC35x, TC33x, TC3Ex, TC3Ax) identifies a set of variants.

In AURIX™ TC3xx Platform the SCU\_CHIPID field CHID encodes the device series. Encoding is defined in the User’s Manual.

#### Package Class

The package class is marked with the “x” in the product name, e.g. TC375 with x=”5”. The following classes are defined:

- “9”: 516 pins
- “8”: 233 pins
- “7”: 292 pins
- “6”: 180 pins
- “5”: 176 pins
- “4”: 144 pins
- “3”: 100 pins
- “2”: 80 pins
- “0”: bare die

## Introduction

In AURIX™ TC3xx Platform the SCU\_CHIPID field CHPK encodes the package. Encoding is defined in the User's Manual. It encodes the number of pins and the package type together. Indirectly with a different package also a different pinning is selected however the same package class can have different pinnings, e.g. ADAS and standard.

## Core Architecture

The core architecture identifies the number of TriCore CPUs:

- “X”: Hexa core (= 6 CPUs)
- “Q”: Quad core (= 4 CPUs)
- “T”: Triple core (= 3 CPUs)
- “D”: Dual core (= 2 CPUs)
- “L”: Single core (= 1 CPU)

## Feature Package

The feature package indicates the set of features available in that device. For details the Variants table in the Datasheet Addendum has to be consulted.

Defined feature packages:

- “A”: ADAS extension
  - These products contain the ADAS subsystem, generally with extended memory (EMEM), SPU, RIF. Emulation features are enabled, HSM is enabled when implemented.
- “P”: HSM enabled
  - These products don't contain the ADAS subsystem and not the Emulation features. HSM is enabled.
- “E”: Emulation device
  - These products are emulation devices for the devices of Feature Package “P”. The ADAS peripherals SPU, RIF are not available. HSM is enabled when implemented.
  - Generally Emulation Devices have the same feature set as the to be emulated product device plus additional MCDS functionality.
- “X”: Feature extension
  - These products contain the ADAS subsystem but only with the extended memory (EMEM). The ADAS peripherals SPU, RIF are not available. HSM is enabled when implemented.
- without second letter: HSM disabled, no ADAS extension, no Emulation device, no Feature extension.
  - These products don't contain the ADAS subsystem and not the Emulation features and HSM is disabled.
- The Datasheet Addendum might define additional second letters.

In the SCU\_CHIPID this is encoded. Bit field “EEA” is set in ADAS, “Feature Extension” and Emulation devices. Bit field SEC is set in HSM enabled devices.

## Flash Size Code

The PFlash size is encoded in the product name as multiple of 64 KByte:

- “16”: 1 MByte
- “32”: 2 MBytes
- “48”: 3 MBytes
- “64”: 4 MBytes
- “96”: 6 MBytes
- “144”: 9 MBytes

## Introduction

- “160”: 10 MBytes
- “192”: 12 MBytes
- “256”: 16 MBytes

In the SCU\_CHIPID this is encoded in the FSIZE field.

## Memory Type

The memory type is currently constant “F” for Flash.

## Frequency

The maximum CPU frequency is encoded with this field. Currently defined values are:

- “160” MHz
- “200” MHz
- “300” MHz

## Package Type

The following package types are currently defined:

- “W”: LQFP with 0.5 mm pitch
- “F”: TQFP with 0.4 mm pitch
- “S”: LFBGA with 0.8 mm pitch
- “”: no letter for bare die

In the SCU\_CHIPID this is encoded together with the package class in the field CHPK.

## Stepping

The last two letters identify the stepping, i.e. different versions of the device hardware including ROM changes. In AURIX™ TC3xx Platform the SCU\_CHIPID field CHREV encodes stepping. Encoding is defined in the User’s Manual.

### 1.2.3.2 Emulation Devices

Emulation Devices “ED” (Feature Package “E”) are compatible to the emulated Feature Package “P” and “” (no second letter) devices. “Compatible” means that they offer the same feature set as the Feature Package “P” and “” device with additional debug and tracing capabilities. These devices can contain additional features that are not disabled.

Emulation strategy:

- TC39x Feature Package “E” is based on TC39x device. It can be used to emulate:
  - TC39x Feature Package “P” and “”.
  - TC38x Feature Package “P” and “”.
- TC37x Feature Package “E” is based on TC37xEXT device. It can be used to emulate:
  - TC37x Feature Package “P” and “”.
  - TC36x Feature Package “P” and “”.

### 1.2.3.3 TC32x

The TC32x device series is based on TC33x silicon. The following table shows feature differences to the TC33x which are valid for all TC32x variants. Feature variants of the general TC32x device may be created.

## Introduction

**Table 10 TC32x Feature Overview Delta to TC33x**

Feature	TC32x
CPUs	Max. Freq.
SRAM per CPU	DSPR
Data Flash	DF0 Size (single-ended)
ASCLIN	Modules
	6

### 1.2.3.4 TC39x With Feature Package “P”

The following table shows feature differences between the TC39x silicon and its variants with feature package “P” (see also [Chapter 1.2.3.1](#), section [Feature Package](#)). Reduced feature variants of this general TC39x feature package “P” device may be created.

**Table 11 TC39x Feature Package “P”**

Feature	TC39x Feature Package “P”
Extension Memory (EMEM)	TCM
	XCM
	XTM
SDMMC	eMMC/SD Interface
SPU	Modules
SPU Lockstep Cmp.	Modules
RIF	Modules

### 1.2.4 Revision History

**Table 12 Revision History**

Reference	Changes to Previous Version	Comment
V1.5.0		
<a href="#">Page 14</a>	Changed for TC33xEXT the number of EVADC converters and channels. Primary converters changed from 4/32 to 6/40 and secondary converters from 2/32 to 0/0.	
<a href="#">Page 15</a>	Corrected for TC33x the GTM configuration of SPE from 0 to 2, of “BRC / DPLL” from “0 / 0” to “1 / 0”, of “CMP / MON” from “0 / 0” to “1 / 1”, of “DTM modules” from “4” to “6 (4 on TOM, 2 on ATOM)”, of “TBU channels” from “2 (TBU0-1)” to “3 (TBU0-2)”.	
<a href="#">Page 15</a>	Removed GTM from TC33xEXT (all GTM features set to 0).	
<a href="#">Page 15</a>	Corrected number of CDTM modules of GTM from 6 to 7 for TC39x. Corrected number of CDTM modules of GTM from 5 to 6 for TC38x and TC38xEXT. Correct the assignment of DTM modules of GTM from “10 on TOM, 10 on ATOM” to “8 on TOM, 12 on ATOM” for TC38x and TC38xEXT.	

## Introduction

**Table 12 Revision History**

Reference	Changes to Previous Version	Comment
<a href="#">Page 15</a>	Removed FlexRay from TC33xEXT.	
<a href="#">Page 16</a>	Changed number of ASCLIN from 12 to 6 for TC33xEXT.	
<a href="#">Page 16</a>	Changed number of CAN modules from 2 to 1 and consequently the number of CAN nodes from “2x4” to “1x4” for TC33xEXT.	
<a href="#">Page 11, 20, 21, 22, 23, 24, 25, 26, 27</a>	Changed in all block diagrams the text in the EVADC sub-blocks. Previous block diagrams showed a non-existing grouping (e.g. “4 x 4”) now the flat converter numbering (e.g. “0-7”) is shown.	
<a href="#">Page 16, 25</a>	Removed IOM from TC33xEXT in Feature Table and its block diagram.	
<a href="#">Page 18</a>	Added support for BGA-180 package with ADAS pinning to TC33xEXT and non-ADAS pinning to TC33x.	
<a href="#">Page 18</a>	Added support for TQFP-80 package with TC33x.	
<a href="#">Page 18</a>	Removed support for TQFP-144 package from TC37xEXT (concrete from TC37x feature package “E” devices). Entered “No” for this package for all TC37x and TC37xEXT devices.	
<a href="#">Page 25</a>	In block diagram of TC33xEXT changed SRI connection of DMA from one interface to two interfaces.	
<a href="#">Page 17</a>	Changed in Feature Table in row “Low Power Feature” the standby RAM capability of TC33xEXT from DLMU0&1 to DLMU0 (same as for TC33x).	
<a href="#">Page 14</a>	Changed in Feature Table in row “DMA” the number of channels from 16 to 64 for TC33x and TC33xEXT.	
<a href="#">Page 16</a>	Changed in Feature Table in row “CAN” the number of modules from 4 to 5 and the numbers of channels from “4 x 4” to “5 x 4” for TC38xEXT.	

### V1.5.1

<a href="#">Page 17</a>	Extended the footnote on AGBT explaining its availability in feature package “E”, “A” and “T” devices.	
<a href="#">Page 15</a>	Changed configuration of GTM of TC33x. Changed from 2 clusters at 100 MHz to 2 clusters at 200 MHz.	
<a href="#">Page 16</a>	Changed documented configuration of SENT of TC39x from “25 + 5 by SW” to “25”. No change of hardware related to this change.	
-	Changed throughout the document the name of the device TC38xEXT to TC3Ex.	
<a href="#">Page 14, 14, 16, 16</a>	Added footnotes to TC3Ex features EVADC, EDSADC, SENT, MSC for which more functionality is implemented than usable in any available package.	

### V1.6.0

<a href="#">Page 12</a>	Added the TC3Ax Feature list to the Table 9.	
<a href="#">Page 28</a>	Added the TC3Ax Block Diagram.	
<a href="#">Page 29</a>	Added TC3Ax to the Device Series list.	
<a href="#">Page 29</a>	Added “80 pins” and “233 pins” in “Package class” options.	

## Introduction

**Table 12 Revision History**

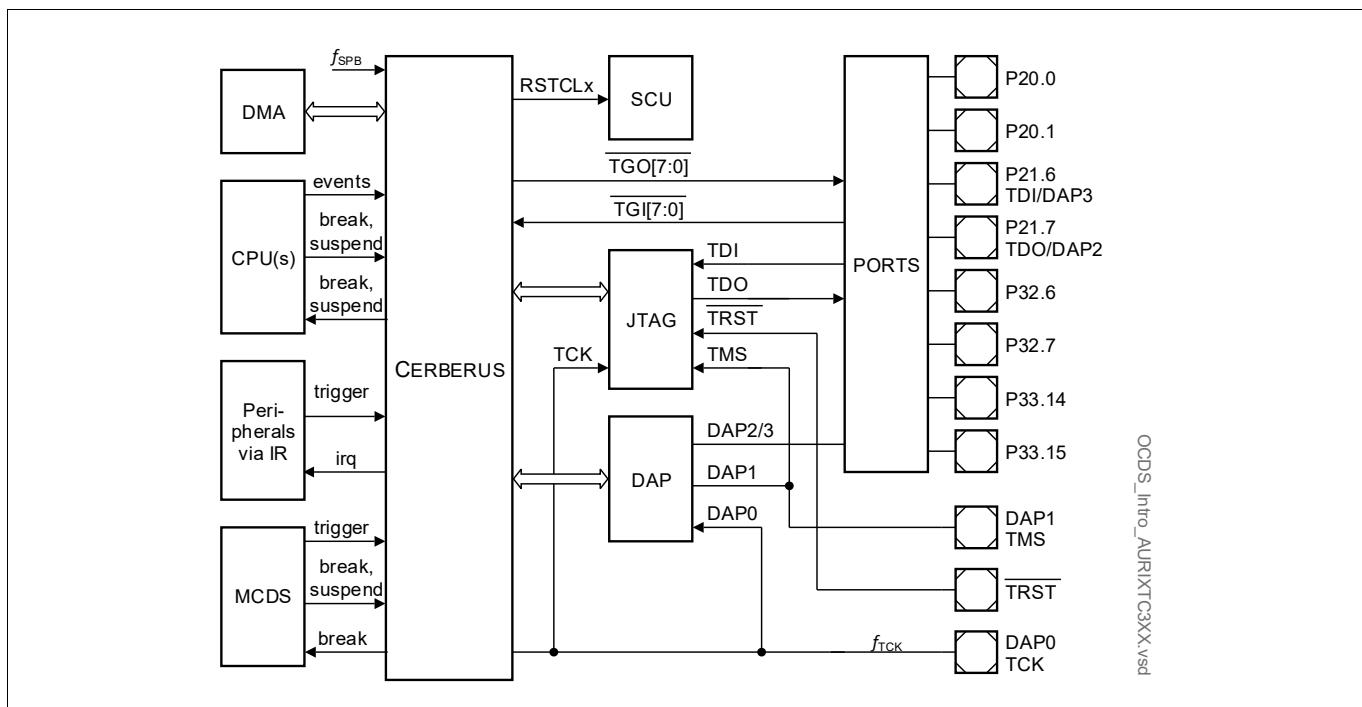

Reference	Changes to Previous Version	Comment
<b>Page 12</b>	Added the row “Power Management System” to the Platform Feature Overview- Table 9.	
	FlexRay for the TC3Ax is not available. Updated Platform Feature Overview- Table 9.	
<b>Page 2</b>	Table 1 ‘Note’ description updated for DAM RAM.	
<b>Page 1</b>	Update kbit, Mbit definitions to kbit/s and Mbit/s respectively in the “Text Conventions” section.	
<b>Page 28, Page 12</b>	Update the TC3Ax Block Diagram and the Feature List Table with the BITMGR0.	
<b>V1.6.1</b>		
<b>Page 31</b>	In chapter 1.2.3.3 removed the wording ‘Reduced’ and replaced with ‘Feature variants of the general TC32x device may be created’.	
<b>Page 28</b>	Updated the TC3Ax Block Diagram with the XBAR2 and CPU2 DSPI size.	
<b>Page 12</b>	Updated the CPU2 DSPI Size for TC3Ax in “Platform Feature Overview - Table 9.	
<b>V1.6.2</b>		
<b>Page 12</b>	Updated Platform Feature Overview- Table 9. with TC33x EVADC Secondary Groups / Channels to 2 /28.	
<b>Page 29</b>	Definition of "Feature Package" - "X" is updated.	
<b>Page 12</b>	Updated the Feature ‘Packages’ to include BGA216 package support for TC3Ax in “Platform Feature Overview” - Table 9.	

## 1.3 On-Chip Debug Support (OCDS)

The Infineon AURIX™ TC3XX devices contain powerful resources for debugging and performance optimization. They provide high visibility and controllability of software, hardware and system, especially also under hard real-time constraints. The resources are either embedded in specific modules (e.g. breakpoint logic of CPUs) or part of the central Cerberus module.

**Figure 12** shows the AURIX™ TC3XX family concept of the OCDS with all potentially usable pins. The same OCDS function is always on the same port pin including full DAP/JTAG functionality but the number of TGI/TGO trigger pins depends on the device type.

Trace functionality is available for TC3XX with miniMCDS, MCDSlight or MCDS. Please refer to the table “Platform Feature Overview” for more details.

**Figure 12 OCDS Block Diagram (Family Concept)**

When acting as a bus master Cerberus shares the master interfaces of the DMA (using a different master tag) to access memories and SFRs attached to the SPB or SRI via the shortest possible path.

### 1.3.1 Introduction

#### Debugging

The application is not yet ready, the system outside of the TC3XX is either not connected or under control by other means so that misbehavior of the software has no catastrophic consequences. The “user” is a software design engineer with thorough knowledge of the device and the system, in other words, no protection is needed. From the tool the user expects

- Download: The memories of the SoC (and of other external memories attached to the SoC) must be written (and programmed in case of non-volatile memories) without need to disassemble the application system.
- Run Control: Each processor core can be stopped and started at will, either separately or synchronously throughout the SoC.

- Visibility: The content of all storage locations inside the SoC, i.e. memories, SFRs and processor registers, can be read and written, preferably even while the system is running.
- Trace: A log of the processing is desired, as detailed (“cycle accurate”) and wide (aligned trace of parallel processes) as possible.

**Note:** *Due to the high speed of the TC3XX tracing has limitations in trace buffer with the standard chip, but a pin and package compatible Device with extended trace capabilities is available.*

### Rapid Prototyping

The application design has reached a state where operation at target speed is possible. The SoC’s tasks are mission critical, but some of the algorithms are still in development. Hardware support is needed for

- Triggering: An external high speed processor is attached to the SoC to perform all processing tasks not yet implemented inside the SoC. This external system must be notified (“triggered”) whenever its services are needed, possibly with detailed information on the kind of service requested.
- Data Exchange: When triggered, the external “bypass” processor must get hold of the input data of its algorithm as fast as possible. After the calculation the results must be written back into the SoC, again with low latency and possibly triggered by another event. Other tasks of the SoC shall not be influenced.

### Calibration

Once the algorithms are fixed there still is need to “tweak” the software. Namely the constants used by the program typically are dependent on external parameters and are “tuned” in the final application, i.e. in the field or even a driving car.

- Overlay: As the constants are stored in non-volatile memory changing them requires an erase-program cycle, which is only possible safely when the application is taken out of service. Therefore RAM is mapped into the address space “over” locations the software addresses as ROM. This RAM can be accessed and changed by the tool concurrently.

**Note:** *The additional RAM offered by the TC3xxED or TC35x, TC3Ax Devices can be used to extend the amount of overlaid ROM considerably.*

- Measurement: To find points still needing attention or simply to judge the results of parameter changes significant internal data of the SoC (variables, sensor data) must be read from the SoC with deterministic timing and high bandwidth.

**Note:** *The MCDS respectively MCDSlight module of the TC3xxED or TC35x, TC3Ax Devices can be used to capture relevant data highly selective and without modification of the application software.*

### 1.3.2 Feature List

Please also refer to debug specific features in other modules, e.g.

- Eight hardware breakpoints for TriCore, based on instruction or data address
- Unlimited number of software breakpoints (DEBUG instruction)
- Trigger generated by the access to a specific bus address by any bus master
- Peripheral trigger and trace with OCDS Trigger Bus (OTGB)
  - Peripherals provide vectors (Trigger Sets) of their most interesting signals.
  - Signals can be routed to trigger pins.
  - Flexible tracing of signal vectors from one to three peripherals in parallel

- Dedicated interrupt resources to handle debug events, both local inside the CPUs (breakpoint trap, software interrupt) and global (triggered by Cerberus), e.g. for implementing monitor programs

### Central functions implemented by Cerberus

- Run/stop and single-step execution independently for each CPU
- Run/stop and time-step execution of the complete device using the Trigger Switch
- Automatic suspension of CPU associated watchdogs and system timers if the CPU is halted by the tool
- All kinds of reset can be requested using only the tool interface.
- Halt-after-Reset for repeatable debug sessions
- Tool access to all SFRs and internal memories independent of the CPUs
- Bus priority of Cerberus can be chosen dynamically to minimize real-time impact.
- Up to 8 package pins can be used optional as with Trigger In/Out ( $\overline{\text{TGI}}/\overline{\text{TGO}}$ ).
- Central OCDS Trigger Switch (OTGS) with 7 independent Trigger Lines to collect debug events from various sources (all CPUs, DMA, all interrupt requesters, bus controllers, several complex peripherals, MCDS, trigger input pins) and distribute them selectively to all CPUs, DMA and trigger output pins
- Central Suspend Switch using up to three Lines of the Trigger Switch infrastructure. This allows to selectively suspend all or only part of the CPUs and peripherals instead of halting them as reaction to any debug event.
- Access to all OCDS resources also for the CPUs themselves for debug tools integrated into the application code.
- Triggered Transfer of data for simple variable tracing
- A dedicated trigger bank (TRIG) with 96 independent status bits is provided to post requests at a central location from application code to the tool.
- The tool is notified automatically when the trigger bank is updated by any processor. No polling via a system bus is required.
- Fault and stress injection for testing the robustness of a system

### Tool Interfaces

Several options exist for the communication channel between tools and devices:

- DAP and JTAG are clocked by the tool.
- Two pin DAP (Device Access Port) protocol for long connections or noisy environments
- Three pin DAP Unidirectional Mode for off-chip transceiver integration (e.g. LVDS)
- Three pin DAP Wide Mode for high bandwidth needs
- Four pin DAP Unidirectional Wide Mode for off-chip transceiver integration with high bandwidth needs
- DAP bit clock can have any frequency up to 160 MHz.
- 15 MByte/s for block read or write, 25-30 MByte/s in Wide Mode and Unidirectional Wide Mode
- Optimized random memory accesses (read word within 0.5  $\mu$ s at 160 MHz)
- CAN (plus software linked into the application code) for embedded purposes with lower bandwidth requirements
- DAPE can be used in parallel to DAP to connect a second tool for Emulation Devices.
- Four pin JTAG (IEEE 1149.1) for standard manufacturing tests
- Lock mechanism to prevent unauthorized tool access to application code

- Hot attach (i.e. physical disconnect/reconnect of the host connection without reset) for all interfaces
- Infineon standard DAS (Device Access Server) implementation for seamless, transparent and parallel tool access over any supported interface
- DAP over CAN Messages (DXCM)

## FAR Support

To efficiently locate and identify faults after integration of an AURIX™ TC3XX device into a system special functions are available:

- Boundary Scan (IEEE 1149.1) via JTAG or DAP.
- SSCM (Single Scan Chain Mode) for structural scan testing of the chip itself.
- DXCPL (DAP over CAN Physical Layer) via CAN pins (AP32264)

*Note: Boundary scan is possible also for locked devices. The security barrier is within CERBERUS.*

### 1.3.3 Family Overview

The OCDS architecture and features are very consistent over the whole AURIX™ TC3XX family. This makes it easy for tool partners and users to switch between different devices. The following tables list all JTAG IDs.

**Table 13 JTAG IDs of AURIX TC3xx Devices**

	<b>TC39x</b>	<b>TC38x</b>	<b>TC37x</b>	<b>TC37xEXT</b>	<b>TC36x</b>
A-step	10205083 <sub>H</sub>	10206083 <sub>H</sub>	10207083 <sub>H</sub>	10208083 <sub>H</sub>	10209083 <sub>H</sub>
B-step	20205083 <sub>H</sub>				

**Table 14 JTAG IDs of AURIX TC3xx Devices (continued)**

	<b>TC35x</b>	<b>TC33xEXT</b>	<b>TC33x</b>	<b>TC3Ex</b>	<b>TC3Ax</b>

### 1.3.4 Tool Interface Recommendations

AURIX™ TC3XX devices are well supported by many tool partners for different types of tools. Standard tool interface for debug, measurement and calibration is DAP due to its reduced pin-count, higher performance (3-6x) and higher robustness (CRC) than JTAG. Please note that the full “JTAG” boundary scan functionality is also available with DAP, it is supported however only by specific tool providers. Please refer to application note AP24003 for more information about the standard DAP connector and board design for high speed DAP. [Table 15](#) lists all pins and considerations for connecting tools.

**Table 15 Tool Relevant Device Pins of AURIX™ TC3XX Family**

<b>Pins</b>	<b>Remark</b>
TRST/DAPE0	DAP: Has to be high at PORST pin release. TRST has a pull-up. JTAG: Needs to be controlled by the tool via the tool connector. The DAPE interfaces can be operated in parallel with the DAP for Emulation Devices.
DAP0/TCK	DAP: Please consider AP24003 for high speed DAP
DAP1/TMS	
DAP2/TDO/DAPE2 TGI3/TGO3	DAP: Needed for three pin modes like high bandwidth Wide Mode and Unidirectional Wide Mode. The standard DAP connector (AP24003) allows to use this pin on demand either for Wide Mode e.g. for measurement or as trigger pin for system debugging. The DAPE interfaces can be operated in parallel with the DAP for Emulation Devices.
DAP3/TDI/DAPE1 TGI2/TGO2	DAP: Needed for four pin mode like high bandwidth Unidirectional Wide Mode. The DAPE interfaces can be operated in parallel with the DAP for Emulation Devices.
VDDSB	1.25 V supply of the ED memory. <ul style="list-style-type: none"><li>• VDDSB has to be supplied when VDD is supplied and the EMEM is unlocked.</li><li>• VDDSB can be unsupplied when VDD is supplied and PORST is active or the EMEM is locked.</li><li>• VDDSB can be supplied when VDD is unsupplied and PORST is active (EMEM standby mode).</li></ul>
VEXT	3.3 V or 5 V external power supply for the device. VEXT decides also the DAP connection voltage.

**Table 15 Tool Relevant Device Pins of AURIX™ TC3XX Family (cont'd)**

Pins	Remark
TGlx/TGOx	Optional trigger pins, overlaid to port pins. Availability depends on device and package type.
AGBT_xyz	AGBT high-speed serial pins in the center ball matrix of EDs in BGA packages. Please connect to VSS if no AGBT is needed.

*Note:* Dedicated DAPE pins are provided for Emulation Device packages, referring to the data sheet and the ED specification.

For more information please contact your Infineon support.

### 1.3.5 Debug Access Server (DAS)

The DAS API provides an abstraction of the physical device interface for tool access. The key paradigm of DAS is to read or write data in one or several address spaces of the target device.

#### DAS Features

- Standard interface for all types of tools
- Efficient and robust methods for data transfer
- Standardized system security support (authorization)
- Several independent tools can share the same physical interface
- Product chip address space is represented with DAS address map 0, EEC with 1
- Infineon's miniWiggler supports DAP, JTAG, SWD and SPD

DAS is not device specific. It can be used for all Infineon 8-, 16- and 32-bit microcontrollers with DAP, JTAG, SWD, or SPD interface. For more information please refer to [www.infineon.com/DAS](http://www.infineon.com/DAS).

## 1.4 Emulation Device (ED)

In the AURIX TC2xx family for most of the so-called production devices a corresponding pin-compatible TC2xxED Emulation device is available. An Emulation Device comprises the unchanged Product Chip Part (SoC) and the Emulation Extension Chip (EEC) part ([Figure 13](#)).

In the AURIX®2G TC3xx family this is similar from a functional perspective. The EEC part contains as well an Extension Memory (EMEM) and a Trace module. The MCDS trace module is on a TC39xED (device name TC39x) and TC37xED (device name TC37xEXT) while the MCDSlight trace module is on a TC33xED (device name TC33xEXT) and a TC35x. Devices with ED functionality are devices with “Feature Package E”.

**Table 17 TC39x/37x/33xED and TC35x, TC3Ax Comparison**

Functionality / Device name	TC39xED / TC39x	TC37xED / TC37xEXT	TC33xED / TC33xEXT	TC35x, TC3Ax
Emulation device for	TC39x TC38x TC3Ex	TC37x TC36x TC33x	TC33xED	TC35x, TC3Ax

AGBT (Aurora)	yes	yes	yes	yes

As shown in [Table 17](#) the TC39xED is the Emulation device for TC38x and TC3Ex. Thermal design and power supply need to accomodate the higher TC39xED power consumption i.e. higher leakage current due to a larger chip (in particular for the EMEM) and higher dynamic current if additional resources (e.g. MCDS) are being used.

### Requirements for TC38x code:

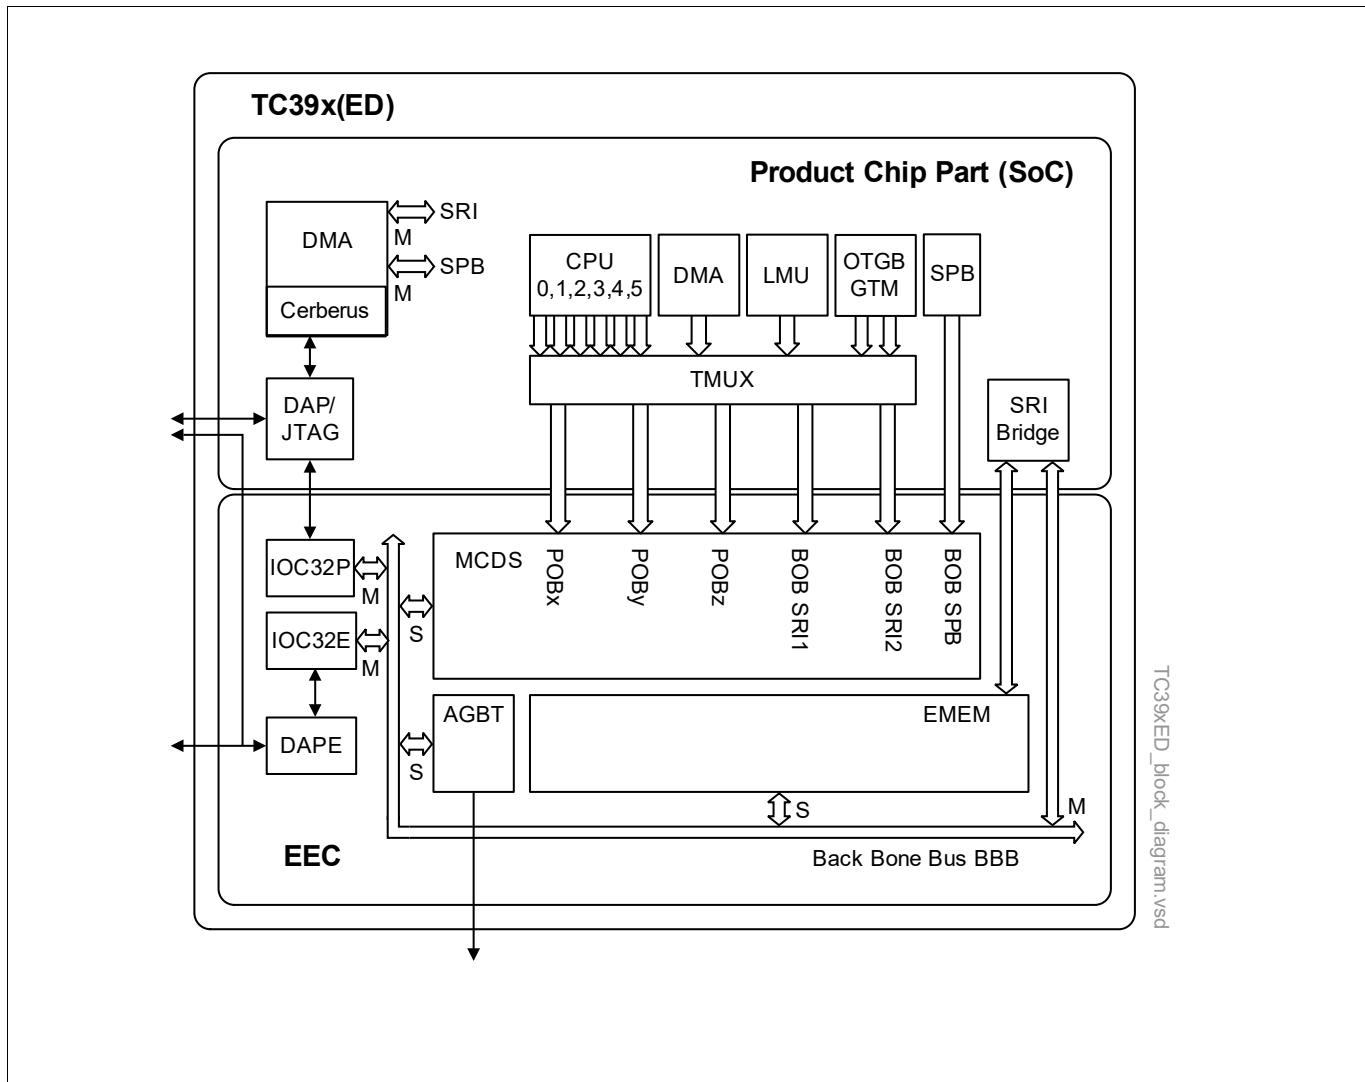

- It needs to be tolerant to the different CHIP and JTAG ID values.
- It may not access reserved address ranges and expect an error if these ranges are present for TC39xED.
- It may not access the miniMCDS subsystem.
- It may not access the upper 12 ASCLIN modules (out of 24).

### Additional requirements for TC3Ex code:

- It may not access the upper 2 out of the 5 CAN modules.
- A workaround is needed if the external clock source pin is used for the RTC in the SCR.

### 1.4.1 Block Diagram

**Figure 13** shows the block diagram of TC39xED as an example. The Product Chip Part is reduced to the directly connected modules only in the drawing. Please refer to **Table 18** for an explanation of the acronyms.

**Figure 13 Block Diagram**

**Table 18 TC39xED Components (Figure 13)**

<b>Component</b>	<b>Definition</b>
AGBT	Aurora GigaBit Trace module on EEC
BBB	Back Bone Bus with FPI protocol
BOB	Bus Observation Block. Trace and trigger logic within MCDS
Cerberus	Central debug and tool access control unit is part of OCDS
DAP	Device Access Port. Fast and robust 2/3 pin tool interface (15/30 MB/s).
DAPE	Independent DAP instance for connecting a second tool to the ED
DMA	Direct Memory Access controller. Shares SRI/SPB bus interfaces with Cerberus.
ED	Emulation Device for calibration, measurement and debug
EEC	Emulation Extension Chip part
EMEM	Extension Memory (calibration and trace memory)
FPI	Flexible Peripheral Interconnect, the protocol of SPB and BBB buses
IOC32P/E	IO Client for accessing BBB by DAP/DAPE
MCDS	Multi-Core Debug Solution
OCDS	On-Chip Debug Support
OTGB	OCDS Trigger Bus: collects interrupt and peripheral trace and trigger signals.
POB	Processor Observation Block
SBCU	SPB Bus Control Unit
SoC	System on Chip (used also for “product chip part”)
SPB	System Peripheral Bus with FPI protocol
SRI	Shared Resource Interconnect cross bar
TMUX	Trace Multiplexer

The Extension Memory (EMEM) as part of the EEC is used for two conceptually different purposes: trace buffering and overlay memory. The size allocation for both parts can be configured in the EMEM module.

For calibration, RAM partitions are mapped into the address ranges of the CPUs, optionally replacing parts of the TC3xx's local Flash. The feature is described in detail in the Overlay section of the TC3xx manual.

Tracing on the other hand is a non intrusive tool to aid the debugging process. Matching elements from the MCDS module are provided to translate the captured signals - routed there from CPUs and other sources - into trace messages. These messages are buffered in EMEM and can then be read by the tool: e.g., via DAP.

### 1.4.2 Feature List

This section lists the features for the TC3xxED and TC35x, TC3Ax devices.

#### Applications

- Software development
  - Debugging
  - Performance analysis and optimization
- Calibration
- Measurement
- Rapid prototyping

#### General Features

- The behavior of a TC3xx device (e.g. TC37x or TC36x) and its corresponding TC3xxED device (e.g. TC37xED) is identical with restrictions listed below **Table 17**
- The package of a TC3xx device and its corresponding TC3xxED device is footprint compatible device
- Minimum number of ED specific pins
- Full access to the EEC part via the regular DAP/JTAG package pins
- No external emulator hardware required other than DAP/JTAG interface
- Tool software running on TriCore has full EEC access e.g. for calibration or measurement
- Protection against reverse engineering by competitors and against manipulation, both for production and emulation device (field trials)
- Additional DAP interface (DAPE) for connecting a second independent tool
- High speed Aurora GigaBit Trace (AGBT) interface

#### Extension Memory Features

- Extension Memory (EMEM) size is up to 4112 KB
- EMEM has two 8 KB XTM tiles, up to eight 256 KB TCM tiles, and up to 2 MB XCM
- EMEM except XTM can be used for calibration, code, constants, or data storage
- Up to 2048 KB can be used for trace buffering
- Continuous trace via DAP / AGBT requires just two XTM tiles (only one XTM tile for AGBT on TC39xA-step)
- Support of independently operating calibration and debug tools
- FIFO functionality for continuous trace (EMEM address triggers in MCDS)
- EMEM is also mapped into the address range of TriCore
- EMEM can be overlaid to Flash
- Code and data fetch from EMEM
- Data retention of RAM during power down by isolated standby power supply
- ECC with SECDED (Single Error Correction, Double Error Detection)

#### Measurement Features

- Highly efficient SW triggering via DAP interface (TRIG)
- Fine Grained Trace Qualification for low-cost Trace Based Measurement (TBM) via DAP
- Aurora GigaBit Trace (AGBT) interface for high-end trace based measurement

## Debug Features

- TriCore program trace (instructions, program flow, functions only)
- Continuous Compact Function Trace (CFT) via DAP
- TriCore data trace (no register file trace)
- Parallel trace of three CPUs, two selected SRI clients, and the SPB bus
- Full visibility of internal peripheral bus (SPB)
- Time aligned trace of all sources
- Trace of internal states and signals of complex peripherals
- Trace of interrupt and DMA requests and processing
- Trace of EVR state and control loop signals
- Breakpoints and watch points based on common event generation logic
- Magnitude comparators working on instruction pointers and memory addresses: A <= IP <= B
- Masked magnitude comparators working on the data busses: DATA = "xxxx55xx"
- Sequential event logic: counters driven by events and equipped with limit comparators are used as event sources again for breakpoint or trace qualification
- Optimized compression of buffered trace data
- Very powerful qualification- and trigger mechanism
- Pre- and post-event trace buffering ("digital oscilloscope")
- Performance counters
- Concurrent trace logging and trace data acquisition up to the bandwidth of the used host interface
- Central time stamp unit to correlate traces from different CPUs and other sources
- Halt the system or parts of it when trace memory is full
- Regular and modular structure of the control blocks and registers
- Trace debug unit power reduction modes with clock gating
- Trace data in EMEM can be decoded after unsolicited PORST
- Output of continuous trace over DAP/DAPE or Aurora GigaBit Trace interface
- HSM bus traffic completely filtered away by default

### 1.4.3 Comparison to AURIX Emulation Devices

TC3xx Emulation Devices are designed as close to the predecessors of the AURIX family as feasible.

#### New Features

- CPU read data value trace
- Trace based measurement (TBM) mode
- Second DAP interface (DAPE) for connecting two tools in parallel
- Unidirectional Wide Mode for DAP interface only (not for DAPE)
- Trace of EVR state and control loop signals
- Option to make HSM accesses visible in SPB trace
- Debug support of EBCU enabled
- EMEM standby supply status bit (SBRCTR.STBPON)

#### Changes

- DAP/DAPE pins supplied by regular VEXT voltage (5V / 3.3V)
- DAP/DAPE pins use TTL level
- Center ball matrix of BGA packages includes dedicated DAPE pins
- Program trace of up to three CPUs in parallel
- Local trace source multiplexer in CPU subsystem (TCMUX)
- Data trace of up to five CPUs (or four + DMA) in parallel for Trace Based Measurement
- GTM has two additional direct 32 bit trace busses to MCDS (OTGBM0/1)
- Improved trace data streaming via DAP (NTN NOW capture)
- BBB access with an SRI to FPI bridge from CPUs (not via LMU)
- EMEM access with SRI to SRI bridge from CPUs (not via LMU)
- EMEM size is up to 4 MB
- EMEM access latency reduced for CPUs
- Up to 2 MB EMEM can be used for trace buffering
- EMEM TCM tile size is 256 KB
- EMEM XTM addressing changed due to changed TCM tile size
- EMEM XTM can only be used for trace data (MCDS, BBB, AGBT). No CPU access anymore.
- EEC addresses are now the same from IOC32P/E and from CPU point of view
- Prolog Code PCEDS addresses changed

#### Discontinued

- Cold start EMEM access via Standby DAP
- FusionQuad™ packages

## 1.4.4 Trace Source Multiplexer

**Figure 13** shows the TMUX multiplexer between the different trace sources and the five flexible observation blocks of the MCDS (BOB SPB is dedicated for SPB). Within the CPU subsystem there is another local multiplexer (TCMUX).

### 1.4.4.1 TMUX Setting Options

For keeping the on-chip wiring of wide high-speed trace busses within reasonable bounds, the trace source setting options for some MCDS observation blocks are significantly reduced (**Table 19**). This reduced set was selected taking into account the use cases for parallel trace listed in [Section 1.4.4.3](#).

**Table 19** Trace Source Multiplexer (TMUX) Setting Options

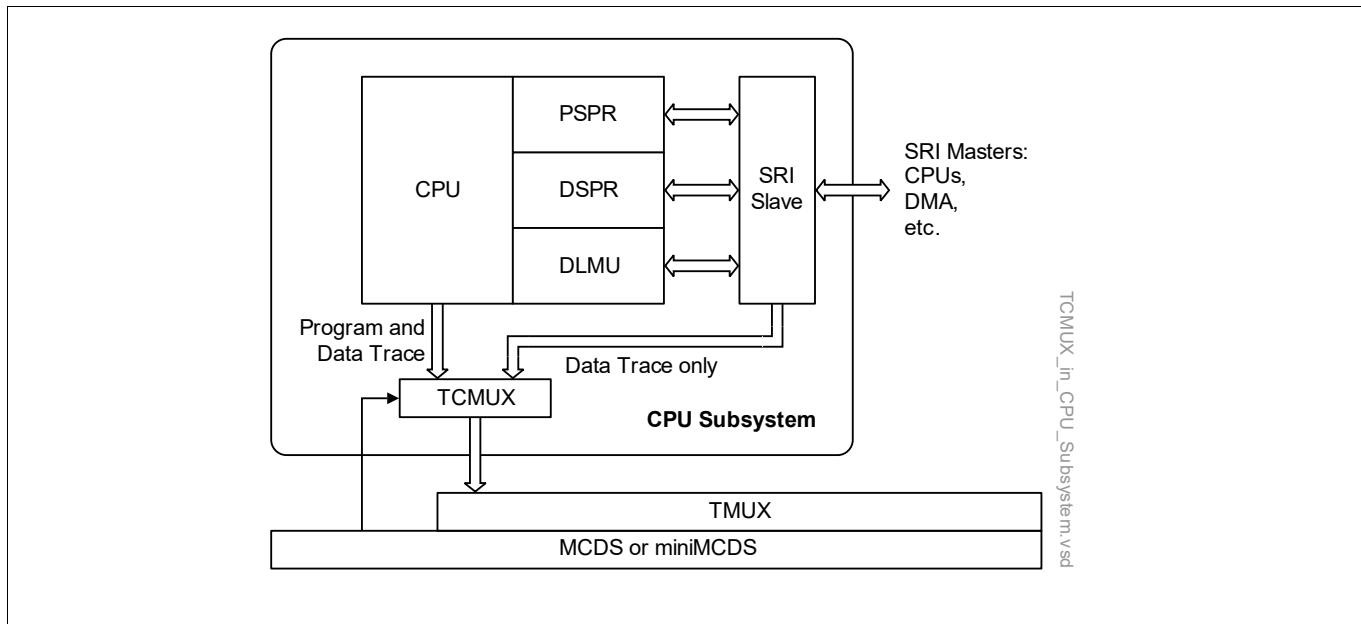

POBx, miniMCDS	POBy	POBz	BOB1	BOB2
CPU0		CPU0		
CPU1	CPU1			
CPU2	CPU2		CPU2 (TBM)	
CPU3	CPU3			CPU3 (TBM)
CPU4	CPU4		CPU4 (TBM)	
CPU5	CPU5			CPU5 (TBM)
LMU0			LMU0	
OLDA			OLDA	
				DMA_MIFO
			SPU0	SPU1
OTGB			OTGB	
OTGBM (GTM)	OTGBM (GTM)			

#### 1.4.4.2 Trace Source Multiplexer in CPU Subsystem (TCMUX)

The trace multiplexer within the CPU Subsystem ([Figure 14](#)) allows selection between:

- CPU pipeline
- PSPR/DSPR/DLMU SRI slave

*Note:* *The data trace of the SRI slave does not include the DMA channel number.*

**Figure 14 TCMUX in CPU Subsystem**

#### **1.4.4.3 Parallel Trace Use Cases**

The following use case examples are supported by the configuration with TCMUX ([Figure 14](#)) and TMUX ([Table 19](#)).

##### **Trace with miniMCDS**

In this use case all trace sources need to be selectable as input for miniMCDS. The associated first row of [Table 19](#) has only the exceptions DMA and SPU. DMA is also covered by the OTGB DMA trace options and the tracing of SRI slaves, which includes the information of DMA as master including channel number. SPU requires a continuous high bandwidth output, which miniMCDS can't provide.

##### **Trace Based Measurement (TBM)**

In this use case a parallel trace of CPUs and DMA is required. The MCDSlight provides two while the MCDS has five observation blocks . For TC39x with six CPUs plus DMA, an almost arbitrary selection from these seven sources can be made.

The data written by the remaining CPU(s) can be measured with list based DAQ, and included for instance with the traced DMA in the MCDS trace data.

##### **Debugging with MCDS**

The following combinations are mandatory for typical debug use cases:

- CPU debugging with 2-3 arbitrary CPUs + OLDA/LMU0/OTGB + DMA + SPB
- GTM debugging with OTGBM (e.g. MCS) + OTGB (e.g. signal groups) + one CPU + SPB
- OTGB + CPU(s) + SPB
- SRI slave + CPU(s)

### 1.4.5 DAP ED Interface (DAPE)

**Figure 13** shows the additional DAPE interface available on all TC3xxED and TC35x, TC3Ax devices. It has the same performance characteristics as the regular DAP interface, and it can be used in parallel to connect a second tool. Its main limitation is the access restriction to the BBB bus. **Table 20** compares DAP/DAPE in terms of features and for different applications.

**Table 20 Comparison DAP/DAPE**

Property	DAP	DAPE
Availability	on each device	TC3xxED and TC35x, TC3Ax only
Number of pins	2-3	
Performance	15-30 MB/s (both can be used in parallel)	
Package Pins	DAP/JTAG/P21	
Additional ED package mapping	no	dedicated DAPE pins on BGA packages
Accessible address ranges	all (SRI, SPB, BBB)	BBB only
Interface locking	yes (OSTATE.IF_LCK)	yes (follows OSTATE.IF_LCK)
Password exchange	yes (COMDATA)	no
Control of Application and System resets	yes (OJCONF)	no
Trigger CPU to tool sources	OTGS, TRIG	OTGS
Trigger CPU to tool signaling	TGIP, IOINFO, TRIGx	TGIP, IOINFO
CPU interrupt request	COM Mode, write SRNs	IOC32E_OJCONF
Debug with run control, flashing, etc.	yes	no
Debug with MCDS trace	yes	
Calibration	yes	no (possible with monitor)
Measurement with DAP	yes	
Measurement with AGBT	yes (DAP needed for AGBT control)	
Rapid prototyping internal	yes	yes with monitor or prolog code
Rapid prototyping external	yes	yes with service monitor

**Attention:** The additional DAPE pads used for BGA packages need to be configured with TTL level.

## 1.5 Software over the Air (SOTA)

### 1.5.1 Overview

All TC3xx devices besides the TC33x and TC33xED have the ability to receive Software updates Over The Air (SOTA) by providing the ability to split the PFLASH into two groups of banks, A and B. When SOTA is enabled, one of these groups of banks can be read and executed from, while the other group can have new code written to it. Thus, though simultaneous read-while-write (RWW) capability is not supported within a single physical PFLASH bank, SOTA is supported by providing the ability to safely and securely perform write and erase operations to the unused group of banks.

### 1.5.2 Functional Description

When SOTA is enabled, a group of PFLASH banks will be mapped to CPU executable address space (defined as ‘active’ banks) and the other group will be mapped to a set of addresses that allows them to be read and written to (defined as ‘inactive’ banks). **When a SOTA update has completed, and the banks are swapped around, only the address mapping will change.** This means that no data needs to be copied and the address ranges being executed from are always the same. The physical address of the PFLASH banks are as described in the standard address map in the Address Map chapter. When a SOTA address map switch from the standard address map is performed, the mapping of the PFLASH banks for read/code execution is described in the alternate address map in the Address Map chapter. In this chapter, the group of banks active in the standard address map is referred to as ‘A’ and the group of banks active in the alternate address map is referred to as ‘B’.

Note that all NVM operations are performed via the DMU using the physical system address of the PFLASH, i.e., an NVM operation always uses the standard address map regardless of swap settings. ‘NVM operation’ is a term used for any command sequence such as a program, erase etc. targeting a FLASH and does not include reads.

The parameters that control SOTA address map switching and related functions are pre-configured in UCB and the hardware configuration is only updated (by on-chip system firmware) during the subsequent System Reset. This prevents unintentional changes during application execution.

On some product variants, a 1MB block will be swapped with a 3MB block. Because the code image must be able to fit in either group A or B, the upper 2MB of the 3MB block cannot be used for program code.

#### 1.5.2.1 Performance considerations

The CPU access to its local Program Flash bank is optimised for maximum performance. This can thus cause a performance variation when executing from different physical PFLASH banks. In order to mitigate this, when SOTA is enabled, CPU fast path to local PFlash must be disabled. This will cause some drop in performance but will ensure identical system performance when executing from either groups of banks.

Another point to note is prefetch accesses. If exact performance parity between each group is required, prefetch access should be disabled completely. If however, only approximate parity is required, one of the four user assignable prefetch buffers should be assigned to each non-local CPU (the first prefetch buffer is permanently assigned to the local CPU.)

#### 1.5.2.2 Configuring for SOTA

### 1.5.2.2.1 Configuration parameters

**Table 22 Configuration Parameters related to SOTA**

Parameter	Overview Description	Copied into register (by SSW during start-up)	See Chapter
<b>SOTA Mode Enable</b>  <b>(UCB OTP.PROCONTP.SW_APEN)</b>	If valid and enabled, SOTA Mode will be entered after the next System Reset.  If valid and enabled then PROCONHSMCx and PROCONHSMCOTP setting configured for active banks will also be applied to inactive banks after the next System Reset.	DMU_HF_PROCONTP.SWAPEN  Enables SOTA bank swapping  Ensures that both group of banks have the same HSM sector protection as programmed in PROCONHSMCx/PROCONHSMCOTPx (if an HSM is present)	DMU
<b>Bank Swap</b>  <b>(UCB_SWAP_ORIG, UCB_SWAP_COPY)</b>	User programmable active address map is standard or alternate address map.  If SOTA Mode is valid and enabled and the SWAP information configured in the UCB_SWAP is valid, then after next System Reset the address map is set accordingly to standard or alternate address map.	SCU_SWAPCTRL	SCU
<b>CPUx Fast Path Disable</b>  <b>(UCB OTP_PROCONTP.CPUDDIS)</b>	Disables direct CPU access to local Program Flash Bank after the next System Reset. Access to local Program Flash routed via SRI instead.	DMU_HF_PROCONTP.DDISx  CPUx_FLASHCON4.DDIS	DMU, CPU

### 1.5.2.2.2 Initial device configuration for SOTA

Following is a recommendation for installing the initial device configuration for a device with SOTA enabled.

Starting from the delivery state, the initial execution image is programmed onto the program flash banks in the active banks. It is recommended that the sectors used are then protected by installing sector specific write protection in the UCB\_PFLASH (for this and all subsequent programming of UCBs, the standard ORIG and COPY programming sequence is to be applied. More details are available in the ‘Security’ section of DMU Chapter).

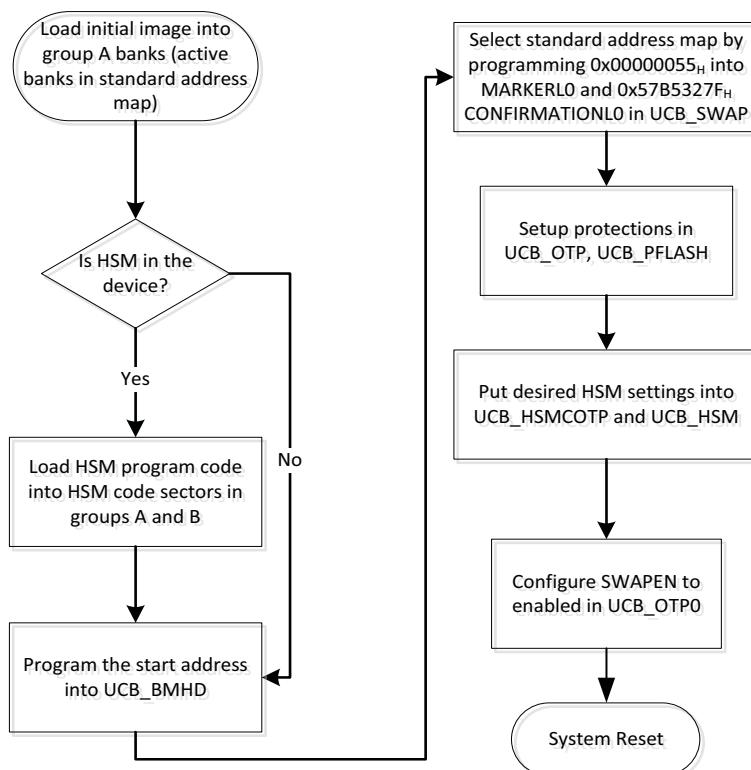

The start address of the initial image is programmed in UCB\_BMHD and the standard programming of the Boot Mode Header UCBs is performed.

In order to select the standard address map (executing from group A, writing to group B),  $00000055_{\text{H}}$  should be programmed into MARKERL0.SWAP field in UCB\_SWAP. This should then be confirmed by writing the system address of MARKERL0.SWAP into MARKERH0.ADDR, the system address of CONFIRMATIONL0.CODE into CONFIRMATIONH0.ADDR and the confirmation code  $57B5327F_{\text{H}}$  into CONFIRMATIONL0.CODE. The details of these UCB\_SWAP fields are available in the UCB Chapter located within the NVM Subsystem Chapter.

UCB OTP is programmed with the necessary values to setup the required OTP, WOP and tuning protection. Note that any OTP or WOP protected sectors cannot be re-programmed with a new image.

If HSM is required, the initial image should be loaded along with the HSM program code which should be put within the PFLASH logical sectors S0 to S39 of the first PFLASH modules of both group A and group B. The customer HSM configuration should be loaded into UCB\_HSMCOTP and UCB\_HSM. Note that any OTP protected HSM sectors cannot be re-programmed with a new image.

Finally, SWAPEN is set to enabled in UCB OTP, thus enabling SOTA mode with the next system reset.

**Figure 15 Initial SWAP configuration**

### 1.5.2.2.3 Runtime SWAP configuration

Following is a recommendation for installing the new image during running application, and configuring the device to swap to the new image.

In order to swap to the new image, first the new program image needs to be loaded into the inactive group of PFLASH banks. In order to do this, first **sector specific write protection must be disabled for those banks (by presenting the UCB\_PFLASH password for the ‘Disable Protection’ command sequence in the DMU)**. Since concurrent NVM operations (like a program or erase) to PFLASH and DFLASH is not supported, PFLASH operations must either be scheduled for times when no DFLASH operation is taking place or any ongoing DFLASH operation must be suspended to allow the PFLASH operation to occur. Thus, there needs to be some synchronization between the EEPROM driver running in the application and the Secure Flash Bootloader which is performing the update.

The newly written image should then have any errors identified and corrected before write protection is re-enabled.

**In the case of a hard failure during SOTA re-programming/erasing of PFLASH, the Replace Logical Sector feature can be used** (See DMU chapter for more details). This feature allows user to map a failing logical sector to a redundant sector using the ‘Replace Logical Sector’ command sequence.

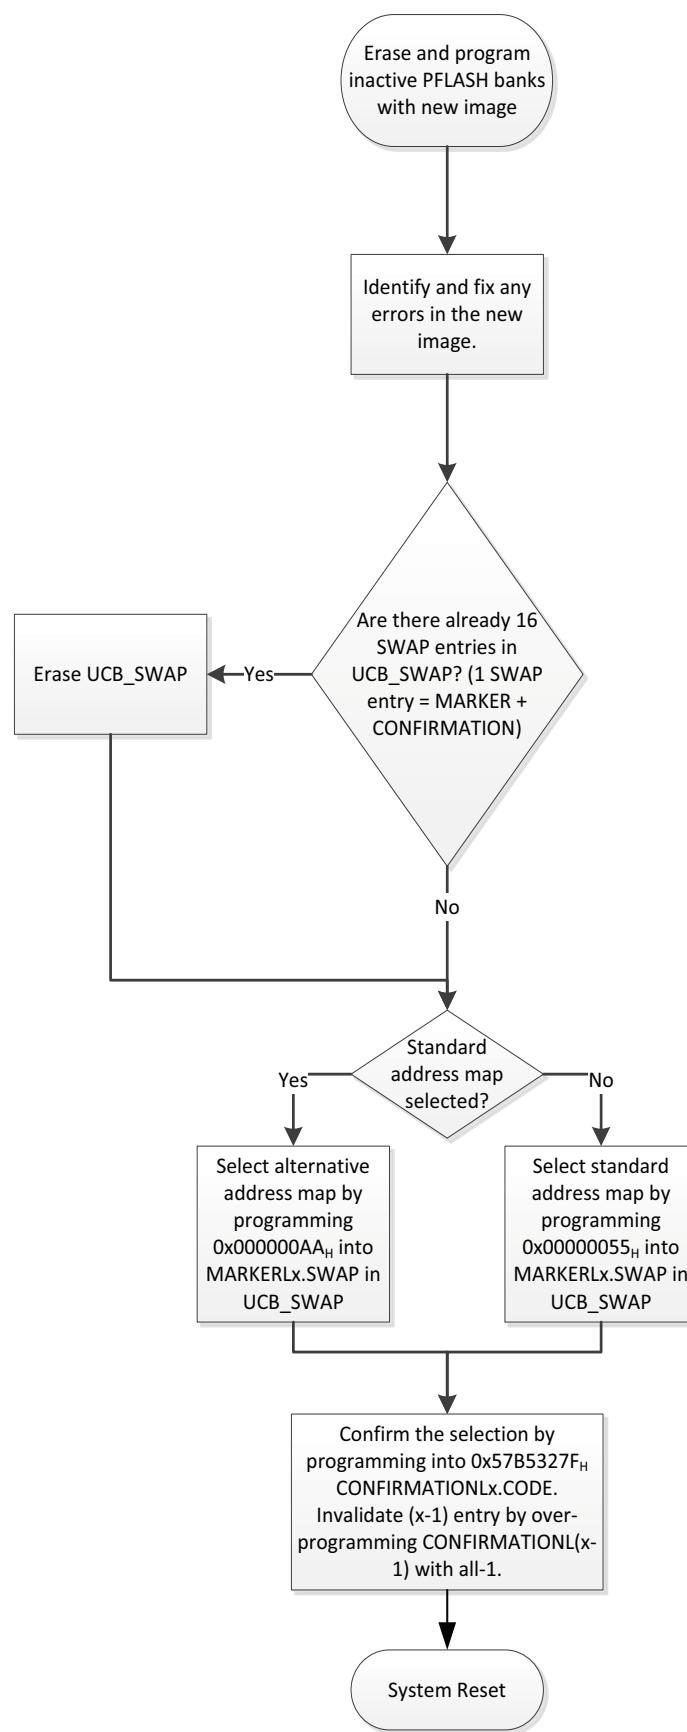

The next step is to **configure the SWAP information** (i.e., configure the address map to be selected) in the **UCB\_SWAP**. After the UCB\_SWAP password has been presented (using the 'Disable Protection' DMU command sequence), MARKERLx.SWAP is changed to  $000000AA_H$  (thus selecting alternate address map) if group B contains the **new image** or  $00000055_H$  (thus selecting standard address map) if group A does. **MARKERHx.ADDR**, **CONFIRMATIONHx.ADDR** and **CONFIRMATIONLx.CODE** is then programmed as with the initial configuration. The previous (x-1) UCB\_SWAP entry is invalidated by over-programming all-1 into CONFIRMATIONL(x-1) and CONFIRMATIONH(x-1) (over-programming with all-1 delivers an ECC correct result for UCB and DFLASH). For all of these, 'x' should be increased by one each time images are swapped, starting from 1 the first time after the initial configuration.

If UCB\_SWAP is full (i.e., 'x' has reached 15), the whole UCB may be erased and 'x' set back to 0 before a new entry is added. The write protection is then re-installed by using the 'Resume Protection' DMU command sequence.

Note that the last valid entry of the SWAP information (i.e., SWAP information stored at the highest value of 'x') is used by the Startup Software for configuring SOTA in the system.

Thus, it is possible to configure 16 SWAPs in the UCB\_SWAP before an erase is required. The maximum number of SWAPs possible during the lifetime of the device is dependent on the Datasheet parameter for PFLASH erase/program cycles ( $N_{E\_P} = 1000$  cycles). In order to perform 1000 SWAP configurations, atleast a total of 124 UCB erase/program cycles is required during the lifetime (two UCB erases required per 16 SWAP updates as both UCB\_SWAP\_ORIG and UCB\_SWAP\_COPY needs to be erased and updated). This needs to be taken into account while updating the other UCBs in order to adhere to the Datasheet parameter for UCB program/erase cycles ( $t_{RTU} = 400$  erase/program cycles for all UCBs together).

To begin running of the new image, a system reset should be triggered (application resets have no effect).

**Figure 16 Runtime SOTA configuration**

### 1.5.3 Safety

If SOTA is disabled, the entirety of the program flash is protected by safety\_endinit which prevents unintentional changes to the program flash's contents. If SOTA is enabled, safety\_endinit protection for the inactive group of banks is automatically removed, thus allowing them to be updated. However, even for the active banks, the requirement for safety application software to be checked before execution remains. More details on the safety\_endinit protection are available in the 'Functional Safety Features' section of the NVM Subsystem chapter.

### 1.5.4 Security

The security protection offered to a NVM operation on the PFLASH remains the same as defined in the 'Security' section of the DMU Chapter irrespective of the active or inactive nature of the PFLASH bank.

There is however, additional measures implemented for handling HSM Exclusive sectors in PFLASH.

If SOTA is enabled, any protection configured in the PROCONHSMCX and PROCONHSMCOTP registers is mirrored to the PFLASH logical sectors S0 to S39 of both the groups A and B. This is to prevent unauthorised access to HSM code being gained via bank swapping. The user must make sure that the secure content image is duplicated between the two groups. Reprogramming sectors marked as HSM exclusive, even when inactive, can only be done by the HSM or Cerberus when HSM debug is enabled.

### 1.5.5 Revision History

**Table 23 Revision History**

Reference	Change to Previous Version	Change Request Comment
<b>V1.0.1</b>		
	Revision History added	
	First-level heading structure created	
	Restructuring of the chapter for better clarity, and addition of programming hints, and details to support SOTA implementation in both hardware and software.	
<b>Chapter 1.</b> <b>5.2.2.2</b>	Clarification of the address to be stored in MARKERH0.ADDR and CONFIRMATIONH0.ADDR	
<b>V1.0.2</b>		
<b>Chapter 1.</b> <b>5.2.2.2</b>	Removed UCB_HSMCFG from the user programming model.	Jira 0000049147-100
<b>Chapter 1.</b> <b>5.2.2.3</b>	Added recommendation to invalidate the previous entry by over-programming with all-1.	Jira 0000052718-112
<b>V1.0.3</b>		
<b>Page 52</b>	<b>Chapter 1.5.2</b> - Typo when referring to B image - should be banks rather than maps.	Jira 0000056754-43
<b>V1.0.4</b>		
<b>Page 55</b>	<b>Chapter 1.5.2.2.3</b> - Due to 64 bit width of page write for UCBs, must over-programming CONFIRMATIONL+H with all-1.	Jira 0000056760-70

## Memory Maps (MEMMAP)

## 2 Memory Maps (MEMMAP)

The MEMMAP specifies the over-arching memory map for all devices in the AURIX TC3xx product family.

The device specific MEMMAP (reflecting the exact silicon content) are specified in the device Appendix books.

### 2.1 Feature List

#### FEATURE LIST

The address map includes the following memories:

- Program Flash Interface (PFI):
  - Program Flash Memory (PF)
- Data Memory Unit (DMU):
  - Data Flash Memory for CPU EEPROM (DF0)
  - User Configuration Blocks (DF0)
  - Configuration Sector (DF0)
  - Data Flash Memory for HSM EEPROM (DF1)
- CPU0 and CPU1:
  - 64 Kbyte of Program Scratch-Pad SRAM (PSPR)<sup>1)</sup>
  - 240 Kbyte of Data Scratch-Pad SRAM (DSPR)<sup>1)</sup>
  - 32 Kbyte of Program Cache (P-Cache)
  - 16 Kbyte of Data Cache (D-Cache)
  - 64 Kbyte of Local Memory Unit (DLMU)
- CPU2 to CPU5:
  - 64 Kbyte of Program Scratch-Pad SRAM (PSPR)<sup>1)</sup>
  - 96 Kbyte of Data Scratch-Pad SRAM (DSPR)<sup>1)</sup>
  - 32 Kbyte of Program Cache (P-Cache)
  - 16 Kbyte of Data Cache (D-Cache)
  - 64 Kbyte of Local Memory Unit (DLMU)
- Local Memory Unit (LMU):
  - LMU SRAM (CPU DLMU or LMU LMURAM)<sup>1)</sup>
  - DAM SRAM (DAMRAM)
- Boot ROM (BROM)

Furthermore, the device has the following on-chip buses:

- System Peripheral Bus (SPB)
- Shared Resource Interconnect (SRI)
- Back Bone Bus (BBB)

### 2.2 Overview

The memory map describes the address locations and access possibilities for the units, memories, and reserved areas as “seen” from the different on-chip buses’ point of view.

<sup>1)</sup> Before used by the application, the memory has to be initialized (see chapter ‘Memory Test Unit’, MTU)

## Memory Maps (MEMMAP)

### 2.3 Functional Description

The bus-specific address maps describe how the different bus master devices react on accesses to on-chip memories and modules, and which address ranges are valid or invalid for the corresponding buses.

The detailed address mapping of e.g. control registers, SRAM blocks or flash banks/sectors within a module is described in the related module chapter.

**Note:** *In addition to the here described system address map, each TriCore has a TriCore IP internal access to its PSPR via C000\_0000<sub>H</sub> and an internal access to its DSPR via D000\_0000<sub>H</sub>. This additional/private view to the local scratch pad SRAMs is described in the CPU chapter.*

**Table 24** defines the acronyms and other terms that are used in the address maps (**Table 25** and **Table 41**).

**Table 24 Definition of Acronyms and Terms**

Term	Description
BBBEE	A bus access is terminated with a bus error on the BBB.
SPBEE	A bus access is terminated with a bus error on the SPB.
SRIE	A bus access is terminated with a bus error on the SRI.
Access	A bus access is allowed and is executed.

#### 2.3.1 Segments

This section summarizes the contents of the segments.

##### Segments 0 and 2

These memory segments are reserved.

##### Segments 1 and 3-7

These memory segments allow access to the CPUs Program and Data Scratch Pad SRAM (PSPR, DSPR), Program and Data Cache SRAMs (PCACHE, DCACHE) as well as TAG SRAMs related to Program and Data Cache (PTAG SRAM<sup>1)</sup> and DTAG SRAM<sup>1)</sup>).

Where DCACHE is supported, DCACHE and DTAG SRAM<sup>1)</sup> can be only accessed if the Data Cache is disabled.

PCACHE and PTAG SRAMs<sup>1)</sup> can be only accessed if the related Program Cache is disabled.

The attribute of these segments (cached / non-cached) can be partially configured<sup>2)</sup> for each CPUs data and program side individually (see CPU chapter: Physical Memory Attribute Registers, PMAX).

##### Segment 8

This memory segment allows cached access to PFlash and BROM.

##### Segment 9

This memory segment allows cached access to LMU and to EMEM.

##### Segment 10

This memory segment allows non-cached access to PFlash, DFlash and BROM.

1) TAG SRAMs are not meant to be used as general SRAMs and can be accessed only with single data access and only with 64 bit aligned address.

2) Mapping of Cache and TAG SRAMs is controlled via the MTU register MTU\_MEMMAP.

## Memory Maps (MEMMAP)

### Segment 11

This memory segment allows non-cached access to LMU and to EMEM.

### Segment 12

This memory segment is reserved.

### Segment 13

This memory segment is reserved.

### Segment 14

This memory segment is reserved.

### Segment 15

The lower 128 Mbyte is SPB address space and the upper 128 Mbyte is SRI address space.

## 2.3.2 Address Map of the On Chip Bus System

All bus master agents can address identical peripherals and memories at identical addresses. The system address map is visible and valid for all CPUs which means that all peripherals and resources are accessible from all TriCore CPUs and other on chip bus master agents.

Parallel access by more than one bus master agent to one slave agent are executed sequentially. Additionally the SRI, SPB and BBB support atomic Read Modify Write sequences from the CPUs.

### 2.3.2.1 Segments 0 to 14

**Table 25** shows the address map of segments 0 to 14.

#### Notes

1. *Write Access Type:* Write access to Flash resources are handled by the DMU module (Flash command sequence, see DMU chapter for details).

**Table 25 Address Map of Segment 0 to 14**

Segment	Address Range	Size	Description	Access Type	
				Read	Write
0	0000 0000 <sub>H</sub> - 0000 0007 <sub>H</sub>	8 Byte	Reserved (virtual address space)	SRIBE / SPBBE <sup>1)</sup>	SRIBE / SPBBE <sup>1)</sup>

15	F000 0000 <sub>H</sub> - FFFF FFFF <sub>H</sub>	256 Mbyte	See <a href="#">Table 41</a>		

- 1) If an SPB access to 0000 0000H occurs, the SPB BCU generates a bus error.
- 2) PCACHE/DCACHE SRAMs (and the corresponding TAG SRAMs) can be only accessed when mapped into the address space (PCACHE / DCACHE disabled. See CPU chapter, register SMACON for details).
- 3) TAG SRAMs are not meant to be used as general SRAMs and can be accessed only with single data access and only with 64 bit aligned address. Mapping of TAG SRAMs in the address map can be used as additional option for memory testing
- 4) TRAM shall not be used as a general SRAM and can only be accessed when OCDS is enabled.
- 5) Host Command Sequence Interpreter
- 6) HSM Command Sequence Interpreter
- 7) See also chapter 'CPU, 'Local and Global Addressing' for CPU local views to segment 'C' and segment 'D'.

### 2.3.2.2 Segment 15

**Table 41** shows the address map of segment 'F' as seen from the SRI and SPB bus masters (bus master agents are described in the chapter On Chip Bus System). It describes the mapping of modules to Segment F. The details of the module address ranges can be found in the module chapters register overview.

**Figure 17** gives an overview about the address mapping of the module address ranges:

- Absolute Addressing Range
  - If a module is addressed in the first 16 Kbyte of segment 'F', the CPU can access the module with absolute addressing mode.
- Others
  - If a module is addressed above the first 16 Kbyte of segment 'F', the CPU can access the module with base + offset.

## Memory Maps (MEMMAP)

**Figure 17 Segment F Structure**

**Table 41 Address Map of Segment 15**

Address Range	Size	Unit	Access Type	
			Read	Write
F000 0000 <sub>H</sub> - F000 01FF <sub>H</sub>	512 Byte	Flexible CRC Engine (FCE0)	Access	Access
F000 0200 <sub>H</sub> - F000 03FF <sub>H</sub>	-	Reserved	SPBBE	SPBBE

FFC4 0000 <sub>H</sub>	- FFFF FFFF <sub>H</sub>	-	Reserved	SRIBE	SRIBE

1) TC38x only

2) MINIMCDS SFR may only be accessed when OCDS is enabled.

3) HSM Command Sequence Interpreter

### 2.3.3 Memory Accesses

The following tables list the types of memories and supported access sizes<sup>1)</sup>:

**Table 42 Standard Read Write Memories (C variable)**

Memory	Byte		Half-word		Word			Double-word		Block Transfer	
	r	w	r	w	r	w	rmw	r	w	r	w
PSPR	y	y	y	y	y	y	y	y	y	y	y
DSPR	y	y	y	y	y	y	y	y	y	y	y
DLMU	y	y	y	y	y	y	y	y	y	y	y
LMURAM	y	y	y	y	y	y	y	y	y	y	y
EMEM	y	y	y	y	y	y	y	y	y	y	y
DAM RAM	y	y	y	y	y	y	y	y	y	y	y
TRAM <sup>1)</sup>	y	y	y	y	y	y	y	y	y	y	y

1) TRAM shall not be used as a general SRAM and can only be accessed when OCDS is enabled.

1) 'y' means: access supported. '-' means: access not supported.

## Memory Maps (MEMMAP)

**Table 43 Standard Read Only Memories (C const)**

Memory	Byte		Half-word		Word			Double-word		Block Transfer	
	r	w	r	w	r	w	rmw	r	w	r	w
BROM	y	-	y	-	y	-	-	y	-	-	-
PFLASH <sup>1)</sup>	y	-	y	-	y	-	-	y	-	y	-
DFLASH <sup>1)</sup>	y	-	y	-	y	-	-	y	-	-	-

1) FLASH memory shall be programmed and erased by command sequences.

**Table 44 Non Standard Memories**

Memory	Byte		Half-word		Word			Double-word		Block Transfer	
	r	w	r	w	r	w	rmw	r	w	r	w
PTAG <sup>1)</sup>	-	-	-	-	y	y	-	-	-	-	-
PCACHE	y	y	y	y	y	y	y	y	y	y	y
DTAG <sup>1)</sup>	-	-	-	-	y	y	-	-	-	-	-
DCACHE	y	y	y	y	y	y	y	y	y	y	y

1) TAG SRAMs are not meant to be used as general SRAMs and can be accessed only with 32-bit data access and only with 64 bit aligned address. Mapping of TAG SRAMs in the address map can be used as additional option for memory testing. The TAG SRAM size is below 24 bit, so the 8 MSB of a 32 bit write or read are don't care.

## 2.4 Revision History

<a href="#">Page 3</a>	CPU2.DSPR address range fixed from 240 to 96 Kbyte.	

## AURIX™ TC3xx Platform Firmware

### 3 AURIX™ TC3xx Platform Firmware

The AURIX™ TC3xx Platform Firmware from user point of view consists of the following functional parts:

- **Startup Software** (short name SSW) including **Support for Software over the Air (SOTA)**
- **Checker Software** (short name CHSW)
- Software modules implementing additional functions:
  - **Bootstrap Loaders** (short name BSL)
  - **Shutdown request handler**
  - **Power Supply Friendly Debug Monitor**

#### 3.1 Functional description

The following Sections describe the functionality of AURIX™ TC3xx Platform Firmware.

##### 3.1.1 Startup Software

The Startup Software is the first software executed after a chip reset.

SSW is executed on CPU0 - all other CPUs are kept in Halt-state during boot, to be started by user software whereas:

- SSW start address in BootROM is the reset value in Program Counter register of the CPU0. From this location an instruction is fetched and this is the first instruction executed after any device start-up.
  - immediately after this entry point the firmware checks for testmode, and in case testmode is selected - jump to test firmware is executed
- the last SSW instruction performs a jump to the first user code instruction. This first user instruction can be fetched from different locations depending on the start-up configuration as selected by the user.

The Startup Software contains procedures to initialize the device depending on one or more from the following:

- information previously stored into dedicated Flash locations
- the current state of special bits/fields in dedicated register/memory locations
- the type of event which has triggered the SSW-execution (the last reset event)
- values applied to external (configuration-) pins (optional)

The SSW can also call ASC and CAN Bootstrap Loader routines.

###### 3.1.1.1 Events triggering SSW execution

SSW execution can be triggered by different events. SSW recognizes the triggering (reset) event and takes (partially) different execution flows.

###### 3.1.1.1.1 Cold (initial) power-on reset

This is the initial powering-up of the device after the supply has been switched off, or in other words - the only way to generate this reset event is by applying power to a previously un-powered device.

The conditions at which the SSW execution starts upon this event include:

- all the registers are in their initial (reset) state
- **Flash is under reset - meaning not active, and not ready to perform any (read/erase/program) operation**
- RAMs' content is undefined
- clock system is in its initial state

## AURIX™ TC3xx Platform Firmware

Due to the overall “fully initial” state of the device upon power-on, the SSW flow is respectively longer in this case and covers the largest number of activities compared to other reset events.

### 3.1.1.1.2 System reset

From SSW point of view, the handling of system reset is generally the same as of “warm power-on”. Therefore further in this Chapter when referring to a system reset - the same SSW handling applies to warm power-on. Exceptions are noted where applicable.

This reset event can be requested by different sources:

- device internal hardware - from modules like watchdog timer and security/memory control logic
- external hardware - when active signal is applied to defined device pin(s)
- software - when defined control bit(s) are respectively installed during user code execution

For most of the sources, generating system reset is a feature configurable by software.

Applying an active low level to the PORST pin generates a system reset only if the supply voltage is above a defined level, within a defined time window. The EVR module triggers an immediate power-on reset if the supply drops below a defined level.

The conditions at which SSW execution starts upon system reset include:

- all the registers affected by these reset types (system and warm power-on) are in their initial (reset) state
- Flash is under reset - meaning not active, and not ready to perform any (read/erase/program) operation
- RAMs' content is the same as just before the system reset has been triggered
- clock system is in its initial state

### 3.1.1.1.3 Application reset

An application reset is similar to a system reset and can be requested by different sources: internal/external hardware as well as software. For all the sources, generating an application reset is a feature configurable by software.

The conditions at which SSW execution starts upon application reset include:

- registers connected to this reset type are in their initial (reset) state
- Flash is in read mode
- all the rest - RAMs and surrounding logic, the clock system and registers under system reset - is not affected by this event.

Application reset is the quickest type of reset.

### 3.1.1.2 Clock system during start-up

The state of the clock system during device start-up depends on the reset event type:

- upon power-on and system reset, the clock system is in its initial state:
  - fSRI=fCPU0 = fFSI=fBACK=100MHz nominal
  - fSPB=fSTM=fBACK/2=50MHz nominal
  - in Emulation Device (ED): fBBB=fBACK/2=50MHz nominal
  - PLL and VCO are in power-down mode
- upon application reset, the clock system does not change its state: therefore, the device runs at the same frequency and clock source as before the reset event

## AURIX™ TC3xx Platform Firmware

### 3.1.1.3 RAM overwrite during start-up

The start-up procedure can overwrite:

- up to 8kByte at the beginning of CPU0 DSPR. Therefore, this area should not be used by application software to save data which must be preserved through a reset.
- up to 1kByte at the beginning of CPU0 PSPR. Therefore this area should not be used by application software to save program code which must be preserved through a reset.

Note: *CPU0 PSPR overwrite here noted does not refer to Bootstrap Loader routines - meaning the code downloaded by BSL is properly handled and not overwritten.*

### 3.1.1.4 Stand-by controller handling during start-up

The start-up procedure will initialize stand-by controller (SCR) RAMs and trigger SCR boot when the last reset:

- was seen by the device as a cold power-on, AND
- has been triggered by EVR pre-regulator - identified by SCU\_RSTSTAT.STBYR=1

In other words, SCR is initialized/started upon cold power-on reset which is not identified as exit from stand-by mode.

Therefore, for proper SCR handling, the user software must take care to reset SCU\_RSTSTAT.STBYR flag via SCU\_RSTCON2.CLRC (refer to SCU Chapter) according to the application - e.g. after the initial system power-on, if SCR usage during stand-by mode is intended.

### 3.1.1.5 Boot Options Summary

This chapter summarizes the AURIX™ TC3xx Platform startup configurations.

For more detailed information and flow description, refer to [Chapter 3.1.1.6](#).

#### Internal Start

In this basic startup mode, the first user instruction is fetched from the Internal Program Flash of the device.

The user code start address defined as STADD is configurable in the Boot Mode Header (BMHDx.STAD) data structure.

#### Bootloader Modes

Different Bootstrap Loader routines are used in these modes to download code or data into the Program Scratchpad RAM of CPU0 (CPU0\_PSPR).

The supported Bootloader selections are:

- ASC Bootloader - ASC communication protocol via ASC pins
- Generic Bootloader via CAN pins - the communication protocol is automatically selected by the SSW between ASC and CAN

After downloading the code, the user code start address is set to the beginning of Program Scratchpad RAM (PSPR).

#### Alternate Boot Modes

In these modes (short name ABM), program code is started from an user-defined address, but only if all defined conditions are satisfied (see [Chapter 3.1.1.6.2](#)). If the conditions are not met, the SSW can fall back to a Bootstrap Loader mode, to allow download and execution of user code.

## AURIX™ TC3xx Platform Firmware

All the information needed for the SSW to handle ABM startup mode is collected into Alternate Boot Mode Headers (ABMHD). The checks are performed according to [Alternate Boot Mode evaluation](#) flow as defined in [Chapter 3.1.1.6.2](#).

If this mode is selected and the ABMHD is valid, the user code start address STADD is set to the respective value from the Alternate Boot Mode Header (ABMHDn.STADABM).

### 3.1.1.6 Boot Mode evaluation sequence

This is a main functional part of AURIX™ TC3xx Platform [Startup Software Main Flow](#) - see also [Figure 22](#) and [Chapter 3.1.1.7.4](#)

Boot Mode evaluation follows the sequence shown on [Figure 18](#) and [Figure 19](#), where three blocks can be differentiated as shown in the next Sections.

**Note:** *All the CRC calculations below pointed are done using the TriCore instruction CRC32 which implements the IEEE 802.3 standard: CRC-32 polynomial is used and the CRC result is bit-reversed and inverted.*

#### 3.1.1.6.1 Evaluation of Boot Mode Headers

A Boot Mode Header is an information structure (see [Table 46](#)) that specifies user startup options, including the starting address of user code.

In AURIX™ TC3xx Platform, [four sets of Boot Mode Headers](#) (BMHDx for x=0, 1, 2, 3) are defined in the User Configuration Blocks (UCB) of Data Flash (DFLASH). Each set contains [an original and copy](#) in UCB\_BMHDx\_ORIG and UCB\_BMHDx\_COPY, respectively.

**Note:** *For full content and layout description - refer to the “User Configuration Block (UCB)” Section in the “Non Volatile Memory (NVM) Subsystem” Chapter.*

## AURIX™ TC3xx Platform Firmware

**Table 46 Boot Mode Header (BMHD) structure**

Field Name	Subfield	Description
BMI	Boot Mode Index - 16 bit	
	PINDIS bit [0]	Mode selection by configuration pins: <b>0B Mode selection by HWCFG pins is enabled</b> 1BMode selection by HWCFG pins is disabled
	HWCFG bits [3:1]	Start-up mode selection: <b>111B Internal start from Flash</b> 110BAAlternate Boot Mode (ABM) 100B Generic Bootstrap Loader Mode (ASC/CAN BSL) 011BASC Bootstrap Loader Mode (ASC BSL) elseinvalid
	LSENA0 bit [4]	Lockstep monitoring control by SSW for CPU0: 0B Lockstep monitoring for CPU0 is disabled <b>1BLockstep monitoring for CPU0 is enabled</b>
	LSENA1 bit [5]	Lockstep monitoring control by SSW for CPU1: <sup>1)</sup> 0B Lockstep monitoring for CPU1 is disabled <b>1BLockstep monitoring for CPU1 is enabled</b>
	LSENA2 bit [6]	Lockstep monitoring control by SSW for CPU2: <sup>1)</sup> 0B Lockstep monitoring for CPU2 is disabled 1BLockstep monitoring for CPU2 is enabled
	LSENA3 bit [7]	Lockstep monitoring control by SSW for CPU3: <sup>1)</sup> 0B Lockstep monitoring for CPU3 is disabled 1BLockstep monitoring for CPU3 is enabled
	LBISTENA bit [8]	LBIST execution start by SSW: 0B LBIST execution start by SSW is disabled <b>1B LBIST execution start by SSW upon cold power-on is enabled</b>
	CHSWENA bits [11:9]	Checker Software (CHSW) execution after SSW: <sup>2)</sup> <b>101B CHSW execution after SSW is disabled</b> else CHSW execution after SSW is enabled
	reserved bits [15:12]	Reserved for future extensions, must be configured to 0 in UCB_BMHDx
BMHDID	---	Boot Mode Header Identifier - 16 bit: <b>B359H</b> BMHDID OK elseBMHDID invalid
STAD	---	Start address (always must be inside PFLASH, word-aligned) - 32 bit: if ABM selectedStart address of the Alternate Boot Mode Header if Internal start selectedStart address of the user code elsenot considered for mode selection
CRCBMHD	---	Check result for the Boot Mode Header - 32 bit
CRCBMHD_N	---	Inverted check result for the Boot Mode Header - 32 bit

- 1) Only if the respective CPUx Lockstep functionality is available on the product, otherwise the bit is Reserved, must be configured to 0 in UCB\_BMHDx
- 2) This bitfield is not evaluated during the SSW flow but by the **Checker Software** - refer to **Chapter 3.1.2**

## AURIX™ TC3xx Platform Firmware

**Attention:** *The requirement in the above Table - STAD to be a valid word-aligned address inside PFLASH (considering the complete PFLASH, not PF0 only) - is always applicable, meaning:*

- *independently which mode is selected - also in case of BSL mode when the value has no effect*
- *independently how is the mode selected - also in case of ABM or Internal start mode selected by pins*

**Attention:** *For the above requirement, both PFLASH address areas for cached and non-cached access are considered as allowed locations by the evaluation procedure.*

The SSW follows these steps to process the Boot Mode Headers and their copies (refer to [Figure 18](#)):

1. set SSW variables/flags to these initial states:
  - a) no valid BMI found usable for boot
  - b) no valid start-up configuration found usable for boot (BOOT\_CFG)
  - c) no configuration from pins selected for boot (BOOT\_PIN)
2. check the status of the currently evaluated UCB\_BMHDX - evaluate bitfields in DMU\_HF\_CONFIRM0 register as follows:
  - for BMHD[n] originals - into PROINBMHDnO bitfields
  - for BMHD[n] copies - into PROINBMHDnC bitfields
  - a) **if the target bitfield indicates status CONFIRMED (10B) or UNLOCKED (01B) - continue with the next step**
  - b) otherwise - the status of current BMHDx is wrong, go to step 17.
3. check the Boot Mode Header Identifier (BMHDID) value against the value in [Table 46](#)
  - a) if value OK - continue with the next step
  - b) otherwise - BMHDID of the current BMHDx is wrong, go to step 17.
4. check the Boot Mode Index (BMI) value against [Table 46](#) - HWCFG subfield must be valid, all undefined bits zero
  - a) if value OK - continue with the next step
  - b) otherwise - BMI of the current BMHDx is wrong, go to step 17.
5. check the Start Address (STAD) value - it must be a valid word-aligned address inside PFlash
  - a) if value OK - continue with the next step
  - b) otherwise - STAD in the current BMHDx is wrong, go to step 17.
6. calculate CRC over the BMHDx content (total 2 words including BMI, BMHDID and STAD) and compare against CRCBMHD value stored inside BMHDx, then invert the calculated value and compare the result against CRCBMHD\_N value from BMHDx
  - a) if both values OK - continue with the next step
  - b) otherwise - the current BMHDx is wrong, go to step 17.
7. check if Boot Mode selection from pins is enabled by the current BMHDx (BMI.PINDIS=0) and in general for the device (DMU\_HF\_PROCONTP.BML=00B)
  - a) if yes - continue with the next step
  - b) otherwise - only configuration from BMI is allowed, go to step 10.
8. check if Boot Mode selection from pins is enabled by low level (zero) latched at HWCFG3 pin upon reset (SCU\_STSTAT.HWCFG[3]=0)
  - a) if yes - continue with the next step
  - b) otherwise - configuration from BMI will be done, go to step 10.
9. prepare Boot Mode selection from pins (the selection still can be canceled) - refer to [Table 47](#)

## AURIX™ TC3xx Platform Firmware

- a) instal the index of current BMHD into BMHD\_INDEX
  - b) instal the mode selection according to SCU\_STSTAT.HWCFG[5:4] into BOOT\_CFG (see the Note below)
  - c) set “configuration from pins” flag into BOOT\_PIN
  - d) go to step 11.
10. prepare Boot Mode selection from BMI (the selection still can be canceled)
- a) instal the index of current BMHD into BMHD\_INDEX
  - b) instal the mode selection according to BMHDx.BMI into BOOT\_CFG (see the Note below)
11. check if Alternate Boot Mode is so far selected for start-up according to BOOT\_CFG
- a) if yes - continue with the next step
  - b) otherwise - no ABM (meaning no further evaluation needed), go to step 13.
12. evaluate Alternate Boot Mode Headers and the user code according to the procedure described in  
**Chapter 3.1.1.6.2**
- a) if procedure is successfully completed - go to step 14.
  - b) otherwise - ABM evaluation failed, go to step 17.
13. check if a Bootstrap Mode is selected according to BOOT\_CFG
- a) if yes - instal the first address of CPU0 Program scratchpad RAM (CPU0\_PSPR) as user code start address into BOOT\_ADDR
  - b) otherwise - instal BMHDx.STAD value as user code start address into BOOT\_ADDR
14. save boot mode information - to be available for HSM and application software
- a) selected boot mode BOOT\_CFG, the index of the valid BMHD BMHD\_INDEX, the flag ORIG/COPY BMHD\_COPY and pin-configuration flag BOOT\_PIN - into **SCU\_STMEM1**
  - b) user code start address BOOT\_ADDR - into SCU\_STMEM2[31:2] (the address is word aligned - bits[1:0] are not changed here), it is to be used also in case of CPU0 kernel reset
15. configure lockstep monitoring feature from the valid BMI found - instal BMI.LSENAn bits into respective LSENn bits of SCU\_LCLCON0/1 registers (n=0,1,2,3)
16. set “BMI\_VALID” and BOOTMODE\_CONFIGURED flags in **SCU\_STMEM1** register and exit the sequence
- 17.
18. according to the currently evaluated BMHDx
- a) if ORIGINAL - switch evaluation to the COPY and restart the sequence from step 1.
  - b) otherwise - exit the sequence (no valid BMHD found so far)

**Attention:** *SSW flow as above described allows evaluation both of UCB\_BMHDx ORIGINAL and COPY, but in reality always only one of these two UCBs can be indicated at any point of time in DMU\_HF\_CONFIRM0 register as being CONFIRMED or UNLOCKED - for more information, refer to DMU Section in “Non Volatile Memory (NVM) Subsystem” Chapter.*

**Therefore:**

- if the ORIGINAL of a given UCB\_BMHDx has been evaluated, the flow will continue with the COPY but it will be immediately exited due to state being different from CONFIRMED or UNLOCKED
- the COPY will be only evaluated if the ORIGINAL is in a state different from CONFIRMED or UNLOCKED.

**Note:** *BOOT\_CFG is installed not (always) directly from BMI or HWCFG but according to the coding in **SCU\_STMEM1** register description.*

## AURIX™ TC3xx Platform Firmware

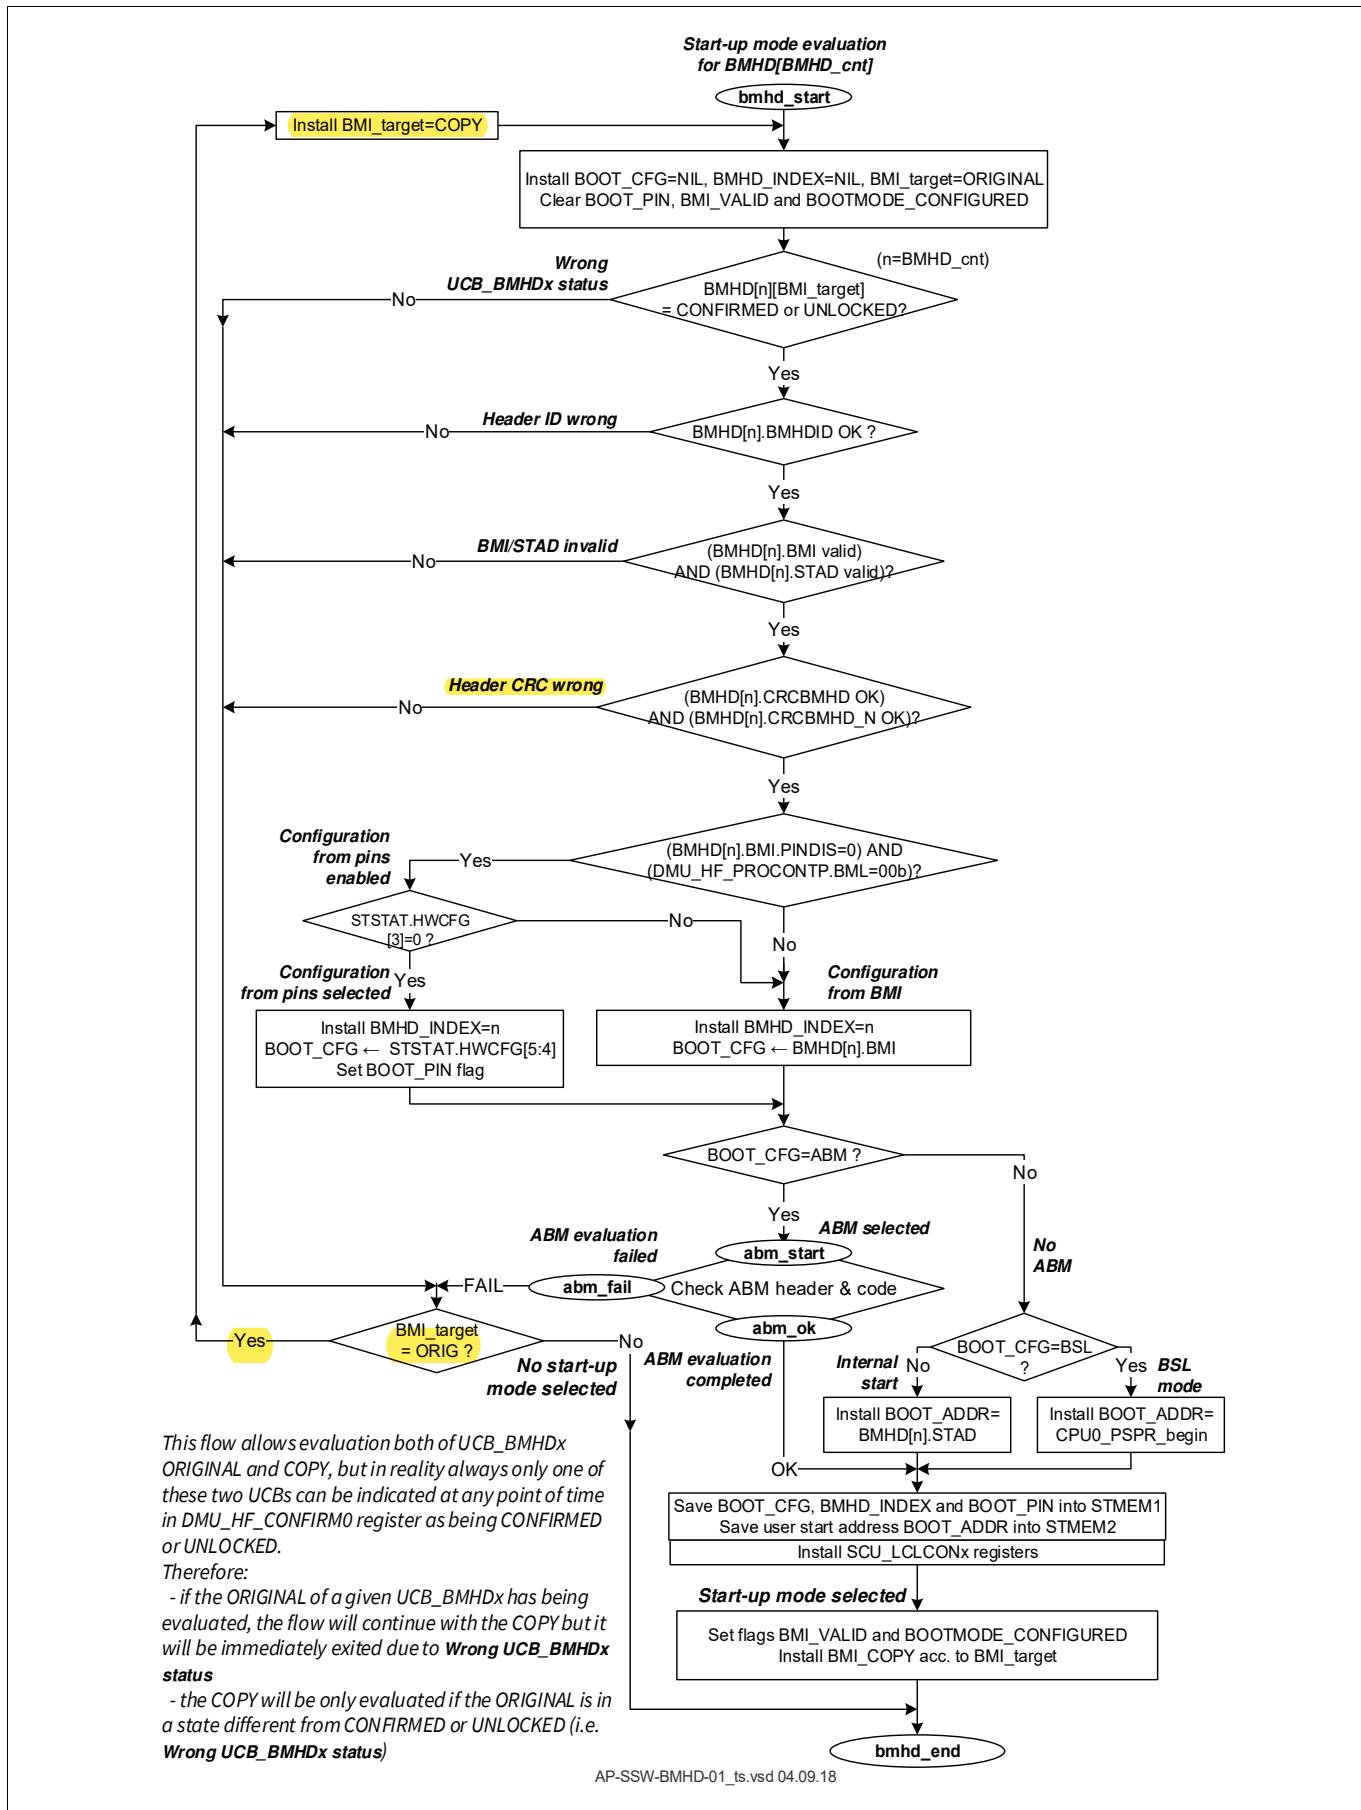

Figure 18 Boot Mode Headers evaluation flow

## AURIX™ TC3xx Platform Firmware

**Table 47 Start-up mode selection by pins in AURIX™ TC3xx Platform**

HWCFG pins		Start-up Mode
[5]	[4]	
1	1	Internal start from Flash
1	0	ABM, Generic Bootstrap Loader on fail
0	1	ABM, ASC Bootstrap Loader on fail
0	0	Generic Bootstrap Loader

### 3.1.1.6.2 Alternate Boot Mode evaluation

Alternate Boot Mode handling is controlled by the content of Alternate Boot Mode Headers. The structure of a single Alternate Boot Mode Header is defined in [Table 48](#).

**Table 48 Alternate Boot Mode Header (ABMHD) structure**

Offset Address	Size Byte	Field Name	Description
00H	4	STADABM	User Code Start Address in ABM mode <sup>1)</sup>
04H	4	ABMH DID	Alternate Boot Mode Header Identifier: FA7C B359H ABMH DID OK else ABMH DID invalid
08H	4	CHKSTART	Memory Range to be checked - Start Address <sup>1)</sup>
0CH	4	CHKEND	Memory Range to be checked - End Address <sup>1)</sup>
10H	4	CRCRANGE	Check Result for the Memory Range
14H	4	CRCRANGE_N	Inverted Check Result for the Memory Range
18H	4	CRCABMHD	Check Result for the ABM Header
1CH	4	CRCABMHD_N	Inverted Check Result for the ABM Header

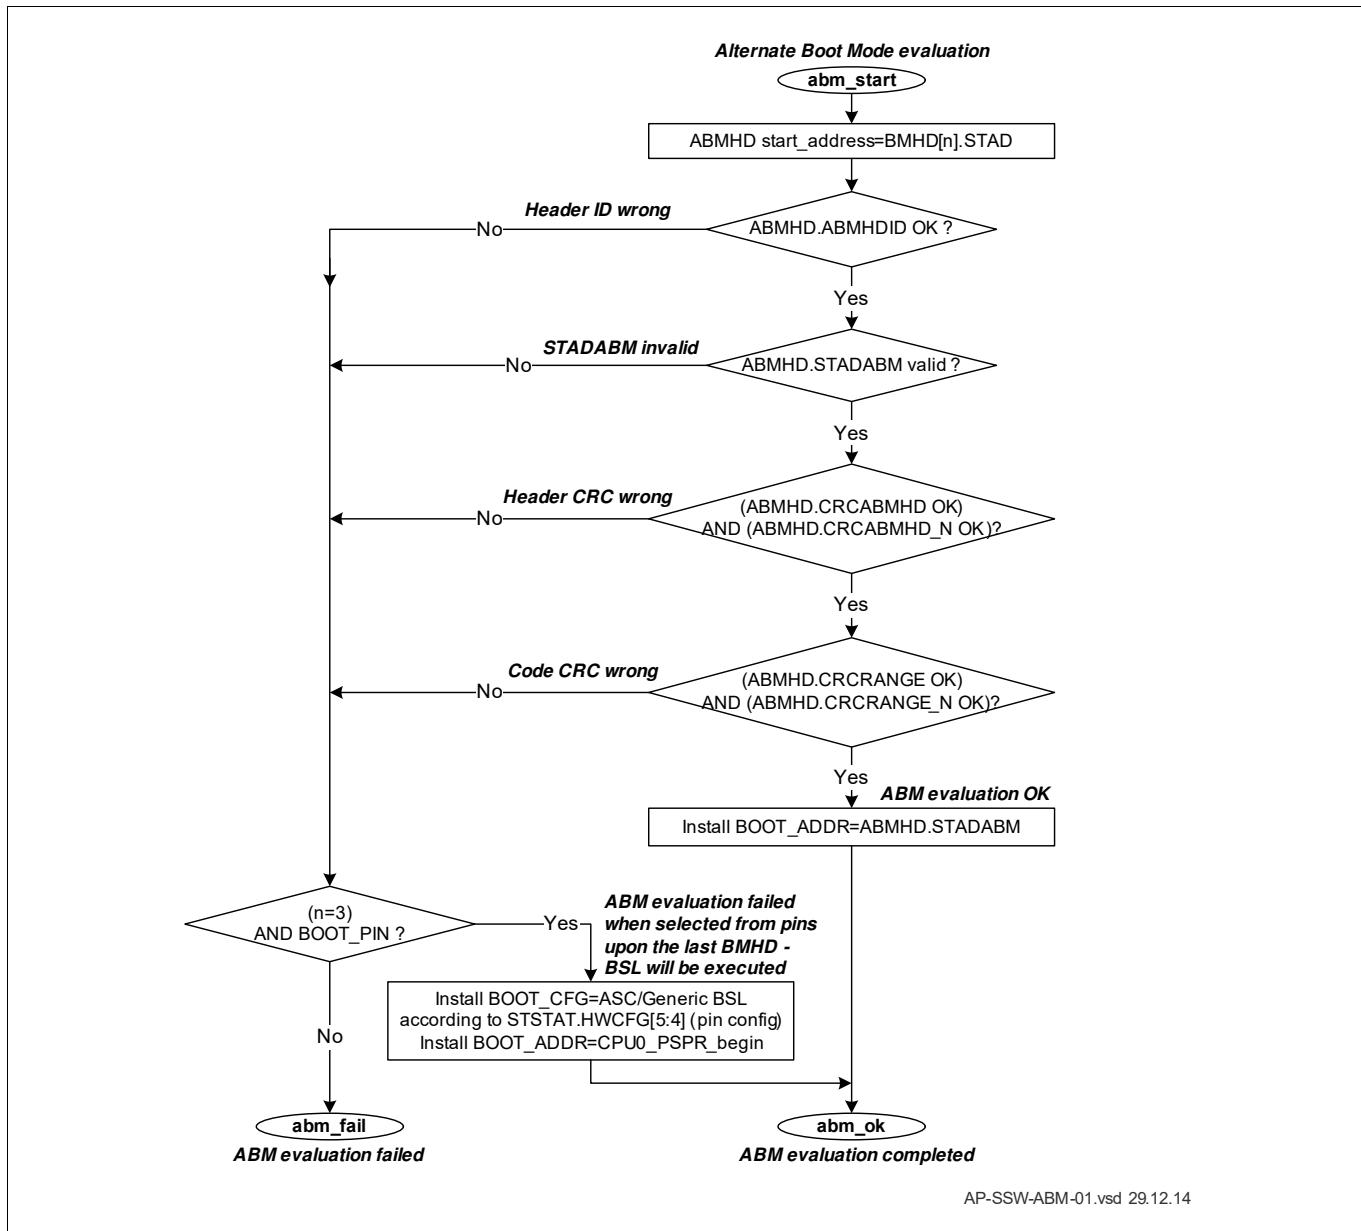

1) All the addresses must be inside PFLASH (considering the complete PFLASH, not PF0 only), word-aligned

In AURIX™ TC3xx Platform Alternate Boot Mode Header(s) can be located starting at arbitrary word-aligned locations inside PFlash. The start address is taken from the STAD field of the Boot Mode Header selecting ABM (refer to [Table 46](#))

**Attention:** Both the PFLASH address areas for cached and non-cached access are considered as allowed locations by this evaluation procedure, whereas both CHKSTART and CHKEND must be either in cached or non-cached segment - mixing not allowed.

Alternate Boot Mode Header (ABMHD) evaluation flow (refer to [Figure 19](#)) includes the following steps:

## AURIX™ TC3xx Platform Firmware

**Figure 19 Alternate Boot Mode evaluation flow**

1. check the Alternate Boot Mode Header Identifier (ABMH DID) value against the value in [Table 48](#)
  - a) if value OK - continue with the next step
  - b) otherwise - ABMH DID is wrong, go to step 6.
2. check the Start Address (STADABM) value - it must be a valid word-aligned address inside PFlash
  - a) if value OK - continue with the next step
  - b) otherwise - STADABM is wrong, go to step 6.
3. calculate CRC over the ABMHD content (total 6 words including STADABM, ABMH DID, CHKSTART, CHKEND, CRCRANGE and CRCRANGE\_N) and compare against CRCABMHD value stored inside ABMHD, then invert the calculated value and compare the result against CRCABMHD\_N value from ABMHD
  - a) if both values OK - continue with the next step
  - b) otherwise - ABMHD is wrong, go to step 6.

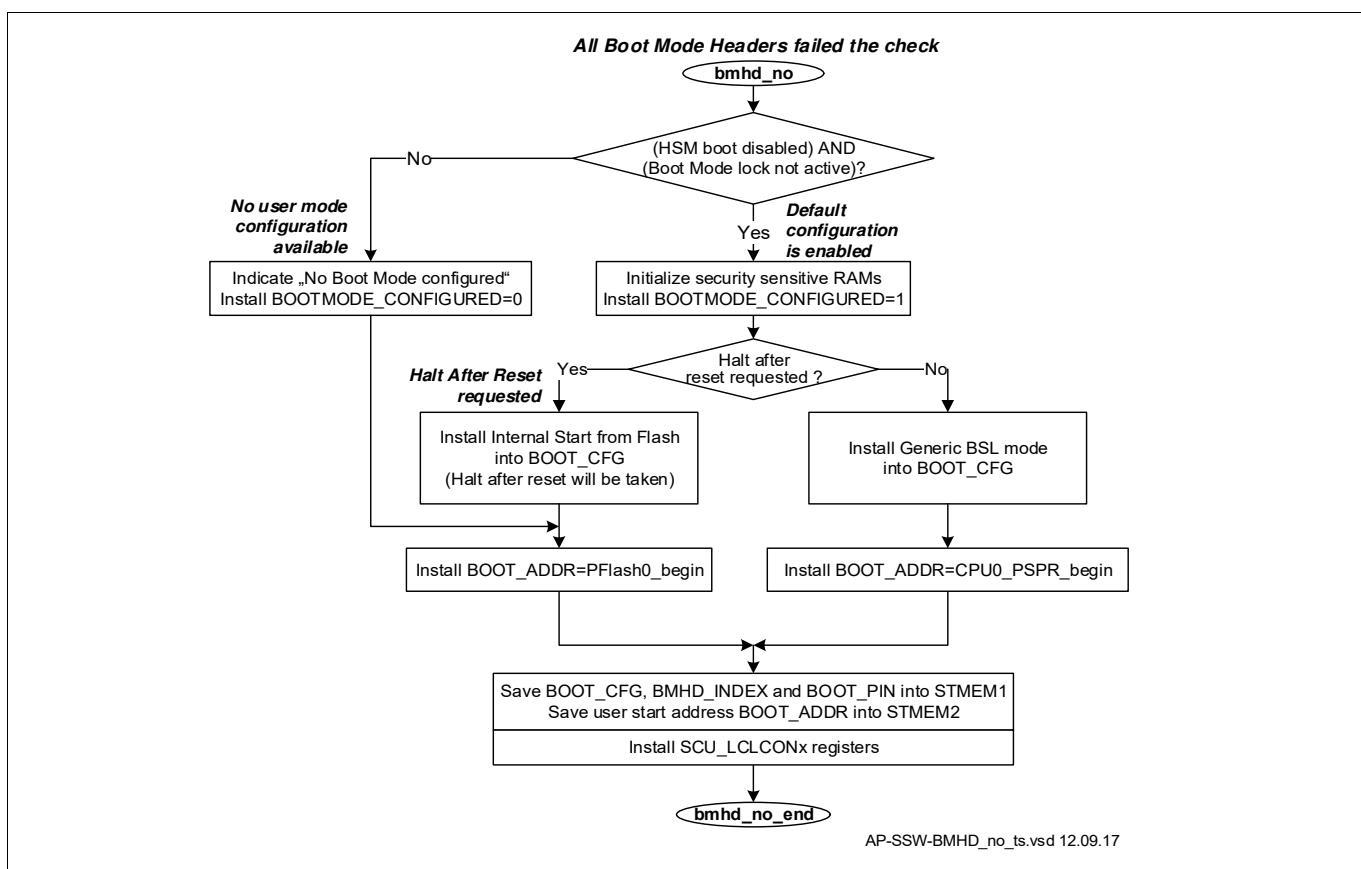

## AURIX™ TC3xx Platform Firmware

4. calculate CRC over the memory area starting with CHKSTART and ending with CHKEEND (word location) and compare against CRCRANGE value stored inside ABMHD, then invert the calculated value and compare the result against CRCRANGE\_N value from ABMHD
  - a) if both values OK - continue with the next step
  - b) otherwise - user code is wrong, go to step 6.
5. instal ABMHD.STADABM value as user code start address into BOOT\_ADDR, then exit ABM evaluation sequence as successfully completed - ABM will be effectively executed
6. check if ABM was selected from pins (BOOT\_PIN set by **Evaluation of Boot Mode Headers** sequence) during evaluation of the last BMHDn (n=3)
  - a) if yes - continue with the next step
  - b) otherwise - exit ABM evaluation sequence as failed
7. configure BSL start-up mode for execution
  - a) instal BOOT\_CFG to ASC or Generic BSL mode according to STSTAT.HWCFG[5:4] (refer to **Table 47**)
  - b) instal the first address of CPU0 Program scratchpad RAM (CPU0\_PSPR) as user code start address into BOOT\_ADDR
  - c) exit ABM evaluation sequence as successfully completed - the selected BSL will be effectively executed

### 3.1.1.6.3 Processing in case no valid BMHD found

If no valid Boot Mode Header was found by the above sequences, the SSW does not execute user code. The SSW prepares the device so that the user can connect, install valid Boot Mode Headers, program application code into PFlash, or install other device configurations.

In such a case, the SSW flow follows **Figure 20**:

**Figure 20 Flow when no valid BMHD found**

## AURIX™ TC3xx Platform Firmware

1. check if “default configuration” is enabled for the device - the condition is HSM boot disabled (DMU\_SP\_PROCONHSMCCFG.HSMBOOTEN=0) and Boot Mode Lock not active (DMU\_HF\_PROCONT.P.BML=00B)
  - a) if yes - set flag BOOTMODE\_CONFIGURED=1 in **SCU\_STMEM1** register, continue with the next step
  - b) if not - indicate “No Boot Mode configured” (reset flag BOOTMODE\_CONFIGURED in **SCU\_STMEM1** register) and go to step 4.

NOTE: In such a case, **Processing in case no Boot Mode configured by SSW** will be executed.
2. initialize security sensitive RAMs
3. For definition which RAMs are security-sensitive - refer to “Memory Test Unit” Chapter.
4. check if Halt After Reset request has been received (CBS\_OSTATE.HARR=1)
  - a) if yes - instal BOOT\_CFG to Internal start from Flash mode
  - b) this mode will not be effectively taken by SSW immediately at its end; halt after reset will be executed instead.
  - c) if not - instal BOOT\_CFG to Generic BSL mode, instal the first address of CPU0 Program scratchpad RAM (CPU0\_PSPR) as user code start address into BOOT\_ADDR, then go to step 5.
5. instal the address with offset 0x0020 in logical sector S40 in PFLASH0 (I.e. 0xA000A020) as user code start address into BOOT\_ADDR
  - a) this start address will not be effectively taken by SSW - either halt after reset will be executed, or SSW will enter an endless loop (see **Chapter 3.1.1.7.9**)
6. save boot mode information so it is available for HSM and application software
  - a) selected boot mode BOOT\_CFG - into SCU\_STMEM1
  - b) the installed start address BOOT\_ADDR - into SCU\_STMEM2[31:2] (the address is word aligned - bits[1:0] are not changed here)
7. configure lockstep monitoring feature as when no valid BMI is found - instal SCU\_LCLCON0.LSEN0=0 (disable lockstep for CPU0)

### 3.1.1.6.4 Processing in case no Boot Mode configured by SSW

If no valid Boot Mode Header was initially found and also the above sequence (**Processing in case no valid BMHD found**) was exited on its first step (because “default configuration” is disabled for the device) - the SSW can not select any start-up mode, meaning no exit from SSW will be effectively taken.

In such a case SSW flow is (refer to **Figure 21**):

- check if debug access is allowed for the device
  - if yes - enable debug access by installing CBS\_OSTATE.IF\_LCK to 1 (done using CBS\_OEC register)
- enter endless NOP loop

## AURIX™ TC3xx Platform Firmware

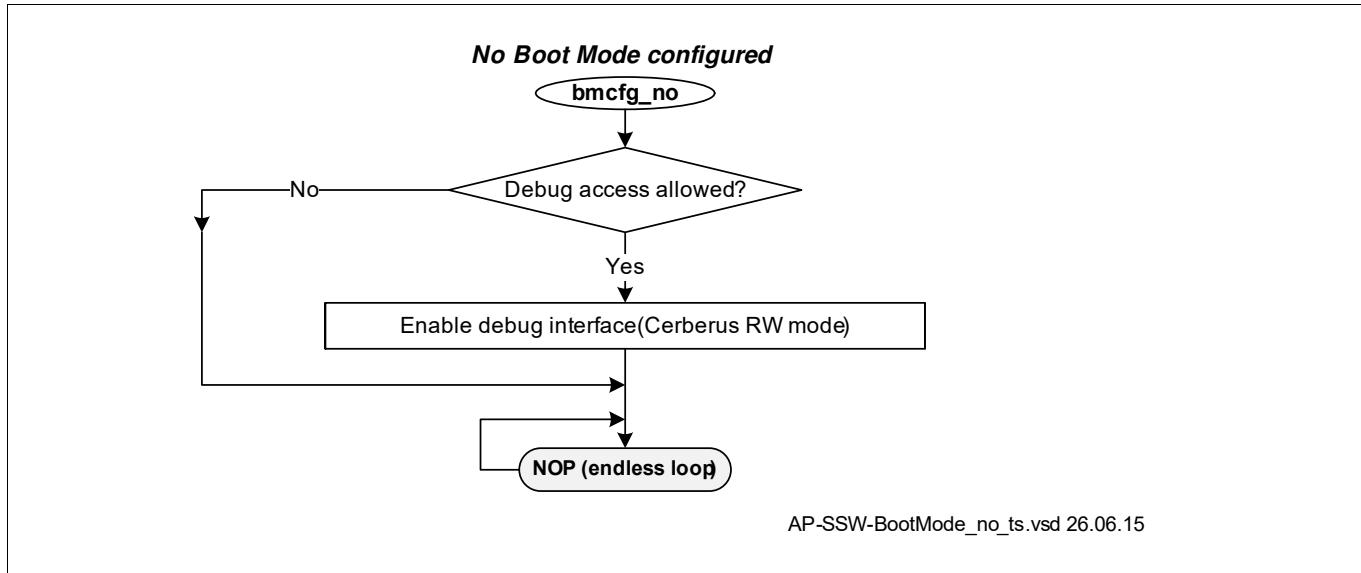

Figure 21 Flow when no boot mode configured

### 3.1.1.7 Startup Software Main Flow

Figure 22 shows the execution steps of the SSW:

## AURIX™ TC3xx Platform Firmware

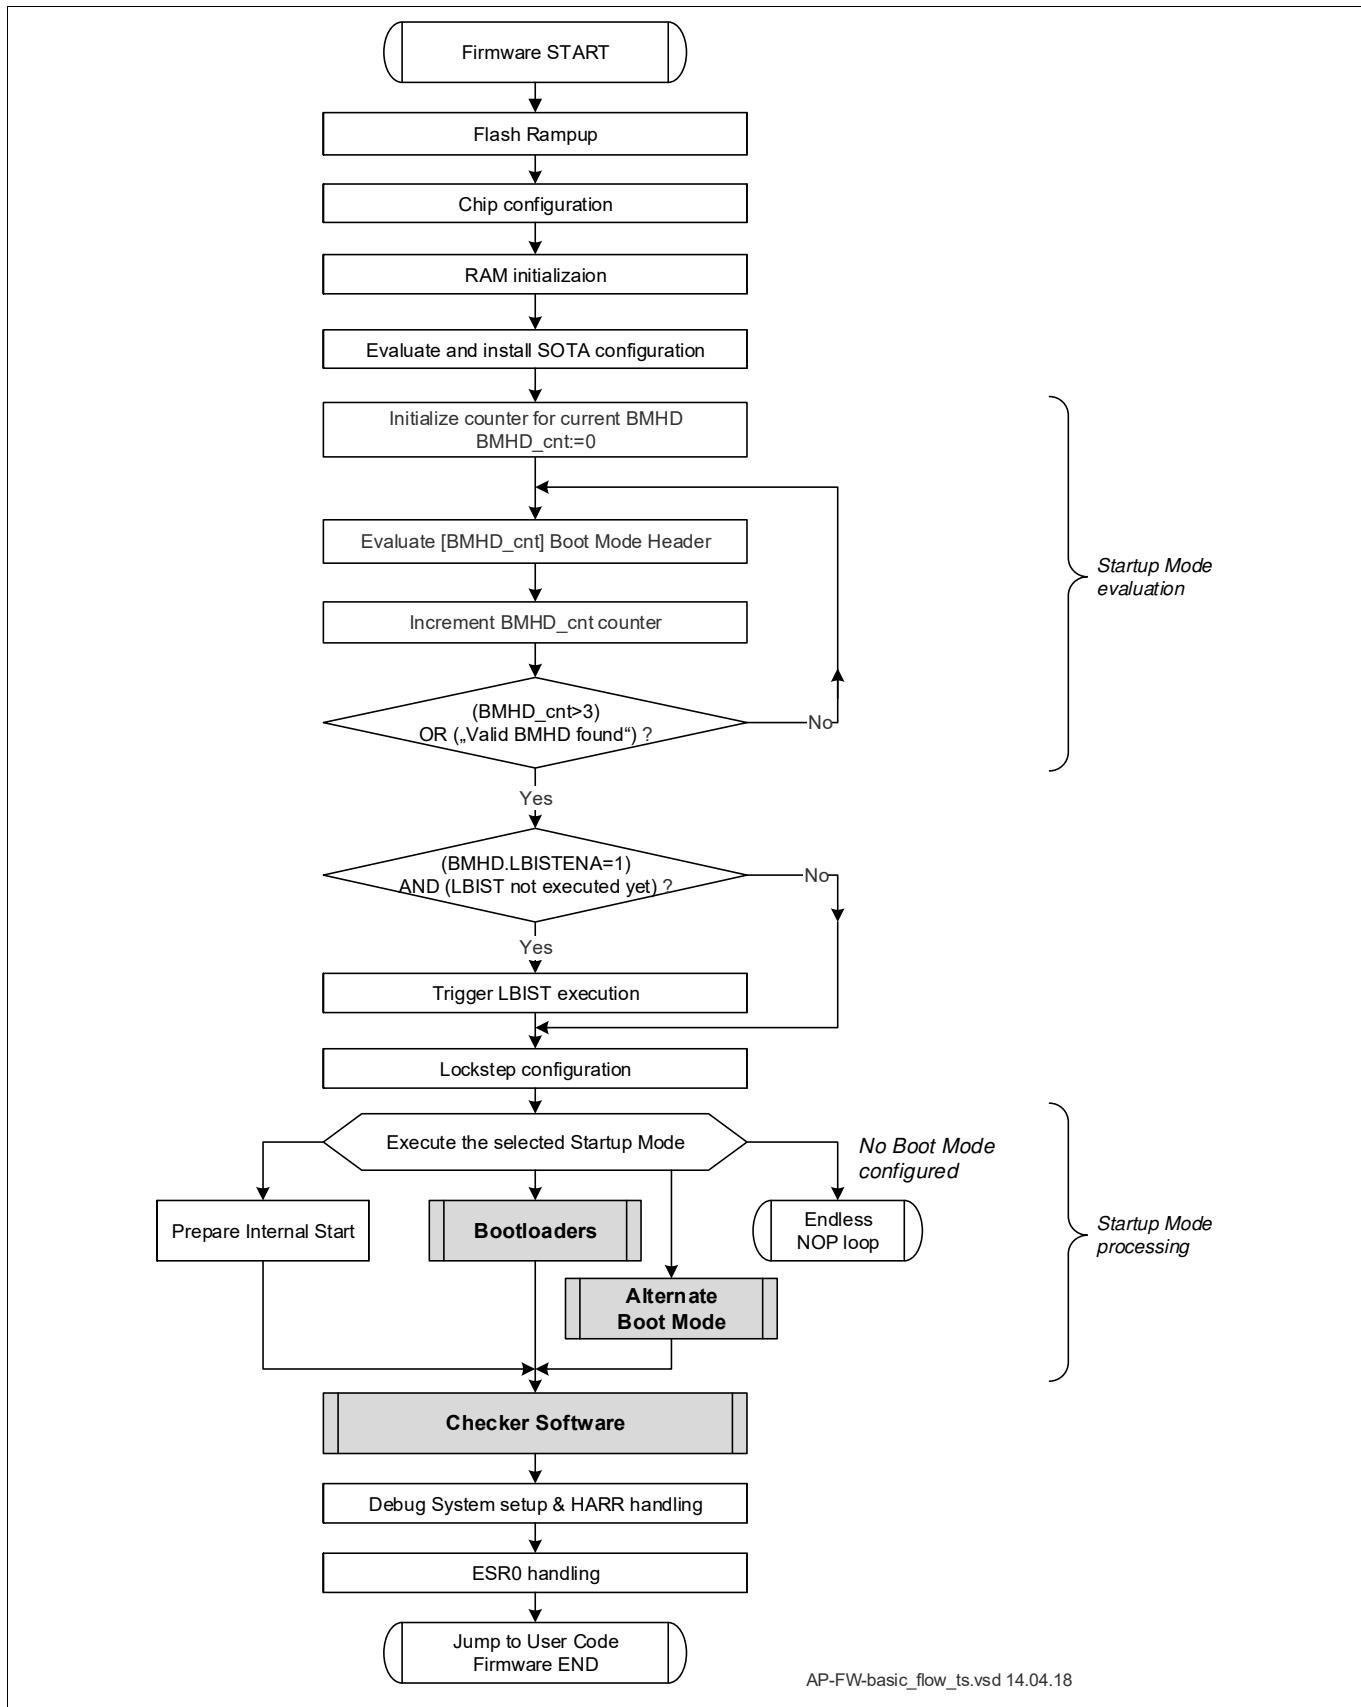

Figure 22 AURIX™ TC3xx Platform Firmware: main flow

## AURIX™ TC3xx Platform Firmware

### 3.1.1.7.1 Flash ramp-up

In this SSW module, the Flash is enabled and brought to a state where all the operations (read, erase, program and command sequences) can be performed within the full range of specified working conditions.

### 3.1.1.7.2 Device Configuration

The target of this SSW module is to initialize a number of AURIX™ TC3xx Platform registers.

### 3.1.1.7.3 RAM Initialization

The AURIX™ TC3xx Platform SSW supports RAM initialization, which is user-configurable by programming sections within UCB\_DFLASH, from which the configuration is installed during start-up into the DMU\_HF\_PROCONRAM register.

*Note:* For content and layout description, refer to the “User Configuration Block (UCB)” and the “Data Memory Unit (DMU)” Sections in the “Non Volatile Memory (NVM) Subsystem” Chapter.

The initialization procedure fills selected RAMs with all zero data content and also installs correct ECC bits, so that accesses to initialized RAMs shall not produce an uncorrectable ECC error.

The following configuration options are available:

- optional initialization upon cold and/or warm power-on of the device
- optional initialization for the RAMs of any separate CPU
- optional initialization for the RAM of any separate Local Memory Unit (LMU)

The RAMs supporting stand-by mode - CPU0\_DLMU and CPU1\_DLMU - are not initialized after wake-up even when selected in DMU\_HF\_PROCONRAM register, if RAM(s) being supplied during stand-by - the conditions checked are:

- for CPU0\_DLMU - PMS\_PMSWSTAT2.STBYRAM=x1xB or xx1B
- for CPU1\_DLMU - PMS\_PMSWSTAT2.STBYRAM=1xxB

### 3.1.1.7.4 Select and execute Startup Modes

The AURIX™ TC3xx Platform SSW evaluates up to four Boot Mode Headers (BMHD) sequentially, each of which may have an Original and a Copy in Data Flash UCBs.

For AURIX™ TC3xx Platform User Startup Configurations and modes refer to [Chapter 3.1.1.5](#). For the flow of evaluating any single BMHD - to [Chapter 3.1.1.6](#).

Once a BMHD evaluation is successfully completed, the selected mode is taken, otherwise: [Processing in case no valid BMHD found](#) or [Processing in case no Boot Mode configured by SSW](#) is executed.

#### Secure Boot option handling

If HSM module is available (according to device configuration), Secure Booting is supported, in which the user code is processed by the HSM.

The SSW supplies information about the current device mode, reset type, the primary selected start-up mode and the effectively taken start-up mode. This information is then available then for the HSM module for boot and user code processing.

### 3.1.1.7.5 LBIST execution

If selected in a valid BMHD by LBISTENA=1 (refer to [Chapter 3.1.1.6](#)), LBIST execution will be triggered by SSW.

## AURIX™ TC3xx Platform Firmware

The configuration applied corresponds to the “LBIST Configuration A” as defined in “LBIST considerations for TC3xx” Section of the product specific Appendix to the Target Specification.

If triggered, LBIST will end with an internal reset, leading to a new execution of the SSW. During this execution, in case of successful LBIST completion (SCU\_LBISTCTRL0.LBISTDONE=1) SSW will not re-trigger LBIST but exit to the user code.

Note, that SSW does not evaluate the result from LBIST execution (in SCU\_LBISTCTRL3 register) - this is to be done by the application software.

### 3.1.1.7.6 Lockstep configuration

Upon cold power-on only, the SSW performs Lockstep configuration as follows:

- if a valid BMI has been found during start-up mode evaluation:
  - lockstep control (for CPUs supporting lockstep) is installed from BMI.LSENAn bits into respective LSENN bits of SCU\_LCLCON0/1 registers (n=0,1,2,3)
- otherwise
  - lockstep for CPU0 is disabled by installing SCU\_LCLCON0.LSEN0=0

### 3.1.1.7.7 Debug System handling

The SSW internal flag Unlock Debug Interface is set to control debug access to the device, according to the following evaluation sequence:

1. The SSW checks whether an external tool has requested debug access by writing a defined content (32-bit value CMD\_KEY\_EXCHANGE) into COMDATA register
  - a) if yes - continue with the next step
  - b) if not - go to step 4.
2. While still in Cerberus Communication mode, the SSW confirms request reception and receives 8 further words from the COMDATA register
3. the data received (256 bits) is sent by SSW to DMU to be checked as debug interface password, and the result is evaluated by SSW:
  - a) if OK - debug password is correct, set SSW internal flag, debug interface will be unlocked, exit the sequence
  - b) otherwise - continue with the next step
4. instal into COMDATA a 32-bit value serving for an external tool to identify the device connected - UNIQUE\_CHIP\_ID\_32BIT

*Note: The name here used (UNIQUE\_CHIP\_ID\_32BIT) should be not misleading - the value considered and written into COMDATA register is NOT identifying uniquely any single device, but the product variant only. In case chip-unique identification is needed, the user Software (or the tool) should read the Unique Chip Identifier from UCB\_USER - refer to the “User Configuration Block (UCB)” Section of the “Non Volatile Memory (NVM) Subsystem” Chapter.*

5. check if Flash read protection is activated:
  - a) if yes - debug interface will be left locked, no debug access to device, exit the sequence
  - b) if not - set SSW internal flag, debug interface will be unlocked, exit the sequence

*Note: If the Debug Interface is configured as locked by the DMU\_HF\_PROCONDBG.DBGIFLCK=1 (bit installed during start-up according to the DFlash UCB\_DBG content), debug access for a device with installed Flash read protection shall be only allowed if correct debug password is received (as of steps 1. to 3. above).*

## AURIX™ TC3xx Platform Firmware

Next, Halt after Reset is prepared if requested. The SSW processing here is as follows:

- check whether external (debug) access to the device will be generally granted
  - if Not -> exit this procedure
- check whether Halt After Reset is requested
  - if Not -> exit this procedure
- configure a Break Before Make breakpoint at the first user code instruction
- enable On-Chip Debug Support system.

### 3.1.1.7.8 ESR0 pin handling

If both of these conditions

- ESR0CNT<=>FFFFH in DMU\_HF\_PROCONDF register (refer to register description in “Data Memory Unit” Section of “Program Memory Unit” Chapter) AND
  - ESR0-pin configuration upon SSW entry is open-drain reset output (SCU\_IOCR.PC0 in [1110B, 1101B])
- are satisfied, SSW will:

- release ESR0 pin - by installing SCU\_ESROCFG.ARC:=1, which clears the Application Reset Indicator in SCU\_ESROCFG.ARI with a configurable delay after device internal reset is released (i.e. CPU0 started). The delay is defined as follows
  - if DMU\_HF\_PROCONDF.ESR0CNT=000H - about 500μsec upon cold power-on, not longer than 40μsec otherwise
  - if DMU\_HF\_PROCONDF.ESR0CNT=001H...FFEH - (ESR0CNT)\*10μsec, where:
    - \* upon cold power-on the minimum possible delay is about 500μsec
    - \* otherwise - the minimum possible delay is about 40μsec
- wait until ESR0 pin is effectively high (indicated by SCU\_IN.P0=1) at the very SSW end, before jumping to the first user instruction

To generate the configurable ESR0 delay after device reset release, the SSW uses System Timer 0 (STM0), and takes into account the following default settings after power-on/system reset:

- STM is reset and starts counting from zero
- STM is clocked with 50MHz i.e. fSTM=fBACK/2

**Attention:** Both the above conditions could be not true after application reset, if default settings are changed by user code executed after power-on/system reset. In such a case, ESR0 handling by SSW will not work correctly, meaning the real prolongation will not correspond to ESR0CNT value configured.

### 3.1.1.7.9 Ending the SSW and Starting the User Code

The last steps executed by the SSW are:

- unlock (in case) Debug Interface
- jump to the first User Instruction at address STADD.

Additionally, if all the following conditions are satisfied:

- the device is an ED
- debug access to device is allowed
- halt after reset is not requested
- the last reset has been a power-on (cold or warm)

## AURIX™ TC3xx Platform Firmware

SSW performs at its very end additional checks and in case all these succeed - the last SSW instruction jumps not to the “standard” STADD but to an address inside EMEM (Emulation Memory). This SSW part implements the sequence defined in AURIX™ TC3xx Platform ED Target Specification, Chapter “Startup with prolog code in EMEM”.

### 3.1.2 Checker Software

The Checker Software (CHSW) is intended to evaluate whether the device configuration and preparation for user code execution - in particular the aspects considered as safety relevant - are correct after completion of the Start-up Software.

#### 3.1.2.1 CHSW execution flow

CHSW (besides the below checks as initial parts from it) is only executed if all the following conditions are fulfilled:

1. Bootmode evaluation done by SSW is found to be correct

To decide on this, CHSW evaluates and compares the boot information stored by SSW into the **Registers providing information on the boot selections** (refer to [Chapter 3.2.1.1](#)) against the boot information from the respective Boot Mode Header UCB (UCB\_BMHDX) area in DFLASH, also in case - hardware configuration pins (HWCFG[5:3]) and other start-up related factors as described in [Chapter 3.1.1.6](#)

2. Valid Boot Mode Index (BMI) has been found and used for start-up mode selection

To remind, in many cases the device may continue code execution after start-up even if no BMHD/BMI has been found by SSW - refer to [Chapter 3.1.1.6.3 Processing in case no valid BMHD found](#). In those scenarios, the (rest of) CHSW is not executed.

3. **The Boot Mode Index taken for start-up does not disable CHSW execution**

The above condition is fulfilled if the BMI taken for start-up contains CHSWENA bitfield not equal to 101B (refer to [Table 46](#)).

## AURIX™ TC3xx Platform Firmware

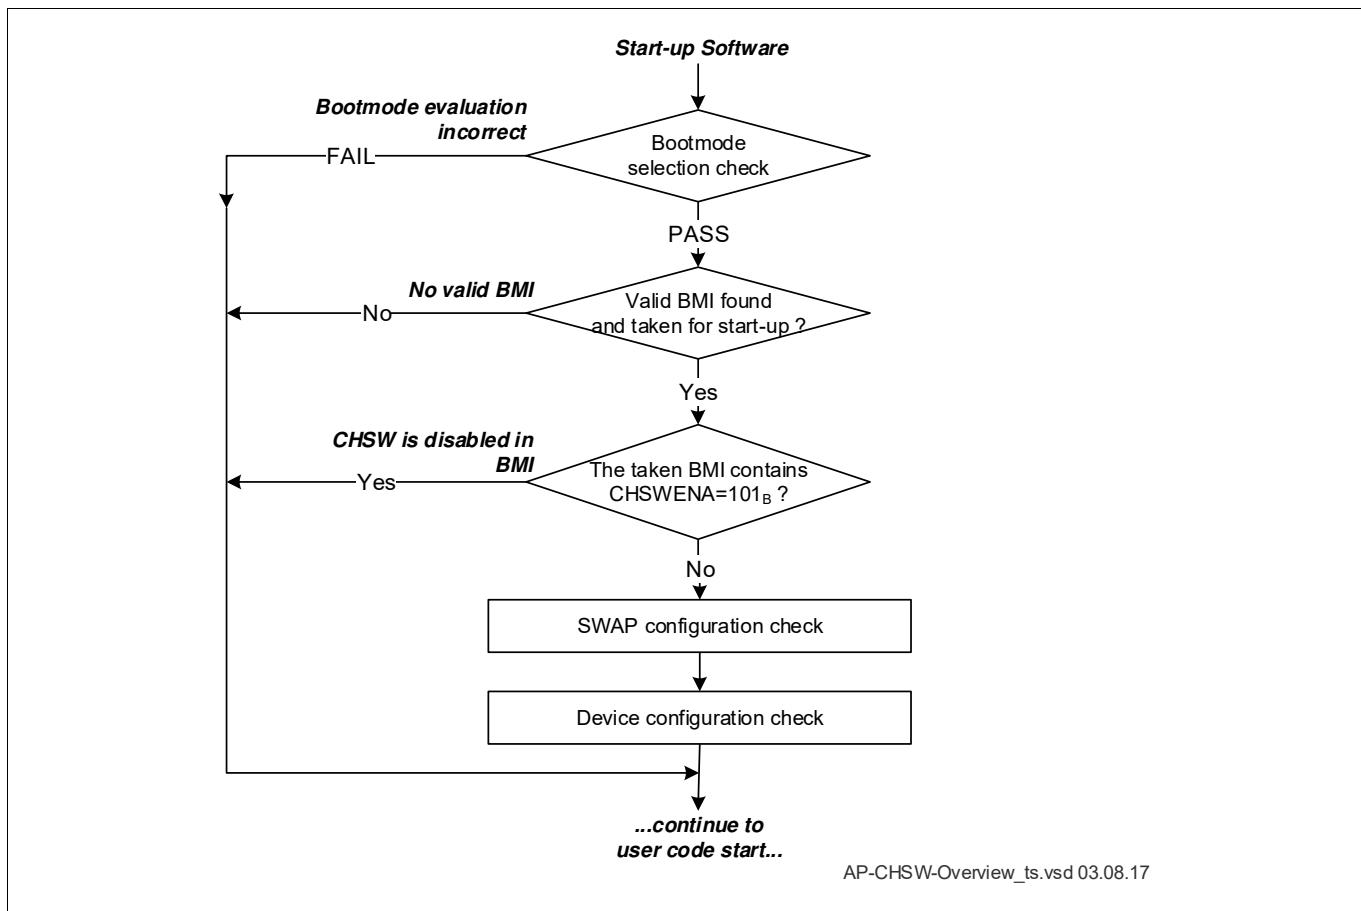

Figure 23 AURIX™ TC3xx Platform Checker Software Overview

If all the above conditions are met - CHSW executes the main device checks as described in the following Section.

### 3.1.2.2 Checks performed by CHSW and exit information

The checks supported by CHSW in AURIX™ TC3xx Platform are listed in [Table 49...Table 53](#) below, to note:

- most of the checks are executed upon defined reset types only
- (some of) the checks are only executed on products implementing the target module to be checked - e.g. devices with EMEM, RIF module, GETH module(s) etc. In particular, EMEM-related checks are only performed on devices implementing Emulation Memory and only for those EMEM module(s) which are effectively present on the product.

CHSW communicates the checks' execution status and result to the user software via the [Registers providing information on the Checker Software activity](#) (refer to [Chapter 3.2.1.2](#)), whereas:

- bits [0] in all the registers SCU\_STMEM3...SCU\_STMEM6 are set to 1 upon user code start
- anyone of the other used bits in all the registers is assigned to a given check supported by CHSW as shown in [Table 49...Table 53](#)
- the bits in any register indicate defined status of the check as follows:
  - SCU\_STMEM3** - the check is started
  - SCU\_STMEM4** - the check failed
  - SCU\_STMEM5** - the check passed

## AURIX™ TC3xx Platform Firmware

- **SCU\_STMEM6** - the check is finished

Following from the above, the overall check status should be interpreted by user software according to **Table 54**.

**Note:** *Device start-up after LBIST execution is handled by TC3xx Firmware as cold power-on, respectively the CHSW results indicated in such a case correspond to the checks executed upon this type of device reset.*

**Table 49 Checks of the reset evaluation**

<b>Check of:</b>	<b>Assigned bits in SCU_STMEM3...6</b>	
	<b>position</b>	<b>name (excluding _C*)</b>
Reset type evaluation upon cold power-on (acc. to CHSW)	4	CPOR
Reset type evaluation upon warm power-on (acc. to CHSW)	5	WPOR
Reset type evaluation upon system reset (acc. to CHSW)	6	SYSR
Reset type evaluation upon application reset (acc. to CHSW)	7	APPR

**Table 50 Checks executed by CHSW upon any device reset**

<b>Check of:</b>	<b>Assigned bits in SCU_STMEM3...6</b>	
	<b>position</b>	<b>name (excluding _C*)</b>
General CHSW execution status	1	CHSWGGEN
Bootmode selection	2	BMSEL
SWAP configuration	3	SWAP
Shutdown request handler entry point (SCU_RSTCON3 register)	11	RSTCON3
Gigabit Ethernet MAC module calibration	21	GETH <sup>1)</sup>
Gigabit Ethernet MAC second module calibration	24	GETH1 <sup>1)</sup>
RIF0 module calibration	22	RIF0
RIF1 module calibration	23	RIF1
PFLASH uncorrectable ECC control settings (CPUx_FLASHCON1 register)	29	FLASHCON1

- 1) The check for Gigabit Ethernet MAC module(s) calibration will fail after application reset, if the application software has not enabled GETH clock (in SCU\_CCUCON5 register) after the previous power-on/system reset(s) - meaning if the module is not used by application - therefore in such use-case anyway the check for this' module calibration is not relevant.

**Table 51 Checks executed by CHSW upon cold power-on only**

<b>Check of:</b>	<b>Assigned bits in SCU_STMEM3...6</b>

SCU_STMEM6.*_CE	0	1	1

### 3.1.2.3 Checker Software exit information for ALL CHECKS PASSED

SCU\_STMEM3...SCU\_STMEM6 registers' content corresponding to "ALL CHECKS PASSED" result from Checker Software upon different reset types is provided by Firmware Chapter of the device specific "Appendix" document.

### 3.1.3 Bootstrap Loaders

These routines provide mechanisms to load a user program via the selected interface by moving code into the Program Scratchpad RAM of CPU0 (CPU0\_PSPR). The loaded code is started after exiting the BootROM.

**Note:** Once a Bootstrap Loader mode is entered, the selected communication protocol (CAN/ASC) must be completely executed according to its definition (as of the below Sections) until the user code is downloaded into the device. No time-out will ever interrupt this process; only a reset can re-start the device.

## AURIX™ TC3xx Platform Firmware

**Table 55 HW Configuration Data for Bootstrap Loader Modes**

Bootstrap Loader Mode	Channel/node	RxD Line	TxD Line
ASC Bootstrap Loader mode	ASCLIN0	P15.3	P15.2
Generic Bootstrap Loader mode - ASC protocol	ASCLIN0	P14.1	P14.0
Generic Bootstrap Loader mode - CAN protocol	MCMCAN0 module CAN1 node	P14.1	P14.0

### 3.1.3.1 ASC Bootstrap loader

The ASC Bootloading routine implements the following steps:

- RxD/TxD pin configuration is done in accordance with the AURIX™ TC3xx Platform definitions. Depending on the start-up mode, the routine is invoked in “ASC Bootloader”-startup mode (ASC-only pins are used), or if ASC protocol is detected in “Generic Bootloader”-mode (CAN/ASC-shared pins are used but configured to ASC module)
- baudrate calculation is done based on the zero Byte sent by the host
- ASCLIN is initialized (without enabling the receiver) to the baudrate as determined (8 data and 1 stop bit)
- acknowledge byte D5H is sent to the host, indicating the device is ready to accept a data transfer
- after the acknowledge byte is transmitted, the receiver is enabled
- the bootloader enters a loop, waiting to receive exactly 128 bytes which are stored as 32 words in CPU0 Program Scratchpad RAM starting from address C000 0000H

Once 128 bytes are received, the SSW continues further - refer to [Figure 22](#). After exiting the SSW, user code will be started from address C000 0000H (CPU0\_PSPR).

Note: *ASC Bootstrap Loader supports also half-duplex mode but this does not mean the RxD and TxD pins should be in such a case directly short-connected at the device boundary. The “single transmission line” must be supported otherwise - the typical implementation includes CAN transceiver circuits respectively using CAN physical layer for data transfer.*

## AURIX™ TC3xx Platform Firmware

### 3.1.3.2 CAN Bootstrap loader

The CAN bootstrap loader (CAN BSL) transfers program code/data from an external host via CAN interface into AURIX™ TC3xx Platform CPU0 Program Scratchpad RAM. It is a primary bootloader, not to be mixed up with the secondary bootloader which can be bought from tool partners.

#### 3.1.3.2.1 CAN BSL summary

The main characteristics of AURIX™ TC3xx Platform CAN Bootstrap Loader include:

- Classical CAN is supported as well as CAN FD (CAN FD only in case of [Configured OSC](#))
- the initial identifier is fixed to 555H
- the number of data frames to be received by BSL is programmable
- for other CAN BSL characteristics - refer to [Chapter 3.1.3.2.4](#)

The communication between the AURIX™ TC3xx Platform and an external host is based on the following three CAN standard frames:

- Initialization frame(s) - sent by the external host to AURIX™ TC3xx Platform
- Acknowledgement frame(s) - sent by the AURIX™ TC3xx Platform to the external host
- Data frame(s) - sent by the external host to AURIX™ TC3xx Platform

#### 3.1.3.2.2 Clock system during CAN BSL

There are two scenarios of AURIX™ TC3xx Platform CAN BSL usage in regard to the clock system, depending on the Oscillator Circuit OSC configuration (refer to “Clocking System” Chapter), whereas the following basics apply:

- the OSC configuration is primary controlled by DMU\_HF\_PROCONDF.OSCCFG bit
- the OSCCFG bit as the complete DMU\_HF\_PROCONDF register is installed during device start-up from UCB\_DFLASH (refer to the “User Configuration Block (UCB)” and the “Data Memory Unit (DMU)” Sections in the “Non Volatile Memory (NVM) Subsystem” Chapter)
- UCB\_DFLASH is user-programmable

The two scenarios for clocking during CAN BSL are described below.

#### Not configured OSC

This is the clock system status after device system and power-on reset if DMU\_HF\_PROCONDF.OSCCFG=0 and usually it's on place in delivery state of the device - meaning if UCB\_DFLASH has not been re-programmed by the customer with OSC information as proper for the design/board where the chip will be used.

In such a case the back-up clock (refer to “Back-up Clock” Section in “Clocking System” Chapter) is used as clock-source for MCAN module during CAN BSL, after performing the following configurations:

- fBACK/5 is selected as clock source fMCANI - CCU\_CCUCON1.MCANDIV=5
- fMCANI is selected as clock source fMCAN - CCU\_CCUCON1.CLKSELMCAN=01B

Following from the above, the MCAN module operates with 20MHz clock for the asynchronous part as provided by the AURIX™ TC3xx Platform internal back-up clock source. In this scenario, less baudrates are supported by CAN BSL (refer to the next Chapter).

#### Configured OSC

OSC configuration is performed by device start-up procedure if DMU\_HF\_PROCONDF.OSCCFG=1 installing information into OSC Control register CCU\_OSCCON according to the relevant UCB\_DFLASH resp. DMU\_HF\_PROCONDF content (refer to “Configuration of the Oscillator” Section in “Clocking System” Chapter).

## AURIX™ TC3xx Platform Firmware

To come into this state and to use fully the CAN BSL functionality, the customer must first re-program the PROCONDF location (related bits/fields) inside UCB\_DFLASH in accordance to the design/board where the chip will be used.

In such a case, the OSC is activated and operating on the frequency provided by the external source (crystal/resonator) connected to XTAL1/2 pins (refer to “External Crystal / Ceramic Resonator Mode” Section in “Clocking System” Chapter), with configuration performed during start-up:

- FOSC0 is selected as clock source fMCAN - CCU\_CCUCON1.CLKSELMCAN=10B

Following from the above, the MCAN module operates with clock for the asynchronous part as provided by the OSC circuit driven by the external source at XTAL, so supporting the full range of baudrates according to [Table 56](#).

### 3.1.3.2.3 CAN BSL usage after application reset

The following scenario:

- the device has been started in CAN BSL mode with a power-on or system reset, AND
- CAN BSL must be executed again upon the consequent application reset(s)

is not feasible for devices with not configured OSC.

If such use-case must be supported - then first the PROCONDF location (related bits/fields) inside UCB\_DFLASH need to be re-programmed to configure the OSC.

### 3.1.3.2.4 Supported CAN features

The number of supported Baud rates and CAN operational modes, as well as the sampling point to be configured on the host side depend on the clock system status during CAN BSL (refer to [Chapter 3.1.3.2.2](#)).

#### Not configured OSC - back-up clock used for CAN

When working with the internal back-up clock source, AURIX™ TC3xx Platform CAN BSL supports:

- Classical CAN only
- sample point of 60%
- limited number of baudrates:
  - 100 KBit/s
  - 125 KBit/s
  - 250 KBit/s
  - 500 KBit/s

#### Configured OSC - external clock source used for CAN

When working with the external clock source at XTAL, AURIX™ TC3xx Platform CAN BSL supports:

- Classical CAN and CAN FD
- sample point of 80%
- a big number of combinations between Classical CAN Baud rates and XTAL/FOSC frequency as shown in [Table 56](#), whereas:
  - “X” marks supported combination
  - “-” marks not supported combination

## AURIX™ TC3xx Platform Firmware

**Table 56 Possible Baudrate and FOSC frequency combinations**

Baudrate (KBits/s) / FOSC (MHz)	4	5	8	10	12	16	20	24	25	40

1000	-	-	X	X	X	X	X	X	-	X

**3.1.3.2.5 CAN BSL flow**

The CAN bootstrap loader flow is shown on [Figure 24](#) and it consists of 3 phases which are described in the next Sections.

The notations used in the below descriptions are:

- ACKID - Acknowledgement Message shall have this 11-bit Identifier (like in register)

## AURIX™ TC3xx Platform Firmware

- DMSGC - Amount of messages, which will be sent including the program
- DMSGID - The data frames will have this 11-bit ID (like in register)
- TSEG1 and TSEG2 - Baudrate as used (copied from register)
- NBTP - Nominal bit timing and Prescaler Register Settings (Classical CAN has arbitration segment only)
- DBTP - Data bit timing and Prescaler Register Settings (Fast Segment)
- DBPM - Data Bytes per Message (DLC= [9, 11] is not allowed)

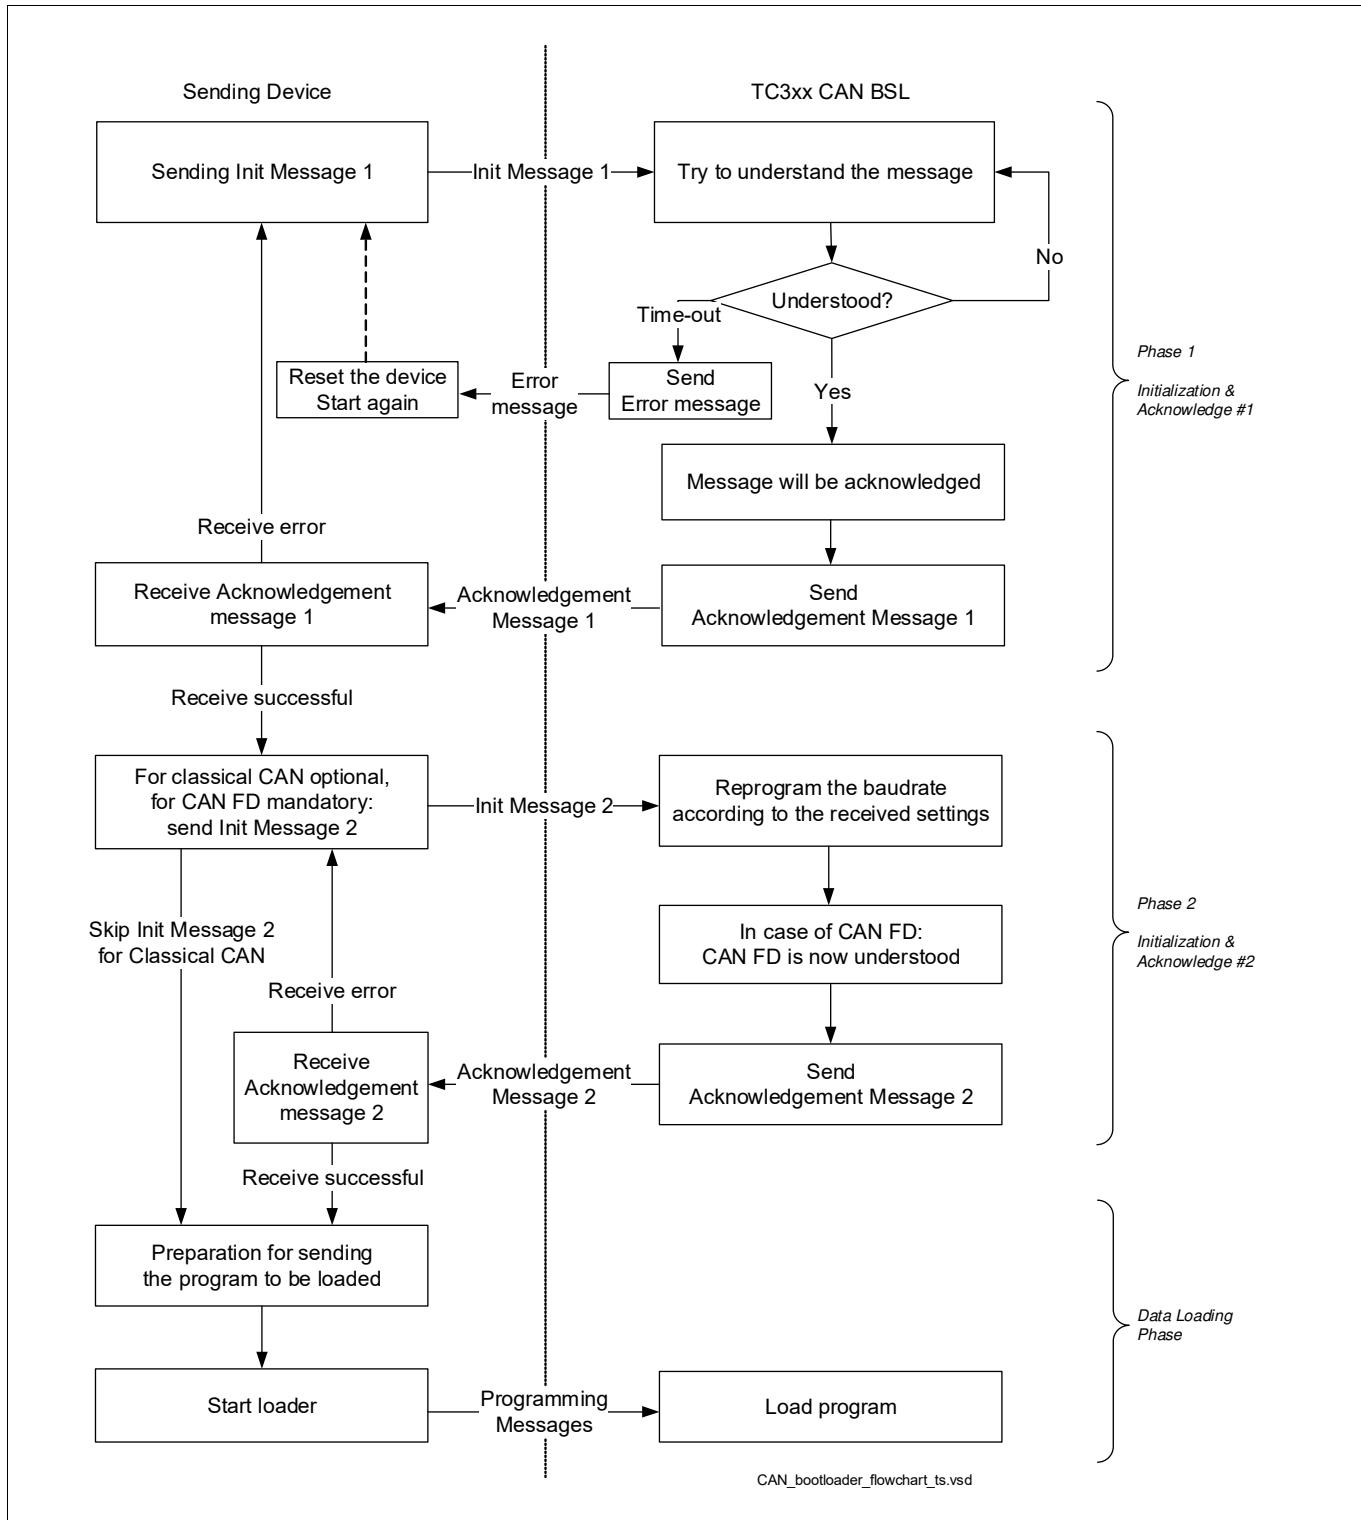

Figure 24 CAN Bootstrap loader flow

## AURIX™ TC3xx Platform Firmware

### Phase 1 (Initialization & Acknowledge #1)

During this phase, CAN BSL tries to determine the CAN baud rate at which the external host is communicating and to understand (receive correctly) the initialization message (classical CAN message) sent by the host.

The above requires that external host sends continuously to the AURIX™ TC3xx Platform **Initialization Message 1** in classical CAN format as shown in **Table 57**.

**Table 57 Initialization Message 1**

Frame Format requested	ID	DLC	DB0	DB1	DB2	DB3	DB4	DB5	DB6	DB7
Classical CAN	0x555	8	0x55	0x55	ACKID Low	ACKID High	DMSGC Low	DMSGC High	DMSGID Low	DMSGID High
CAN FD	0x555	10	0x55	0x55	ACKID Low	ACKID High	DMSGC Low	DMSGC High	DMSGID Low	DMSGID High

CAN BSL evaluates the incoming messages trying to identify a content according to **Table 57** within the range of baudrate configurations from **Table 56** and according to the result:

- if the message is understood - then the CAN BSL
  - configures the MCAN module for the selected baudrate settings
  - acknowledges the next received **Initialization Message 1** - Tx ACK bit field as dominant
  - sends **Acknowledgement Message 1** with the format shown in **Table 58**; this message also informs the host whether the reception was error-free or not
- if initialization messages can not be understood for any supported baudrate settings
  - CAN BSL sends Error message with the format shown in **Table 59**
  - CAN BSL terminates - the device should be re-started with a reset

**Table 58 Acknowledgement Message 1**

Frame	ID	DLC	DB0	DB1	DB2	DB3	DB4	DB5	DB6	DB7
Message received error free	ACKID	8 or 10	ACKID Low	ACKID High	DMSGC Low	DMSGC High	DMSGID Low	DMSGID High	TSEG1	TSEG2
Faulty DLC	ACKID or if not received 0xAA	as received	0xAA	0xAA	0xAA	0xAA	0xAA	0xAA	0xAA	0xAA

**Table 59 Error message (No baudrate detected)**

Frame	ID	DLC
I don't understand	0xAAA	0

### Phase 2 (Initialization & Acknowledge #2)

Once having **Acknowledgement Message 1** from CAN BSL successfully received, the host can send **Initialization Message 2** with the format shown in **Table 60**, whereas this message is:

- required - if CAN FD must be used further on

## AURIX™ TC3xx Platform Firmware

- optional - allowing the host to provide a more precise baud rate for further classical CAN operation; in such a case, jump in baudrate in any direction for the arbitration segment is not allowed

**Table 60 Initialization Message 2**

Frame Format requested	ID	DLC	DB0	DB1	DB2	DB3	DB4	DB5	DB6	DB7
Classical CAN	0x555	4	NBTP. NTSEG2	NBTP. NTSEG1	NBTP. [23..16]	NBTP. [31..24]				
CAN FD	0x555	8	NBTP. NTSEG2	NBTP. NTSEG1	NBTP. [23..16]	NBTP. [31..24]	DBTP.[ 7..0]	DBTP.[ 15..8]	DBTP.[ 23..16]	DBPM

If after sending **Acknowledgement Message 1**, **Initialization Message 2** is received but not **Programming message** (differentiation done upon the message ID) - the CAN BSL analyses this message against the format shown in **Table 60** and then:

- if classical CAN has been requested (DLC=8)
  - install the (more precise) baudrate settings (NBTP register) as received
  - send **Acknowledgement Message 2** (refer to **Table 60**)
- if CAN FD has been requested (DLC=4)
  - enable CAN FD
  - install the baudrate settings (NBTP and DBTP registers) as received
  - take the received DBPM to be used as DLC for the upcoming Programming messages
  - send **Acknowledgement Message 2** (refer to **Table 60**)
- if the message has been wrongly received - DLC other than 4 or 8)
  - send **Acknowledgement Message 2** indicating “Faulty DLC” (refer to **Table 60**)

**Table 61 Acknowledgement Message 2**

Frame	ID	DLC	DB0	DB1	DB2	DB3	DB4	DB5	DB6	DB7
Message received error free	ACKID	4 or 8	NBTP.N TSEG2	NBTP.N TSEG1	NBTP. [23..16]	NBTP. [31..24]	DBTP. [7..0] (CAN FD only)	DBTP. [15..8] (CAN FD only)	DBTP. [23..16] (CAN FD only)	DBPM (CAN FD only)
Faulty DLC	ACKID	as received	0xAA	0xAA	0xAA	0xAA	0xAA	0xAA	0xAA	0xAA

**Acknowledgement Message 2** sent by CAN BSL and indicating “Error free” tells the external host, the device is now ready to receive data frames.

### Data Loading Phase

After receiving **Acknowledgement Message 2** from CAN BSL or if **Phase 2 (Initialization & Acknowledge #2)** has been skipped, the host starts sending **Programming messages** with the format shown in **Table 62**. CAN BSL receives the data and stores it CPU0 Program Scratchpad RAM starting from address C000 0000H.

Both communication partners evaluate the data message count until the requested number of CAN data frames has been transmitted.

After the reception of the last CAN data frame, CAN BSL terminates and returns to the main SSW flow (refer to **Figure 22**).

## AURIX™ TC3xx Platform Firmware

After exiting the SSW, user code will be started from address C000 0000H (CPU0 PSPR).

**Table 62 Programming message**

Frame Format requested	ID	DLC	DB0	DB1	DB2	DB3	DB4	DB5	DB6	DB7
Classical CAN	DMSGID as ID not as register entry	8	Hex Code Byte	Hex Code Byte	Hex Code Byte	Hex Code Byte	Hex Code Byte	Hex Code Byte	Hex Code Byte	Hex Code Byte
CAN FD	DMSGID as ID not as registry entry	DBPM	Hex Code Bytes amount of Data Bytes is defined in DBPM							

### 3.1.4 Support for Software over the Air (SOTA)

After power-on and system reset, the AURIX™ TC3xx Platform SSW evaluates the SOTA configuration installed in UCB\_SWAP\_ORIG/COPY and enables accordingly the SWAP functionality which allows to switch between the banks of the device PFLASH.

If a valid SOTA configuration is found in UCB\_SWAP\_ORIG/COPY, then the SSW executes the following:

- disable the direct access to PFLASH (the direct read paths CPUx-PFLx) by installing 1 into all CPUx\_FLASHCON4.DDIS bits
- install into SRU\_SWAPCTRL.ADDRCFG register:
  - Address region A active - if SWAP\_A marker is found
  - Address region B active - if SWAP\_B marker is found

### 3.1.5 Shutdown request handler

All the active CPUs in AURIX™ TC3xx Platform jump unconditionally to the entry point of this handler upon any warm reset request.

Hardware guarantees that this handler can not be interrupted by any other (interrupt/trap) request. Once the handler ends, all the CPUs are in stable passive state reached by a controlled ramp-down sequence, preventing big current jumps.

At its entry point (common for all the CPUs), the firmware causes any running CPU to jump to its own handler. For this purpose, the CORE\_ID register is read; because this register value is individual for any CPU - upon CORE\_ID=0, 1, 2, 3, 4 or 6 the firmware jumps to the routine for the respective CPU.

Note: for CPU5, CORE\_ID=6.

The functionality of all handlers is similar, namely:

- prepare work data for execution of average-power loop
- execute average-power loop until SCU\_RSTCON2.TOUTyy=1
- execute WAIT instruction

## AURIX™ TC3xx Platform Firmware

Upon completion of the above sequence, CPUx reaches a passive state yy microseconds after shutdown request activation, where:

- yy=20 for CPU2 and CPU5
- yy=40 for CPU1 and CPU4
- yy=60 for CPU0 and CPU3

### 3.1.6 Power Supply Friendly Debug Monitor

The AURIX™ TC3xx Platform BootROM contains a routine called Power Supply Friendly Debug Monitor (PSFDM). The purpose of this routine is to minimize the risk of getting EVR voltage over/undershoot due to a sudden current drop when more than one CPU is halted by OCDS, and to avoid a current peak when the CPUs are released from halt.

The PSFDM routine is an independent/stand alone module inside the BootROM that is not executed during device start-up. It is intended to be used by CPUs as a debug trap handler instead of halting. This means the debugger must configure properly the debug trap vector - it should point to address AFFF FC80H (inside BootROM).

Upon a debug event, the trap will be triggered for all configured CPUs, starting PSFDM execution. The CPUs can be halted individually by the tool if needed.

The PSFDM routine contains a “repeat action until condition” loop:

- the action represents a sequence of instructions that is meant to consume as much power as a typical application. For this purpose, a mixture between two TriCore instructions is implemented:
  - most power intensive (MADD.Q)
  - least power intensive (NOP)
- the condition to exit the loop is CBS\_TLS.TL2=0 (OTGS Trigger Line 2 is deactivated)

To continue user code execution, the debugger must:

- release from halt those CPUs which have been halted - so all the CPUs are running PSFDM as debug trap handler
- activate OTGS Trigger Line 2 - all the CPUs exit PSFDM (by RTE) and continue user code execution

At the end, after debug trap the CPUs are restarted in parallel, with a few cycles slack due to the individual CBS\_TLS.TL2 polling.

## 3.2 Registers

AURIX™ TC3xx Platform contains several registers exclusively dedicated to usage by Firmware as below described. These registers provide user with information about the results from start-up mode evaluation done by SSW.

## AURIX™ TC3xx Platform Firmware

## 3.2.1 Firmware specific usage of device registers

## 3.2.1.1 Registers providing information on the boot selections

## SCU\_STMEM1

## Start-up Memory Register 1

(for address - refer to SCU Chapter)

## AURIX™ TC3xx Platform Firmware

Field	Bits	Type	Description
BOOT_ADDR	31:2	r	<b>Address of the first user-code instruction, taken after SSW</b> <b>NOTE:</b> this address is always word-aligned, therefore bits [1:0] are effectively taken as zero

**3.2.1.2 Registers providing information on the Checker Software activity**

Note: *EMEM-related checks - indicated by STMEMx[17:16] - are only performed on devices implementing Emulation Memory (EMEM) and only for those EMEM module(s) which are effectively present on the product.*

*The proper handling on this topic is assured by respective CHSW Reference Tables content in Config Sector (CFS).*

**SCU\_STMEM3**

**Start-up Memory Register 3 (for address - refer to SCU Chapter)**      **Reset Value: 0000 0000<sub>H</sub>**

## On-Chip System Connectivity {and Bridges}

### 4 On-Chip System Connectivity {and Bridges}

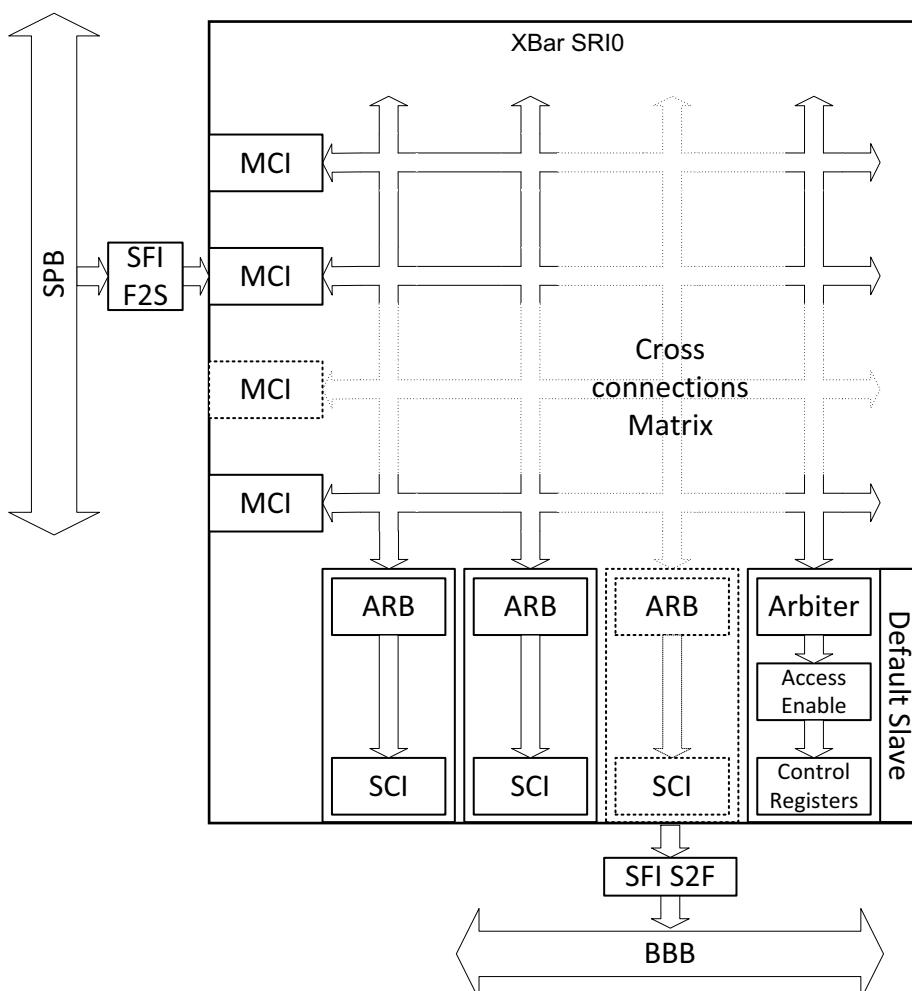

The AURIX™ TC3xx Platform has three independent on-chip connectivity resources:

- System Resource Interconnect Fabric (SRI Fabric)
- System Peripheral Bus (SPB)
- Back Bone Bus (BBB)

The SRI Fabric connects the TriCore CPUs, the DMA module, and other high bandwidth requestors to high bandwidth memories and other resources for instruction fetches and data accesses.

The SPB connects the TriCore CPUs, the DMA module, and other SPB masters to the medium and low bandwidth peripherals. SPB masters do not directly connect to the SRI Fabric, and will access SRI attached resources via a SFI\_F2S Bridge: see [Section 4.6](#).

The BBB connects the TriCore CPUs, the DMA module, and SPB masters with ADAS resources. SRI Masters do not directly connect to the BBB, but access BBB attached resources via a SFI\_S2F Bridge: see [Section 4.7](#). SPB masters also do not directly connect to the BBB, but access BBB attached resources via bridging over the SRI Fabric.

**Figure 25 Block diagram**

## On-Chip System Connectivity {and Bridges}

### 4.1 Feature List

The System Resource Interconnect (SRI) is the connectivity fabric for TriCore CPUs and high performance modules such as the DMA. A key component of the fabric is the SRI crossbar, which connects all the agents in one SRI domain. The SRI crossbar carries the transactions between the SRI Masters and SRI Slaves of the domain.

The SRI crossbar supports parallel transactions between different SRI Master and SRI Slave agents. In addition to the parallelism of concurrent requests, it also supports pipelined requests from an SRI Master to a SRI Slave.

#### SRI features

SRI feature overview:

- Single and burst read and write transactions (up to 4 x 64bit bursts)
- Atomic Read Modify Write transactions
- Pipelined transactions from SRI Masters to SRI Slaves
- Arbiter for each SRI Slave, with individual configuration
  - two round-robin groups, high and low priority
  - control of bandwidth to the high priority group
- EDC (Error Detection Code) on all address and control information transferred from SRI Master to SRI Slave
  - EDC on all data and control information transferred from SRI Master to SRI Slave for writes and RMWs
  - EDC on all data and control information transferred from SRI Slave to SRI Master for reads and RMWs

#### 4.1.1 What is new in the SRI Fabric

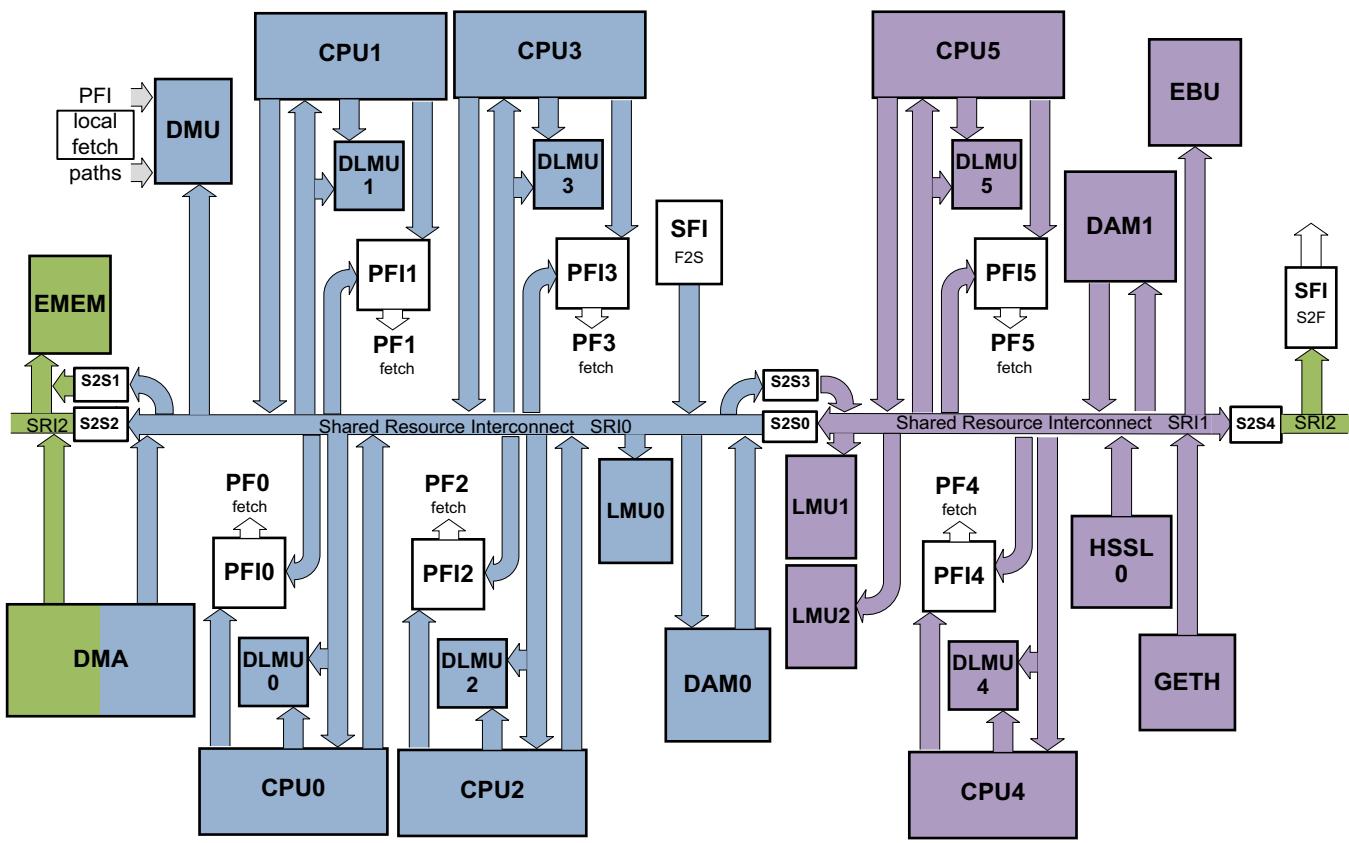

Major differences of the AURIX™ connectivity compared to previous AURIX™ based products.

- SRI Fabric can now consist of one or multiple independent crossbars
- SRI Crossbar arbitration scheme simplified to two layer round-robin

### 4.2 Overview

The SRI Fabric consists of one or more crossbars which support single and burst data transfers. If there are multiple crossbars, they are connected by bridges (S2S bridges: see [Section 4.5](#)).

## On-Chip System Connectivity {and Bridges}

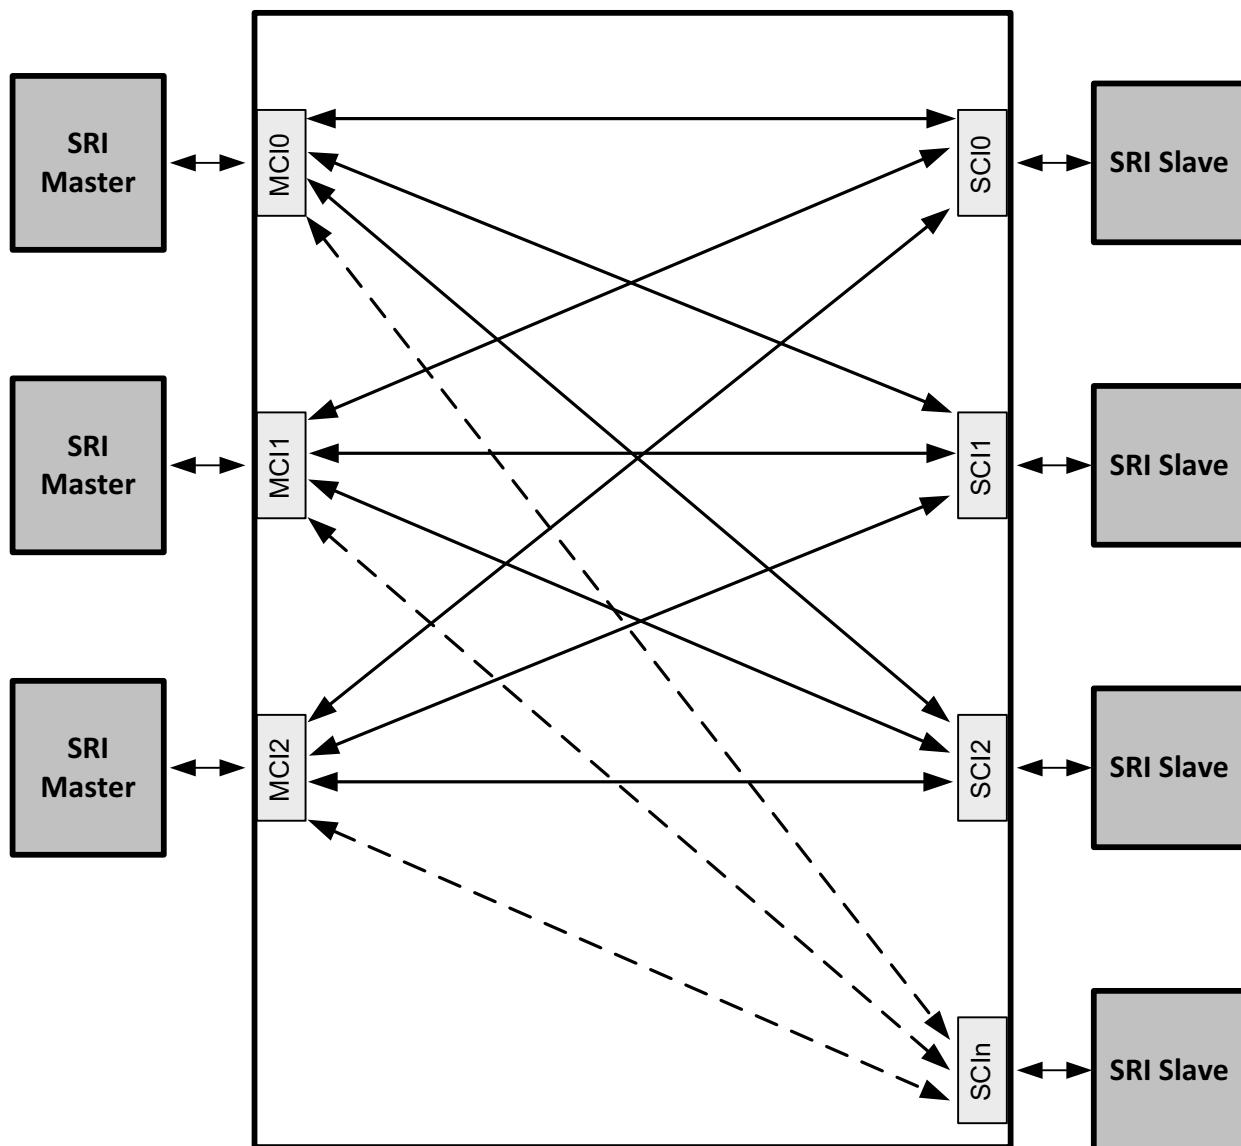

**Figure 26 Overview of the different SRI domains**

SRI agents (masters and slaves) which are connected to the same crossbar form an SRI domain. There will be at least one and possibly more SRI domains in AURIX™ TC3xx Platform family members. As an example the TC39xB has three domains: Domain 0 with 4 CPUs, Domain 1 with 2 CPUs, and Domain 2 with ADAS and debug functionality. S2S bridges are special in that they are present in two domains.

Due to the S2S bridging, all SRI Masters can directly address (access) most SRI Slaves, regardless of the SRI domain to which the master or slave is directly attached. Note: the reason for stating most slaves, rather than all slaves, is that even within the a single SRI domain, there may be masters and slaves which are not connected, since there is no functional need to communicate.

## On-Chip System Connectivity {and Bridges}

**Figure 27 SRI crossbar point to point connection scheme**

The SRI crossbar provides SRI Master Connection Interfaces (MCI<sub>x</sub>) to connect SRI Master modules and SRI Slave Connection Interfaces (SCI<sub>x</sub>) to connect SRI Slave modules to the SRI crossbar. There is one arbiter per connected SRI Slave module and the infrastructure for the enabled read/write data paths.

The SRI Fabric will always include at least one slave that provides housekeeping functions. The major purpose of these functions is to allow access to the SRI Fabric control and status registers. The second purpose is to respond (with an error) to all SRI transactions which address no other SRI Slave.

Please note that only those SRI Master to SRI Slave connections are implemented that are required for the system functionality; for example, an S2S master from another domain does not need to connect to an S2S slave connecting back to the same domain.

The SRI Fabric provides arbitration that allows the configuration of SRI Master priorities to be different for every SRI Slave. For support of system level diagnosis the SRI Fabric includes resources to capture SRI Error and SRI Transaction ID errors.

## On-Chip System Connectivity {and Bridges}

**Table 64 SRI Fabric Terms**

Term	Description
Agent	An SRI agent is any master or slave device which is connected to the SRI Fabric.
Master	An SRI master device is an SRI agent which is able to initiate transactions on the SRI Fabric.
Slave	An SRI slave device is an SRI agent which is not able to initiate transactions on the SRI. It is only able to respond to transactions operations that are directed to it by the SRI Fabric.
SRI crossbar	The SRI crossbar provides the interconnects between Masters and Slaves in the same domain. The SRI crossbar includes arbitration mechanisms and error capture capabilities.
MCI	Each Master is connected via one Master Connection Interface. The SRI Fabric contains control and status registers which affect MCI priority and provide related error information.
SCI	Each Slave is connected via one Slave Connection Interface. The SRI Fabric contains control and status registers which include control and error informations related to the SCI.
Domain	An SRI domain consists of those agents which are connected to a specific SRI crossbar. There will be at least one Master (or S2S bridge acting as a Master) and at least one Slave (or S2S bridge acting as a Slave), and an instance of a crossbar providing full or partial connectivity between all the agents in the domain.
Arbiter	If two (or more) Masters attempt to access the same Slave, the arbiter provides the decisions as to the order in which Masters gain access. The order is determined by the two-level round-robin mechanism implemented in the arbiter and the configuration programmed by the user.

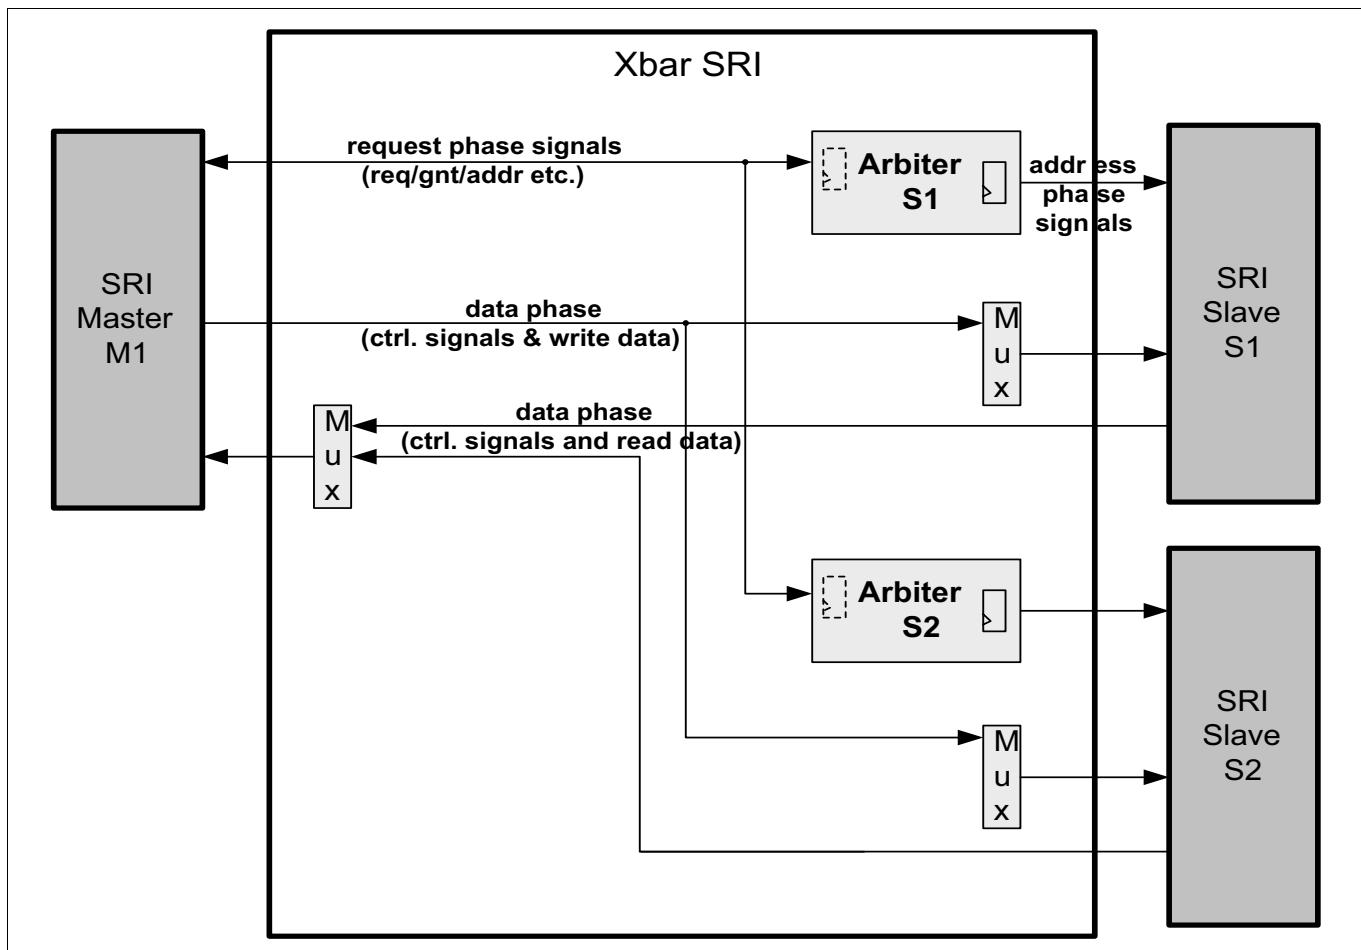

### 4.3 Functional Description

For configuration and debug, a certain amount of detail about the working of the SRI Fabric is required. Following is sufficient functional information to perform those tasks.

#### 4.3.1 Operational Overview

This section describes the functionality of the SRI crossbar module in order to enable the user to configure the SRI Fabric control registers, and to interpret the status and error capture resources.

## On-Chip System Connectivity {and Bridges}

**Figure 28 Example SRI crossbar connections between one SRI Master and two SRI Slaves**

The SRI crossbar can perform several transactions for different masters in parallel if the masters are accessing different slaves.

### 4.3.1.1 Master Connection Interface (MCI)

Each SRI Master in the system is mapped to master related control and status register bits and bit fields via its MCI number (see [Section 4.3.4](#)).

The MCI number is completely separate from the Master Tag(s) generated from the SRI Master connected to that MCI. However, the set of Master Tags presented by a specific MCI is fixed for a given device.

### 4.3.1.2 Slave Connection Interface (SCI)

Each SRI Slave in the system is mapped to slave related control and status register bits and bit fields via its SCI number (see [Section 4.3.4](#)).

### 4.3.1.3 Slave Arbiter

Each SCI has an associated arbiter which includes all the functionality for the following tasks:

- Arbitration: selection of the winning master when multiple requests are concurrent.
- Error capture: errors detected by a Slave (some errors are detected by Masters) will have transaction information captured where possible and the condition (if enabled) signalled to the system via the interrupt router (INT).

## On-Chip System Connectivity {and Bridges}

### 4.3.1.4 Default Slave

A default slave is an SRI Slave which implements several necessary housekeeping functions. As an SRI Slave, it has its own SCI and arbiter. A default slave may service a single or multiple domains. In a multiple domain system there will be more than one default slave. The allocation of default slaves to domains is fixed and its SCI number cannot be changed. A default slave provides these functions:

- access to some or all of the SRI Fabric control and status registers.
- all transactions that are accesses to non-existent address regions<sup>1)</sup> in a domain (if there are multiple domains), or the complete system (if there is a single domain), are provided to a default slave for a clean error response.
- implementation of the OLDA region (see next section).

For accesses to the control and status registers, only single data transactions of word size (32-bit) are supported. Any other transaction types are not supported. Unsupported transactions are acknowledged with an error. Each default slave will have its own valid address space, which is used for accesses to its allocated Fabric control and status registers. For a detailed description of the registers see [Chapter 4.4](#).

A default slave finishes SRI transactions to non-existent addresses (both reads and write) with an error, which will activate the error capturing mechanism of the default slave's arbiter.

**Note:** *A read from an SRI Master to a non-existent address on the BBB may be handled both by the Bus Control Unit on the BBB, and also reported on the SRI Fabric by the SFI\_S2F\_Bridge. In the SRI Fabric, this transaction information will be captured by the SFI\_S2F\_Bridge's arbiter, rather than the default slave for the domain. A write from an SRI Master to a non-existent address on the BBB will be posted and only directly reported on the BBB, and may be indirectly reported to the system otherwise.*

### 4.3.1.5 OnLine Data Acquisition (OLDA)

A default slave may also provide OnLine Data Acquisition (OLDA) region support. The OLDA is an address space where writes can complete without error but no memory is addressed. This allows production code to be written which writes data to memory, where the memory is only present in the Emulation Device. When running on an Emulation Device, the user can map EMEM to the OLDA region address space using the memory overlay feature, and the write data is then stored in the EMEM. When running in the Production Device, a default slave (when OLDA is enabled) terminates writes to the OLDA address space without error, even though no memory exists at the target address, and the write data is discarded.

If OLDA support is enabled in a default slave, direct write accesses (without redirection) to the OLDA range are not really executed, and they do not generate a bus error trap<sup>2)</sup>. If OLDA support is not enabled, write accesses will generate a bus error trap.

OLDA support is enabled by setting bit OLDAEN to 1 in a domain 0 BRCON register.

The base address of the virtual OLDA memory range(s) is defined in the memory map chapter. Accesses to the OLDA range are also supported in cached address space for all masters, but consider the footnote for the consequences for CPUs on cached write accesses<sup>2)</sup>.

Read accesses to the OLDA range generate a bus error trap, if not redirected to a physically available overlay block. Successful accesses to the OLDA memory range will only take place when the accesses are redirected to real, physical memory<sup>3)</sup>.

1) non-existent address regions = all Reserved address ranges described in the Memory Map chapter.

2) Write accesses to a cached memory address will trigger a read to fill the cache line before the data is written to the cache. This read will trigger a bus error.

3) This is mentioned for completeness as it is not really intended usage.

## On-Chip System Connectivity {and Bridges}

Note that switching on or off the OLDA function takes a finite amount of time after the register write completes. It is therefore possible for an immediately subsequent access to be pipelined to the default slave providing the OLDA region, and be acknowledged with either the “on” or “off” behavior. Accesses from the same master can be simply synchronised by a read back of the modified control registers before any accesses of interest; however for other masters more specific synchronisation is required.

**Note:** *In OTARx registers, any target address can be selected for redirection, including addresses in the OLDA range. However, the handling of direct accesses to the OLDA range is completely controlled in a default slave.*

### 4.3.1.6 Control and Status Register Access Protection

The SRI Fabric control and status registers are protected by a master TAG ID-based access protection mechanism. Each on-chip resource with direct or indirect bus master capability has a unique master TAG ID that can be used to identify the master of an on-chip bus transaction.

Access Enable:

TAG ID based protection means that on-chip write access to the SRI control and status registers can be disabled for each master TAG ID individually (with the exception of the Access Enable registers themselves, which are Safety Endinit protected). For a disabled master TAG ID, access will be terminated with an error acknowledge.

Access Enable Registers (ACCEN1/0) have these properties:

- define which master TAG ID is allowed write access to SRI control and status registers
- are Safe Endinit write protected

After reset, all ACCEN1/0 access enable bits and access control bits are enabled. The access protection mechanism must be configured to put the system into what is required for a safe operation.

### 4.3.2 Arbitration Details

Each SCI arbiter has access to all arbitration/address phase signals from the MCIs it is connected to, and views all requests from MCIs in parallel.

#### 4.3.2.1 Master Request Arbitration

The underlying arbitration mechanism is round-robin, which is simple to understand and is starvation-free. The general concept of round-robin is granting requests to masters in a circular order. The implemented round-robin mechanism is sometimes referred to as ‘round-robin work conserving’ as requests are not delayed if the ‘nominal winner’ is inactive; see **Round-robin Groups** below for more detail.

To support real-time behavior with more control over latencies of some Masters’ transactions, this scheme is enhanced. The specific arbitration supports two round-robin priority levels - a high priority level and a low priority level. Each level implements a round-robin arbitration scheme between participants in that level. In addition, the number of transactions continuously granted to the high priority level can be increased by use of the High Priority Round Share parameter; see **Two-Round Interaction** below for details.

#### Arbitration Configuration

The arbiter for each SCI is configurable for the priority of those MCI to which it is connected: see **Chapter 4.4.2**. The priorities (low or high) of each connected MCI can be programmed for each arbiter individually, via the arbiter PRIORITY register: see **Register "PRIORITY $x$  (x=0-15)"**. The priority of each master is defined by a single bit in the register that corresponds to its MCI number in the domain. This per-arbiter configuration allows a given master to be handled with different priorities for accesses to different slaves.

## On-Chip System Connectivity {and Bridges}

After reset most enabled MCIs are set to the low priority level, although bridges and DMAs are typically set to high priority.

For error diagnosis purposes, the arbiter samples all the necessary transaction information and provides this in [Register "ERRADDRx \(x=0-15\)"](#) and [Register "ERRRx \(x=0-15\)"](#) if an SRI protocol error occurs.

### Round-robin Groups

If more than one master is mapped to the priority of a round-robin group, the requests of the mapped masters will be handled by the round-robin algorithm.

After the winner of a round-robin group is granted a transaction, the round-robin group starts a new arbitration round. In this round the next highest MCI ID number which is requesting a transaction will win the arbitration. If there is no requesting MCI with a higher ID number in the round-robin group, the algorithm will consider the lowest MCI ID number in the group that is requesting, followed by the next higher MCI ID number and so on.

The mechanism works by selecting each requesting master slot in turn per arbitration cycle, in ascending order: MCIO to MCIx-1 (for x MCIs in the domain). If a master doesn't have a request in the current cycle of arbitration then it is bypassed for the next slot, and so on. Thus, if only one master is requesting over a given time period, that master will be selected consecutively during multiple arbitration rounds, without incurring any latency.

### Two-Round Interaction

In arbitrating between high priority masters, the low priority MCIs are collectively viewed as a request. After at most 'High Priority Round Share' consecutive high priority master transactions, the low priority round is granted an access. The evaluated winner of the low priority round then carries out its transaction. If there are no high-priority MCIs, or no low-priority MCIs, the scheme operates as a single-level round-robin arbitration.

### Request Latency

If no other transaction is pending, a transaction from an MCI commences in the next clock. If there are multiple requests pending, or arrive at the same time, then the latency depends on whether the MCI is in the high or low priority round share, and how many other requestors are in each round. [Table 65](#) shows the worst case number of transactions that a Master might have to wait before its transaction can commence in a domain with the maximum of 8 Masters.

**Table 65 Master Request Latency**

Number of High Priority/ Low Priority Masters	High Priority Round Share	Worst case delay in arbitrations for a High Priority Master	Worst case delay in arbitrations for a Low Priority Master
0 / 8	(0)	N.A.	7
1 / 7	1	1	13
	2	1	20
	3	1	27
	4	1	34
	5	1	41
	6	1	48
	7	1	55

## On-Chip System Connectivity {and Bridges}

**Table 65 Master Request Latency**

Number of High Priority/ Low Priority Masters	High Priority Round Share	Worst case delay in arbitrations for a High Priority Master	Worst case delay in arbitrations for a Low Priority Master
2 / 6	2	2	17
	3	2	23
	4	2	29
	5	2	35
	6	2	41
	7	2	47
3 / 5	3	3	19
	4	3	24
	5	3	29
	6	3	34
	7	3	39
4 / 4	4	4	19
	5	4	23
	6	4	27
	7	4	31
5 / 3	5	5	17
	6	5	20
	7	5	23
6 / 2	6	6	13
	7	6	15
7 / 1	7	7	7
8 / 0	(0)	7	N.A.

The latency for domains with fewer masters can be computed simply:

If there is only a single round of arbitration (high or low), then

```
max_delay = number_of_masters - 1
```

If there are two rounds (high and low) of arbitration, then for a high priority master:

```
HP_max_delay = number_of_high_priority_masters
```

and for a low priority master:

```
LP_max_delay = ((HPRS+1) x number_of_low_priority_masters) - 1
```

The worst case number of clock cycles a Master might have to wait will depend on the response time of the respective slave. So, if for example, the SRI Slave has a response time of 10 clocks, the worst case wait in clock cycles for a low priority master in a 2 high, 6 low configuration with a high priority share set to 7 is 470 clocks. Usually SRI slaves will have a deterministic response time to transactions (although it might vary between read and write transactions, and the data width to be transferred). It is typically only in the case of off-chip accesses (such as the EBU) where there might be high variation in transaction times.

## On-Chip System Connectivity {and Bridges}

### 4.3.3 SRI Errors

SRI Error conditions can be detected by both masters and slaves depending upon the condition. Errors are reported via alarms to the SMU or interrupts or traps taken by a CPU.

For some errors, a slave can signal the corresponding master that an error has happened, which results in an immediate termination of the current transaction. For other errors during a transaction, the transaction continues, but the error is tracked by the SRI Fabric, and may be signalled via an alarm or an interrupt if enabled in both the SRI Fabric and interrupt router (INT).

There are three error types:

- SRI Protocol Errors
- SRI Transaction ID Errors
- SRI EDC Errors

Note: the term EDC error refers here to the combined set of SRI EDC features (SRI Address phase EDC, SRI Write Data EDC and SRI Read Data EDC). Although the encoding scheme could allow for correction of single bit errors, the decoders are configured to only use detection as this provides a higher coverage against multi-bit errors.

#### 4.3.3.1 SRI Protocol Errors

The following error conditions are detected by SRI Slaves and result in error termination of the transaction (SRI protocol error) to the SRI Master and/or an alarm:

- non-existent address region accessed by an SRI Master<sup>1)</sup>
- reserved address within an existing memory region
- unsupported or reserved opcodes
- access level is incorrect (supervisor register accessed in user mode)
- access protection is configured to not allow the current SRI Master read access<sup>2)</sup>
- access protection is configured to not allow the current SRI Master write access<sup>3)</sup><sup>4)</sup>
- unsupported operation to a specific register
- EDC invalid for the address phase

For testing purposes, an SRI Protocol Error can be generated by the application software with an access to a reserved address (see chapter Memory Map).

Those SRI Slaves which have detected a protocol error can be determined by inspection of [Register "PESTAT"](#).

#### 4.3.3.2 SRI Transaction ID Errors

A transaction ID is an identifier connected to all phases of a transaction, in order to make the transaction unique in the SRI Fabric during the transaction's lifetime.

The transaction ID is used by SRI Masters and SRI Slaves to identify errors (usually transient) in the SRI Fabric that might result in data packets received by a master or slave that do not correspond to the started transaction. If the read/write transaction identifier doesn't match the transaction identifier sent during the address phase, this is a Transaction ID error and tracked by the SRI Fabric.

In addition to SRI Fabric errors, forcing a Transaction ID Error is used in situations where at the data source side (the SRI Master for write transactions and the SRI Slave for read transactions), a data phase has to be invalidated

1) The accesses to non-existent address regions are checked by a default slave.

2) Read protection is intended to protect memories and not SFR ranges.

3) MiniMCDS SFR range is not protected. Debug functionality.

4) Some slaves don't issue a bus error. In that case the write is prevented and an alarm is issued. This is the case for CPU, LMU, EBU and EMEM

## On-Chip System Connectivity {and Bridges}

(e.g. detection of an uncorrectable error from an accessed memory). In these situations, an invalid transaction ID is sent in order to invalidate the data phase.

For testing purposes, an SRI Transaction ID error condition can be generated by injecting a non-correctable error into one of the SRAMs (e.g. CPU Scratch Pad SRAM), and then reading the corrupted data by an SRI Master.

Those SRI Masters and SRI Slaves which have detected a Transaction ID error can be determined by inspection of **Register "TIDSTAT"**.

### 4.3.3.3 SRI EDC Errors

The SRI Fabric provides EDC protection for the:

- Address phase of an SRI transaction
- Transmitted read and write data phases

#### SRI Address Phase EDC Errors

- If an SRI Slave detects an SRI address phase EDC error, it finishes the transaction with SRI error acknowledge (a protocol error) and does not process it further
- In addition to the protocol error, each SRI Slave signals an address EDC error to the SMU as an alarm

See the **Error Handling** section for details on Protocol Error configuration and information capture.

#### SRI Write Data EDC Errors

An SRI Slave will check each data phase of a write transaction, (1, 2 or 4 phases depending on the transaction length) for EDC validity.

If an SRI Slave detects an SRI write data EDC error, it is signalled to the SMU as an alarm.

Whether a SRI Slave merely monitors the EDC error condition, or attempts to prevent the state update, is not defined by the SRI infrastructure, but should be described by each SRI Slave Agent.

#### SRI Read Data EDC Errors

An SRI Master will check each data phase of a read transaction, (1, 2 or 4 phases depending on the transaction length) for EDC validity.

If an SRI Master detects an SRI read data EDC error, it is signalled to the SMU as an alarm.

Whether an SRI Master merely monitors the EDC error condition, or attempts to prevent the usage of the returned data is not defined by the SRI infrastructure, but should be described by each SRI Slave-Agent.

Because of their key role, the behavior of CPU is reiterated here. A trap will be taken by the CPU if a received 64-bit phase of data is used by the CPU. A phase might not be used if a cache line is requested and the beat containing the EDC error is not required for the instruction stream or the data load instruction. If any part of a received memory line contains an EDC error, a possible cache update is aborted and the received data is discarded.

### 4.3.3.4 Error Handling

If an arbiter recognises that its associated SRI Slave has signalled an SRI Protocol error for a transaction, the arbiter samples all relevant information of the transaction in the diagnostic registers (**ERRx (x=0-15)** and **ERRADDRx (x=0-15)**). An indication of this error can be provided to the interrupt router (INT), and this indication can be controlled, via the **PECONx (x=0-15)**.PEEN control bit. Only when this bit is set is the error information captured and the trigger condition signalled to the interrupt router.

## On-Chip System Connectivity {and Bridges}

### Notes

1. The two error registers **ERRx (x=0-15)** and **ERRADDRx (x=0-15)** in each arbiter are updated with the content of the currently processed transaction in the data phase. The registers are only updated if they are not locked due to an earlier protocol error.

The stored information can be read from the arbiter via word reads.

The error capture registers in the arbiter will not be updated again until the indication is acknowledged to the slave arbiter module by software (set the respective **PECONx (x=0-15).PEACK**).

The error capture registers will be locked after the first error. This results in the non capture of subsequent error information from the same SRI Domain, until the write releasing the lock is processed.

A master or a slave can detect a transaction ID error. An indication of this error can be provided to the interrupt router (INT), and this indication can be controlled via the **TIDEN.ENMCI** and **TIDEN.ENSCI** control bits. Only if the relevant enable bit is set is the error condition captured in **TIDSTAT**, and the trigger condition signalled to the interrupt router.

### Notes

1. While a status bit for a error source is set in either the **PESTAT** or **TIDSTAT** register, a new error from this particular source doesn't generate a new indication.
2. Each agent in the SRI Bus system has two error conditions: protocol errors, and Transaction ID errors. All errors from an SRI Bus domain share a single SRN in the interrupt router (INT) for each SRI Domain.

### 4.3.3.5 Error Tracking Capability

The SRI crossbar tracks all SRI transactions for SRI protocol errors. In addition it tracks information about SRI transaction ID errors. This is done by all arbiters in parallel, since the SRI crossbar supports the processing of multiple transactions from masters and slaves in parallel, which can result in concurrent events at different SCIs.

For this purpose, each arbiter has two registers where it samples the transaction information of the transaction where the first protocol error happened.

**Note:** *Protocol errors will lock the error registers. All subsequent error events will not be captured in the error registers until the lock is released.*

Further protocol errors will be ignored by an arbiter that has detected a protocol error until the capture mechanism is re-activated via the arbiter internal control register. A detected protocol error is signalled by the arbiter to the per-domain error status register **PESTAT**. Each error signal can be masked individually by the **PECONx (x=0-15)** control registers in the arbiter modules for SCIx. In addition the **ERRx (x=0-15)** and **ERRADDRx (x=0-15)** registers are accessible in each SCIx.

For transaction ID errors of write transactions, the SCIs propagate errors to the associated bit in the lower half of the per-domain register **TIDSTAT**. For transaction ID errors of read transactions, the MCIs propagate errors to the assigned bit in the upper half of the same register.

Once an error is signalled from an arbiter or an MCI/SCI to the system, the system can read out the error status registers to find out which arbiter(s) or master/slave have detected an error. The system can then perform more detailed diagnostics by reading out the error registers in the respective arbiter for a protocol error. The error information captured for an SRI protocol error allows the identification of the master via the sampled master tag ID, and the final destination via the captured target address. In addition, the **ERRx (x=0-15)** register samples the opcode and the read, write, and supervisor signals of the transaction.

In addition to the pure transaction information, the SRI **ERRx (x=0-15)** captures some additional information. In the AURIX™ family, this additional information is only provided by the DMA peripheral, to indicate the channel performing the transaction. **Table 66** shows the encoding of the MCI\_SBS bit field for the AURIX™ family.

## On-Chip System Connectivity {and Bridges}

**Table 66 Encoding of MCI\_SBS in ERRx (x=0-15)**

MCI_SBS[7:0]	Bit field encoding
MCI_SBS[7:0]	This field is only defined if the master TAG ID in the TR_ID field is a DMA hardware resource group. MCI_SBS[7] provides the DMA Move Engine number MCI_SBS[6:0] provides the DMA channel number

After reading all relevant error information, the error capture mechanism should be re-enabled.

### 4.3.3.6 Indication Event Interactions

There are some interactions between indication events. In general, several indications from the same, or a different source (arbiter, MCI or SCI) can occur at the same time. One indication could occur several times before a service request routine services it.

The following examples describe the system behavior without rearming from a service routine when all consecutive indications/events come from the same domain.

#### Two Consecutive Protocol Errors

The first protocol error is captured, together with the generation of an indication to the system. The second protocol error is not captured, since the registers ERR and ERRADD are already locked, and no indication is generated.

#### Two Consecutive Transaction ID Errors

The first transaction ID error generates an indication to the system. The second transaction ID error will not generate an indication to the system.

### 4.3.3.7 Releasing the lock from registers ERR and ERRADD

If the ERR and ERRADD registers are locked. When the registers are locked, the lock can be released by writing a 1 to PECONx.PEACK.

### 4.3.4 Implementation of the SRI Fabric

This chapter describes the SRI Fabric implementation in the AURIX™. The knowledge of the specific implementation (e.g. the connection of the SRI Master / SRI Slave devices to the Fabric) is necessary in order to:

- define the arbitration priority for masters (using their MCI number)
- map error information to the connected slave devices (using their SCI number)
- map SRI crossbar (arbiter) control registers to connected slave devices

The first part of the chapter includes tables for each SRI domain that describes:

- the mapping of SRI Master devices to MCIs
- the mapping of SRI Slave devices to SCIs
- the implementation of specific connections between MCIs and SCIs

#### Notes

1. *Each CPUx (x = 0...5) has only a single SRI Master connection, where both code fetches and data accesses are presented (labelled CPUx in MCI tables).*

## On-Chip System Connectivity {and Bridges}

2. Each CPU $x$  ( $x = 0 \dots 5$ ) has both an SRI Slave connection for access to its associated PFlash (labelled CPU $xP$  in SCI tables), and an SRI Slave connection for access to its associated SRAMs, SFRs and CSFRs (labelled CPU $xS$  in SCI tables).

AURIX™ family members smaller than the TC38x do not have a Domain 1.

### 4.3.4.4 Mapping of SRI Slaves to Domain 1 Slave Interfaces

[Figure 32](#) shows the mapping of slave modules to the SRI crossbar Slave Interfaces (SCI0 - SCI15). Most of the SRI crossbar control registers are related to the SRI crossbar Slave Interfaces (SCI0 - SCI15) or the SRI crossbar Master Interfaces. Therefore it is important to know which AURIX™ TC3xx Platform SRI Slave device relates to which SRI crossbar Slave Interface or arbiter module.

## 4.4 Registers

Figure 35 along with Table 67 show all the registers of the SRI Fabric. The absolute register address is calculated from the Module Base Address (see Appendix document) by adding the Offset Address of the specific register and (0x20\*i), where ‘i’ is the index of the associated SCI.

### SRI Fabric Register Overview

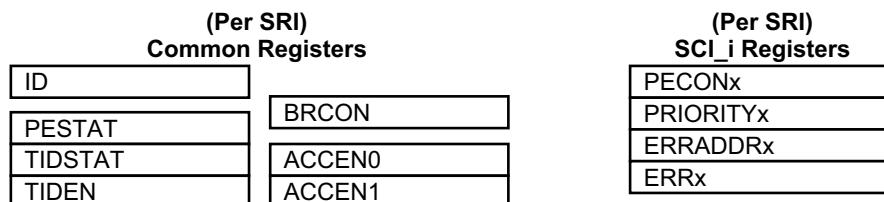

Figure 35 SRI Fabric Registers for all Domains

### Notes

1. Addresses listed in column “Offset Address” of Table 67 are word (32-bit) addresses on double word alignment. All odd-word addresses are reserved.
2. SRI control registers can be accessed only with SDTW (32-bit) transactions. 8-bit, 16-bit, 64-bit and RMW transactions are undefined.

Table 67 Register Overview - DOM (ascending Offset Address)

Short Name	Long Name	Offset Address	Access Mode		Reset	Page Number

## On-Chip System Connectivity {and Bridges}

### 4.4.1 Domain Common Registers

#### Identification Register

The identification register identifies the module, and provides revision and type information. The table below describes the identification register, which is implemented per domain.

ID															
Identification Register (00408 <sub>H</sub> ) Application Reset Value: 0004 D0XX <sub>H</sub>															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
MOD_NUMBER															
r															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
MOD_TYPE								MOD_REV							
r								r							

Field	Bits	Type	Description
MOD_REV	7:0	r	<b>Module Revision Number</b> This bit field defines the module revision number. The value of a module revision starts with 01H (first revision).
MOD_TYPE	15:8	r	<b>Module Type</b> The bit field is set to D0H which defines the module as a 32-bit module.
MOD_NUMBE R	31:16	r	<b>Module Number Value</b> This bit field defines a module identification number. The value for the SRI Fabric is 0004H.

#### Protocol Error Status Register

Note: Only the bits assigned to implemented SCIs are present. Bits corresponding to unimplemented SCIs are treated as reserved bits, which will be read as 0, and should be written with 0. See [Chapter 4.3.4](#) for which SCI is implemented.

#### PESTAT

PESTAT

0	5:1, 8:7, 12:11, 31:20	r	<b>Reserved</b> Read as 0; shall be written with 0.
0	6, 10, 19:13	rw	<b>Reserved</b> Read as 0; shall be written with 0.
1	9	rw	<b>Reserved</b> Read as 1; shall be written with 1.

### Access Enable Register 0

The Access Enable Register 0 controls access for transactions with the on chip bus master TAG ID 0 to 31 (see On Chip Bus chapter for the TAG ID <-> master mapping). The registers ACCEN0 / ACCEN1 provide one enable bit for each possible 6-bit TAG ID. The mapping of TAG IDs to ACCEN0.ENx is: EN0 -> TAG ID 0, EN1 -> TAG ID 1, ... EN31 -> TAG ID 31. For modules connected to SRI bus, ACCEN0 register controls write accesses from all on chip bus masters. Read access is not controlled.

### ACCENO

#### Access Enable Register 0

## On-Chip System Connectivity {and Bridges}

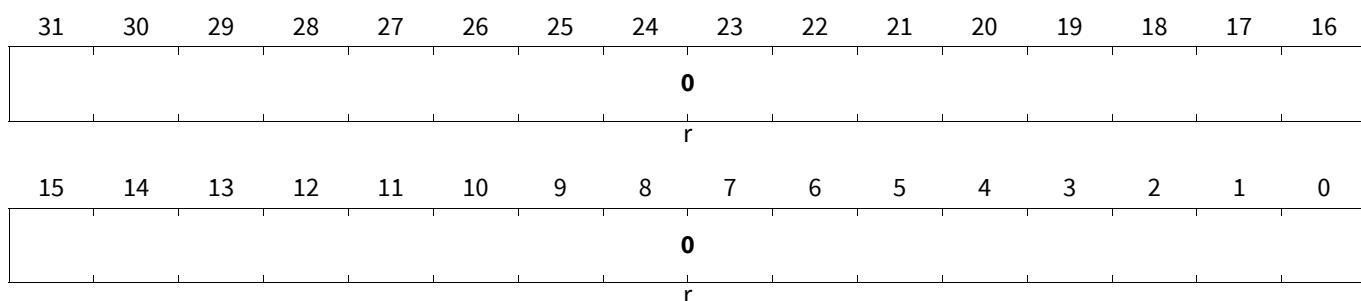

Field	Bits	Type	Description
<b>ENn (n=0-31)</b>	n	rw	<p><b>Access Enable for Master TAG ID n</b></p> <p>This bit enables write access to the module kernel addresses for transactions with the Master TAG ID n:</p> <ul style="list-style-type: none"> <li>0<sub>B</sub> Write access will not be executed</li> <li>1<sub>B</sub> Write access will be executed</li> </ul>

### Access Enable Register 1

The Access Enable Register 1 controls access for transactions with the on chip bus master TAG ID 32 to 63 (see On Chip Bus chapter for the TAG ID <-> master mapping). ACCEN1 is not implemented with register bits, as the related TAG IDs belong to masters that cannot access the SRI SFR's in AURIX™ devices. All writes from master TAG ID's > 32 will result in the write access not to be executed. The mapping of TAG IDs to ACCEN1.ENx is: EN0 -> TAG ID 32, EN1 -> TAG ID 33, ... EN31 -> TAG ID 63

#### ACCEN1

**Access Enable Register 1** (004F8<sub>H</sub>) Application Reset Value: 0000 0000<sub>H</sub>

Field	Bits	Type	Description
<b>0</b>	31:0	r	<p><b>Access Enable Register 1</b></p> <p>Read as 0; should be written with 0. Write access will not be executed</p>

## On-Chip System Connectivity {and Bridges}

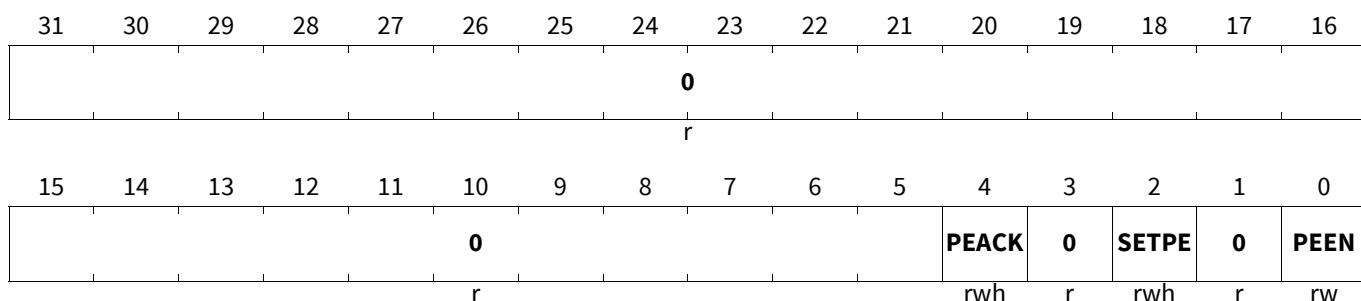

### 4.4.2 SCI Control Registers

Note: Only the registers assigned to implemented SCIs are present. Registers for unimplemented SCIs are treated as reserved. See [Chapter 4.3.4](#) for which SCIs are implemented.

#### Protocol Error Control Register x

##### PECONx (x=0-15)

**Protocol Error Control Register x**       $(00000_H + x*20_H)$       **Application Reset Value: 0000 0001<sub>H</sub>**

Field	Bits	Type	Description
PEEN	0	rw	<b>Protocol Error Enable</b> 0 <sub>B</sub> Protocol errors are not indicated and no information is captured. 1 <sub>B</sub> Protocol errors are indicated and information is captured.
SETPE	2	rwh	<b>Set Protocol Error</b> This allows SW to mimic a protocol error and present an indication similar to a hardware detected error. After setting this bit, it is automatically cleared by the hardware in the cycle after the write. 0 <sub>B</sub> No protocol error indication is generated 1 <sub>B</sub> A protocol error indication is generated
PEACK	4	rwh	<b>Protocol Error Acknowledge</b> Writing a one to this bit while it's set has the following results: The error lock of the corresponding ERRADDRx and ERRx are released, and the registers will be updated for the next protocol error detected (see <a href="#">Chapter 4.3.3.5</a> ). After setting this bit, it is automatically cleared by the hardware in the cycle after the write. 0 <sub>B</sub> Default value 1 <sub>B</sub> A Protocol Error for this arbiter has been indicated. The corresponding ERRADDR and ERR registers are not updated for new errors.
0	1, 3, 31:5	r	<b>Reserved</b> Read as 0; should be written with 0.

#### SCIx Arbiter Priority Register

Identical functionality can be achieved by setting all priorities to high compared with setting all priorities to low. HPRS only affects arbitration when high priority requests arrive so frequently that there are no arbitration rounds with only low priority requests. When this occurs (no high priority free arbitration rounds), a maximum of HPRS

## On-Chip System Connectivity {and Bridges}

grants are given to high priority masters, and then a single grant is given to the low priority round robin winner. See [Table 65](#) for effects on latency on different numbers of high priority requesters and different values of HPRS.

**Note:** Only the MCIn\_P bits assigned to implemented MCIs are present. Bits corresponding to unimplemented MCIs are treated as reserved bits. See [Chapter 4.3.4](#) for implemented MCI per domain.

3. Reset values for bits/bitfields coupled to masters or slaves that are not configured or enabled are zero.
4. The reset value for SRI0.PRIORITYx ( $x=0..19$ ) is  $0007\ 0043_H$ ; SRI1.PRIORITYx ( $x=0..5$ ) is  $0007\ 0002_H$ ; and SRI2.PRIORITYx ( $x=0..4$ ) is  $0007\ 0000_H$ .

### PRIORITYx ( $x=0-15$ )

<b>SCIx Arbiter Priority Register</b>																<b>(00008<sub>H</sub>+x*20<sub>H</sub>)</b>		<b>Application Reset Value: 0007 0XXX<sub>H</sub></b>

Field	Bits	Type	Description
MCIn_P (n=0-11)	n	rw	<b>MCIn Priority</b> 0 <sub>B</sub> MCIn requests are arbitrated in the low priority round robin. 1 <sub>B</sub> MCIn requests are arbitrated in the high priority round robin.
<b>HPRS</b>	18:16	rw	<b>High Priority Round Share</b> Number of transactions to give to the high priority round robin before a transaction from low priority round (when request saturated). This number may not be less than the number of high priority MCI programmed via. MCIn_P.
<b>0</b>	15:12, 31:19	r	<b>Reserved</b> Read as 0; should be written with 0.

### SCI x Error Address Capture Register

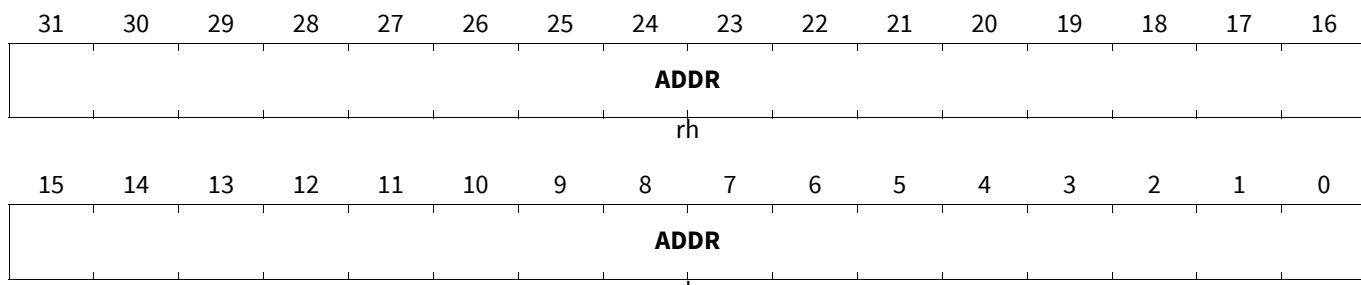

#### Notes

1. The default value can differ from the one shown here, because a constant can be used to reduce the number of compared bits in the arbitration if a slave occupies only a limited address area. For more details, see the design specification of the SRI crossbar.

## On-Chip System Connectivity {and Bridges}

### ERRADDRx (x=0-15)

**SCI x Error Address Capture Register** **(00010<sub>H</sub>+x\*20<sub>H</sub>)** **Application Reset Value: 0000 0000<sub>H</sub>**

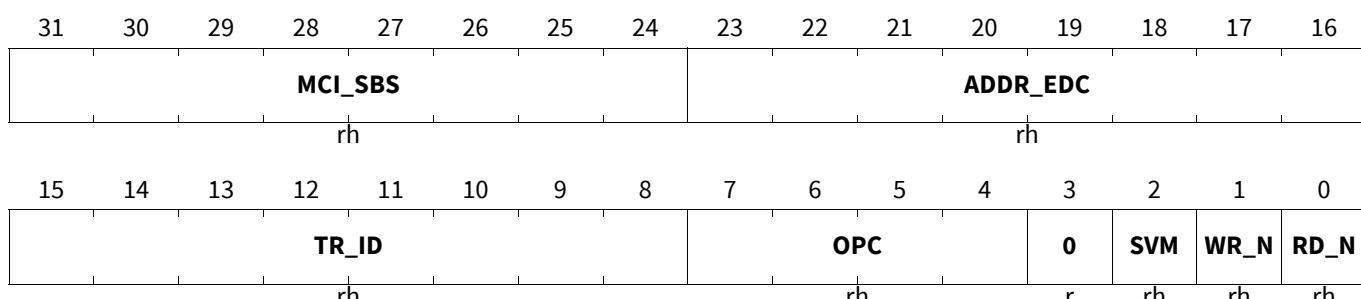

Field	Bits	Type	Description
<b>ADDR</b>	31:0	rh	<b>Transaction Address</b> This bitfield contains the address of the erroneous transaction from the address phase

### SCI x Error Capture Register

### ERRx (x=0-15)

**SCI x Error Capture Register** **(00018<sub>H</sub>+x\*20<sub>H</sub>)** **Application Reset Value: 0000 0000<sub>H</sub>**

Field	Bits	Type	Description
<b>RD_N</b>	0	rh	<b>Read Status - RD</b> $0_B$ The read signal line was asserted (read or start of RMW transaction) $1_B$ The read line was deasserted (no read transaction)
<b>WR_N</b>	1	rh	<b>Write Status - WR</b> $0_B$ The write signal line was asserted (write or start of RMW transaction) $1_B$ The write signal line was deasserted (no write transaction)
<b>SVM</b>	2	rh	<b>Supervisor Mode Status</b> $0_B$ The supervisor mode signal line was deasserted $1_B$ The supervisor mode signal line was asserted
<b>OPC</b>	7:4	rh	<b>Operation Code</b> This field contains the opcode of the erroneous transaction; see <a href="#">Table 68</a> for details.

## On-Chip System Connectivity {and Bridges}

Field	Bits	Type	Description
<b>TR_ID</b>	15:8	rh	<b>Transaction ID</b> This field contains the Master's transaction ID of the erroneous transaction. The Transaction ID is built out of the Master's 6-bit unique TAG ID (TR_ID[5:0]), and a 2-bit running number TR_ID[7:6].
<b>ADDR_EDC</b>	23:16	rh	<b>Address Phase Error Detection Information</b> This field contains the Address Phase Error Detection Information of the erroneous transaction.
<b>MCI_SBS</b>	31:24	rh	<b>MCI Sideband Signals [7:0]</b> This bit field contains the MCI Sideband Signals [7:0] that are related to the transaction information captured. In the AURIX™ family, the sideband signals are used by the DMA to provide information about the DMA requestor of a DMA transaction (for the encoding see <a href="#">Table 66</a> ).
<b>0</b>	3	r	<b>Reserved</b> Read as 0; should be written with 0.

### OPC encoding

The OPC field contains information about the type of SRI transaction for which information has been captured. For single data transactions, this field indicates the number of bytes. For block transfer, this field indicates the expected number of data beats.

**Table 68 Operation Code Encoding**

OPC[3:0]	Identifier	Description
0000	SDTB	Single Data Transfer Byte(8 bit)
0001	SDTH	Single Data Transfer Half-Word(16 bit)
0010	SDTW	Single Data Transfer Word(32 bit)
0011	SDTD	Single Data Transfer Double-Word(64 bit)
0100-0111	-	Reserved
1000	BTR2	Block Transfer Request (2 transfers) Wrap Around Addresses are used.
1001	BTR4	Block Transfer Request (4 transfers) Wrap Around Addresses are used.
1010-1111	-	Reserved

## On-Chip System Connectivity {and Bridges}

### 4.5 S2S Bridge

The S2S bridge is unidirectional, but bidirectional functionality is achieved where required by placing two bridges in opposite directions between two SRI domains. S2S bridges transmit all SRI transaction types transparently (no master tag or address modification). They are designed to minimize latency between the two domains connected by the bridge.

#### Error Behavior

The S2S bridge is special in its handling of errors. It transmits most errors and does not report them itself.

#### 4.5.1 EDC Errors

Address EDC errors are passed from the initiating domain and left to the receiving slave, to interrupt or raise alarms as configured.

Read data EDC errors are transferred from the slave domain to the initiating master, to interrupt or raise alarms as configured.

Write data EDC errors will be transferred from the initiating domain, and left to the receiving slave to interrupt or raise alarms as configured.

#### 4.5.2 Protocol Errors

SRI protocol errors on reads are transferred from the slave domain to the initiating master, to interrupt or raise alarms as configured.

As write transactions are buffered, SRI protocol errors will not be signalled in the initiating SRI domain by the S2S bridge, as it has no knowledge of the error condition. In the receiving domain, protocol errors will be left to the receiving slave, to interrupt or raise alarms as configured.

#### 4.5.3 Transaction ID Errors

Transaction ID errors on reads are transferred from the slave domain to the initiating master, to interrupt or raise alarms as configured.

Transaction ID errors on writes are transferred from the master domain to the receiving slave, to interrupt or raise alarms as configured.

#### 4.5.4 Transaction Errors for Writes via S2S Bridge

Write transactions from one SRI domain to another SRI domain, resources are handled as posted writes. This means that a write operation from a SRI Master through the S2S Bridge can be finished on the source SRI Fabric, and the S2S autonomously completes the write later on the destination SRI Fabric. If the S2S write transaction results in an error on the destination domain, the error information is not passed back to the source SRI Fabric.

Note that this behavior occurs only for write operations via the S2S Bridge. It can also be triggered by the write cycle of a read-modify-write transaction that causes an error on the destination SRI domain.

## On-Chip System Connectivity {and Bridges}

### 4.6 SFI\_F2S Bridge

This section describes the functionality of the SFI\_S2S Bridge, a bridge from the SPB to the SRI Fabric.

#### 4.6.1 Functional Overview

The SFI\_S2S Bridge implements a uni-directional bus bridge that forwards transactions from an implementation of an FPI protocol bus, in this instance the System Peripheral Bus (SPB), to the SRI Fabric. The bridge supports all FPI transactions on the SPB and those transactions of the SRI Fabric required to implement them.

The bridge is transparent for the address of a transaction and the master TAG of the SPB master. However, transactions are mapped as described in [Table 69](#). For performance reasons, write transactions from SPB masters to SRI resources are handled as posted writes. The SFI\_F2S bridge is able to buffer multiple posted writes.

**Table 69 FPI Transaction to SRI Transaction Mapping**

FPI Transaction (32-bit data bus)	SRI Transaction (64-bit data bus)
Single Byte Transfer(8-bit)	Single Data Transfer Byte(8 bit)
Single Half-Word Transfer(16-bit)	Single Data Transfer Half-Word(16 bit)
Single Word Transfer(32-bit)	Single Data Transfer Word(32 bit)
2-Word Block Transfer	Single Data Transfer Double-Word(64 bit)
4-Word Block Transfer (aligned)	Block Transfer Request (2 transfers)
8-Word Block Transfer (aligned)	Block Transfer Request (4 transfers).

#### Transaction Errors for Writes via the SFI\_F2S Bridge

Write transactions from SPB masters to SRI resources are handled as posted writes. This means that a write operation from a SPB master through the SFI\_F2S Bridge can finish on the SPB, and the SFI\_F2S autonomously completes the write later on the SRI. If the SRI write transaction results in an error, the error information is not passed back to the SPB bus. The error condition will be left to the receiving SRI slave to interrupt or raise alarms as configured.

Note that this behavior occurs only for write operations via the SFI\_F2S Bridge. It can also be triggered by the write cycle of a read-modify-write transaction which causes an error on the SRI Fabric.

## On-Chip System Connectivity {and Bridges}

### 4.7 SFI\_S2F Bridge

This section describes the functionality of the SFI\_S2F Bridge, a bridge from the SRI Fabric to the BBB.

#### 4.7.1 Functional Overview

The SFI\_S2F Bridge is implemented as an uni-directional bus bridge that forwards transactions from the SRI Fabric to the Back Bone Bus (BBB). The bridge supports all SRI transactions on the SRI Fabricm, and those transactions of the FPI Bus required to implement them.

The bridge is transparent for the address of a transaction and the master TAG of the SRI master. However, transactions are mapped as described in **Table 70**. For performance reasons, write transactions from the SRI to BBB resources are handled as posted writes. The SFI\_S2F bridge is able to buffer multiple posted writes.

**Table 70 SRI Transaction to FPI Transaction Mapping**

SRI Transaction (64-bit data bus)	FPI Transaction (32-bit data bus)
Single Data Transfer Byte(8 bit)	Single Byte Transfer (8-bit)
Single Data Transfer Half-Word(16 bit)	Single Half-Word Transfer (16-bit)
Single Data Transfer Word(32 bit)	Single Word Transfer (32-bit)
Single Data Transfer Double-Word(64 bit)	2-Word Block Transfer (aligned)
Block Transfer Request (2 transfers)	4-Word Block Transfer
Block Transfer Request (4 transfers).	8-Word Block Transfer

#### Transaction Errors for Writes via the SFI\_S2F Bridge

Write transactions from SRI Masters to BBB resources are handled as posted writes. This means that a write operation from a SRI Master through the SFI\_S2F Bridge can be finished on the SRI Fabric, and the SFI\_S2F autonomously completes the write later on the BBB. If the BBB write transaction results in an error on the BBB, the error information is not passed back to the SRI Fabric. The error condition is detected by the control logic of the BBB (BCU on the BBB), to interrupt or raise alarms as configured.

Note that this behavior occurs only for write operations via the SFI\_S2F Bridge. It can also be triggered by the write cycle of a read-modify-write transaction that causes an error on the BBB.

### 4.8 Resource Access Times

These tables describe the CPU access times to various resources in CPU clock cycles for the AURIX™ TC3xx Platform. In the case of load or fetch accesses, the access times are the minimum number of CPU stall cycles to complete the access. If there is a conflict for the resource accessed, there may be additional stall cycles till the conflicting access completes.

For write access, the access times are the maximum for a sequence of such access (non-conflicting). In many cases for a singleton access, or a short sequence, write buffering reduces the stall effect seen by a CPU, sometimes to 0. However, as with loads and fetches, if there is a conflict for the resource accessed, there may be additional stall cycles till the conflicting access completes.

## On-Chip System Connectivity {and Bridges}

**Table 71 Access latency for global resources**

CPU Access Type	CPU stall cycles
Data read from System Peripheral Bus (SPB) <sup>1)</sup>	(4 + Module Wait State <sup>2)</sup> ) ( $f_{CPU} = f_{SPB}$ ) 2 * (4 + Module Wait State <sup>2)</sup> ) ( $f_{CPU} = 2*f_{SPB}$ ) 3 * (4 + Module Wait State <sup>2)</sup> ) ( $f_{CPU} = 3*f_{SPB}$ )
Data write to System Peripheral Bus (SPB) <sup>1)</sup>	(4 +Module Wait State <sup>2)</sup> ) ( $f_{CPU} = f_{SPB}$ ) 2 * (4 + Module Wait State <sup>2)</sup> ) ( $f_{CPU} = 2*f_{SPB}$ ) 3 * (4 + Module Wait State <sup>2)</sup> ) ( $f_{CPU} = 3*f_{SPB}$ )
Data read from Back Bone Bus (BBB) <sup>3)</sup> (TC39x, TC37xED)	9 + (5 + Module Wait State <sup>2)</sup> ) ( $f_{CPU} = f_{BBB}$ ) 9 + 2 * (5 + Module Wait State <sup>2)</sup> ) ( $f_{CPU} = 2*f_{BBB}$ )
Data write to Back Bone Bus (BBB) <sup>3)</sup> (TC39x, TC37xED)	5 + (4 + Module Wait State <sup>2)</sup> ) ( $f_{CPU} = f_{BBB}$ ) 5 + 2 * (4+ Module Wait State <sup>2)</sup> ) ( $f_{CPU} = 2*f_{BBB}$ )
Data read from Back Bone Bus (BBB) (TC35x, TC33xED)	6 + (5 + Module Wait State <sup>2)</sup> ) ( $f_{CPU} = f_{BBB}$ ) 6 + 2 * (5 + Module Wait State <sup>2)</sup> ) ( $f_{CPU} = 2*f_{BBB}$ )
Data write to Back Bone Bus (BBB) (TC35x, TC33xED)	3 + (4 + Module Wait State <sup>2)</sup> ) ( $f_{CPU} = f_{BBB}$ ) 3 + 2 * (4 + Module Wait State <sup>2)</sup> ) ( $f_{CPU} = 2*f_{BBB}$ )

- 1) The final number of stall cycles will depend on the real number of WS generated by the target resource.
- 2) The number of wait states for read and for write accesses is  $\geq 1$  and depends on the accessed module and its configuration.
- 3) When SFI\_S2F is connected to XBar2 (TC39x and TC37xED) there is an additional latency due to access going through an S2S.

### Notes on System Peripheral Bus

Access to critical module registers is implemented with 1 Wait State (e.g. QSPI, ASCLIN, EVADC and DSADC result registers, DMA). Other modules are partially implemented with  $> 1$  Wait State where a single wait state implementation was not possible.

Additional Wait States due to:

- Access to module internal SRAMs (e.g. MCAN, DMA, ERAY, GTM)
- System infrastructure modules (e.g. MTU, STM)
- Access to module registers mapped to a different clock domain (e.g. STM, GTM)
- Access to control registers in large and complex modules that require internal registers stages to meet the timing (e.g. GTM)

**Table 72 CPU Accesses: Stall cycles for local and SRI resources**

	Local CPU	Local SRI	Remote SRI Domain <sup>1)</sup>
Data read from DSPR	0	7	10
Data write to DSPR	0	5, 3 <sup>2)</sup>	5, 4 <sup>2)</sup>
Instruction fetch from DSPR	See local SRI column <sup>3)</sup>	7	10
Data read from DLMU	0	7	10
Data write to DLMU	2	5, 3 <sup>2)</sup>	5, 4 <sup>2)</sup>
Instruction fetch from DLMU	See local SRI column <sup>3)</sup>	7	10
Data read from PSPR	See local SRI column <sup>3)</sup>	7	10
Data write to PSPR	See local SRI column <sup>3)</sup>	5, 3 <sup>2)</sup>	5, 4 <sup>2)</sup>

## On-Chip System Connectivity {and Bridges}

**Table 72 CPU Accesses: Stall cycles for local and SRI resources**

	Local CPU	Local SRI	Remote SRI Domain <sup>1)</sup>
Instruction fetch from PSPR	0	7	10
Data read from PFlash	5 + PWS <sup>4)</sup>	10 + PWS <sup>4)</sup>	13 + PWS <sup>4)</sup>
Instruction fetch from PFlash (buffer miss)	2 + PWS <sup>5)</sup>	9 + PWS <sup>5)</sup>	12 + PWS <sup>5)</sup>
Instruction fetch from PFlash (buffer hit)	3	6	9
Data read from LMU	n.a.	7	10
Data write to LMU	n.a.	5, 3 <sup>2)</sup>	5, 4 <sup>2)</sup>
Instruction fetch from LMU	n.a.	7	10
Data read from DFlash	n.a.	5 + 3*(3+DCWS) <sup>6)</sup>	8 + 3*(3+DCWS) <sup>6)</sup>
DFlash runs on FSI clock. $f_{CPU} = 3*f_{FSI}$			
Data read access from EMEM (TC39x, TC37xED)	n.a.	n.a.	14, 15 <sup>7)</sup>
Data write access to EMEM (TC39x, TC37xED)	n.a.	n.a.	9
Data read access from EMEM (TC35x, TC33xED)	n.a.	11, 12 <sup>7)</sup>	n.a.
Data write access to EMEM (TC35x, TC33xED)	n.a.	9	n.a.
Data read access from EMEM (TC3Ax)	n.a.	11, 12 <sup>7)8)</sup>	14, 15 <sup>7)9)</sup>
Data write access to EMEM (TC3Ax)	n.a.	9 <sup>8)</sup>	9 <sup>9)</sup>
Data read access from DAM	n.a.	10	13
Data write access to DAM	n.a.	7	7

- 1) Only applies to products with SRI extenders. Additional latency due to access going through an S2S
- 2) With pipelining
- 3) Data access to code side memories or Code accesses to data side memories are made via the SRI bus
- 4) PWS: Configured PFlash Wait States (Includes cycles for PFlash access cycles only). ECC correction latency is only incurred when the incoming data requires ECC correction.
- 5) PWS: Configured PFlash Wait States (Includes cycles for PFlash access cycles only). ECC correction latency is only incurred when the incoming data requires ECC correction.
- 6) DCWS: Configured DFlash Corrected Wait States (Includes cycles for DFlash access cycles and ECC correction latency)
- 7) The EMEM works on  $f_{BBB}$  clock which is lower than the  $f_{SRI}$  there could be one additional synchronisation cycle for the request to be acknowledged by the EMEM.
- 8) EMEM4 and EMEM5 are located on domain 0
- 9) EMEM0/EMEM1/EMEM2/EMEM3 are located on domain 2

### Notes on PFlash and DFlash accesses

The PFlash waitstates are described in the NVM section and their configuration is done via the HF\_PWAIT register. The DFlash waitsates are described in the NVM section and their configuration is done via the HF\_DWAIT register. In both cases the values programmed in the registers are 1 less than the actual value. (e.g. HF\_DWAIT.RFLASH=9 corresponds to 10 read cycles, and similarly HF\_DWAIT.ECC=1 corresponds to 2 ECC cycles).

e.g: Number of Stall cycles for HF\_DWAIT.RFLASH=9 and HF\_DWAIT.ECC=1 accessed on the local SRI

$$\begin{aligned}
 \text{DCWS} &= (\text{DFLASH READ CYCLES}) + (\text{DFLASH ECC CYCLES}) \\
 &= (\text{HW_DWAIT.RFLASH} + 1) + (\text{HW_DWAIT.ECC} + 1) \\
 &= 12
 \end{aligned}$$

$$\text{Stall Cycles} = 5 + 3 * (3 + \text{DCWS})$$

## 4.10 FPI Interconnect

The System on Chip communication is based on two On Chip Bus protocols:

- Shared Resource Interconnect (SRI, Cross Bar based interconnect, 64 bit data bus)
- Fast Peripheral Interconnect (FPI, Multi-Master interconnect, 32 bit data bus)

The SRI connects the TC1.6 CPUs, the main high bandwidth peripherals and the DMA module to its local resources for instruction fetches and data accesses.

The FPI connects the high speed peripherals, e.g. TC1.6 CPUs, DMA, to the medium and low bandwidth peripherals.

### Scope of this Document

This document is valid for the TC3xx and covers the topics:

- FPI Bus architecture
- FPI Bus instances (SPB, BBB)
- FPI Bus Operations

### 4.10.1 Feature List

The FPI Bus interconnects the on-chip peripheral functional units with the processor subsystem.

The FPI Bus is designed to be quick to be acquired by on-chip functional units, and quick to transfer data. The low setup overhead of the FPI Bus access protocol guarantees fast FPI Bus acquisition, which is required for time-critical applications.

The FPI Bus is designed to sustain high transfer rates. Pipelining of transfers is supported by the parallel handling of request, address and data phases of transfers which allow the FPI Bus to operate close to its peak bandwidth.

Additional features of the FPI Bus include:

- Optimized for high speed and high performance
- Support of multiple bus masters and pipelined transactions
- 32-bit wide address and data buses
- 8-, 16-, and 32-bit data transfers
- 64-, 128-, and 256-bit block transfers
- Slave-controlled wait state insertion
- Timeout detection and handling
- Support of atomic CPU operations e.g. LDMST, ST.T, SWAP.W, CMPSWP and SWPMSK
- Flexible arbitration schemes (priority, one round robin group, starvation prevention)
- Starvation prevention mechanism that can take care that even low priority requests will be granted after a configurable number of arbitration cycles, permanently enabled
- Default slave (takes over transactions to not implemented address)
- Debug support (captures transaction information in case of a timeout or bus error)
- Address Phase includes Master TAG ID and Supervisor Mode information
- All slave modules implemented with a TAG ID based access protection that provides a generic write protection for the control registers (SPB/BBB: write protection only)
- Information integrity support covering SPB/BBB address phase signals, transmitted read/write data and control signals
- SPB/BBB Address Phase includes Supervisor Mode information (covered by the FPI information integrity support)

The functional units of the device are connected to the FPI Bus via FPI Bus interfaces. An FPI Bus interfaces acts as bus agents, requesting bus transactions on behalf of their functional unit, or responding to bus transaction requests.

There are two types of bus agents:

- FPI Bus master agents can initiate FPI Bus transactions and can also act as slaves.
- FPI Bus slave agents can only react and respond to FPI Bus transaction requests in order to read or write internal registers of slave modules as for example memories.

When an FPI Bus master attempts to initiate a transfer on the FPI Bus, it first signals a request for bus ownership to the bus control unit (SBCU). When bus ownership is granted by the SBCU, an FPI Bus read or write transaction is initiated. The unit targeted by the transaction becomes the FPI Bus slave, and responds with the requested action.

Some functional units operate only as slaves, while others can operate as either masters or slaves on the FPI Bus.

FPI Bus arbitration is performed by the Bus Control Unit (SBCU) of the FPI Bus. In case of bus errors, the SBCU generates an interrupt request to the CPU and provides debugging information about the actual bus error to the CPU.

#### 4.10.1.1 Delta to TC2xx

Major differences of the AURIX™ TC3xx Platform Bus System architecture compared to previous TC2xx products:

- Assignment of TAG IDs to on chip bus master resources was changed (see [On Chip Bus Master TAG Assignments](#))
- Adapted mapping of SPB master interfaces SBCU\_DBGRNT and SBCU\_DBGNTT register bits.
- FPI EDC: Introduced End to End Error Detection (EDC) mechanism ([FPI Bus Integrity Support](#))
- FPI EDC: Introduced BCU control registers for the EDC mechanism (see also SBCU and EBCU Registers in the Appendix document, chapter BCU)
  - BCU\_ALSTAT0, EDC Alarm Status Register
  - BCU\_ALCLR $x$  ( $x=0-3$ ), EDC Alarm Clear Register
  - BCU\_ALCTRL, EDC Control Register
  - BCU\_FEGEN, FPI Error Generation Register
- Adapted priority mapping of SPB master interfaces (BCU\_PRIOH and BCU\_PRIOL registers))
- FPI arbitration algorithm: Added Round Robin group to Priority 8 ([“FPI Bus Arbitration” on Page 38](#))
- FPI arbitration: Adapted the default configuration of the FPI master priorities
- Back Bone Bus (BBB): the description of the Back Bone Bus BCU (EBCU) was added

#### 4.10.2 Overview

The AURIX™ TC3xx Platform has up to two FPI Bus instances:

- System Peripheral Bus (SPB): Main non-ADAS system and communication peripherals
- Back Bone Bus (BBB): Emulation Device related and ADAS related peripherals, available in ADAS / Emulation Devices only

This section gives an overview of the on-chip FPI Bus instances (SPB, BBB). It describes its Bus Control Units (SBCU, EBCU), the bus characteristics, bus arbitration, scheduling, prioritizing, error conditions, and debugging support.

#### 4.10.2.1 Bus Transaction Types

This section describes the SPB transaction types.

## Single Transfers

Single transfers are byte, half-word, and word transactions that target any slave connected to SPB. Note that the SFI Bridge operates as an SPB master.

## Block Transfers

Block transfers operate in principle in the same way as single transfers do, but one address phase is followed by multiple data phases. Block transfers can be composed of 2 word, 4 word, or 8 word transfers.

**Note:** *In general, block transfers (2 word, 4 word, or 8 word) cannot be executed in the AURIX™ TC3xx Platform with peripheral units that operate as FPI Bus slaves during an FPI Bus transaction.*

Block transfers are initiated by the following CPU instructions: LD.D, LD.DA, MOV.D, ST.D and ST.DA. Additionally there are communication peripherals that are able to generate block transfers (e.g. Ethernet).

## Atomic Transfers

Atomic transfers are generated by LDMST, ST.T and SWAP.W instructions that require two single transfers. The read and write transfer of an atomic transfer are always locked and cannot be interrupted by another bus masters. Atomic transfers are also referenced as read-modify-write transfers.

**Note:** *See also [Table 75](#) for available FPI Bus transfer types.*

### 4.10.2.2 Reaction of a Busy Slave

If an FPI Bus slave is busy at an incoming FPI Bus transaction request, it can delay the execution of the FPI Bus transaction. The requesting FPI Bus master releases the FPI Bus for one cycle after the FPI Bus transaction request, in order to allow the FPI Bus slave to indicate if it is ready to handle the requested FPI Bus transaction. This sequence is repeated as long as the slave indicates that it is busy.

**Note:** *For the FPI Bus default master, the one cycle gap does not result in a performance loss because it is granted the FPI Bus in this cycle as default master if no other master requests the FPI Bus for some other reasons.*

### 4.10.2.3 Address Alignment Rules

FPI Bus address generation is compliant with the following rules:

- Half-word transactions must have a half-word aligned address ( $A_0 = 0$ ). Half-word accesses on byte lanes 1 and 2 addresses are illegal.
- Word transactions must always have word-aligned addresses ( $A[1:0] = 00_B$ ).
- Block transactions must always have block-type aligned addresses.

### 4.10.2.4 FPI Bus Basic Operations

This section describes some basic transactions on the FPI Bus.

The example in [Figure 36](#) shows the three cycles of an FPI Bus operation:

1. **Request/Grant Cycle:** The FPI Bus master attempts to perform a read or write transfer and requests for the FPI Bus. If the FPI Bus is available, it is granted in the same cycle by the FPI Bus controller.
2. **Address Cycle:** After the request/grant cycle, the master puts the address on the FPI Bus, and all FPI Bus slave devices check whether they are addressed for the following data cycle.

3. **Data Cycle:** In the data cycle, either the master puts write data on the FPI Bus which is read by the FPI Bus slave (write cycle) or vice versa (read cycle).

Transfers 2 and 3 show the conflict when two master try to use the FPI Bus and how the conflict is resolved. In the example, the FPI Bus master of transfer 2 has a higher priority than the FPI Bus master of transfer 3.

Bus Cycle	1	2	3	4	5	
Transfer 1	Request/ Grant	Address Cycle	Data Cycle			
Transfer 2		Request/ Grant	Address Cycle	Data Cycle		
Transfer 3			Request/Grant	Address Cycle	Data Cycle	

MCA06109

**Figure 36 Basic FPI Bus Transactions**

At a block transfer, the address cycle of a second transfer is extended until the data cycles of the block transfer are finished. In the example of [Figure 37](#), transfer 1 is a block transfer, while transfer 2 is a single transfer.

Bus Cycle	1	2	3	4	5	6	7	
Transfer 1	Request/ Grant	Address Cycle	Data Cycle	Data Cycle	Data Cycle	Data Cycle		
Transfer 2		Request/ Grant					Address Cycle	Data Cycle

MCA06110

**Figure 37 FPI Bus Block Transactions**

#### 4.10.3 Functional Description (SBCU, EBCU)

The AURIX™ TC3xx Platform incorporates up to two FPI Bus Control Units:

- SBCU on the System Peripheral Bus (SPB)
- EBCU on the Back Bone Bus (BBB), available in ADAS / Emulation devices only

##### 4.10.3.1 FPI Bus Arbitration

The arbitration unit of the BCU arbitrates among the master interfaces that are requesting for bus access. The priority for each master is defined in the registers PRIOH and PRIOL. During arbitration, the bus is granted to the requesting master with the highest priority. If no request is pending, the bus is granted to a default master. If no bus master takes the bus, the BCU itself will set the FPI Bus into an idle state. The BCU arbitrates always at the end of the current Address Phase and decides which master agent shall be granted.

The mapping of implemented master agents to the PRIOH / PRIOL register is described in the Appendix document, chapter BCU.

The arbitration is done at the end of a transaction

#### 4.10.3.1.1 Arbitration on the System Peripheral Bus

The AURIX™ TC3xx Platform has multiple bus master connected to the SPB

- Each master is assigned to 4-bit priority bit field in the PRIOH or in the PRIOL register
- The value in a priority bit field defines the related SPB master priority used for the bus arbitration
- A lower priority number has a higher priority, 0 is the highest priority

#### 4.10.3.1.2 Default Master

Any FPI master must be able to act as default master. If no master is requesting for bus access, the FPI master that was most recently granted will be granted to the Default Master. After reset, the master with the priority 0 will be the Default Master.

#### 4.10.3.1.3 Arbitration Algorithms

The arbitration algorithm implemented in the BCU combines three layers of arbitration

- Priority driven arbitration of master agents with a pending request (Priority 0 - 15, 0 = highest priority)
- Round Robin arbitration for a group of up to 8 master on Priority 8.
- Starvation Prevention mechanism that can increase master priorities during Starvation Prevention process

The default priority of each connected FPI master agent can be changed during runtime via its related bit field in the registers PRIOH and PRIOL (see 'Changing Master Priorities').

It must be ensured that two FPI master agents don't have the same priority, with the exception of Priority 8 (round robin group priority).

If more than one master is configured with the same priority (but not with the round robin priority 8) the arbitration will still work but the sequence how these master will be granted can not be guaranteed.

##### Priority Driven Arbitration

The general arbitration algorithm is priority driven where priority 0 is the highest priority and 15 the lowest one. If multiple masters are requesting, the master with the highest priority will win the next arbitration round (see also starvation prevention').

##### Round Robin Group

Priority 8 is implemented as a Round Robin group that can be used for max. 8 master agents.

The Round Robin Group algorithm arbitrates among all master agents with Priority 8 that are requesting for bus access. The winner of the RR arbitration will be treated as a normal master request with priority 8 within the Priority Driven arbitration algorithm.

If only one master is mapped to a round robin group priority, the master's request will be treated as normal master request with priority 8 within the Priority driven arbitration algorithm.

After the winner of a round robin group is granted, the requesting master configured to priority 8 with the next higher index number will be selected as next winner of the round robin group. If there is no requesting master with a higher index number in the round robin group, the algorithm will start with the requesting master with the lowest index number in the round robin group, going to the next higher index number and so on. The index numbers are defined in the registers PRIOH, PRIOL.

##### Default Master Priorities after Reset

The default priority settings should be optimal for most applications. Where required, the arbitration setting can be adapted to the specific application needs (see 'Changing Master Priorities').

The default master agent priorities are described in the Appendix document, chapter BCU.

## Changing Master Priorities

Master priorities must be configured during ramp up as long as only one FPI master agent is active (e.g. CPU0 on SPB, SFI\_S2F on BBB). Master priorities must not be changed while multiple FPI master agents are active / enabled.

## Starvation Prevention

Starvation prevention takes care that even requesting low priority master agents will be granted after a period, where the period length can be controlled by BCU control registers. Because of the priority driven arbitration algorithm, it is possible that a lower-priority bus requestor may never be granted the bus if one or more higher-priority bus requestor continuously requests for, and receives, bus ownership. To protect against bus starvation of lower-priority masters, the starvation prevention mechanism of the BCU will detect such cases and momentarily raise the priority of the lower-priority requestor to the highest priority (above all other priorities), thereby guaranteeing it access.

Starvation protection employs a counter that is decremented each time an arbitration is performed on the connected FPI bus. When the counter is counted down to zero it is always re-loaded with the starvation period value in the BCU\_CON.SPC bit field. When the counter is counted down to zero, for each active bus request a request flag is stored in the BCU. This flag is cleared automatically when a master is granted the bus.

When the next counter period is finished and not all request flags were cleared, a starvation event happened. This masters related to the remaining request flags will now be set to the highest priority and will be granted in the order of their configured priority ranking.

If a master that is processing its transaction under starvation condition is retried, its corresponding request flag is automatically set again.

Starvation protection is permanently enabled. The sample period of the counter is programmed through bit field BCU\_CON.SPC. SPC must be larger than the number of masters. Its reset value is FF<sub>H</sub>.

### 4.10.3.2 FPI Bus Error Handling

When an error occurs on an FPI Bus, its BCU captures and stores data about the erroneous condition and generates a service request if enabled to do so. The error conditions that force an error-capture are:

- Error Acknowledge: An FPI Bus slave responds with an error to a transaction.
- Un-implemented Address: No FPI Bus slave responds to a transaction request.
- Time-out: A slave does not respond to a transaction request within a certain time window. The number of bus clock cycles that can elapse until a bus time-out is generated is defined by bit field BCU\_CON.TOUT.

When a transaction causes an error, the address and data phase signals of the transaction causing the error are captured and stored in registers.

- The Error Address Capture Register (BCU\_EADD) stores the 32-bit FPI Bus address that has been captured during the erroneous FPI Bus transaction.
- The Error Data Capture Registers (BCU\_EDAT) stores the 32-bit FPI Bus data bus information that has been captured during the erroneous FPI Bus transaction.
- The Error Control Capture Register (BCU\_ECON) stores status information of the bus error event.

If more than one FPI Bus transaction generates a bus error, only the first bus error is captured. After a bus error has been captured, the capture mechanism must be released again by software. The lock is removed by reading the register BCU\_ECON which clears the BCU\_ECON.ERRCNT bit field.

**Note:** It is recommended to read in a debug session register ECON last as this removes the lock and a new error can already modify the content of the other two registers EDAT and EADD.

If a write transaction from TriCore causes an error on the SPB, the originating master is not informed about this error as it is not an SPB master agent. With each bus error- capture event, a service request is generated, and an interrupt can be generated if enabled and configured in the corresponding service request register.

### Interpreting the BCU Control Register Error Information

Although the address and data values captured in registers BCU\_EADD and BCU\_EDAT, respectively, are self-explanatory, the captured FPI Bus control information needs some more explanation.

Register BCU\_ECON captures the state of the read (RDN), write (WRN), Supervisor Mode (SVM), acknowledge (ACK), ready (RDY), abort (ABT), time-out (TOUT), bus master identification lines (TAG) and transaction operation code (OPC) lines of the FPI Bus.

The SVM signal is set to 1 for an access in Supervisor Mode and set to 0 for an access in User Mode. The time-out signal indicates if there was no response on the bus to an access, and the programmed time (via BCU\_TOUT) has elapsed. TOUT is set to 1 in this case. An acknowledge code has to be driven by the selected slave during each data cycle of an access. These codes are listed in [Table 74](#).

**Table 74 FPI Bus Acknowledge Codes**

Code (ACK)	Description
00 <sub>B</sub>	NSC: No Special Condition.
01 <sub>B</sub>	Reserved
10 <sub>B</sub>	RTY: Retry. Slave can currently not respond to the access. Master needs to repeat the access later.
11 <sub>B</sub>	ERR: Bus Error, last data cycle is aborted.

Transactions on the FPI Bus are classified via a 4-bit operation code (see [Table 75](#)). Note that split transactions (OPC = 1000<sub>B</sub> to 1110<sub>B</sub>) are not used in this AURIX™ TC3xx Platform.

**Table 75 FPI Bus Operation Codes (OPC)**

OPC	Description
0000 <sub>B</sub>	Single Byte Transfer (8-bit)
0001 <sub>B</sub>	Single Half-Word Transfer (16-bit)
0010 <sub>B</sub>	Single Word Transfer (32-bit)
0100 <sub>B</sub>	2-Word Block Transfer
0101 <sub>B</sub>	4-Word Block Transfer
0110 <sub>B</sub>	8-Word Block Transfer
1111	No operation
0011 <sub>B</sub> , 0111 <sub>B</sub> , 1000 <sub>B</sub> - 1110 <sub>B</sub>	Reserved

### 4.10.4 FPI Bus Integrity Support

All transactions through the FPI Bus are protected with an Error Detection mechanism (EDC). The mechanism is defined and implemented in order to detect errors in between active FPI master and slave agents during a transaction e.g.:

- Transaction Address Phase errors
- Transaction Data Phase errors

- Errors in the transmitted Data
- Situations where no Slave, the wrong Slave or multiple Slaves respond to a transaction
- Situations where multiple Master are initiating transactions in parallel
- Active Master: Master that initiates a transaction
- Active Slave: Slave that is selected in the Address Phase

On detection of an error the Bus Control Unit (BCU) signals an alarm to the Safety Management Unit (SMU). For further analysis and decisions the BCU provides detailed informations where the error was detected.

The implemented solution ensures that only relevant errors will generate an alarm.

This includes

- The bus signals from the active master through the interconnect
- The bus signals from the active slave through the interconnect
- General control signals during a transaction to detect erroneous active slave / master interfaces
- FPI\_RDY='1' is used as qualifier for valid Data Phase / Address Phase / ECC informations

**Note:** *The integrity support provides in this implementation error detection capabilities only. For this, Error Correction Codes (ECC) codes will be used. The additional capabilities of the used ECC will be used for an improved error detection. Therefore the extension '\_ECC' is used in this chapter for related registers/FPI signals and SMU alarm signals.*

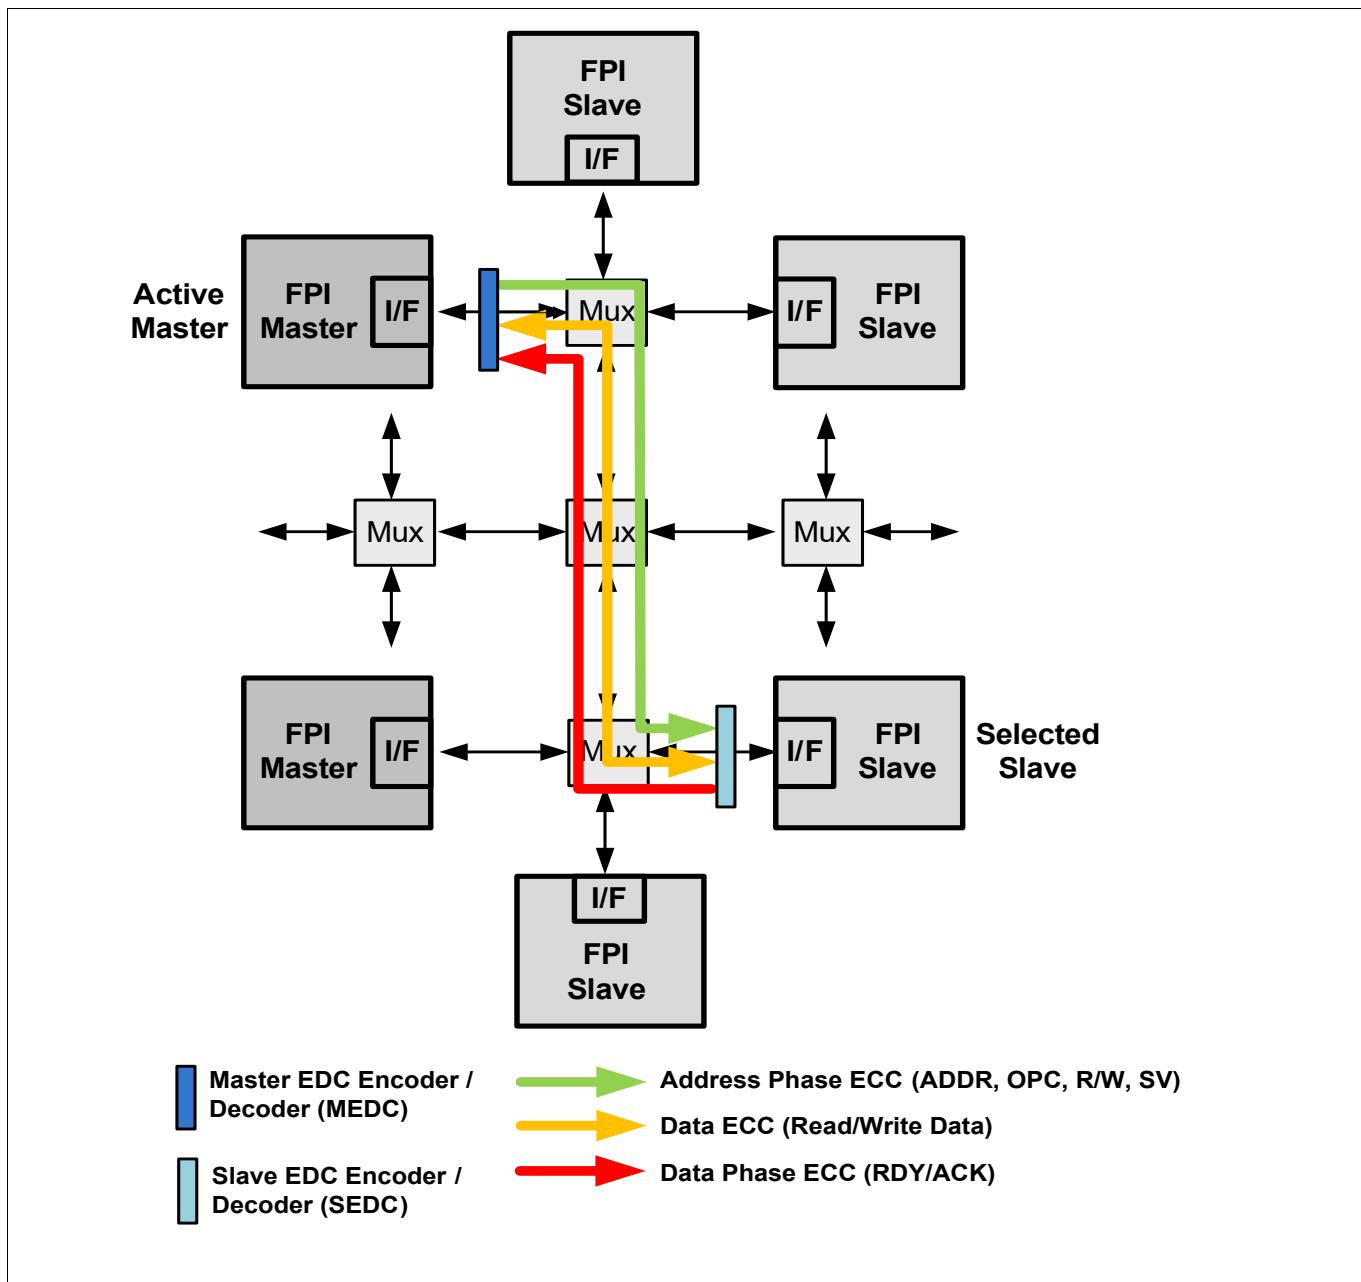

Figure 38 FPI EDC: Protection of Master → Slave data path through bus fabric

#### 4.10.4.1 Safety Support

##### BCU Alarm signals

Each instance of the FPI interconnect provides one alarm signal to the SMU, covering three alarm events:

- Alarm on detection of an FPI Bus Error by the BCU (Bus Error is a fatal error)
- Alarm on detection of a Timeout situation
- Alarm on detection of a FPI EDC error

For further analysis of the alarm:

- BCU captures informations of the first transaction that was terminated with Error Acknowledge or Timeout. The capture mechanism covers all relevant transaction informations inc. grant signals, 32-bit address, op-

code, TAG ID, 32-bit data, acknowledge code and FPI protocol control signals of the transactions address/data phase.

- BCU provides additional informations to identify the connected FPI slave / master interface where the FPI EDC error was detected

### **Capture of transaction informations on bus error**

The BCU capture mechanism capture the first transaction with a fatal error.

SW can release the mechanism again.

The capture mechanism covers all relevant transaction informations including:

- master grant signal status
- 32-bit address
- OP-code
- TAG ID
- 32-bit data
- acknowledge code
- FPI protocol control signals of the transactions address/data phase

The BCU can be configured to generate an interrupt for fatal errors (Error Acknowledge, Timeout, no slave responding) in parallel to the SMU alarm.

The related Service Request Nodes (SRN) and its Service Request Control registers (SRC) in the Interrupt Router (IR) module are:

- SRC\_BCUSPB (Service Request Control register related to the SBCU interrupt)
- SRC\_BCUBBB (Service Request Control register related to the EBCU interrupt)

### **Starvation Prevention**

The FPI arbitration algorithm in the BCU provides a starvation prevention mechanism. This feature of the BCU ensures that even requesting low priority master agents will be granted after a period, where the period length is defined via SBCU control registers.

The Starvation prevention is permanently enabled.

### **Time-out detection**

The BCU provides a time-out detection mechanism. This mechanism detects if a slave does not respond to a transaction request within a configurable time window. The time-out mechanism is also implemented in the FPI bus protocol. A dedicated TIMEOUT signal forces the active master / slave interfaces to release the bus if the BCU has detected a timeout situation. On detection of time-out situation the BCU signals an alarm to the SMU.

### **Register Access protection**

The BCU control registers are protected by the Register Access Protection, including the TAG ID based access protection mechanism (see ACCENO).

On detection of an Register Access Protection violation the BCU finish the transaction with Error Acknowledge. This will be detected by the BCU monitor function and signalled as alarm to the SMU.

### **Default Slave mechanism**

The FPI bus fabric implementation shows per default:

- FPI\_RDY = '1'

- FPI\_ACK = '11' (Error Ack)
- FPI\_DP\_ECC = '11' (Invalid ECC for RDY/ACK default)

This means that an EDC error will be detected for the active master interface when:

- the master access a reserved address (BCU sends alarm to SMU)
- the addressed FPI slave does not respond (BCU sends alarm to SMU)
- the default master is not driving the data phase signals during the default master address phase while the granted master looks at FPI\_RDY to identify the start/end of its address phase and the selected slave looks at FPI\_RDY to identify the start of its data phase (alarm from active master interface and active slave interface to BCU, BCU sends the alarm to SMU)

#### 4.10.4.2 FPI EDC Overview

The FPI EDC covers the FPI address, data and control signals from a FPI master agent output to the addressed FPI slave agent input during a transaction.

The FPI Bus Fabric includes

- a dedicated FPI Slave Encoder / Decoder Module (SEDM) for each connected Slave Interface
- a dedicated FPI Master Encoder / Decoder Module (MEDM) for each connected Master Interface

An Encoder / Decoder Module includes all ECC en-/decoder that are required to generate/check the ECC for the address and data phases of a transaction. The encoder/decoder module uses the FPI output enable signals of the related FPI master/slave interface to enable the encoding/decoding.

*Note: The FPI EDC is not working in the first 4 FPI bus cycles after an reset of the FPI bus fabric.*

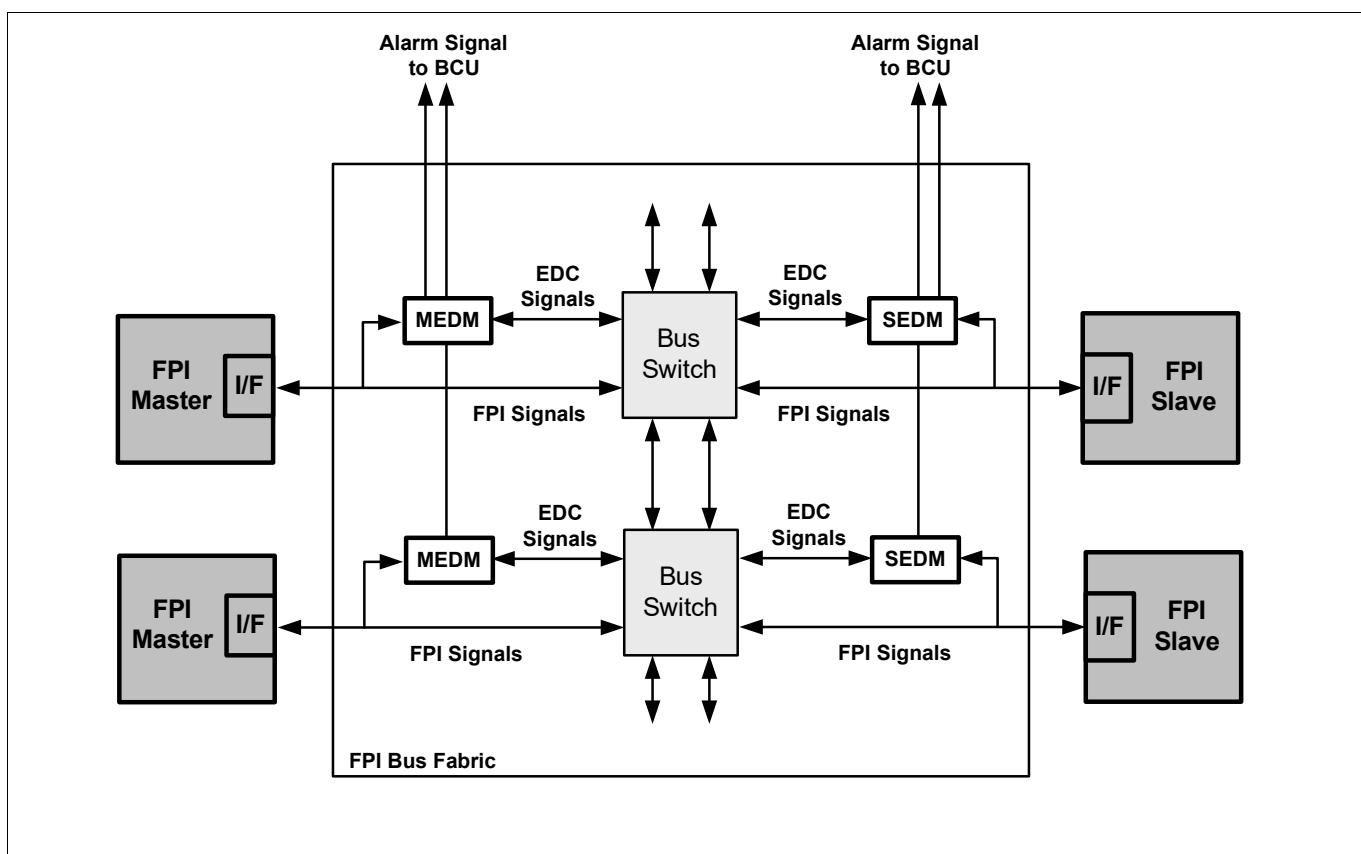

Figure 39 FPI EDCAURIX™ TC3xx Platform: encoder / decoder alarm signals

#### 4.10.4.3 Error Injection

The FPI EDC implementation allows to test all MEDM and SEDM decoder and the related alarm signal paths to the SMU by Error Injection.

The error injection is controlled via the BCU Error Generation control register BCU\_FEGEN.

- SBCU: Errors to test Slave related decoders are injected via the CPU0 MEDM encoder
- EBCU: Errors to test Slave related decoders are injected via the SFI\_S2F MEDM encoder
- Errors to test Slave related decoders are injected via the BCU SEDM encoder
- Errors to test other control signals (e.g. address/data-phase/data enable signals) are injected via the BCU.

##### MEDM decoder test

To test MEDM decoders with its related alarm signal path to the SMU the following sequence can be used:

- Enable the error injection related to the Encoder where an error has to be injected in BCU SEDM via the register BCU\_FEGEN (e.g. read data error).
- The FPI master related to the MEDM where the decoder alarm signal path has to be tested access the BCU with the an appropriate transaction (e.g. DMA reads a BCU control register in order to get an DMA related FPI EDC alarm)
- Disable the error injection by clearing the BCU\_FEGEN bits.

##### SEDM decoder test

To test SEDM decoders with its related alarm signal path to the SMU the following sequence can be used (example for an SPB test, BBB can be tested accordingly but with CPU access through the SFI\_S2F bridge):

- Enable the error injection related to the CPU0 Encoder where an error has to be injected in BCU MEDM via the register BCU\_FEGEN (e.g. address phase error).
- CPU0 has to access now the FPI slave related to the SEDM where the decoder alarm signal path has to be tested (e.g. CPU0 data access to FCE to get an alarm from the FCE related alarm signal on the SPB)
- Disable the error injection by clearing the BCU\_FEGEN bits.

**Note:** *The error injection mechanism is static. Means: errors will be injected in the related CPU0 MEDM encoder and/or the BCU related SEDM encoder as long the BCU\_FEGEN bit is set.*

#### 4.10.4.4 SPB: Mapping of ALARM signals to SBCU\_ALSTATx and SBCU\_ALCLRx registers

The mapping of the FPI EDC alarm signals (MEDM / SEDM modules) and the alarm from the SBCU internal output enable checks to the Alarm Status (SBCU\_ALSTATx; x=0-3) and Alarm Clear (SBCU\_ALCLRx; x=0-3) registers are described in the following tables.

**Note:** *The module interfaces mentioned in the tables below are per default of type 'Slave Agent'. Master agent interfaces are described as 'Master'.*

**Attention:** *These tables are showing the family mapping of alarm signals. For the effective mapping see the register specifications in Chapter 4.10.2.*

#### 4.10.5 Debug

For debugging purposes, the BCU has the capability for breakpoint generation support. This OCDS debug capability is controlled by the Cerberus module and must be enabled by it (indicated by bit BCU\_DBCNTL.EO).

When BCU debug support has been enabled (EO = 1), any breakpoint request generated by the BCU to the Cerberus disarms the BCU breakpoint logic for further breakpoint requests. In order to rearm the BCU breakpoint logic again for the next breakpoint request generation, bit BCU\_DBCNTL.RA must be set. The status of the BCU breakpoint logic (armed or disarmed) is indicated by bit BCU\_DBCNTL.OA.

There are three types of trigger events:

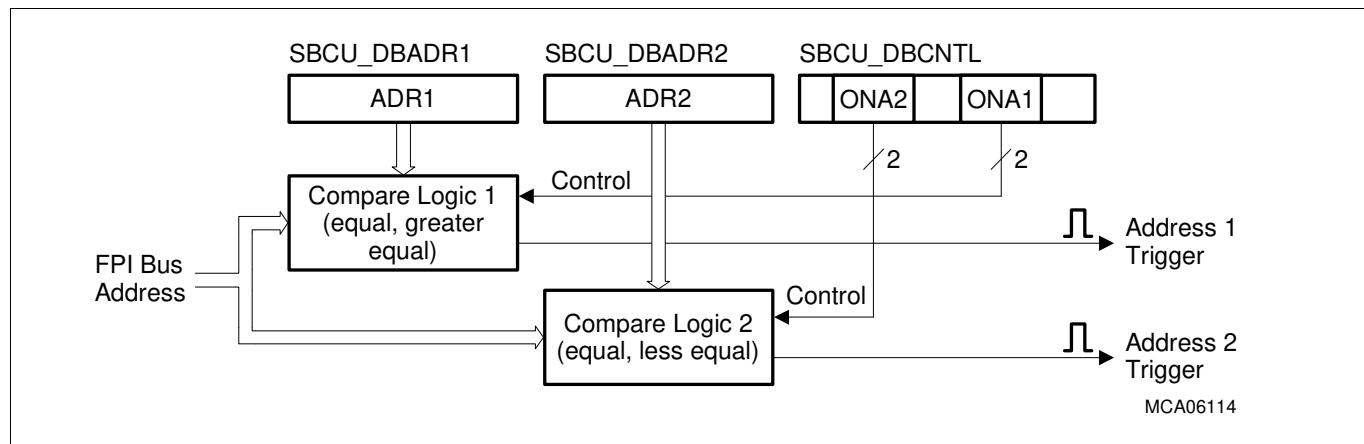

- Address triggers
- Signal triggers
- Grant triggers

##### 4.10.5.1 Address Trigger

The address debug trigger event conditions are defined by the contents of the BCU\_DBADR1, BCU\_DBADR2, and BCU\_DBCNTL registers. A wide range of possibilities arise for the creation of debug trigger events based on addresses. The following debug trigger events can be selected:

- Match on one signal address
- Match on one of two signal addresses
- Match on one address area
- Mismatch on one address area

Each pair of DBADRx registers and DBCNTL.ONAx bits determine one possible debug trigger event. The combination of these two possible debug trigger events defined by DBCNTL.CONCOM1 determine the address debug trigger event condition.

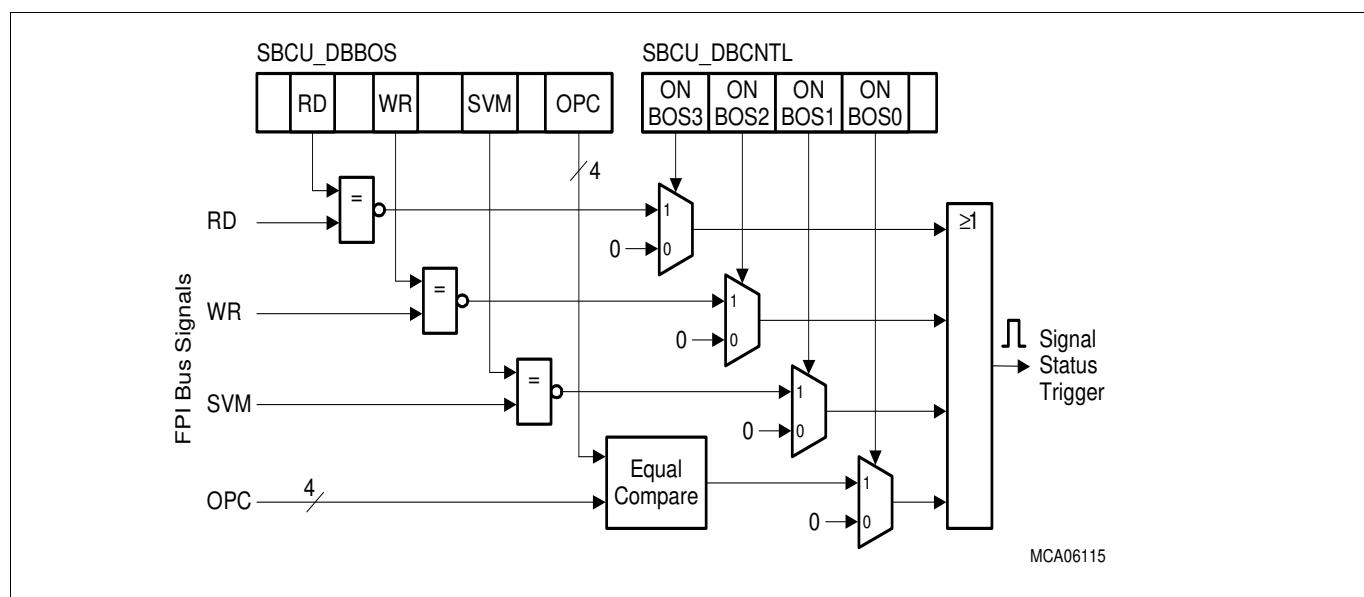

**Figure 40 Address Trigger Generation**

#### **4.10.5.2 Signal Status Trigger**

The signal status debug trigger event conditions are defined by the contents of the BCU\_DBBOS and BCU\_DBCNTL registers. Depending on the selected configuration a wide range of possibilities arise for the creation of a debug trigger event based on FPI Bus status signals. Possible combinations are:

- Match on a single signal status
  - Match on a multiple signal status

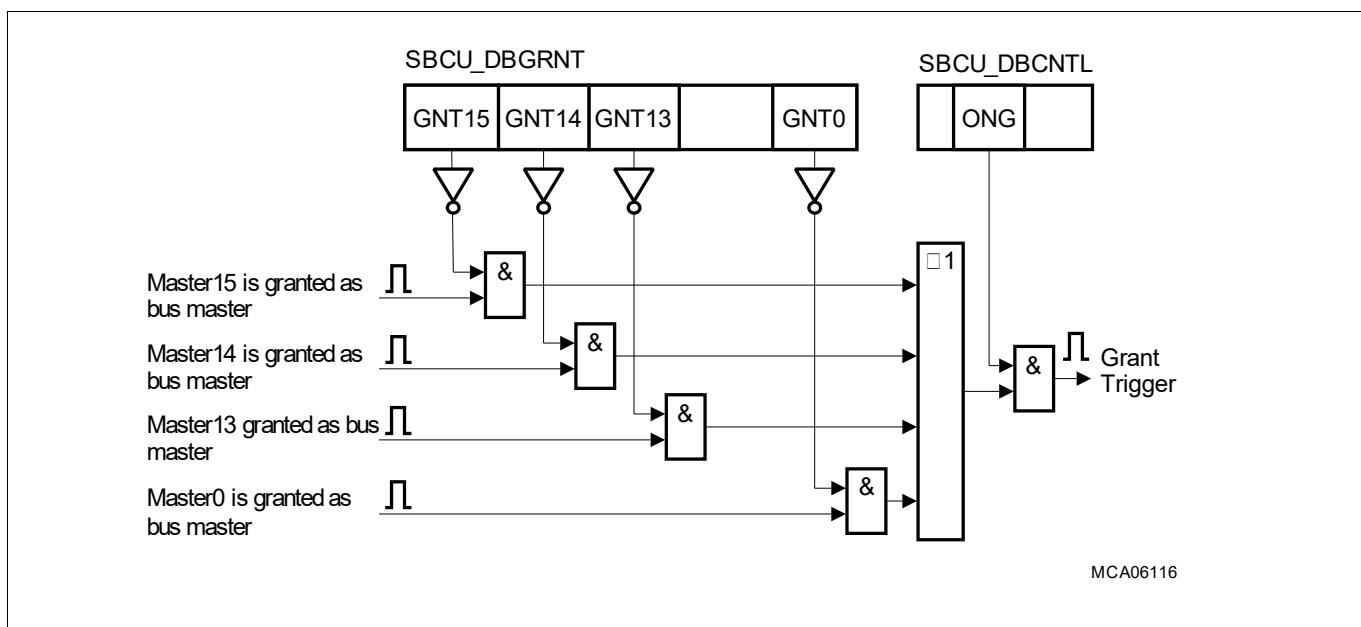

With the multiple signal match conditions, all single signal match conditions are combined with a logical **AND** to the signal status debug trigger event signal. The selection whether or not a single match condition is selected can be enabled/disabled selectively for each condition via the BCU\_DBCNTL.ONBOSx bits.

**Figure 41 Signal Status Trigger Generation**

#### 4.10.5.3 Grant Trigger

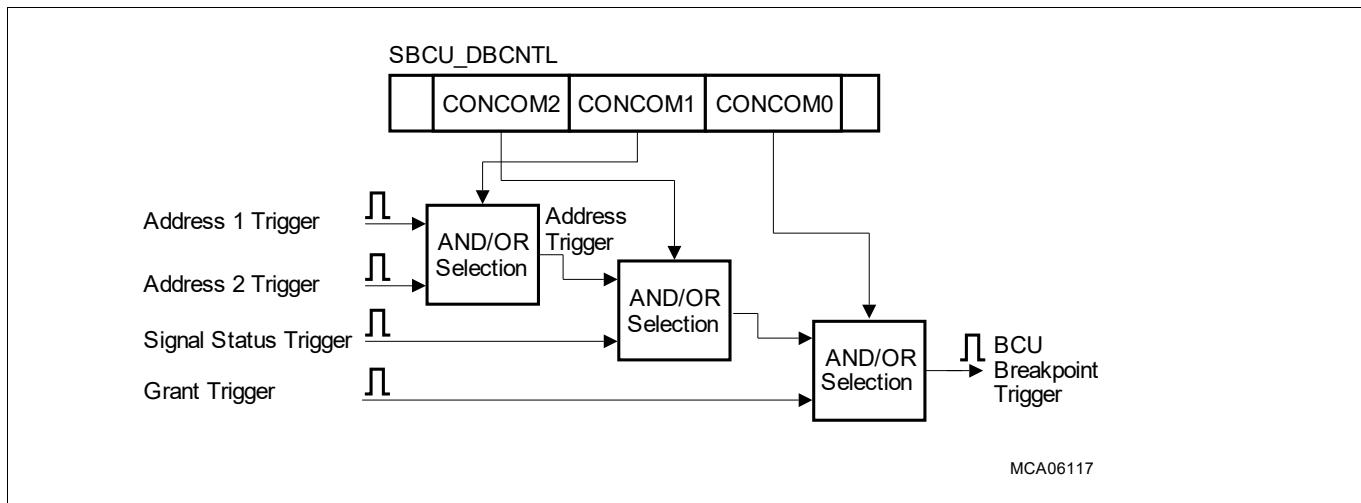

The signal status debug trigger event conditions are defined via the registers SBCU\_DBGRNT and SBCU\_DBCNTL. Depending on the configuration of these registers, any combination of FPI Bus master trigger events can be configured. Only the enabled masters in the SBCU\_DBGRNT register are of interest for the grant debug trigger event condition. The grant debug trigger event condition can be enabled/disabled via bit SBCU\_DBCNTL.ONG (see [Figure 42](#)).

**Figure 42** Grant Trigger Generation

#### 4.10.5.4 Combination of Trigger Events

The combination of the four debug trigger signals to the single BCU breakpoint trigger event is defined via the bits CONCOM[2:0] of register BCU\_DBCNTL (see [Figure 43](#)). The two address triggers are combined to one address trigger that is further combined with signal status and grant trigger signals. A logical AND or OR combination can be selected for the BCU breakpoint trigger generation.

**Figure 43 BCU Breakpoint Trigger Combination Logic**

#### 4.10.5.5 BCU Breakpoint Generation Examples

This section gives three examples of how BCU debug trigger events are programmed.

##### OCDS Debug Example 1

- Task: Generation of a BCU debug trigger event on any SPB write access to address  $00002004_H$  or  $000020A0_H$  by an SPB master.

For this task, the following programming settings for the BCU breakpoint logic must be executed:

- Writing BCU\_DBADR1 =  $0000\ 2004_H$
- Writing BCU\_DBADR2 =  $0000\ 20A0_H$
- Writing BCU\_DBCNTL =  $C1115010_H$ :
  - $ONBOS[3:0] = 1100_B$  means that no signal status trigger is generated (disabled) for a read signal match AND write signal match condition according to the settings of bits RD and WR in register BCU\_DBBOS. Debug trigger event generation for Supervisor Mode signal match and op-code signal match condition is disabled.
  - $ONA2 = 01_B$  means that the equal match condition for debug address 2 register is selected.
  - $ONA1 = 01_B$  means that the equal match condition for debug address 1 register is selected.
  - $ONG = 1$  means that the grant debug trigger is enabled.
  - $CONCOM[2:0] = 101_B$  means that the address trigger is created by address trigger 1 OR address trigger 2 ( $CONCOM1 = 0$ ), and that the grant trigger is ANDed with the address trigger ( $CONCOM0 = 1$ ), and that the signal status trigger is ANDed with the address trigger ( $CONCOM2 = 1$ ).
  - $RA = 1$  means that the BCU breakpoint logic is rearmed.
- Writing BCU\_DBGRNT =  $FFFFFD7_H$ : means that the grant trigger for the SPB master is enabled.

5. Writing  $\text{BCU\_DBBOS} = 00001000_{\text{H}}$ :  
means that the signal status trigger is generated on a write transfer and not on a read transfer.

### OCDS Debug Example 2

- Task: generation of a BCU debug trigger event on any half-word access in User Mode to address area  $01FFFFFF_{\text{H}}$  to  $02FFFFFF_{\text{H}}$  by any master.

For this task, the following programming settings for the BCU breakpoint logic must be executed:

- Writing  $\text{BCU\_DBADR1} = 01FFFFFF_{\text{H}}$
- Writing  $\text{BCU\_DBADR2} = 02FFFFFF_{\text{H}}$
- Writing  $\text{BCU\_DBCNTL} = 32206010_{\text{H}}$ :
  - $\text{ONBOS}[3:0] = 0011_B$  means that the signal status trigger is disabled for a read or for write signal status match but enabled for Supervisor Mode match AND op-code match conditions according to the settings of bit SVM and bit field OPC in register  $\text{BCU\_DBBOS}$ .
  - $\text{ONA2} = 10_B$  means that the address 2 trigger is generated if the FPI Bus address is less or equal to  $\text{BCU\_DBADR2}$ .
  - $\text{ONA1} = 10_B$  means that the address 1 trigger is generated if the FPI Bus address is greater or equal to  $\text{BCU\_DBADR1}$ .
  - $\text{ONG} = 0$  means that the grant debug trigger is disabled.
  - $\text{CONCOM}[2:0] = 110_B$  means that the address trigger is created by address trigger 1 AND address trigger 2 ( $\text{CONCOM1} = 1$ ), and that the grant trigger is OR-ed with the address trigger ( $\text{CONCOM0} = 0$ ), and that the signal status trigger is AND-ed with the address trigger ( $\text{CONCOM2} = 1$ ).
  - $\text{RA} = 1$  means that the BCU breakpoint logic is rearmed.
- Writing  $\text{BCU\_DBGRNT} = FFFFFFFF_{\text{H}}$ :  
means that no grant trigger for SPB masters is selected (“don’t care” because also disabled by  $\text{ONG} = 0$ ).
- Writing  $\text{BCU\_DBBOS} = 00000001_{\text{H}}$ :  
means that the signal status trigger is generated for read ( $\text{RD} = 0$ ) and write ( $\text{WR} = 0$ ) half-word transfers ( $\text{OPC} = 0001_B$ ) in User Mode ( $\text{SVM} = 0$ ).

#### 4.10.6 Registers

**Table 84 Register Overview - BCU (ascending Offset Address)**

<b>Short Name</b>	<b>Long Name</b>	<b>Offset Address</b>	<b>Access Mode</b>		<b>Reset</b>	<b>Page Number</b>

#### 4.10.6.1 Registers Description

##### Module Identification Register

The identification register allows the programmer version-tracking of the module. The table below shows the identification register which is implemented in the SBCU module.

ID															
Module Identification Register (0008 <sub>H</sub> ) Application Reset Value: 0000 6AXX <sub>H</sub>															
31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16															
0															
r															
15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0															
MOD_NUMBER MOD_REV															
r r															

Field	Bits	Type	Description
MOD_REV	7:0	r	<b>Module Revision Number</b> This bit field defines the module revision number. The value of a module revision starts with 01H (first revision).
MOD_NUMBE R	15:8	r	<b>Module Number Value</b> This bit field defines a module identification number. The value for the LBCU module is 006AH.
0	31:16	r	<b>Reserved</b> Read as 0; should be written with 0.

##### BCU Control Register

The SBCU Control Register controls the overall operation of the SBCU, including setting the starvation sample period, the bus time-out period, enabling starvation-protection mode, and error handling.

## CON

## BCU Control Register

(0010<sub>H</sub>)Application Reset Value: FF09 FFFF<sub>H</sub>

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
<b>SPC</b>															
															<b>DBG</b>
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
<b>TOUT</b>															

Field	Bits	Type	Description
<b>TOUT</b>	15:0	rw	<b>BCU Bus Time-Out Value</b> The bit field determines the number of System Peripheral Bus time-out cycles. Default after reset is FFFF <sub>H</sub> (= 65536 bus cycles).  Note: TOUT value must be >= 5.
<b>DBG</b>	16	rw	<b>BCU Debug Trace Enable</b> The bit enables/disables the error capture mechanism for the registers BCU_ECON, BCU_EADD, BCU_EDAT. The bit does not affect the SMU alarm or the BCU interrupt that are send on detection case of an error condition. 0 <sub>B</sub> SBCU debug trace disabled 1 <sub>B</sub> SBCU debug trace enabled (default after reset)
<b>SPC</b>	31:24	rw	<b>Starvation Period Control</b> Determines the sample period for the starvation counter. Must be larger than the number of masters. The reset value is FF <sub>H</sub> .
<b>0</b>	18:17, 23:20	r	<b>Reserved</b> Read as 0; should be written with 0.
<b>1</b>	19	r	<b>Reserved</b> Read as 1; should be written with 0.

## Arbiter Priority Register High

## PRIOH

## Arbiter Priority Register High

(0014<sub>H</sub>)Application Reset Value: FEDC BA98<sub>H</sub>

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
<b>MASTER15</b>				<b>MASTER14</b>				<b>MASTER13</b>				<b>MASTER12</b>			
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
<b>MASTER11</b>				<b>MASTER10</b>				<b>MASTER9</b>				<b>MASTER8</b>			

Field	Bits	Type	Description
<b>MASTERi (i=8-15)</b>	4*i-29:4*i-32	rw	<b>Master i Priority</b> This bit field defines the priority on the SPB for master i access to the SPB. A lower number has a higher priority in the arbitration round than a higher one.

### Arbiter Priority Register Low

#### PRIOL

**Arbiter Priority Register Low** **(0018<sub>H</sub>)** **Application Reset Value: 7654 3210<sub>H</sub>**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
<b>MASTER7</b>				<b>MASTER6</b>				<b>MASTER5</b>				<b>MASTER4</b>			
rw					rw				rw				rw		
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
<b>MASTER3</b>				<b>MASTER2</b>				<b>MASTER1</b>				<b>MASTER0</b>			
rw					rw				rw				rw		

Field	Bits	Type	Description
<b>MASTERi (i=0-7)</b>	4*i+3:4*i	rw	<b>Master i Priority</b> This bit field defines the priority on the SPB for master i access to the SPB. A lower number has a higher priority in the arbitration round than a higher one.

### BCU Error Control Capture Register

#### ECON

**BCU Error Control Capture Register** **(0020<sub>H</sub>)** **Application Reset Value: 0000 0000<sub>H</sub>**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
<b>OPC</b>				<b>TAG</b>				<b>RDN</b>		<b>WRN</b>	<b>SVM</b>	<b>ACK</b>		<b>ABT</b>	
rw					rw				rw				rw		
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
<b>RDY</b>	<b>TOUT</b>	<b>ERRCNT</b>													
rwh	rwh														

Field	Bits	Type	Description
<b>ERRCNT</b>	13:0	rwh	<b>FPI Bus Error Counter</b> ERRCNT is incremented on every occurrence of an FPI Bus error. EERRCNT is reset to 0 after the ECON register is read. <sup>1)</sup>

Field	Bits	Type	Description
<b>TOUT</b>	14	rwh	<b>State of FPI Bus Time-Out Signal</b> This bit indicates the state of the time-out signal at an FBI Bus error. $0_B$ No time-out occurred $1_B$ Time-out has occurred
<b>RDY</b>	15	rwh	<b>State of FPI Bus Ready Signal</b> This bit indicates the state of the ready signal at an FBI Bus error. $0_B$ Wait state(s) have been inserted. Ready signal was active $1_B$ Ready signal was inactive
<b>ABT</b>	16	rwh	<b>State of FPI Bus Abort Signal</b> This bit indicates the state of the abort signal at an FBI Bus error. $0_B$ Master has aborted an FPI Bus transfer. Abort signal was active $1_B$ Abort signal was inactive
<b>ACK</b>	18:17	rwh	<b>State of FPI Bus Acknowledge Signals</b> This bit field indicates the acknowledge code that has been output by the selected slave at an FPI Bus error. Coding see <a href="#">Table 74</a> . $00_B$ NSC: No special case $01_B$ Reserved $10_B$ RTY: Retry $11_B$ ERR: Bus Error
<b>SVM</b>	19	rwh	<b>State of FPI Bus Supervisor Mode Signal</b> This bit indicates whether the FPI Bus error occurred in Supervisor Mode or in User Mode. $0_B$ Transfer was initiated in User Mode $1_B$ Transfer was initiated in Supervisor Mode
<b>WRN</b>	20	rwh	<b>State of FPI Bus Write Signal</b> This bit indicates whether the FPI Bus error occurred at a write cycle (see <a href="#">Table 85</a> ).
<b>RDN</b>	21	rwh	<b>State of FPI Bus Read Signal</b> This bit indicates whether the FPI Bus error occurred at a read cycle (see <a href="#">Table 85</a> ).
<b>TAG</b>	27:22	rwh	<b>FPI Bus Master Tag Number Signals</b> This bit field indicates the FPI Bus master TAG number (definitions see <a href="#">Table 86</a> ).
<b>OPC</b>	31:28	rwh	<b>FPI Bus Operation Code Signals</b> The FPI Bus operation codes are defined in <a href="#">Table 75</a> .

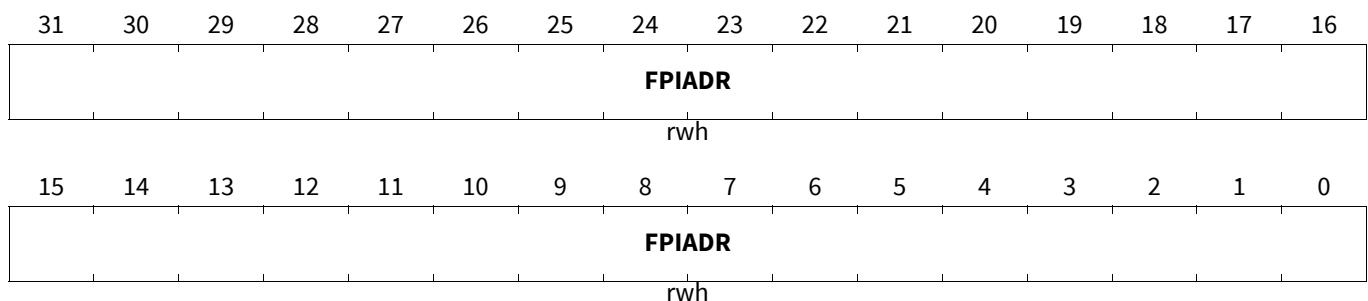

- 1) Aborted accesses to a 0 wait state SPB slave may also increment ERRCNT when the slave generates an error acknowledge.

**Table 85 FPI Bus Read/Write Error Indication**

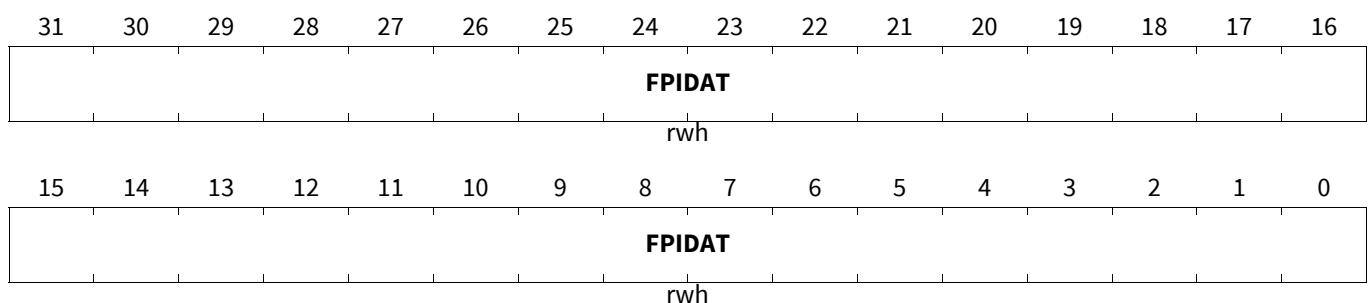

RD	WR	FPI Bus Cycle
0	0	FPI Bus error occurred at the read transfer of a read-modify-write transfer.
0	1	FPI Bus error occurred at a read cycle of a single transfer.

**Table 85 FPI Bus Read/Write Error Indication (cont'd)**

<b>RD</b>	<b>WR</b>	<b>FPI Bus Cycle</b>
1	0	FPI Bus error occurred at a write cycle of a single transfer or at the write cycle of a read-modify-write transfer.
1	1	Does not occur.

**BCU Error Address Capture Register****EADD****BCU Error Address Capture Register (0024<sub>H</sub>) Application Reset Value: 0000 0000<sub>H</sub>**

<b>Field</b>	<b>Bits</b>	<b>Type</b>	<b>Description</b>
<b>FPIADR</b>	31:0	rwh	<b>Captured FPI Bus Address</b> This bit field holds the 32-bit FPI Bus address that has been captured at an FPI Bus error. Note that if multiple bus errors occurred, only the address of the first bus error is captured.

**BCU Error Data Capture Register****EDAT****BCU Error Data Capture Register (0028<sub>H</sub>) Application Reset Value: 0000 0000<sub>H</sub>**

<b>Field</b>	<b>Bits</b>	<b>Type</b>	<b>Description</b>
<b>FPIDAT</b>	31:0	rwh	<b>Captured FPI Bus Data</b> This bit field holds the 32-bit FPI Bus data that has been captured at an FPI Bus error. Note that if multiple bus errors occurred, only the data of the first bus error is captured.

## BCU Debug Control Register

## DBCNTL

BCU Debug Control Register (0030<sub>H</sub>) Debug Reset Value: 0000 7003<sub>H</sub>

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
<b>ONBO S3</b>	<b>ONBO S2</b>	<b>ONBO S1</b>	<b>ONBO S0</b>	<b>0</b>	<b>ONA2</b>	<b>0</b>	<b>ONA1</b>								<b>ONG</b>
rw	rw	rw	rw	r	rw	r	rw	r	rw	rw	r	r	r	rw

<b>0</b>	<b>CONC OM2</b>	<b>CONC OM1</b>	<b>CONC OMO</b>			<b>0</b>	<b>HSMD BGEN</b>	<b>HSMTRTREN</b>	<b>RA</b>		<b>0</b>	<b>OA</b>	<b>EO</b>		
r	rw	rw	rw	r		r	r	r	w	r	r	rh	r		

Field	Bits	Type	Description
<b>EO</b>	0	r	<b>Status of BCU Debug Support Enable</b> This bit is controlled by the Cerberus and enables the BCU debug support.  $0_B$ BCU debug support is disabled $1_B$ BCU debug support is enabled (default after reset)
<b>OA</b>	1	rh	<b>Status of BCU Breakpoint Logic</b> The OA bit is set by writing a 1 to bit RA. When OA is set, registers DBGNTT, DBADRT and DBDAT are reset. Also DBBOST is reset with the exception of the bit field FPIRST.  $0_B$ The BCU breakpoint logic is disarmed. Any further breakpoint activation is discarded $1_B$ The BCU breakpoint logic is armed
<b>RA</b>	4	w	<b>Rearm BCU Breakpoint Logic</b> Writing a 1 to this bit rearms BCU breakpoint logic and sets bit OA = 1. RA is always reads as 0.
<b>HSMTRTREN</b>	6:5	r	<b>Status of HSM Transaction Trace Logic</b> $00_B$ HSM transaction tracing and capturing of HSM transactions in the BCU is disabled $01_B$ HSM transaction tracing and capturing of HSM transactions in the BCU is disabled $10_B$ HSM transaction address can be traced, capturing of HSM transactions in the BCU is allowed $11_B$ HSM transaction address and data can be traced, capturing of HSM transactions in the BCU is allowed
<b>HSMDBGEN</b>	7	r	<b>Status of HSM Debug Mode</b> $0_B$ HSM module is not in debug mode $1_B$ HSM module is in debug mode

Field	Bits	Type	Description
<b>CONCOM0</b>	12	rw	<p><b>Grant and Address Trigger Relation</b></p> <p><b>0<sub>B</sub></b> The grant phase trigger condition and the address trigger condition (see CONCOM1) are combined with a logical OR for further control</p> <p><b>1<sub>B</sub></b> The grant phase trigger condition and the address trigger condition (see CONCOM1) are combined with a logical AND for further control.</p>
<b>CONCOM1</b>	13	rw	<p><b>Address 1 and Address 2 Trigger Relation</b></p> <p><b>0<sub>B</sub></b> Address 1 trigger condition and address 2 trigger condition are combined with a logical OR to the address trigger condition for further control</p> <p><b>1<sub>B</sub></b> Address 1 trigger condition and address 2 trigger condition are combined with a logical AND to the address trigger condition for further control</p>
<b>CONCOM2</b>	14	rw	<p><b>Address and Signal Trigger Relation</b></p> <p><b>0<sub>B</sub></b> Address trigger condition (see CONCOM1) and signal status trigger conditions are combined with a logical OR for further control</p> <p><b>1<sub>B</sub></b> Address phase trigger condition (see CONCOM1) and the signal status trigger conditions are combined with a logical AND for further control</p>
<b>ONG</b>	16	rw	<p><b>Grant Trigger Enable</b></p> <p><b>0<sub>B</sub></b> No grant debug event trigger is generated</p> <p><b>1<sub>B</sub></b> The grant debug event trigger is enabled and generated according the settings of register DBGRNT</p>
<b>ONA1</b>	21:20	rw	<p><b>Address 1 Trigger Control</b></p> <p><b>00<sub>B</sub></b> No address 1 trigger is generated</p> <p><b>01<sub>B</sub></b> An address 1 trigger event is generated if the FPI Bus address is equal to DBADR1</p> <p><b>10<sub>B</sub></b> An address 1 trigger event is generated if FPI Bus address is greater or equal to DBADR1</p> <p><b>11<sub>B</sub></b> same as 00<sub>B</sub></p>
<b>ONA2</b>	25:24	rw	<p><b>Address 2 Trigger Control</b></p> <p><b>00<sub>B</sub></b> No address 2 trigger is generated.</p> <p><b>01<sub>B</sub></b> An address 2 trigger event is generated if the FPI Bus address is equal to DBADR2</p> <p><b>10<sub>B</sub></b> An address 2 trigger event is generated if FPI Bus address is less or equal to DBADR2</p> <p><b>11<sub>B</sub></b> same as 00<sub>B</sub></p>

Field	Bits	Type	Description
<b>ONBOS0</b>	28	rw	<b>Op code Signal Status Trigger Condition</b> $0_B$ A signal status trigger is generated for all FPI Bus op-codes except a “no operation” op-code $1_B$ A signal status trigger is generated if the FPI Bus op-code matches the op-code as defined in DBBOS.OPC
<b>ONBOS1</b>	29	rw	<b>Supervisor Mode Signal Trigger Condition</b> $0_B$ The signal status trigger generation for the FPI Bus Supervisor Mode signal is disabled. $1_B$ A signal status trigger is generated if the FPI Bus Supervisor Mode signal state is equal to the value of DBBOS.SVM
<b>ONBOS2</b>	30	rw	<b>Write Signal Trigger Condition</b> $0_B$ The signal status trigger generation for the FPI Bus write signal is disabled. $1_B$ A signal status trigger is generated if the FPI Bus write signal state is equal to the value of DBBOS.WR
<b>ONBOS3</b>	31	rw	<b>Read Signal Trigger Condition</b> $0_B$ The signal status trigger generation for the FPI Bus read signal is disabled. $1_B$ A signal status trigger is generated if the FPI Bus read signal state is equal to the value of DBBOS.RD
<b>0</b>	3:2, 11:8, 15, 19:17, 23:22, 27:26	r	<b>Reserved</b> Read as 0; should be written with 0.

### BCU Debug Address 1 Register

#### DBADR1

##### BCU Debug Address 1 Register

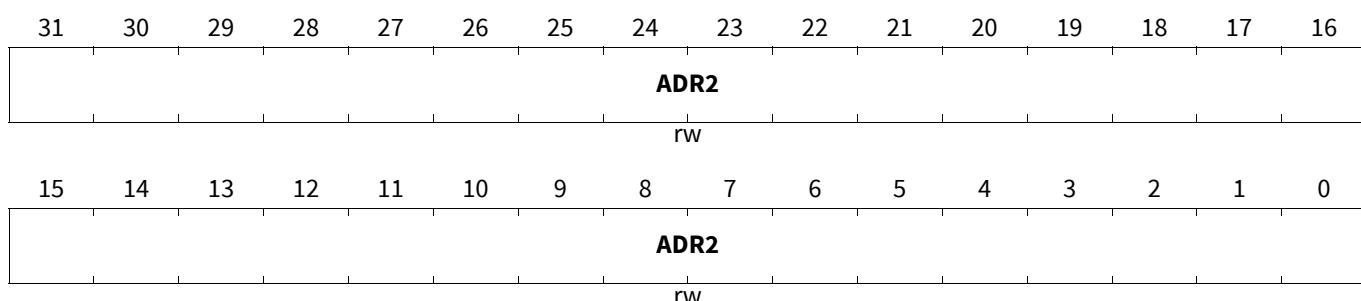

(0038<sub>H</sub>)Debug Reset Value: 0000 0000<sub>H</sub>

Field	Bits	Type	Description
ADR1	31:0	rw	<b>Debug Trigger Address 1</b> This register contains the address for the address 1 trigger event generation.

### BCU Debug Address 2 Register

#### DBADR2

##### BCU Debug Address 2 Register

(003C<sub>H</sub>)Debug Reset Value: 0000 0000<sub>H</sub>

Field	Bits	Type	Description
ADR2	31:0	rw	<b>Debug Trigger Address 2</b> This register contains the address for the address 2 trigger event generation.

## BCU Debug Bus Operation Signals Register

### DBBOS

**BCU Debug Bus Operation Signals Register (0040<sub>H</sub>)**      **Debug Reset Value: 0000 0000<sub>H</sub>**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
0															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
r			<b>RD</b>	r		<b>0</b>		<b>WR</b>	r	<b>0</b>		<b>SVM</b>			<b>OPC</b>

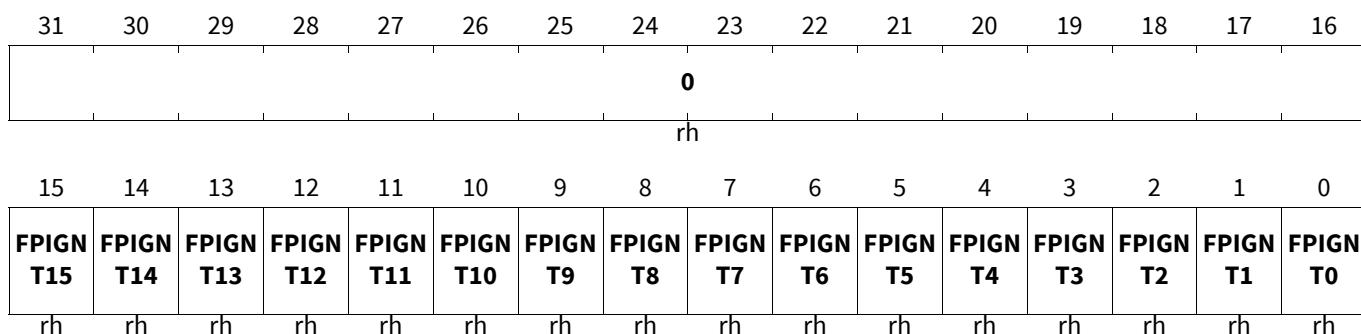

Field	Bits	Type	Description
<b>OPC</b>	3:0	rw	<b>Opcode for Signal Status Debug Trigger</b> This bit field determines the type (opcode) of an FPI Bus transaction for which a signal status debug trigger event is generated (if enabled by DBCNTL.ONBOS0 = 1). Other bit combinations are reserved. 0 <sub>H</sub> Trigger on single byte transfer selected 1 <sub>H</sub> Trigger on single half-word transfer selected 2 <sub>H</sub> Trigger on single word transfer selected 4 <sub>H</sub> Trigger on 2-word block transfer selected 5 <sub>H</sub> Trigger on 4-word block transfer selected 6 <sub>H</sub> Trigger on 8-word block transfer selected F <sub>H</sub> Trigger on no operation selected
<b>SVM</b>	4	rw	<b>SVM Signal for Status Debug Trigger</b> This bit determines the mode of an FPI Bus transaction for which a signal status debug trigger event is generated (if enabled by DBCNTL.ONBOS1 = 1). 0 <sub>B</sub> Trigger on User Mode selected 1 <sub>B</sub> Trigger on Supervisor Mode selected
<b>WR</b>	8	rw	<b>Write Signal for Status Debug Trigger</b> This bit determines the state of the WR signal of an FPI Bus transaction for which a signal status debug trigger event is generated (if enabled by DBCNTL.ONBOS2 = 1). 0 <sub>B</sub> Trigger on a single write transfer or write cycle of an atomic transfer selected 1 <sub>B</sub> No operation or read transaction selected
<b>RD</b>	12	rw	<b>Read Signal for Status Debug Trigger</b> This bit determines the state of the RD signal of an FPI Bus transaction for which a signal status debug trigger event is generated (if enabled by DBCNTL.ONBOS3 = 1). 0 <sub>B</sub> Trigger on a single read transfer or read cycle of an atomic transfer selected 1 <sub>B</sub> No operation or write transfer selected

Field	Bits	Type	Description
0	7:5, 11:9, 31:13	r	<b>Reserved</b> Read as 0; should be written with 0.

### BCU Debug Trapped Master Register

#### DBGNTT

##### BCU Debug Trapped Master Register

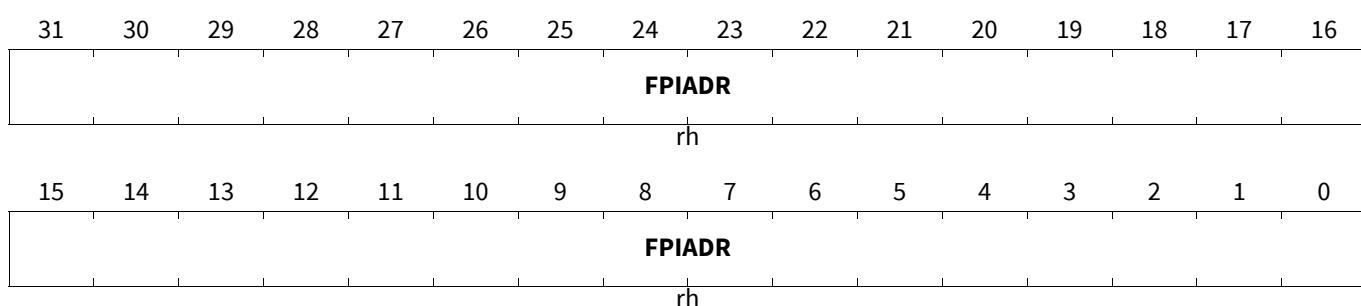

(0044<sub>H</sub>)Debug Reset Value: 0000 FFFF<sub>H</sub>

Field	Bits	Type	Description
FPIGNTi (i=0-15)	i	rh	<b>Master</b> 0 <sub>B</sub> Master i was the FPI bus master. 1 <sub>B</sub> Master i was not the FPI Bus master
0	31:16	rh	<b>Reserved</b> Read as 1 after reset; reading these bits will return the value last written.

### BCU Debug Trapped Address Register

#### DBADRT

##### BCU Debug Trapped Address Register

(0048<sub>H</sub>)Debug Reset Value: 0000 0000<sub>H</sub>

Field	Bits	Type	Description
FPIADR	31:0	rh	<b>FPI Bus Address Status</b> This register contains the FPI Bus address that was captured when the OCDS break trigger event occurred.

## BCU Debug Trapped Bus Operation Signals Register

### DBBOST

#### BCU Debug Trapped Bus Operation Signals Register(004C<sub>H</sub>)

Debug Reset Value: 0000 3180<sub>H</sub>

## FPI Error Generation Control Register

The FEGEN register controls the injection of errors in the FPI Error Detection Code mechanism.

Errors will be injected in the FPI EDC related encoders and output enable checks in:

- BCU FPI Slave related Slave Encoder Decoder Module (SEDM)
  - CPU0 FPI Master related Master Encoder Decoder Module (MEDM)
  - BCU FPI TIMEOUT signal
  - BCU FPI GRANT signals
  - All groups of FPI Slave / Master output enable signals that are checked in the BCU

FEGEN

**EPI Error Generation Control Register** (0084..) **Application Reset Value:** 0000 0000..

#### 4.10.6.2 System Registers

Figure 44 shows these system registers which include registers for:

The BCU module includes the following AURIX™ TC3xx Platform standard system registers

- Register access protection

The following standard system registers are not included:

- Module Clock Control
- Module Kernel Reset
- OCDS Control and Status Register

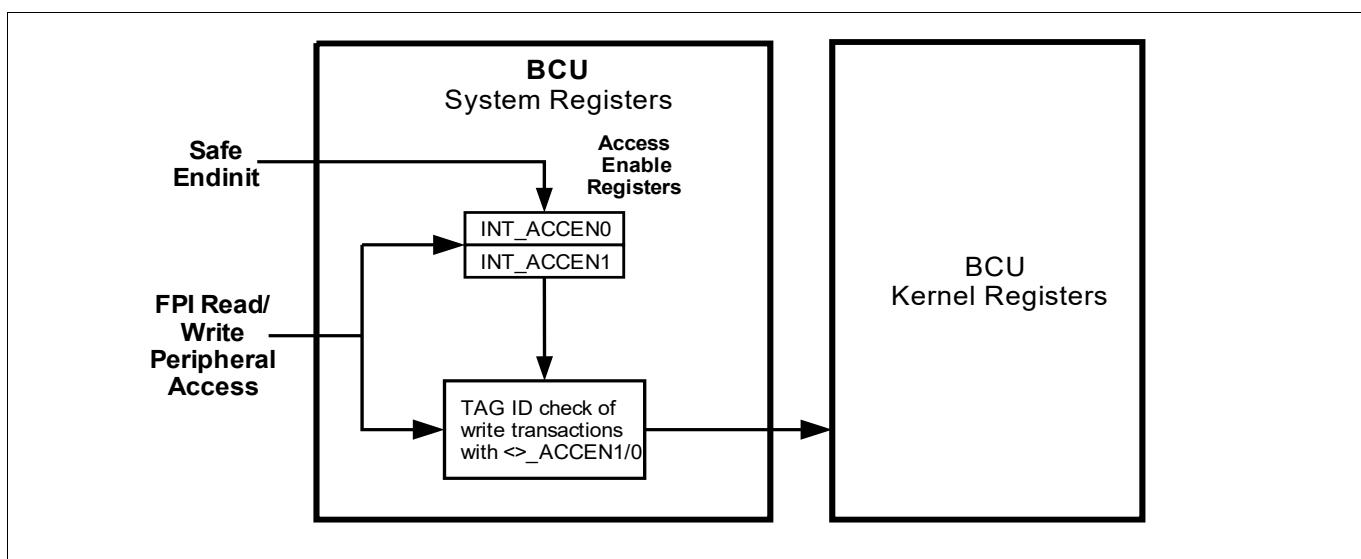

Figure 44 FPI, BCU Implemented System Registers

#### 4.10.6.3 Register Access Protection (ACCEN1/0)

The module provides a master TAG ID based write access protection as part of the safety concept. Each on chip resource with direct or indirect bus master capability has a unique master TAG ID that can be used to identify the master of an on chip bus transaction (see also chapter On Chip Bus Systems).

The SRC register is write protected via an On Chip Bus Master TAG-ID protection (see [Chapter 4.10.6.3](#)). This protection is controlled via the Interrupt Router control registers ACCEN10 and ACCEN00.

TAG ID based protection means that the support of write transactions to the FPI, BCU control registers can be enabled / disabled for each master TAG ID individually. For a disabled master TAG ID, write access will be disconnected with error acknowledge, read access will be processed (see also [Figure 44](#)).

The register access protection is controlled via the registers INT\_ACCEN1 and INT\_ACCEN0 where each bit is related to one encoding of the 6 bit On Chip Master TAG ID.

The INT\_ACCEN1/0 registers are controlling the write access to all module control. The system registers INT\_ACCEN1/0 are Safety Endinit protected.

After reset, all access enable bits and access control bits are enabled, access protection mechanism has to be configured and checked to bring the system in a safe state.

##### Access Enable Register 1

The Access Enable Register 1 controls write access for transactions with the on chip bus master TAG ID 100000B to 111111B (see On Chip Bus chapter for the products TAG ID <-> master peripheral mapping). ACCEN11/01 are not implemented with register bits as the related On Chip Bus Master TAG IDs are not used in the AURIX devices.

Mapping of TAG IDs to ACCEN1.ENx: EN0 -> TAG ID 100000B, EN1 -> TAG ID 100001B, ... ,EN31 -> TAG ID 111111B.

##### ACCEN1

#### 4.10.6.4 Kernel Reset Registers (KRST1/0, KRSTCLR)

The BCU does not support the module kernel reset feature and does include the kernel reset registers (KRST1, KRST0, KRSTCLR).

#### 4.10.6.5 Clock Control Register (CLC)

The FPI, BCU module does not include the module clock control (CLC).

*Note:* The FPI, BCU module does not support the Clock Control register functionality which means that the FPI, BCU module clock can not be disabled by the CLC register.

#### 4.10.6.6 OCDS Control and Status Register (OCS)

The FPI, BCU module does not include OCDS Control and Status (OCS) register.

*Note:* The module does not support the OCS register functionality.

#### 4.10.7 On Chip Bus Master TAG Assignments

Each master interface on the System Peripheral Bus and on the SRI Bus is assigned to a 6-bit identification number, the master TAG number (see **Table 86**). This makes it possible for software debug and MCDS purposes to distinguish which master has performed the current transaction.

**Table 86 On Chip Bus Master TAG Assignments**

TAG-Number	Module	Location	Visibility	Description

**CPU Subsystem**

## 5 CPU Subsystem

This chapter describes the implementation-specific options of the TC1.6.2P TriCore CPUs found in the AURIX™ series of devices.

This chapter should be read in conjunction with the TriCore Architecture Manual. Topics covered by the architecture manual include:-

- Architectural Overview
- Programming Model
- CPU Registers
- Tasks and Functions
- Interrupt Handling
- Traps
- Memory Protection System
- Temporal Protection System
- Floating Point Operations
- Debug
- Instruction Set

## CPU Subsystem

### 5.1 Feature List

Key CPU Features include:

#### Architecture

- 32-bit load store architecture
- 4 Gbyte address range ( $2^{32}$ )
- 16-bit and 32-bit instructions for reduced code size
- Data types:
  - Boolean, integer with saturation, bit array, signed fraction, character, double-word integers, signed integer, unsigned integer, IEEE-754 single-precision floating point
- Data formats:
  - Bit, byte (8-bits), half-word (16-bits), word (32-bits), double-word (64-bits)
- Byte and bit addressing
- Little-endian byte ordering for data, memory and CPU registers
- Multiply and Accumulate (MAC) instructions: Dual  $16 \times 16$ ,  $16 \times 32$ ,  $32 \times 32$
- Saturation integer arithmetic
- Packed data
- Addressing modes:
  - Absolute, circular, bit reverse, long + short, base + offset with pre- and post-update
- Instruction types:
  - Arithmetic, address arithmetic, comparison, address comparison, logical, MAC, shift, coprocessor, bit logical, branch, bit field, load/store, packed data, system
- General Purpose Register Set (GPRS):
  - Sixteen 32-bit data registers
  - Sixteen 32-bit address registers
  - Three 32-bit status and program counter registers (PSW, PC, PCXI)
- Debug support (OCDS):
  - Level 1, supported in conjunction with the CPS block
  - Level 3, supported in conjunction with the MCDS block (Emulation Device only).
- Flexible memory protection system providing multiple protection sets with multiple protection ranges per set.
- Temporal protection system allowing time bounded real time operation.

#### TC1.6.2P Implementation

- Most instructions executed in 1 cycle
- Branch instructions in 1, 2 or 3 cycles (using dynamic branch prediction)
- Wide memory interface for fast context switch
- Automatic context save-on-entry and restore-on-exit for: subroutine, interrupt, trap
- Six memory protection register sets
- Dual instruction issuing (in parallel into Integer Pipeline and Load/Store Pipeline)
- Third pipeline for loop instruction only (zero overhead loop)
- Single precision Floating Point Unit (IEEE-754 Compatible)

---

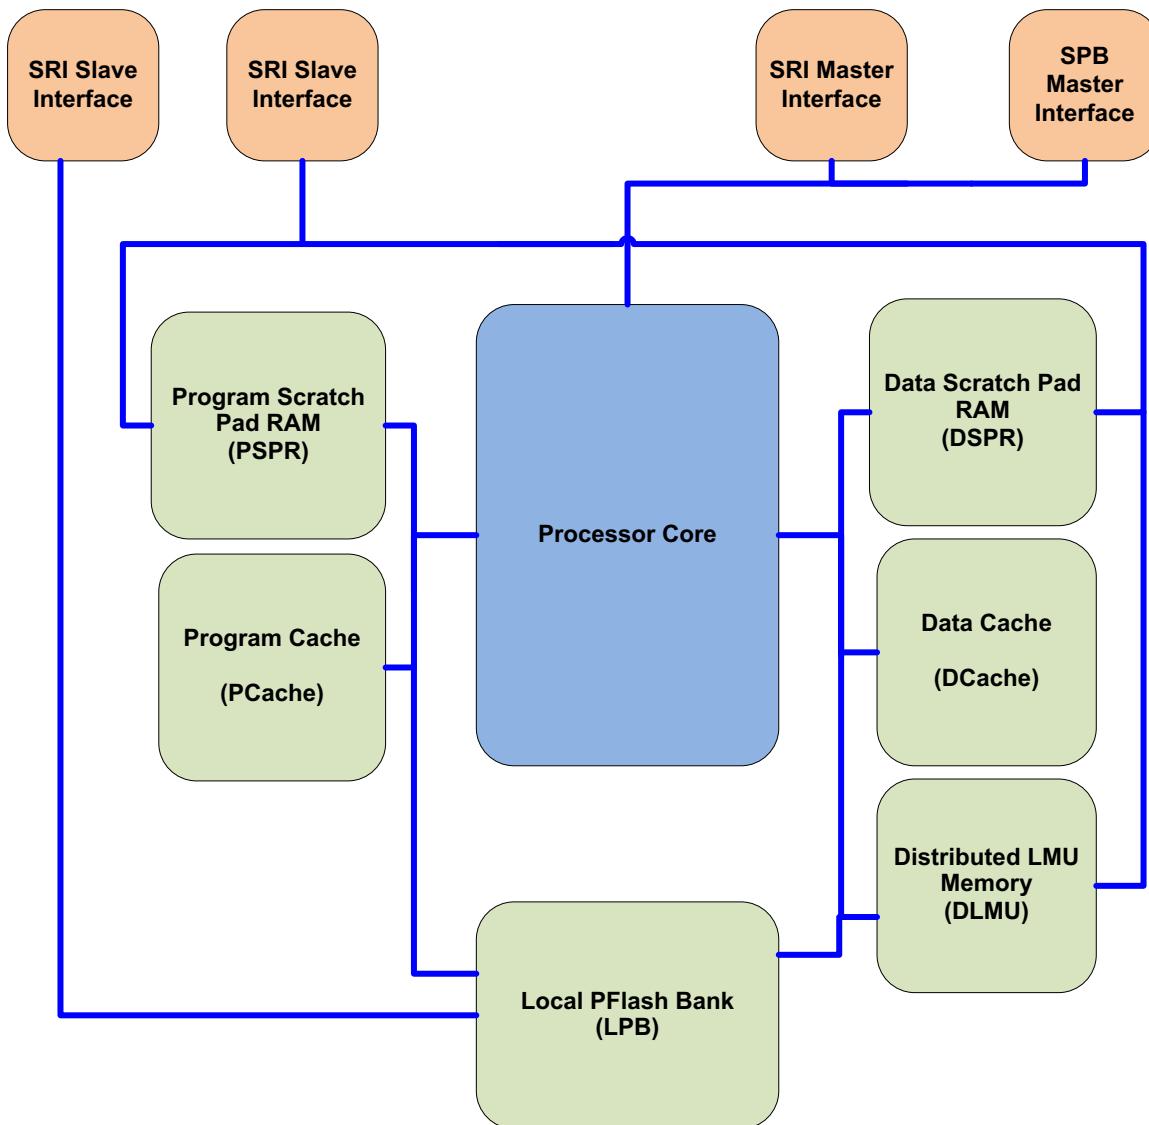

## CPU Subsystem

- Dedicated Integer divide unit
- 18 data memory protection ranges, 10 code memory protection ranges arranged in 6 sets

## CPU Subsystem

### 5.2 Overview

The following sections give an overview of the TC1.6.2P Implementation

**Figure 45 Processor Core, Local Memory and connectivity**

The processor core connects to the following memories and bus interfaces (where implemented)

- Data Scratchpad SRAM (DSPR)
- Program Scratchpad SRAM (PSPR)
- Data Cache (DCache)
- Program Cache (PCache)
- Distributed LMU memory (DLMU)
- Local Pflash bank (LPB)
- SRI slave interface (x2)
- SRI master Interface
- SPB master interface

## CPU Subsystem

### 5.2.1 CPU Diagram

The Central Processing Unit (CPU) comprises of an Instruction Fetch Unit, an Execution Unit, a General Purpose Register File (GPR), a CPU Slave interface (CPS), and Floating Point Unit (FPU).

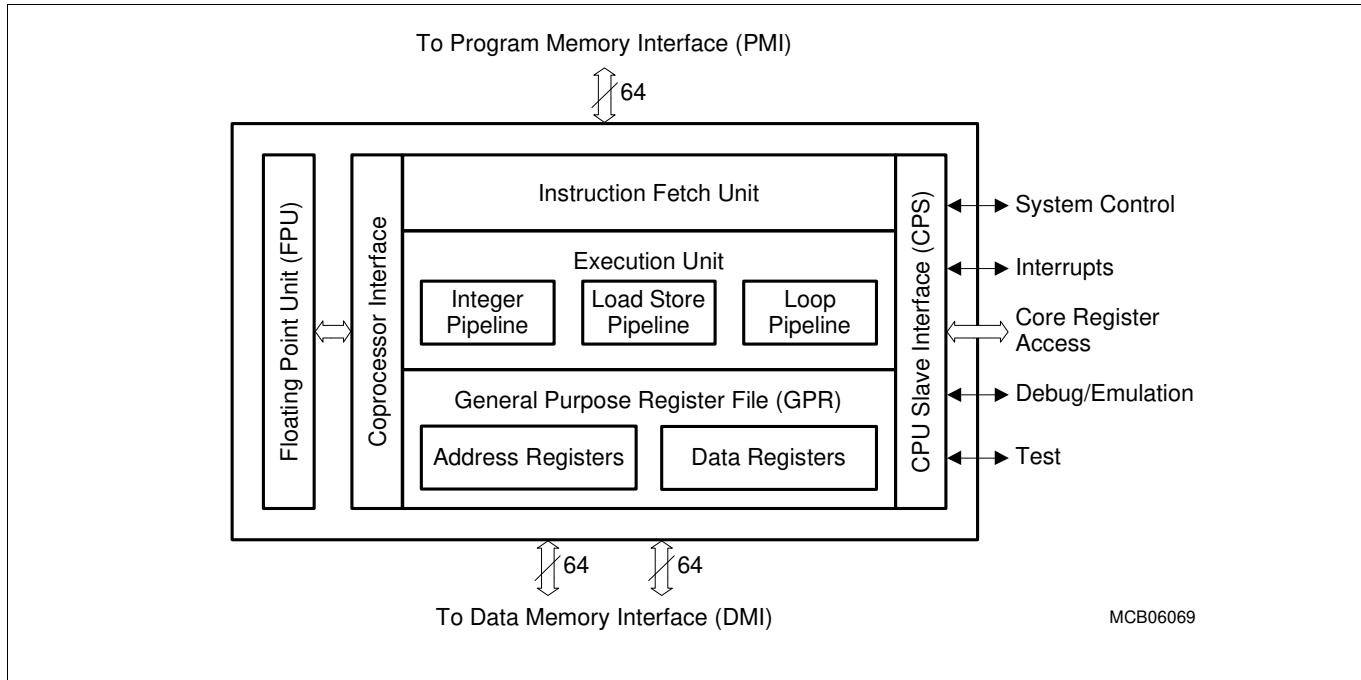

Figure 46 CPU Block Diagram

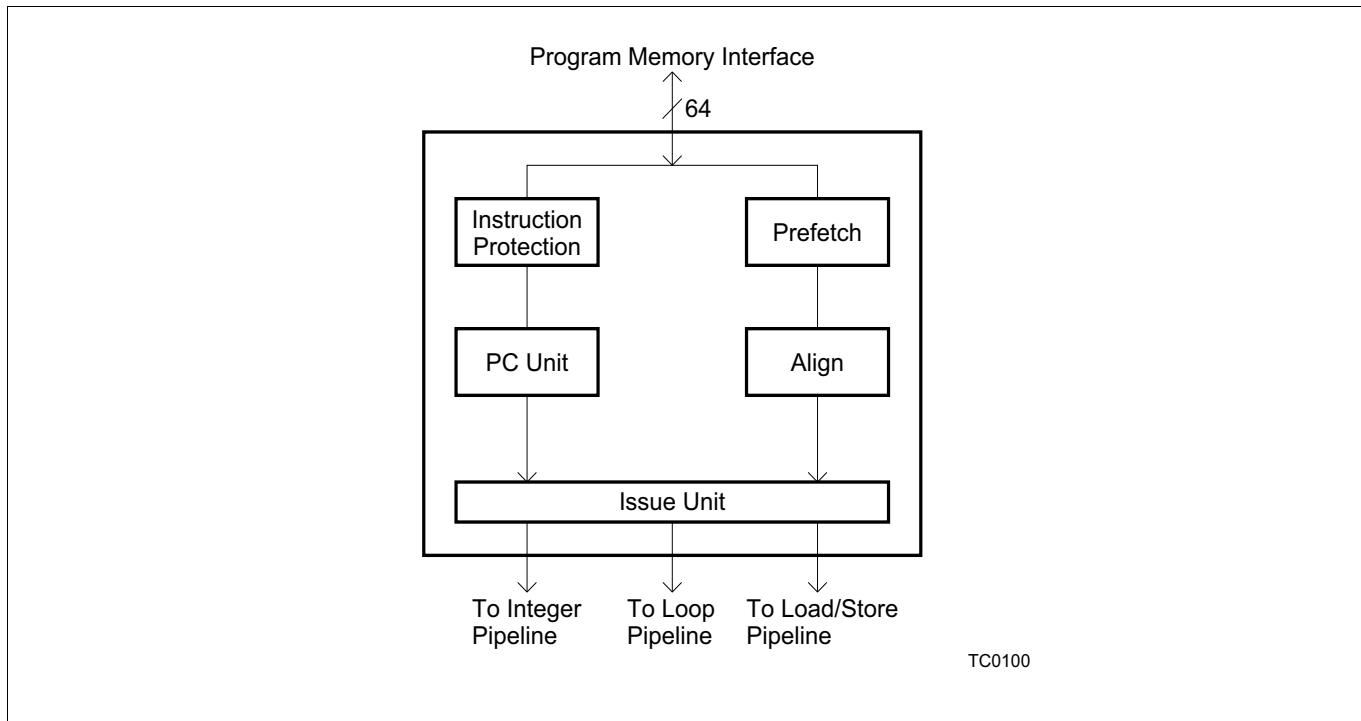

### 5.2.2 Instruction Fetch Unit

The Instruction Fetch Unit pre-fetches and aligns incoming instructions from the 64-bit wide Program Memory Interface (PMI). Instructions are placed in predicted program order in the Issue fifo. The Issue fifo buffers up to six instructions and directs the instruction to the appropriate execution pipeline.

The Instruction Protection Unit checks the validity of accesses to the PMI and the integrity of incoming instructions fetched from the PMI.

The branch unit examines the fetched instructions for branch conditions and predicts the most likely execution path based on previous branch behavior. The Program Counter Unit (PC) is responsible for updating the program counters.

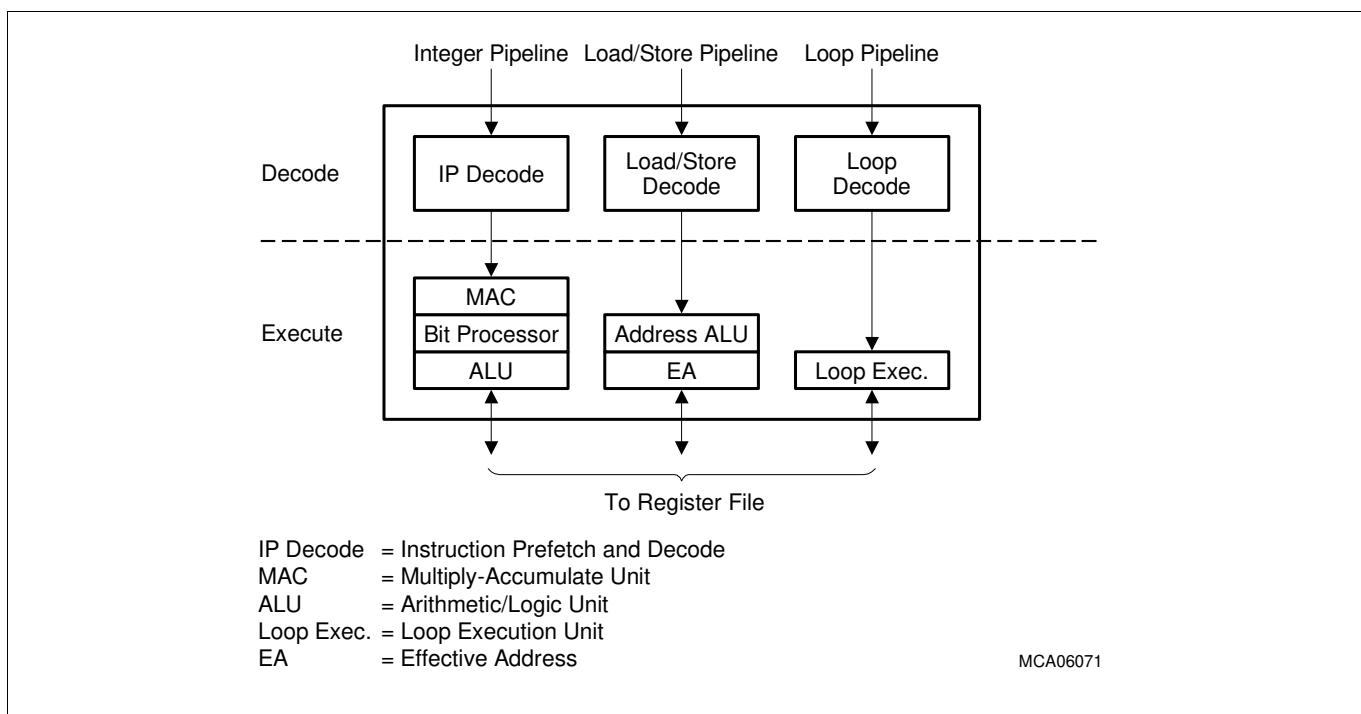

## CPU Subsystem

**Figure 47 Instruction Fetch Unit**

### 5.2.3 Execution Unit

The Execution Unit contains the Integer Pipeline, the Load/Store Pipeline and the Loop Pipeline. All three pipelines operate in parallel, permitting up to three instructions to be executed in one clock cycle. In the execution unit all instructions pass through a decode stage followed by two execute stages. Pipeline hazards (stalls) are minimised by the use of forwarding paths between pipeline stages allowing the results of one instruction to be used by a following instruction as soon as the result becomes available.

**Figure 48 Execution Unit**

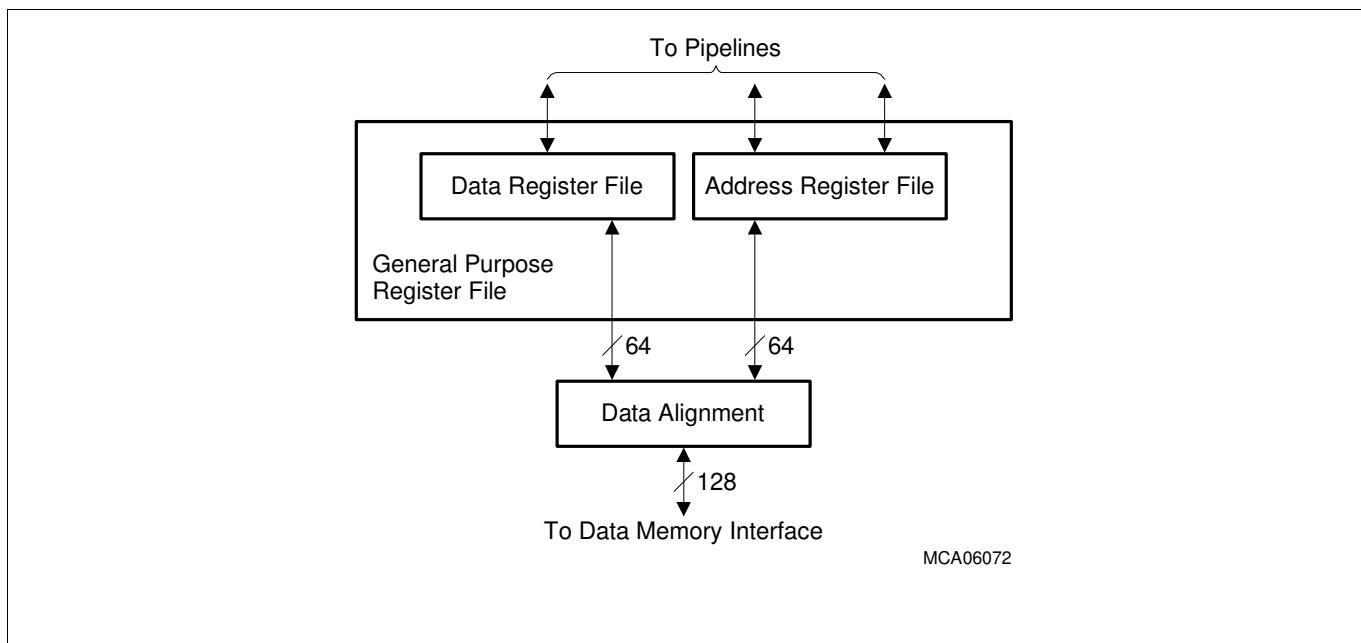

## CPU Subsystem

### 5.2.4 General Purpose Register File

The CPU has a General Purpose Register (GPR) file, divided into an Address Register File (registers A0 through A15) and a Data Register File (registers D0 through D15).

The data flow for instructions issued to the Load/Store Pipeline is steered through the Address Register File.

The data flow for instructions issued to/from the Integer Pipeline and for data load/store instructions issued to the Load/Store Pipeline is steered through the Data Register File.

**Figure 49 General Purpose Register File**

## 5.3 Functional Description

### 5.3.1 Summary of functional changes from AURIX

The TC1.6.2P CPU utilises the same core processing hardware as the TC1.6P processor used in the AURIX series of devices. The main enhancements and changes are listed below:-

- A portion of the LMU memory (called DLMU) is distributed between the processors to provide high performance access to global SRAM
- The PFlash memory is distributed between the processors to provide high performance access to a local PFlash bank. (LPB)
- New instructions (See architecture manual for details):-
  - CRC32B.W, CRC32L.W, CRC32.B (CRC32 for big endian, little endian and byte data)
  - CRCN (arbitrary width and polynomial CRC calculation)
  - SHUFFLE (Reorder bytes within word)
  - POPCNT (count number of bits set in word)
  - FTOHP, HPTOF (Half precision floating point conversion)
  - LHA (Load high bits of address value)
- Enhanced memory protection

## CPU Subsystem

- Number of protection sets increased to 6 (was 4), The PSW.PRS field has been extended to reflect this.
- Number of code protection ranges increased to 10 (was 8)
- Number of data protection ranges increased to 18 (was 16)
- The temporal protection system is extended to provide a dedicated exception timer.
- Independent core resets implemented. (Individual cores may be independently reset as required)
- To exit boot halt the SYSCON.BHALT should be cleared (Was DBGSR.HALT)
- The overlay system is extended to support additional processor cores.
- The store buffer data merge functionality is extended to merge consecutive half words into words and consecutive words into double words.
- The safety protection system has been extended to cover external read and write accesses to local DSPPR/PSPR and DLMU, and to cover external read accesses to the LPB.
- The CPU\_ID has changed (to 0x00C0C020 for TC39X A-Step)

### 5.3.2 Summary of changes from TC39x A-Step

The following changes have been implemented between the TC39x A-step and subsequent devices.

- Extension of ACCEN enable registers to support > 32 bus masters (ACC\*B registers now active)
- Implementation of FLASHCON4.DDIS to provide the ability to disable direct access to Local PFlash.
- Increase in DSPPR sizes for CPU0,1 (96K -> 240K)
- The CPU\_ID has changed to 0x00C0C021
- Emulator space disable bit added to SYSCON register (SYSCON.ESDIS)
- Temporal protection and exception timers are frozen during Suspend.
- Modification to ICU interface to drive invalid ECC values at all times except when there is a valid ACK

**CPU Subsystem****5.3.3 AURIX™ Family CPU configurations**

The different CPU and local memory configurations for the AURIX™ family of devices are detail in the following tables:

**Table 88 Processor and local memory configuration of the TC39x**

Processor	CORE_ID	Program Cache	Program Scratch Pad	Data Cache	Data Scratch Pad	DLMU	LPB	Standby DLMU SRAM	Lock-Step

## CPU Subsystem

### 5.3.4 CPU Implementation-Specific Features

This section describes these implementation-specific features of the TC1.6.2P CPUs. For a complete description of all registers, refer to the TriCore Architecture Manual.

#### 5.3.4.1 Context Save Areas / Context Operations

The CPU uses a uniform context-switching method for function calls, interrupts and traps. In all cases the Upper Context of the task is automatically saved and restored by hardware. Saving and restoring of the Lower Context may be optionally performed by software.

The Context Save Areas (CSA) and addresses targeted by explicit context load/store instructions (e.g. LDLCX) may be placed in DSPR, DLMU or external memory (cached or uncached).

##### CSA Placement in DSPR or DLMU

The actual timing of context operations is dependent upon the placement of the Context Save Areas. Maximum performance is achieved when the Context Save Area is placed in DSPR. In this case all context save and restores operations take four cycles (assuming no external interference). If the CSA is placed in the DLMU context save and restores operations take eight cycles

##### CSA Placement in Cached External Memory

In this case, the timing is also dependent on the state of the Data Cache. The best case Data Cache operation occurs when context saves do not incur a cache line writeback, and context restores hit in the data cache. In this case all context saves and restores take eight cycles.

#### 5.3.4.2 Program Counter (PC) Register

The Program Counter (PC) holds the address of the instruction that is currently fetched and forwarded to the CPU pipelines. The CPU handles updates of the PC automatically.

Software can use the current value of the PC for various tasks, such as performing code address calculations. Reading the PC through software executed by the CPU must only be done with an MFCR instruction. Such a read will return the PC of the MFCR instruction itself. Explicit writes to the PC through an MTCR instruction must not be done due to possible unexpected behavior of the CPU. The PC may be written only when the CPU is halted.

The CPU must not perform Load/Store instructions to the mapped address of the PC in Segment 15. A MEM trap will be generated in such a case. Bit 0 of the PC register is read-only and hard-wired to 0.

#### 5.3.4.3 Store Buffers

To increase performance the TC1.6.2P CPUs implements store buffering to decouple memory write operations from CPU instruction execution. All stores from the CPU are placed in the store buffer prior to being written to local memory or transferred via the bus system. Write data is taken from the store buffers and written to memory when the target memory or bus interface becomes available. In normal operation the CPU will prioritise memory load operations over store operations in order to improve performance unless:-

- The store buffer is full.
- The load is to peripheral space and a store to peripheral space exists in the store buffer. (In order peripheral space access).
- The load or store is part of a read-modify-write operation.

Typically the operation of the store buffer is invisible to the end user. If there is a requirement that data is written to local memory prior to execution of a subsequent instruction then a DSYNC instruction may be used to flush the store buffers. If the data is targeted at either the SRI or the SPB address ranges, then a DSYNC instruction may be used to flush the store buffers followed by a load operation from the targeted slave address range.

---

## CPU Subsystem

To improve performance the store buffer will merge consecutive data values to reduce the number of memory accesses required. The following operations are merged in the store buffer

- Consecutive byte writes to the same half word location.
- Consecutive half-word writes to the same word location.
- Consecutive word writes to the same double word location.

The TC1.6.2P CPU store buffer can hold the data for up to 6 stores operations.

Store buffer operation may be disabled by setting the SMACON.IODT bit. This should not be done in normal execution as it will severely limit performance.

## CPU Subsystem

### 5.3.4.4 Interrupt System

An interrupt request can be generated by the on-chip peripheral units, or it can be generated by external events. Requests can be targeted to any CPU.

The interrupt system evaluates service requests for priority and to identify whether the CPU should receive the request. The highest-priority service request is then presented to the CPU by way of an interrupt.

On taking an interrupt the CPU will vector to a unique PC generated from the interrupt priority number and the Base Interrupt Vector (BIV). The spacing between the vector PCs in the interrupt vector table may be selected to be either 32 Bytes or 8 Bytes using BIV[0].

The TC1.6.2P implements a fast interrupt system. This system avoids unnecessary context save and restore operations and hence speeds up interrupt routine entry. A fast interrupt is triggered when:-

- An Interrupt is pending
- A Return From exception instruction is being executed (RFE)
- The priority of the pending interrupt is greater than the priority level that would be returned to should the RFE be executed (ICR.PIPN > PCXI.PCPN).
- Interrupts will be enabled should the RFE be executed. (PCXI.PIE == 1)
- Fast Interrupts are not otherwise disabled due to the presence of MTCR instructions or context operations in the pipeline.

*Note: Only MTCR operations to the following registers will disable fast interrupt PCXI, PCX, PSW, PC, SYSCON, CPU\_ID, CORE\_ID, BIV, BTV, ISP, ICR, FCX, LCX, DMS, DCX, DBGTCR.*

Without the fast interrupt operation the RFE would cause a restore of the upper context immediately followed by a save of the same upper context back to exactly the same memory location (Minimum 8 cycles). The fast interrupt system replaces this redundant restore/save sequence with a load of PCXI/PSW/A10/A11 (Minimum 1 Cycle) from the saved context. System state at the end of the fast interrupt is the same as if the standard RFE/Interrupt sequence had been performed.

### 5.3.4.5 Trap System

The following traps have implementation-specific properties.

#### UOPC - Unimplemented Opcode (TIN 2)

The UOPC trap is raised on optional MMU instructions, coprocessor two and coprocessor three instructions.

#### OPD - Invalid Operand (TIN 3)

The CPU raised OPD traps for instructions that take even-odd register pairs as an operand where if the operand specifier is odd.

#### DSE - Data Access Synchronous Error (TIN 2)

The Data Access Synchronous Bus Error (DSE) trap is generated by the DMI module when a load access from the CPU encounters certain error conditions, such as a Bus error, or an out-of-range access to DSPr. When a DSE trap is generated, the exact cause of the error can be determined by reading the Data Synchronous Trap Register, DSTR. For details of possible error conditions and the corresponding flag bits in DSTR, see [Table “CPUx Data Synchronous Trap Register” on Page 91](#).

## CPU Subsystem

### **DAE - Data Access Asynchronous Error (TIN 3)**

The Data Access Asynchronous Error Trap (DAE) is generated by the DMI module when a store or cache management access from the CPU encounters certain error conditions, such as an Bus error. When a DAE trap is generated, the exact cause of the error can be determined by reading the Data Asynchronous Trap Register, DATR. For details of possible error conditions and the corresponding flag bits in DATR, see [Table “CPUx Data Asynchronous Trap Register” on Page 92](#).

### **PIE Program Memory Integrity Error (TIN 5)**

The PIE trap is raised whenever an uncorrectable memory integrity error is detected in an instruction fetch from a local memory or the SRI bus. The trap is synchronous to the erroneous instruction. The trap is of Class-4 and has a TIN of 5.

Program memories are protected from memory integrity errors on a 64 bit basis. A non-inhibited PIE trap is raised when an attempt is made to execute an instruction from any fetch group containing a memory integrity error.

The PIEAR and PIETR registers may be interrogated to determine the source of any error more precisely. PIE traps are inhibited if PIETR.IED is set.

### **DIE Data Memory Integrity Error (TIN 6)**

The DIE trap is raised whenever an uncorrectable memory integrity error is detected in a data access to a local memory or the SRI bus. The trap is of Class-4 and has a TIN of 6.

DIE traps are always asynchronous independent of the operation which encountered the error.

A DIE trap is raised if any memory half word (local memory) or double word (SRI bus) accessed by a load/store operation contains an uncorrectable error and no other DIE trap have been raised since the clearing of the DIETR.IED bit. The DIEAR and DIETR registers may be interrogated to determine the source of any error more precisely. Subsequent DIE traps are inhibited if DIETR.IED is set.

### **MPX Memory Protection Execute (TIN 4)**

The MPX trap is raised whenever a program attempts to execute an instruction from a memory area for which it does not have execute permission and memory protection is enabled. The trap is of Class-1 and has a TIN of 4.

The TC1.6.2P compares the 64bit aligned fetch group address with the range(s) defined by the memory protection system to determine whether or not execution is permitted.

### **5.3.4.6 WAIT Instruction**

The WAIT instruction will suspend execution until the occurrence of one of the following events.

- Enabled Interrupt
- Non-Maskable Interrupt
- Asynchronous Trap
- Idle Request
- Suspend Request
- Asynchronous Debug Halt or Trap Request

### **5.3.4.7 Invalid Opcode**

The opcode 0x36 is invalid for all TC1.6.2P CPUs in Infineon AURIX™ devices. Unused program memory filled with 0x36363636 etc will generate a IOPC (Invalid Opcode) trap if execution is attempted.

## CPU Subsystem

### 5.3.4.8 Speculation extent

The TC1.6.2 CPU may perform both **necessary** and **speculative** accesses.

- **Necessary accesses** are those that the CPU is required to make to correctly compute the program
- **Speculative accesses** are those that the CPU may make in order to improve performance either in correct or incorrect anticipation of a necessary access.

The following speculative accesses are performed by the TC1.6.2P CPU

Speculative fetch accesses:- The processor may speculative fetch up to 64 bytes of instruction on the predicted execution path.

Speculative data read accesses:- For cached data locations the processor will read an entire cache containing data read for a required access.

The processor does not perform speculative instruction execution.

The processor does not perform speculative write accesses.

The processor does not perform speculative accesses to peripheral space.

### 5.3.4.9 Instruction Memory Range Limitations

To ensure the processor cores are provided with a constant stream of instructions the Instruction Fetch Units will speculatively fetch instructions from up to 64 bytes ahead of the current PC.

If the current PC is within 64 bytes of the top of an instruction memory the Instruction Fetch Unit may attempt to speculatively fetch instruction from beyond the physical memory range. This may then lead to error conditions and alarms being triggered by the bus and memory systems.

The upper 64 bytes of any memory should therefore not be used for instruction storage. This memory area should be initialised and written as “all zeros”.

### 5.3.4.10 Atomicity of Data Accesses

The data alignment rules along with the number of bus transactions for each access type are detailed in the following tables:

#### Alignment Rules

**Table 98 Alignment rules for non-peripheral space**

Access type	Access size	Alignment of address in memory	Min/Max number of SRI bus transactions
Load, Store Data Register	Byte	Byte ( $1_H$ )	1/1
	Half-Word	2 bytes ( $2_H$ )	1/1
	Word	2 bytes ( $2_H$ )	1/2 *
	Double-Word	2 bytes ( $2_H$ )	1/3 *
Load, Store Address Register	Word	4 bytes ( $4_H$ )	1/1
	Double-Word	4 bytes ( $4_H$ )	1/2 *
SWAP.W, LDMST, CMPSWAP.W, SWAPMSK.W, ST.T	Word	4 bytes ( $4_H$ )	1/1
Context Operations	16 x 32-bit registers	64 bytes ( $40_H$ )	2/2 *

## CPU Subsystem

**Table 99 Alignment rules for peripheral space**

Access type	Access size	Alignment of address in memory	Min/Max Number of SRI bus transactions	Min/Max Number of SPB bus transactions
Load, Store Data Register	Byte	Byte (1 <sub>H</sub> )	1/1	1/1
	Half-Word	2 bytes (2 <sub>H</sub> )	1/1	1/1
	Word	4 bytes (4 <sub>H</sub> )	1/1	1/1
	Double-Word	8 bytes (8 <sub>H</sub> )	1/1	1/1
Load, Store Address Register	Word	4 bytes (4 <sub>H</sub> )	1/1	1/1
	Double-Word	8 bytes (8 <sub>H</sub> )	1/1	1/1
SWAP.W, LDMST, ST.T CMPSWAP.W, SWAPMSK.W	Word	4 bytes (4 <sub>H</sub> )	1/1	1/1
Context Operations	16 x 32-bit registers	Not Permitted	-	-

In the case where a single access results in a single bus transaction atomicity of the data is preserved when viewed from any bus master.

In the case where a single access leads to multiple bus transactions (marked as “\*” in the above tables) then atomicity needs to be considered. In these accesses it is possible for another bus master to read or write the target memory location between the bus transactions required to complete the access.

In the case of word and double word access to the SRI bus the number of bus transactions will be 1 for naturally aligned data values and hence atomicity will be preserved.

The atomicity of data accesses to CPU CSFR registers is not guaranteed if the local processor is performing a MTCR instruction to the same CSFR register.

The instructions SWAP.W, LDMST, CMPSWAP.W, SWAPMSK.W, ST.T are always atomic in operation. They perform a word read followed by a word write to a word aligned memory location. Both read and write access permissions must exist for the word aligned address.

### 5.3.4.11 A11 usage

In normal usage A11 will always contain the target of the next RET or RFE instruction. The processor uses this fact to speculatively load the return target ahead of the execution of the RET/RFE instruction. Code that modifies the A11 (e.g. test code) should be aware that any value stored in A11 may be used as the target of such speculation. If the value in A11 is not a valid address the speculation may lead to error conditions and alarms being triggered by the bus and memory systems.

It is therefore recommended that A11 should only ever contain a valid address value.

### 5.3.4.12 Independent Core Kernel Reset

The CPU core may be reset while the rest of the system remains operational. A module reset can be triggered by the safety management unit (SMU) or by writing ‘1’ into both of the module reset registers CPU\_KRST1.RST and register CPU\_KRST0.RST.

The cause of the last reset to occur is indicated by the CPU\_KRST0.RSTSTAT0/1 bits. The status bits may be cleared by writing CPU\_KRSTCLR.CLR to one.

The CPU\_KRSTCLR, CPU\_KRST1 and CPU\_KRST0 registers are protected by system\_endinit.

Registers related to the Debug Reset (Class 1) and the FLASHCON registers are not influenced by the kernel reset.

---

## CPU Subsystem

### 5.3.4.12.1 Kernel Reset Registers

The following registers control the operation of the kernel reset functionality.

## CPU Subsystem

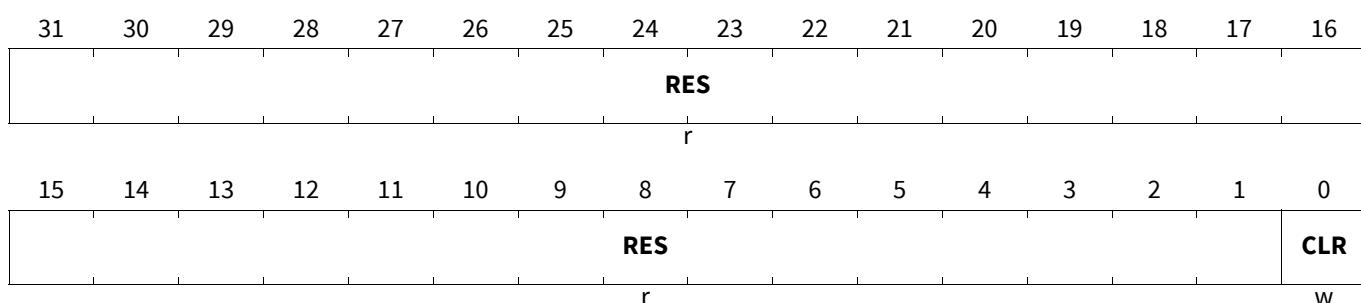

### Register Descriptions

#### CPUx Reset Clear Register

The Kernel Reset Register Clear register is used to clear the Kernel Reset Status bits (CPU\_KRST0.RSTSTAT). This register is protected by system registers ENDINIT.

#### KRSTCLR

**CPUx Reset Clear Register** **(0D008<sub>H</sub>)** **Application Reset Value: 0000 0000<sub>H</sub>**

Field	Bits	Type	Description
CLR	0	w	<b>Kernel Reset Status Clear</b> Read always as 0. $0_B$ No action $1_B$ Clear Kernel Reset Status KRST0.RSTSTAT[1:0]
RES	31:1	r	<b>Reserved</b> Read as 0; should be written with 0.

#### CPUx Reset Register 0

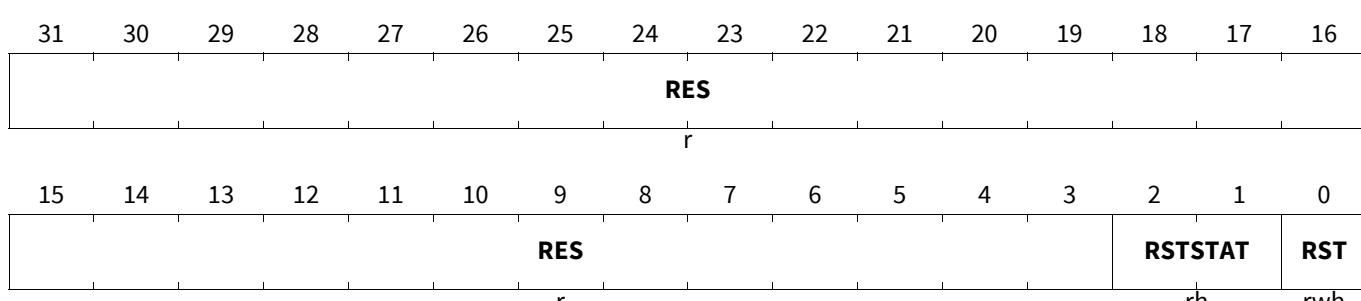

The CPU Kernel Reset Register 0 is used to reset the CPU kernel. CPU registers related to the Debug Reset (Class 1) and the FLASHCON registers are not influenced. To reset a module kernel it is necessary to set the RST bits by writing with '1' in both CPU Kernel Reset Registers. The RST bits will be re-set at the end of the kernel reset sequence.

CPU Kernel Reset Register 0 includes a kernel reset status bits that is set to '1' at the start of the reset sequence. These bit can be used to detect that a kernel reset was processed. These bits can be re-set to '0' by writing '1' to the related KRSTCLRx.CLR register bit.

This register is protected by system registers ENDINIT.

#### KRST0

**CPUx Reset Register 0** **(0D000<sub>H</sub>)** **Application Reset Value: 0000 0000<sub>H</sub>**

## CPU Subsystem

Field	Bits	Type	Description
<b>RST</b>	0	rwh	<p><b>Kernel Reset</b></p> <p>This reset bit can be used to request a kernel reset. The kernel reset will be executed if the reset bits of both kernel registers are set.</p> <p>The RST bit will be cleared (re-set to '0') by the BPI_FPI after the kernel reset was executed.</p> <p>0<sub>B</sub> No kernel reset was requested 1<sub>B</sub> A kernel reset was requested</p>
<b>RSTSTAT</b>	2:1	rh	<p><b>Kernel Reset Status</b></p> <p>This bit indicates whether a kernel reset was executed or not. This bit is set immediately after the execution of a kernel reset.</p> <p>These bits can be cleared by writing '1' to the CLR bit in the related KRSTCLR register.</p> <p>00<sub>B</sub> No kernel reset was executed 01<sub>B</sub> Kernel reset was requested by hardware since last clear (SMU) 10<sub>B</sub> Kernel reset was requested by software since last clear (KRST)</p>
<b>RES</b>	31:3	r	<p><b>Reserved</b></p> <p>Read as 0; should be written with 0.</p>

### CPUx Reset Register 1

The CPU Kernel Reset Register 1 is used to reset the CPU kernel. To reset the CPU kernel it is necessary to set the RST bits by writing with '1' in both Kernel Reset Registers CPU\_KRSTx1.RST and CPU\_KRSTx0.RST). The RST bit will be re-set at end of the reset sequence. This register is protected by system registers ENDINIT.

---

**CPU Subsystem****5.3.4.13 CPU Clock Control**

The effective CPU execution frequency may be reduced by programming the associated CCUCONn.CPUxDIV register (Where x is the core number). The effective execution frequency seen by the processor is given by the following equation.

(5.1)

$$f_{\text{cpu}} = f_{\text{sri}} \frac{(64 - \text{CPUxDIV})}{64}$$

Where Fcpu is the effective frequency seen by the processor and Fsri is the base SRI frequency. A CPUxDIV value of 0 results in the core being clocked at the SRI frequency (no frequency reduction).

To avoid synchronisation issues typically associated with clock division the clock control mechanism stalls the issue of instructions into the processor pipeline rather than by modifying the actual applied clock. An incoming instruction fetch packet is stalled for the number of cycles required to approximate the required execution frequency. The stall is seen by the processor as a stall in the instruction stream in the same way a stalling instruction memory would be seen.

In most scenarios this mechanism provides a good approximation to clock division based control. The actual reduction in effective frequency will be dependent on the code executed.

## CPU Subsystem

### 5.3.4.14 CPU Core Special Function Registers (CSFR)

This section describes implementation specific features of the Core Special Function Registers.

#### 5.3.4.14.1 Registers

The implementation-specific Program Status Word Register (PSW) is an extension of the PSW description in the TriCore Architecture Manual. The status flags used for FPU operations overlay the status flags used for Arithmetic Logic Unit (ALU) operations.

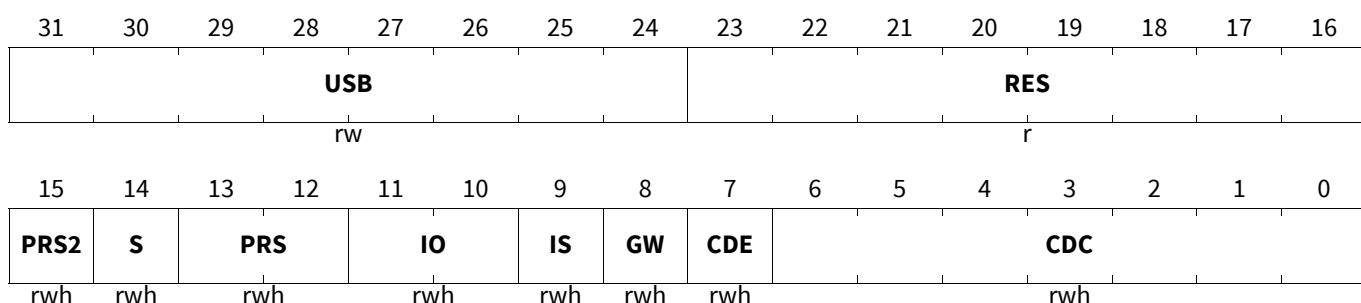

##### CPUx Program Status Word

###### PSW

**CPUx Program Status Word** **(1FE04<sub>H</sub>)** **Application Reset Value: 0000 0B80<sub>H</sub>**

###### CPU\_PSW

**Short address for domain CSFR** **(0FE04<sub>H</sub>)** **Application Reset Value: 0000 0B80<sub>H</sub>**

Field	Bits	Type	Description
CDC	6:0	rwh	<p><b>Call Depth Counter</b></p> <p>Consists of two variable width subfields. The first subfield consists of a string of zero or more initial 1 bits, terminated by the first 0 bit. The remaining bits form the second subfield (CDC.COUNT) which constitutes the Call Depth Count value. The count value is incremented on each Call and is decremented on a Return.</p> <p>0cccccc<sub>B</sub> : 6-bit counter; trap on overflow.</p> <p>10cccccc<sub>B</sub> : 5-bit counter; trap on overflow.</p> <p>110cccccc<sub>B</sub> : 4-bit counter; trap on overflow.</p> <p>1110ccc<sub>B</sub> : 3-bit counter; trap on overflow.</p> <p>11110cc<sub>B</sub> : 2-bit counter; trap on overflow.</p> <p>111110c<sub>B</sub> : 1-bit counter; trap on overflow.</p> <p>1111110<sub>B</sub> : Trap every call (Call Trace mode).</p> <p>1111111<sub>B</sub> : Disable Call Depth Counting.</p> <p>When the call depth count (CDC.COUNT) overflows a trap (CDO) is generated.</p> <p>Setting the CDC to 1111110<sub>B</sub> allows no bits for the counter and causes every call to be trapped. This is used for Call Depth Tracing.</p> <p>Setting the CDC to 1111111<sub>B</sub> disables Call Depth Counting.</p>

## CPU Subsystem

Field	Bits	Type	Description
CDE	7	rwh	<p><b>Call Depth Count Enable</b>            Enables call-depth counting, provided that the PSW.CDC mask field is not all set to 1.            If PSW.CDC = 1111111<sub>B</sub>, call depth counting is disabled regardless of the setting on the PSW.CDE bit.</p> <p>0<sub>B</sub> Call depth counting is temporarily disabled. It is automatically re-enabled after execution of the next Call instruction.</p> <p>1<sub>B</sub> Call depth counting is enabled.</p>
GW	8	rwh	<p><b>Global Address Register Write Permission</b>            Determines whether the current execution thread has permission to modify the global address registers. Most tasks and ISRs use the global address registers as ‘read only’ registers, pointing to the global literal pool and key data structures. However a task or ISR can be designated as the ‘owner’ of a particular global address register, and is allowed to modify it. The system designer must determine which global address variables are used with sufficient frequency and/or in sufficiently time-critical code to justify allocation to a global address register. By compiler convention, global address register A[0] is reserved as the base register for short form loads and stores. Register A[1] is also reserved for compiler use. Registers A[8] and A[9] are not used by the compiler, and are available for holding critical system address variables.</p> <p>0<sub>B</sub> Write permission to global registers A[0], A[1], A[8], A[9] is disabled.</p> <p>1<sub>B</sub> Write permission to global registers A[0], A[1], A[8], A[9] is enabled.</p>
IS	9	rwh	<p><b>Interrupt Stack Control</b>            Determines if the current execution thread is using the shared global (interrupt) stack or a user stack.</p> <p>0<sub>B</sub> User Stack. If an interrupt is taken when the IS bit is 0, then the stack pointer register is loaded from the ISP register before execution starts at the first instruction of the Interrupt Service Routine (ISR).</p> <p>1<sub>B</sub> Shared Global Stack. If an interrupt is taken when the PSW.IS bit is 1, then the current value of the stack pointer is used by the Interrupt Service Routine (ISR).</p>

## CPU Subsystem

Field	Bits	Type	Description
<b>IO</b>	11:10	rwh	<b>Access Privilege Level Control (I/O Privilege)</b> Determines the access level to special function registers and peripheral devices. 00 <sub>B</sub> User-0 Mode No peripheral access. Access to memory regions with the peripheral space attribute are prohibited and results in a PSE or MPP trap. This access level is given to tasks that need not directly access peripheral devices. Tasks at this level do not have permission to enable or disable interrupts. 01 <sub>B</sub> User-1 Mode Regular peripheral access. Enables access to common peripheral devices that are not specially protected, including read/write access to serial I/O ports, read access to timers, and access to most I/O status registers. Tasks at this level may disable interrupts. 10 <sub>B</sub> Supervisor Mode Enables access to all peripheral devices. It enables read/write access to core registers and protected peripheral devices. Tasks at this level may disable interrupts. 11 <sub>B</sub> Reserved

### CPUX Data Access Cacheability Register

The Physical Memory Attributes registers (PMA0,PMA1,PMA2) define the physical memory attribute for each segment in the physical address space. The register is CPUX ENDINIT protected and can be read with the MFCR instruction and written by the MTCR instruction. Note that when changing the value of the registers both the instruction and data caches should be invalidated, a DSYNC instruction should be executed immediately prior to the MTCR with an ISYNC instruction executed immediately following. This is required to maintain coherency of the processors view of memory.

The register PMA0 defines the data access cacheability of the segment in the physical address space. If bit n in the register is set then segment-n will be seen as cacheable for data accesses.

PMA0 is freely programmable with the following restrictions:

- In PMA0 Segment-C and Segment[7-CORE\_ID] must have the same value.

Irrespective of the setting of the PMA registers the following constraints are always enforced.

- Segments-F and segment-E are constrained to be Peripheral space and hence non-cacheable.
- Segment-A is constrained to be non-cacheable memory
- Segment-D and Segment[7-CORE\_ID] are constrained to be non-cacheable for data accesses.

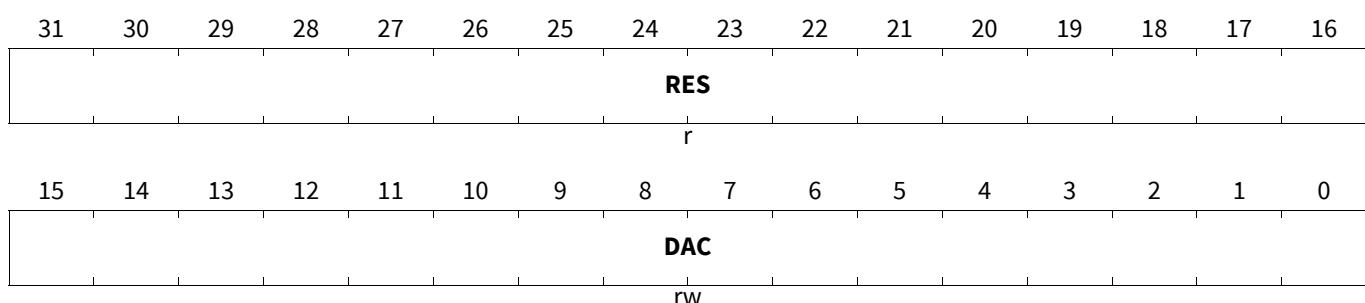

## CPU Subsystem

Field	Bits	Type	Description
SRC3	31:0	rh	<b>Captured SRC3 Operand</b> The SRC3 operand of the captured instruction. Only valid when FPU_TRAP_CON.TST is asserted.

#### 5.3.4.17 CPU Memory Protection Registers

There are six Memory Protection Register Sets per CPU. The sets specify memory protection ranges and permissions for code and data. The PSW.PRS bit field determines which of these sets is currently in use by the CPU. (Note: the three bit PRS field is composed as PRS[2:0] == {PSW[15],PSW[13],PSW[12]})

The CPUs each implement 18 data and 10 code range comparators. These may be flexibly shared amongst the protection sets to provide a maximum of 18 data ranges and 10 code ranges per set.

The protection registers protect the whole address space (In previous TriCore implementations the memory protection system did not cover peripheral space.) The granularity of the protection ranges is 8 bytes for data and 32bytes for code.

Code protection ranges define which memory areas the CPU may fetch instructions from. Instruction fetches from an area outside a valid code protection range will lead to a trap condition.

Data protection ranges define which memory areas the CPU may access for read and/or write operations. Each range may be separately enabled for read and/or write access. Data read accesses from an area outside a valid data protection range with read permissions will lead to a trap condition. Data write accesses to an area outside a valid data protection range with write permissions will lead to a trap condition.

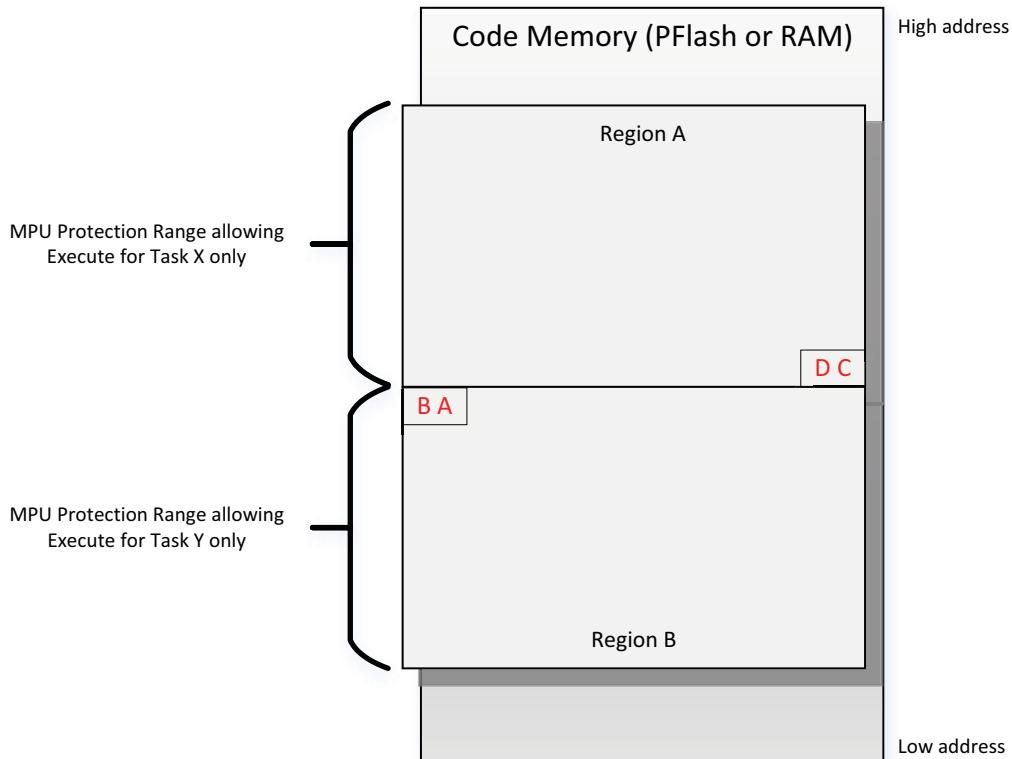

There are no implementation specific features of the Memory Protection Registers. They are described in detail in the TriCore Architecture Manual.

#### Crossing protection boundaries

When protection is enabled the TC1.6.2P checks the base address of instruction fetch and data access operations against the enabled MPU protection ranges. If this base address is outside of the enabled protection ranges a trap will be raised. The TC1.6.2P does not check the full extent of instruction fetch or data access. An instruction fetch or data access that starts at the very top of an enabled region may therefore extend into a non-enabled region without triggering a trap condition.

## CPU Subsystem

In the following example a 4-byte instruction “DCBA” is placed at valid location “A” in protection Region-B but extends into invalid Region-A. Execution of this instruction will not lead to an MPX trap condition even though a portion of the instruction extends into an invalid region.

**Figure 50 Crossing protection boundaries**

To maintain separation between protection regions the following buffers regions should be placed between each memory protection region.

Code protection regions

- Buffer size 2 Bytes<sup>1)\*</sup>

Data protection regions containing STLCX or STUCX context data

- Buffer size 56 Bytes

Data protection regions not containing STLCX or STUCX context data

- Buffer size 6 bytes\*

1) In reality the minimum buffer size will be 8-bytes due to protection region granularity.

## CPU Subsystem

**5.3.4.18 Temporal Protection Registers**

To guard against task runtime overrun the CPU implements a temporal protection system. This system consists of three independent decrementing counters (TPS\_TIMERn) arranged to generate a Temporal Asynchronous Error trap (TAE - Class-4, Tin-7) on decrement to zero. A control register (TPS\_CON) contains status and control bits for temporal protection system. The temporal protection system is enabled by the SYSCON.TPROTEN register bit. The Temporal Protection Registers are Core Special Function Registers. They are described in detail in the TriCore Architecture Manual.

While the CPU is in Suspen the temporal protection timer clocks are frozen. The Timers will restart once the CPU leaves Suspend mode.

**5.3.4.18.1 Temporal Protection Registers****CPUx Temporal Protection System Control Register**

### CPUX Temporal Protection System Timer Register y

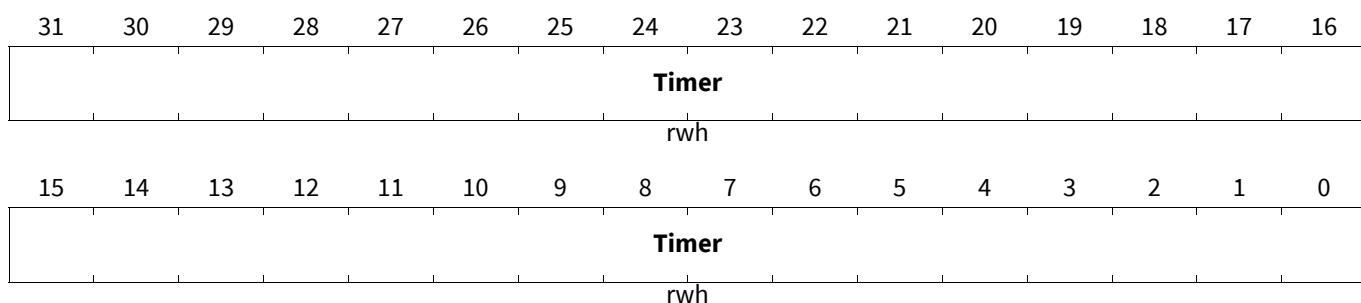

Definition of the Temporal Protection System Timer register y.

#### TPS\_TIMERy (y=0-2)

**CPUX Temporal Protection System Timer Register y(1E404<sub>H</sub>+y\*4) Application Reset Value: 0000 0000<sub>H</sub>**

#### CPU\_TPS\_TIMERy (y=0-2)

**Short address for domain CSFR (0E404<sub>H</sub>+y\*4) Application Reset Value: 0000 0000<sub>H</sub>**

Field	Bits	Type	Description
Timer	31:0	rwh	<b>Temporal Protection Timer</b> Writing zero de-activates the Timer. Writing a non-zero value starts the Timer. Any write clears the corresponding TPS_CON.TEXP flag. Read returns the current Timer value.

#### 5.3.4.19 Exception Timer

For AURIX™ the temporal protection system is extended to include a dedicated exception timer. If a selected Trap or NMI is not serviced within a defined time period a safety alarm is generated. The exception timer is part of the TriCore temporal protection system and must be enabled by setting the SYSCON.TPROTEN bit.

There are two distinct periods during the handling of an exception. The first period is between the CPU receiving a trap request and the start of the entry sequence for that particular trap. The second period is between trap handler entry and the exit of the trap handler with an RFE instruction. These two periods are separately timed with an 12-bit exception entry timer and a 24-bit exception exit timer respectively.

The exception entry timer is loaded with a predefined value on receipt of an enabled class of NMI or trap, it then decrements each cycle until the entry sequence for the trap is detected. If the timer decrements to zero a safety alarm is raised to be handled by the SMU.

The detailed function of the exception entry timer is as follows:-

- The exception entry timer load value is held in the register TPS\_EXTIM\_ENTRY\_LVAL.ENTRY\_LVAL.
- If the ENTRY\_LVAL value is zero the exception entry timer is disabled.
- The four least significant bits of ENTRY\_LVAL are constrained to be zero.
- The exception entry timer current value is held in the register TPS\_EXTIM\_ENTRY\_CVAL.ENTRY\_CVAL
- When inactive the exception entry timer has a ENTRY\_CVAL value of 0.
- If inactive then on receipt of an exception entry timer start request the exception entry timer will be loaded with the ENTRY\_LVAL value and start decrementing. If the exception entry timer has a non-zero value when a start request is received then no action is taken.

## CPU Subsystem

- If the exception entry timer is inactive then on an exception entry timer start request the class and tin of the requesting trap are recorded in the TPS\_EXTIM\_STAT.ENTRY\_CLASS and TPS\_EXTIM\_STAT.ENTRY\_TIN registers.
- The exception entry timer will decrement by 1 on each processor clock when non-zero. If it decrements from 1 to 0 a timeout alarm is generated to the SMU.
- An exception entry timer start request is generated on receipt of a trap or NMI request for an enabled trap class.
- The register TPS\_EXTIM\_CLASS\_EN contains an 8 bit field with a separate enable for each of the defined trap classes. Only classes of trap for which the enable bit is set will generate an exception entry timer start request.
- The exception entry timer stops decrementing when an entry sequence commences for the trap which generated the start request. The TPS\_EXTIM\_ENTRY\_CVAL.EXIT\_CVAL, TPS\_EXTIM\_ENTRY\_STAT.ENTRY\_CLASS and TPS\_EXTIM\_ENTRY\_STAT.ENTRY\_TIN are cleared
- In the AURIX™ TriCore implementation synchronous traps are always taken as soon as they are requested hence only asynchronous traps and NMIs are timed by the exception entry timer.
- When the exception entry timer is disabled, TPS\_EXTIM\_STAT.ENTRY\_CLASS and TPS\_EXTIM\_STAT.ENTRY\_TIN are set to 0 unless either \_AT bits of the TPS\_EXTIM\_STAT register is set

The exception exit timer is loaded with a predefined value on detection of an entry sequence for an enabled class of trap or NMI, then decrements each cycle until the RFE indicating the exit of the trap or NMI handler is detected. If the timer decrements to zero a safety alarm is raised to be handled by the SMU.

The detailed function of the exception exit timer is as follows:-

- The exception exit timer load value is held in the register TPS\_EXTIM\_EXIT\_LVAL.EXIT\_LVAL
- If the EXIT\_LVAL value is zero the exception exit timer is disabled.
- The four least significant bits of EXIT\_LVAL are constrained to be zero.
- The exception exit timer current value is held in the register TPS\_EXTIM\_EXIT\_CVAL.EXIT\_CVAL
- When inactive the exception exit timer has a EXIT\_CVAL value of 0.
- If inactive then on receipt of an exception exit timer start request the exception exit timer will be loaded with the EXIT\_LVAL value and start decrementing. If the exception exit timer has a non-zero value when a start request is received then no action is taken.
- If the exception exit timer is inactive then on an exception exit start request the current value of FCX is recorded in the TPS\_EXTIM\_STAT.EXIT\_FCX register and the class and tin of the trap are recorded in the TPS\_EXTIM\_STAT.EXIT\_CLASS and TPS\_EXTIM\_STAT.EXIT\_TIN registers.
- The exception exit timer will decrement by 1 on each processor clock when non-zero. If it decrements from 1 to 0 a timeout alarm is generated to the SMU.
- An exception exit timer start request is generated on entry to a trap or NMI handler for an enabled trap class.
- The register TPS\_EXTIM\_CLASS\_EN contains an 8bit field with a separate enable for each of the defined trap or NMI classes. Only classes of trap for which the enable bit is set will generate an exception exit timer start request.
- The exception exit timer stops decrementing when an RFE is executed for the trap which generated the start request. The TPS\_EXTIM\_EXIT\_CVAL.EXIT\_CVAL, TPS\_EXTIM\_FCX.EXIT\_FCX, TPS\_EXTIM\_STAT.EXIT\_CLASS and TPS\_EXTIM\_STAT.EXIT\_TIN are cleared
- To ensure the exit timer is only stopped for the correct trap the current FCX value at exit timer start is stored into the TPS\_EXTIM\_FCX.EXIT\_FCX register. On execution of an RFE instruction the return FCX value (the value of FCX after the RFE) is compared with the FCX value held in the TPS\_EXTIM\_FCX.EXIT\_FCX register. If they match then this indicates the successful completion of the trap handler and the exception exit timer is cleared to zero.

## CPU Subsystem

- When the exception exit timer is disabled, TPS\_EXTIM\_STAT.EXIT\_CLASS, TPS\_EXTIM\_STAT.EXIT\_TIN and TPS\_EXTIM\_FCX are set to 0 unless either \_AT bits of the TPS\_EXTIM\_STAT register is set.

The current status of the exception timer is held in the TPS\_EXTIM\_STAT register:-

- If the exception entry timer times out the TPS\_EXTIM\_STAT.ENTRY\_AT bit is set and an alarm raised to the SMU
- If the exception exit timer times out the TPS\_EXTIM\_STAT.EXIT\_AT bit is set and an alarm raised to the SMU
- If either of the \_AT bits is set then the current state of the TPS\_EXTIM\_ENTRY\_CVAL, TPS\_EXTIM\_EXIT\_CVAL, TPS\_EXTIM\_FCX and TPS\_EXTIM\_STAT register are held until the TPS\_EXTIM\_STAT register is cleared.
- The exception timer may be stopped and cleared by writing the reverse of the current TPS\_EXTIM\_STAT contents to the TPS\_EXTIM\_STAT register location (all other values will be ignored). This allows trap handlers to safely modify the context save areas where required without risk of reset. The TPS\_EXTIM\_ENTRY\_CVAL, TPS\_EXTIM\_EXIT\_CVAL, EXTIM\_EXIT\_FCX and TPS\_EXTIM\_STAT registers are cleared by this operation.
- If an enabled asynchronous trap is pending (i.e. the entry timer is active) then attempting to stop the exception timer by writing the TPS\_EXTIM\_STAT register will not result in the entry timer being reset.
- The exception timer system is clocked whenever the primary clock input to the core is active (it is therefore active during idle).

## CPU Subsystem

### 5.3.4.19.1 Exception Timers Registers

#### CPUx Exception Entry Timer Load Value

This register contains the count value to be loaded into the exception timer on detection of an enabled exception.

##### TPS\_EXTIM\_ENTRY\_LVAL

CPUx Exception Entry Timer Load Value **(1E440<sub>H</sub>)**

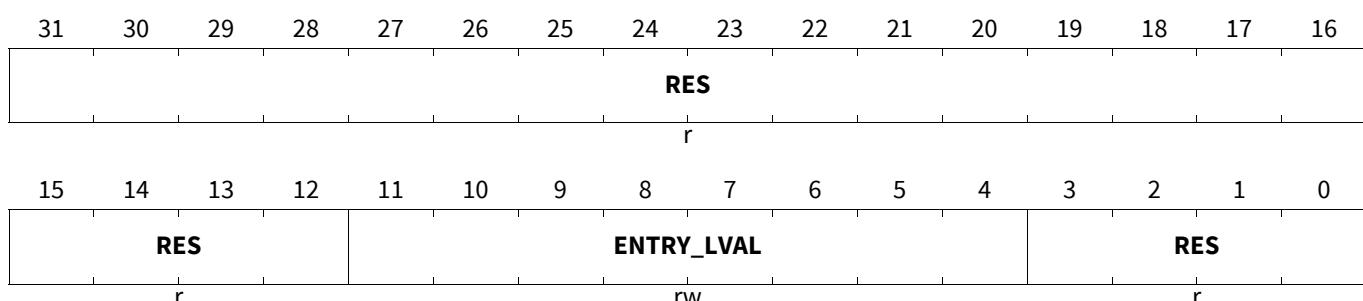

**Application Reset Value: 0000 0000<sub>H</sub>**

##### CPU\_TPS\_EXTIM\_ENTRY\_LVAL

Short address for domain CSFR

**(0E440<sub>H</sub>)**

**Application Reset Value: 0000 0000<sub>H</sub>**

Field	Bits	Type	Description
<b>RES</b>	3:0, 31:12	r	<b>Reserved</b> The lower 4 bits are not writeable and always return zero
<b>ENTRY_LVAL</b>	11:4	rw	<b>Exception Entry Timer Load value</b> Value loaded into the exception entry timer on detection of an enabled exception. Bits [3:0] are constrained to be 0

#### CPUx Exception Exit Timer Load Value

This register contains the count value to be loaded into the exception timer on detection of an enabled exception.

##### TPS\_EXTIM\_EXIT\_LVAL

CPUx Exception Exit Timer Load Value **(1E448<sub>H</sub>)**

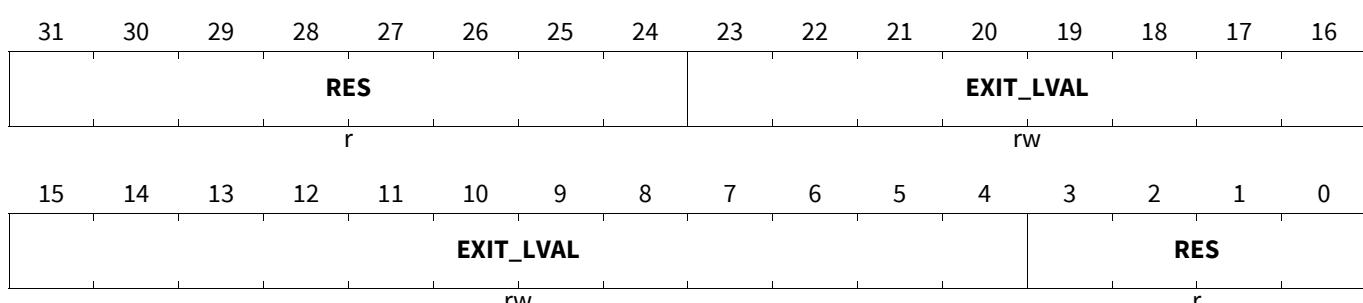

**Application Reset Value: 0000 0000<sub>H</sub>**

##### CPU\_TPS\_EXTIM\_EXIT\_LVAL

Short address for domain CSFR

**(0E448<sub>H</sub>)**

**Application Reset Value: 0000 0000<sub>H</sub>**

Field	Bits	Type	Description
<b>RES</b>	3:0, 31:24	r	<b>Reserved</b> The lower 4 bits are not writeable and always return zero

**CPU Subsystem**

Field	Bits	Type	Description
<b>EXIT_LVAL</b>	23:4	rw	<b>Exception Exit Timer Load value</b> Value loaded into the exception exit timer on detection of an enabled exception. Bits [3:0] are constrained to be 0

**CPUx Exception Entry Timer Current Value**

This register contains the current count value of the exception entry timer. A non-zero value indicates that the counter is active.

**TPS\_EXTIM\_ENTRY\_CVAL**

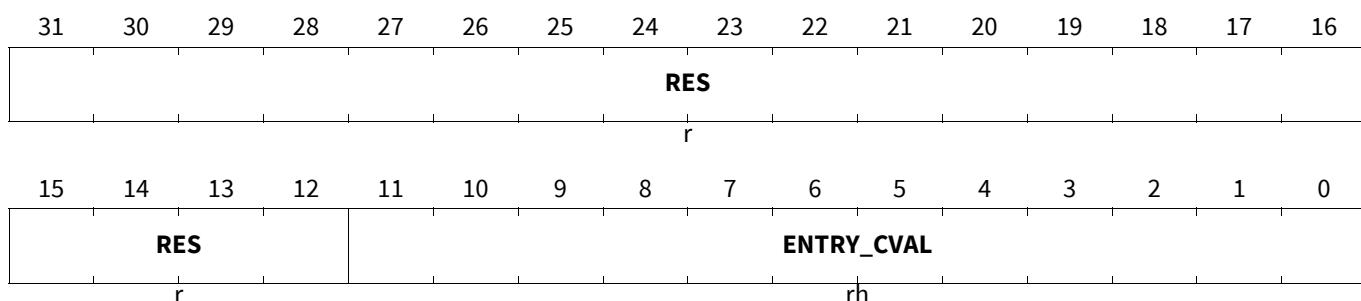

**CPUx Exception Entry Timer Current Value** **(1E444H)**

**Application Reset Value: 0000 0000H**

**CPU\_TPS\_EXTIM\_ENTRY\_CVAL**

**Short address for domain CSFR** **(0E444H)**

**Application Reset Value: 0000 0000H**

Field	Bits	Type	Description
<b>ENTRY_CVAL</b>	11:0	rh	<b>Exception Entry Timer Current Value</b> Current value of the exception entry timer.
<b>RES</b>	31:12	r	<b>Reserved</b>

**CPUx Exception Exit Timer Current Value**

This register contains the current count value of the exception exit timer. A non-zero value indicates that the counter is active.

**TPS\_EXTIM\_EXIT\_CVAL**

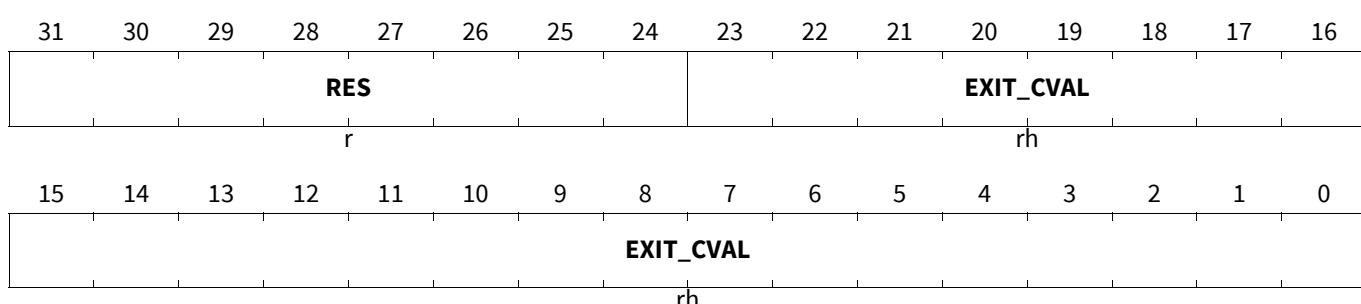

**CPUx Exception Exit Timer Current Value** **(1E44CH)**

**Application Reset Value: 0000 0000H**

**CPU\_TPS\_EXTIM\_EXIT\_CVAL**

**Short address for domain CSFR** **(0E44CH)**

**Application Reset Value: 0000 0000H**

## CPU Subsystem

Field	Bits	Type	Description
<b>EXIT_CVAL</b>	23:0	rh	<b>Exception Exit Timer Current Value</b> Current value of the exception exit timer.
<b>RES</b>	31:24	r	<b>Reserved</b>

### CPUx Exception Timer Class Enable Register

This register contains the class enables for the exception timer. Only those traps with an enabled class will trigger an exception timer start.

#### TPS\_EXTIM\_CLASS\_EN

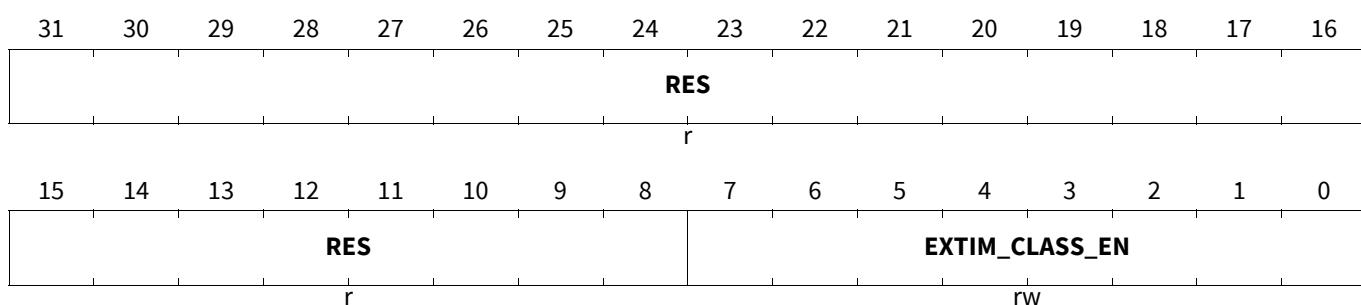

**CPUx Exception Timer Class Enable Register**  $(1E450_H)$

**Application Reset Value:** 0000 0000<sub>H</sub>

#### CPU\_TPS\_EXTIM\_CLASS\_EN

**Short address for domain CSFR**  $(0E450_H)$

**Application Reset Value:** 0000 0000<sub>H</sub>

Field	Bits	Type	Description
<b>EXTIM_CLASS_EN</b>	7:0	rw	<b>Exception Timer Class Enables</b> Trap Class enables for exception timer.
<b>RES</b>	31:8	r	<b>Reserved</b>

### CPUx Exception Timer Status Register

This register contains information of the last trap to trigger the exception timer. A write of the reverse of the current value to this register will stop the exception timer and clear this register and the TPS\_EXTIM\_CVAL and TPS\_EXTIM\_FCX register.

#### TPS\_EXTIM\_STAT

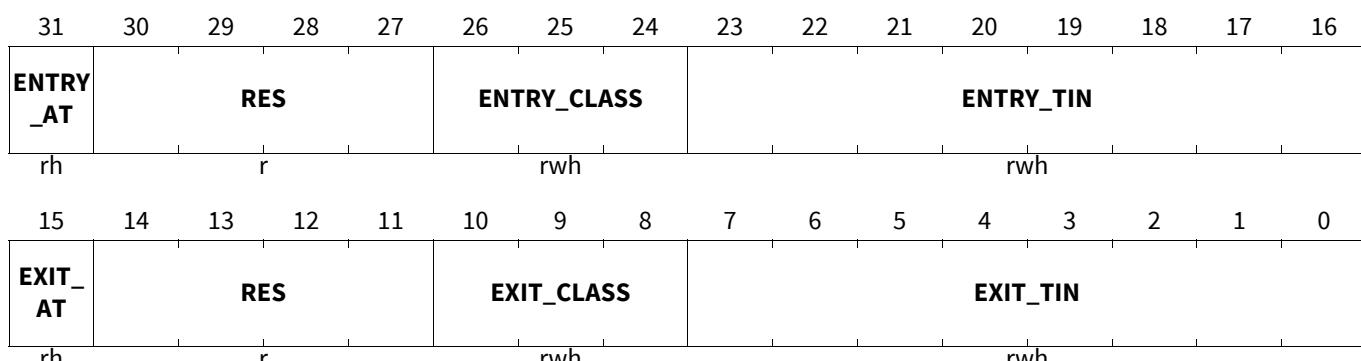

**CPUx Exception Timer Status Register**  $(1E454_H)$

**Application Reset Value:** 0000 0000<sub>H</sub>

#### CPU\_TPS\_EXTIM\_STAT

**Short address for domain CSFR**  $(0E454_H)$

**Application Reset Value:** 0000 0000<sub>H</sub>

## CPU Subsystem

Field	Bits	Type	Description
<b>EXIT_TIN</b>	7:0	rwh	<b>Exception Exit Timer TIN</b> Exception Exit Timer TIN of triggering trap.
<b>EXIT_CLASS</b>	10:8	rwh	<b>Exception Exit Timer Class</b> Exception exit Timer Class of triggering trap.
<b>RES</b>	14:11, 30:27	r	<b>Reserved</b>
<b>EXIT_AT</b>	15	rh	<b>Exception Exit Timer Alarm Triggered</b> Exception Exit Timer Alarm triggered sticky bit. Alarm triggered since last cleared.
<b>ENTRY_TIN</b>	23:16	rwh	<b>Exception Entry Timer TIN</b> Exception Entry Timer TIN of triggering trap.
<b>ENTRY_CLASS</b>	26:24	rwh	<b>Exception Entry Timer Class</b> Exception Entry Timer Class of triggering trap.
<b>ENTRY_AT</b>	31	rh	<b>Exception Entry Timer Alarm Triggered</b> Exception Entry Timer Alarm triggered sticky bit. Alarm triggered since last cleared.

### CPUx Exception Timer FCX Register

This register contains FCX information of the last trap to trigger the exception exit timer.

#### TPS\_EXTIM\_FCX

#### CPUx Exception Timer FCX Register

(1E458<sub>H</sub>)

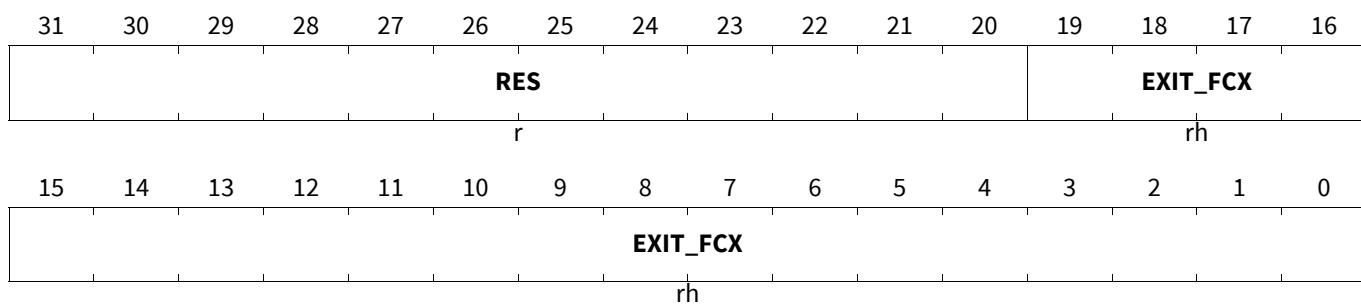

Application Reset Value: 0000 0000<sub>H</sub>

#### CPU\_TPS\_EXTIM\_FCX

#### Short address for domain CSFR

(0E458<sub>H</sub>)

Application Reset Value: 0000 0000<sub>H</sub>

Field	Bits	Type	Description
<b>EXIT_FCX</b>	19:0	rh	<b>Exception Exit Timer FCX</b> Exception Exit Timer FCX of triggering trap.
<b>RES</b>	31:20	r	<b>Reserved</b>

## CPU Subsystem

### 5.3.4.20 Memory Integrity Registers

To monitor and debug the integrity of the memory subsystems the following registers are provided.

#### 5.3.4.20.1 Register Descriptions

##### Program Integrity Error Information Registers

Two architecturally visible registers (PIETR, PIEAR) allow software to localise the source of the last detected program memory integrity error.

These registers are updated when a program integrity error condition is detected and the PIETR.IED bit is zero. On update the PIETR.IED bit is set to one and remains set until cleared by software. Whilst PIETR.IED is set further hardware updates of PIETR and PIEAR are inhibited. The various error scenarios are defined below.

##### Program Integrity errors during instruction fetch from program memory

When an error is detected during a program fetch from a program memory the IE\_S, IE\_C, IE\_T, IE\_LPB bits are updated to denote in which memory structure the error was detected. If the IE\_C bit is set the E\_INFO field will be updated with the cache way. The PIEAR register is updated with the address of the access. If the error detected is an uncorrectable bit error the IE\_UNC bit is set, The IED bit is set and all other PIETR register bits are set to zero. Since instruction fetches are speculative, the PIETR and PIEAR registers may be updated without a corresponding PIE trap

##### Program Integrity errors during a memory read initiated by an external access

When an error is detected during an external bus read from program memory the IE\_S, IE\_C bits are updated to denote in which memory structure the error was detected. The IE\_BS is set and E\_INFO updated. The PIEAR register is updated with the address of the access. If the error detected is an uncorrectable error the IE\_UNC bit is set, The IED bit is set and all other PIETR register bits are set to zero. Note that a memory read can be generated by a sub word write operation. The IE\_C bit can only ever be set if the cache is mapped into memory in SIST mode. In this case the E\_INFO field indicates the tag of the requesting master.

##### Program Integrity errors due to safety protection

When a safety protection violation is detected during a program memory access or during access to the CPU registers the IE\_SP, IE\_BS bits are set and the E\_INFO field updated. The PIEAR register is updated with the address of the access. The IED bit is set and all other PIETR register bits are set to zero.

##### Program Integrity errors due to ECC errors at the bus interface

When an ECC error is detected at the program bus interface (either master or slave) the IE\_BI bit is set. If the error is during an external access the IE\_BS bit is set and the E\_INFO fields updated. The PIEAR register is updated with the address of the access. If the error detected is an uncorrectable error the IE\_UNC bit is set. The IED bit is set and all other PIETR register bits are set to zero. If an ECC error is detected in the address phase of a request at the bus slave interface Then the IE\_ADDR and IED bits are set, all other bits are cleared.

##### Program integrity error - Memory Test Mode Violation

The PIETR.IE\_MTMV bit is set if the cache controller attempt to access the PMem (PCache/PSPR) or Ptag memories while they are in a test mode.

## CPU Subsystem

### CPUx Program Integrity Error Trap Register

#### PIETR

CPUx Program Integrity Error Trap Register (19214<sub>H</sub>)

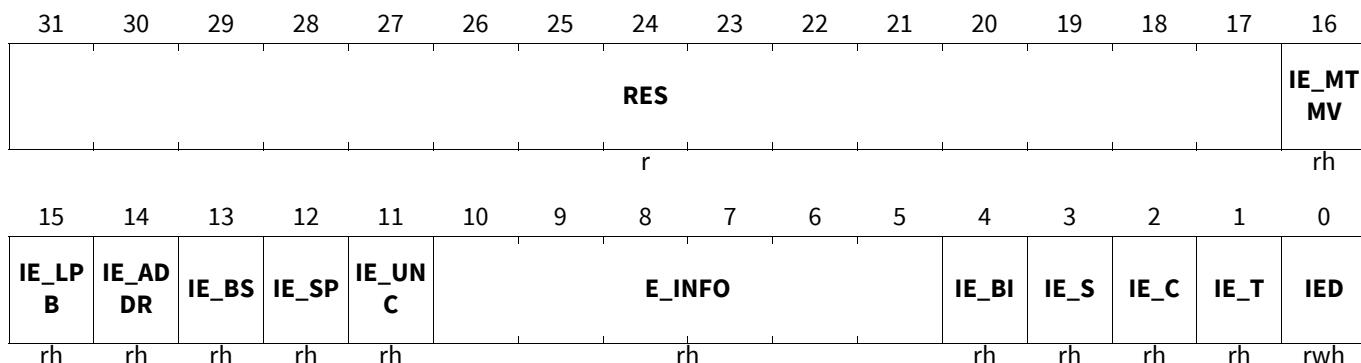

Application Reset Value: 0000 0000<sub>H</sub>

#### CPU\_PIETR

Short address for domain CSFR

(09214<sub>H</sub>)

Application Reset Value: 0000 0000<sub>H</sub>

Field	Bits	Type	Description
<b>IED</b>	0	rwh	<b>Integrity Error Detected</b> 0 <sub>B</sub> Write: Clear IED bit, re-enable PIETR and PIEAR update. Read : No data integrity error condition occurred 1 <sub>B</sub> Write : No Effect. Read: Data integrity error condition detected. <b>IE_BS</b>	13	rh	<b>Bus Slave Access Indicator</b>
<b>IE_ADDR</b>	14	rh	<b>Address Phase error detected at SRI slave interface</b>
<b>IE_LPB</b>	15	rh	<b>Integrity Error - Local Pflash bank</b>
<b>IE_MTMV</b>	16	rh	<b>Memory Test Mode Violation detected</b>
<b>RES</b>	31:17	r	<b>Reserved</b>

## CPU Subsystem

### CPUx Program Integrity Error Address Register

#### PIEAR

CPUx Program Integrity Error Address Register( $19210_{\text{H}}$ )

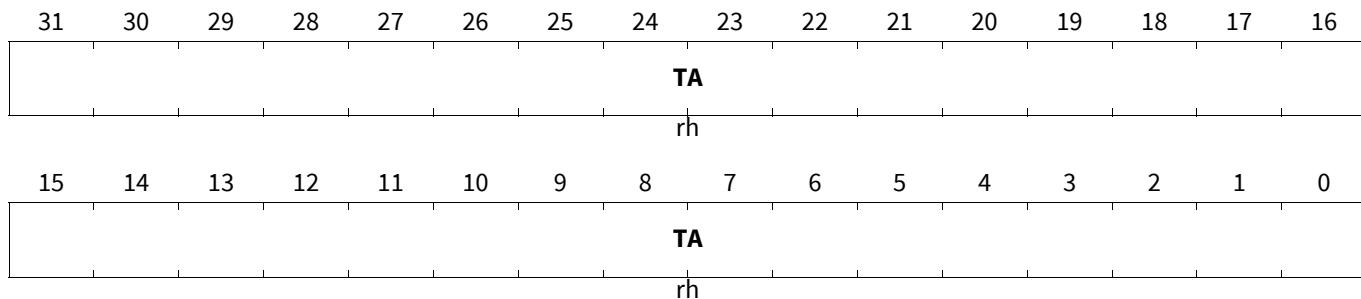

Application Reset Value:  $0000\ 0000_{\text{H}}$

CPU\_PIEAR

Short address for domain CSFR

( $09210_{\text{H}}$ )

Application Reset Value:  $0000\ 0000_{\text{H}}$

Field	Bits	Type	Description
<b>TA</b>	31:0	rh	<b>Transaction Address</b> Physical address being accessed by operation that encountered program integrity error.

## CPU Subsystem

### Data Integrity Error Information Registers

Two architecturally visible registers (DIETR, DIEAR) allow software to localise the source of the last detected uncorrectable data memory integrity error.

These registers are updated when an uncorrectable data integrity error condition is detected and the DIETR.IED bit is zero. On update the DIETR.IED bit is set to one and remains set until cleared by software. Whilst DIETR.IED is set further hardware updates of DIETR and DIEAR are inhibited. The various error scenarios are defined below.

#### Data Integrity errors during load from data memory

When an error is detected during a load from a data memory the IE\_S, IE\_C, IE\_T and IE\_LPB, IE\_DLMU bits are updated to denote in which memory structure the error was detected. If the IE\_C bit is set the E\_INFO field will be updated with the cache way. The DIEAR register is updated with the address of the access. If the error detected is an uncorrectable error the IE\_UNC bit is set. The IED bit is set and all other DIETR register bits are set to zero. Note that a memory read may also be generated by a sub word write operation or a cache line eviction.

#### Data Integrity errors during a memory read initiated by an external access

When an error is detected during an external bus read from data memory the IE\_S, IE\_C, IE\_DLMU bits are updated to denote in which memory structure the error was detected. The IE\_BS is set and E\_INFO updated. The DIEAR register is updated with the address of the access. If the error detected is an uncorrectable error the IE\_UNC bit is set. The IED bit is set and all other DIETR register bits are set to zero. Note that a memory read may also be generated by a sub word write operation or a cache line eviction. The IE\_C bit can only ever be set if the cache is mapped into memory in SIST mode. In this case the E\_INFO field indicates the tag of the requesting master.

#### Data Integrity errors due to safety protection

When a safety protection violation is detected during a data memory access the IE\_SP, IE\_BS bits are set and the E\_INFO field updated. The DIEAR register is updated with the address of the access. The IED bit is set and all other DIETR register bits are set to zero.

#### Data Integrity errors due ECC errors at the bus interface

When an ECC error is detected at the data bus interface (either master or slave) the IE\_BI bit is set. If the error is during an external access the IE\_BS bit is set and the E\_INFO fields updated. The DIEAR register is updated with the address of the access. If the error detected is an uncorrectable error the IE\_UNC bit is set. The IED bit is set and all other DIETR register bits are set to zero.

#### Data integrity error - Memory Test Mode Violation

The DIETR.IE\_MTMV bit is set if the cache controller attempt to access the DMEM (Dcache/DSPR), Dtag or DLMU memories while they are in a test mode.

### CPUx Data Integrity Error Address Register

This register contains the physical address accessed by the operation that encountered a uncorrectable data memory integrity error. This register is only updated if DIETR.IED is zero.

**CPU Subsystem****DIEAR****CPUx Data Integrity Error Address Register (19020<sub>H</sub>)****Application Reset Value: 0000 0000<sub>H</sub>****CPU\_DIEAR****Short address for domain CSFR (09020<sub>H</sub>)****Application Reset Value: 0000 0000<sub>H</sub>**

Field	Bits	Type	Description
<b>TA</b>	31:0	rh	<b>Transaction Address</b> Physical address being accessed by operation that encountered data integrity error.

## CPU Subsystem

### SIST (Software In-System) Test Support

The CPU protects against memory integrity errors by ECC protection of the local CPU memories. This has the side-effect of requiring memory blocks wider than the normal data access path to the memory. The additional ECC storage bits are not easily accessible via the existing data paths, causing problems where software based testing of the memories is required. The CPU memories also include embedded memory arrays, such as the tag memories, which are not ordinarily accessible by the usual CPU datapaths. In order to address this problem, the CPUs include modes allowing all local memory arrays to be accessed, both as a backup for SSH based memory test and to allow the test and debug of the fault tolerant memory systems.

Each memory may be accessed either in normal operation, data array only or ECC check array only. This is controlled by the ECCS registers of the associated SSH controller.

The IODT bit controls read/write operation ordering. In normal operation (IODT=0) non-dependent read operations may overtake write operations. When SMACON.IODT is set all memory operations are performed in program order.

The SMACON register is protected by the safety\_endinit signal.

The mapping of cache and tag memories to the TriCore address space is controlled by the MTU\_MEMMAP register. See the MTU chapter for details.

### CPUx SIST Mode Access Control Register

## CPU Subsystem

### 5.3.4.21 CPU Core Debug and Performance Counter Registers

The CPU Core Debug and performance counter registers are available for debug purposes. For a complete description of all registers, refer to the TriCore Architecture Manual.

#### 5.3.4.21.1 Counter Source Details

Details of the Performance counter sources is given below.

##### **IP\_DISPATCH\_STALL**

The counter is incremented on every cycle in which the Integer dispatch unit is stalled for whatever reason.

##### **LS\_DISPATCH\_STALL**

The counter is incremented on every cycle in which the Load-Store dispatch unit is stalled for whatever reason.

##### **LP\_DISPATCH\_STALL**

The counter is incremented on every cycle in which the Loop dispatch unit is stalled for whatever reason.

##### **PCACHE\_HIT**

The counter is incremented whenever the target of a cached fetch request from the fetch unit is found in the program cache.

##### **PCACHE\_MISS**

The counter is incremented whenever the target of a cached fetch request from the fetch unit is not found in the program cache and hence a bus fetch is initiated.

##### **MULTI\_ISSUE**

The counter is incremented in any cycle where more than one instruction is issued.

##### **DCACHE\_HIT**

The counter is incremented whenever the target of a cached request from the Load-Store unit is found in the data cache.

##### **DRB\_HIT**

The counter is incremented whenever the target of a cached request from the Load-Store unit is found in the data read buffer.

##### **DCACHE\_MISS\_CLEAN**

The counter is incremented whenever the target of a cached request from the Load-Store unit is not found in the data cache and hence a bus fetch is initiated with no dirty cache line eviction.

##### **DRB\_MISS**

The counter is incremented whenever the target of a cached request from the Load-Store unit is not found in the data read buffer and hence a bus fetch is initiated.

##### **DCACHE\_MISS\_DIRTY**

The counter is incremented whenever the target of a cached request from the Load-Store unit is not found in the data cache and hence a bus fetch is initiated with the writeback of a dirty cache line.

## CPU Subsystem

### TOTAL\_BRANCH

The counter is incremented in any cycle in which a branch instruction is in a branch resolution stage of the pipeline (IP\_EX1, LS\_DEC, LP\_DEC).

### PMEM\_STALL

The counter is incremented whenever the fetch unit is requesting an instruction and the Instruction memory is stalled for whatever reason.

### DMEM\_STALL

The counter is incremented whenever the Load-Store unit is requesting a data operation and the data memory is stalled for whatever reason.

## Performance Counter Registers

The various counter sources listed above may be selected for counting by programming the M1, M2 and M3 fields in the CCTRL register. (See the TriCore architecture manual for register details). The mappings are listed below.

Register	Description	Offset Address
CCTRL	Counter Control Register.	FC00 <sub>H</sub>
CCNT	CPU Clock Count Register.	FC04 <sub>H</sub>
ICNT	Instruction Count Register.	FC08 <sub>H</sub>
M1CNT	Multi Count Register 1.	FC0C <sub>H</sub>
M2CNT	Multi Count Register 2.	FC10 <sub>H</sub>
M3CNT	Multi Count Register 3.	FC14 <sub>H</sub>

**Table 100 MultiCount Configuration**

CCTRL M1/M2/M3	M1CNT Count Function	M2CNT Count Function	M3CNT Count Function
000	IP_DISPATCH_STALL	LS_DISPATCH_STALL	LP_DISPATCH_STALL
001	PCACHE_HIT	PCACHE_MISS	MULTI_ISSUE
010	DCACHE_HIT	DCACHE_MISS_CLEAN	DCACHE_MISS_DIRTY
011	TOTAL_BRANCH	PMEM_STALL	DMEM_STALL

---

**CPU Subsystem****5.3.4.22 CPU Subsystem Register Summary**

This section summaries the CPU Subsystem registers. For complete descriptions of all registers refer to the TriCore Architecture Manual.

To increase performance all stores to CSFR or SFR register locations from the SRI are posted writes and complete silently. SRI stores to non-existent CSFR or SFR locations are not errored.

A disallowed access either via the SRI or with MTCR/MFCR to any CPU register (e.g. attempted write to read only register, attempted user mode access to SV, attempted access to E without Endinit, etc.) will NOT result in an Error.

**CPU Subsystem****5.3.4.22.1 Summary of CSFR Reset Values and Access Modes**

This section summarizes the reset values and access modes of the CPU CSFR registers.

**Table 101 Register Overview - CORE\_SPECIAL\_FUNCTION\_REGISTERS (ascending Offset Address)**

## CPU Subsystem

### 5.3.5 CPU Instruction Timing

This section gives information on CPU instruction timing by execution units.

#### Definition of Terms:

- **Repeat Rate**

Assuming the same instruction is being issued sequentially, repeat is the minimum number of clock cycles between two consecutive issues. There may be additional delays described elsewhere due to internal pipeline effects when issuing a different subsequent instruction.

- **Result Latency**

The number of clock cycles from the cycle when the instruction is issued to the cycle when the result value is available to be used as an operand to a subsequent instruction or written into a GPR. Result latency is not meaningful for instructions that do not write a value into a GPR.

- **Address Latency**

The number of clock cycles from the cycle when the instruction is issued to the cycle when the addressing mode updated value is available as an operand to a subsequent instruction or written into an Address Register.

- **Flow Latency**

The number of clock cycles from the cycle when the instruction is issued to the cycle when the next instruction (located at the target location or the next sequential instruction if the control change is conditional) is issued.

## CPU Subsystem

## 5.3.5.1 Integer-Pipeline Instructions

These are the Integer-Pipeline instruction timings for each instruction.

## 5.3.5.1.1 Simple Arithmetic Instruction Timings

Each instruction is single issued.

**Table 114 Simple Arithmetic Instruction Timing**

Instruction	Result Latency	Repeat Rate	Instruction	Result Latency	Repeat Rate
<b>Integer Pipeline Arithmetic Instructions</b>					
<b>ABS</b>	1	1	<b>MAX.H</b>	1	1

<b>MADDMS.H</b>	3	1	<b>MSUBMS.H</b>	3	1
<b>MADDR.H</b>	3	1	<b>MSUBR.H</b>	3	1
<b>MADDR.Q</b>	3	1	<b>MSUBR.Q</b>	3	1
<b>MADDRS.H</b>	3	1	<b>MSUBRS.H</b>	3	1
<b>MADDRS.Q</b>	3	1	<b>MSUBRS.Q</b>	3	1
<b>MADDS.H</b>	3	1	<b>MSUBS.H</b>	3	1
<b>MADDS.Q</b>	3	1	<b>MSUBS.Q</b>	3	1
<b>MADDSU.H</b>	3	1	<b>MSUBAD.H</b>	3	1
<b>MADDSUM.H</b>	3	1	<b>MSUBADM.H</b>	3	1
<b>MADDSUMS.H</b>	3	1	<b>MSUBADMS.H</b>	3	1
<b>MADDSUR.H</b>	3	1	<b>MSUBADR.H</b>	3	1
<b>MADDSURS.H</b>	3	1	<b>MSUBADRS.H</b>	3	1
<b>MADDSUS.H</b>	3	1	<b>MSUBADS.H</b>	3	1

For All MADD, MSUB and MUL type instructions the result latency is reduced to 1 for accumulator forwarding between similar instructions.

## CPU Subsystem

For MADD.Q, MADDS.Q, MSUB.Q, MSUBS.Q Instructions:

MADD.Q, MADDS.Q, MSUB.Q, MSUBS.Q	Result Latency	Repeat Rate
16 × 16	3	1
16 × 32	3	1
32 × 32	3	1

### 5.3.5.1.4 Control Flow Instruction Timing

Control flow instruction timing for TC1.6.2P is complicated by the use of branch target buffers and fetch FIFOs.

- Incorrectly predicted LS instructions incur a three cycle branch recovery penalty.
- Incorrectly predicted IP instructions incur a four cycle branch recovery penalty.
- Correctly predicted not taken branches incur no penalty
- Correctly predicted taken branch incur a penalty of up to two cycles depending on the state of the fetch FIFOs and the branch target buffer.
- Loop instructions incur the same penalty as an LS conditional jump instruction.

Assumptions

- All target locations yield a full instruction in one access (i.e. not 16-bits of a 32-bit instruction).
- All code fetches take a single cycle.
- Timing is best case; no cache misses for context operations, no pending stores.

**Table 117 Control flow timing**

Prediction-Result	Flow Latency (LS, LP)	Repeat rate (LS,LP)	Flow Latency (IP)	Repeat Rate (IP)
Correct Not-Taken	1	1	1	1
Correct Taken	1-2	1-2	1-2	1-2
Incorrect Not-Taken	3	4	3	4
Incorrect Taken	3	4	3	4

## CPU Subsystem

## 5.3.5.2 Load-Store Pipeline Instructions

This section summarizes the Load-Store Pipeline instructions.

## 5.3.5.2.1 Address Arithmetic Timing

Each instruction is single issued.

**Table 118 Address Arithmetic Instruction Timing**

Instruction	Result Latency	Repeat Rate	Instruction	Result Latency	Repeat Rate
<b>Load Store Arithmetic Instructions</b>					
<b>ADD.A</b>	1	1	<b>GE.A</b>	1	1
<b>ADDIH.A</b>	1	1	<b>LT.A</b>	1	1
<b>ADDSC.A</b>	2	1	<b>NE.A</b>	1	1
<b>ADDSC.AT</b>	2	1	<b>NEZ.A</b>	1	1
<b>EQ.A</b>	1	1	<b>SUB.A</b>	1	1
<b>EQZ.A</b>	1	1	<b>NOP</b>	1	1
<b>Trap and Interrupt Instructions</b>					
<b>DEBUG</b>	-	1	<b>TRAPS<sup>1)</sup></b>	-	1
<b>DISABLE</b>	-	1	<b>TRAPV<sup>1)</sup></b>	-	1
<b>ENABLE</b>	-	1	<b>RSTV</b>	-	1
<b>RESTORE</b>	-	1	<b>WAIT<sup>2)</sup></b>	-	1
<b>Move Instructions</b>					
<b>MFCR</b>	2	1	<b>MOV.A</b>	1	1
<b>MTCR</b>	1	1	<b>MOV.AA</b>	1	1
<b>MOVH.A</b>	1	1	<b>MOV.D</b>	1	1
<b>Sync Instructions</b>					
<b>DSYNC</b>	-	1	<b>ISYNC<sup>3)</sup></b>	-	1

- 1) Execution cycles when no TRAP is taken. The execution timing in the case of raising these TRAPs is the same as other TRAPs such as SYSCALL.
- 2) The latency of the WAIT instruction is hidden by the context save of the interrupt. Effective latency is zero.
- 3) Repeat rate assumes that code refetch takes a single cycle.

## CPU Subsystem

**5.3.5.2.2 CSA Control Flow Instruction Timing**

This section summarizes the timing of CSA Control Flow instructions.

- All targets yield a full instruction in one access (not 16-bits of a 32-bit instruction).
- All code fetches take a single cycle. Timing is best case; no cache misses for context operations, no pending stores.

**Table 119 CSA Control Flow Instruction Timing**

Instruction	Result Latency	Repeat Rate	Instruction	Result Latency	Repeat Rate
<b>CALL</b>	4-8	4-8	<b>SYSCALL</b>	4-8	4-8
<b>CALLA</b>	4-8	4-8	<b>SVLCX</b>	4-8	4-8
<b>CALLI</b>	4-8	4-8	<b>RSLCX</b>	4-8	4-8
<b>RET</b>	4-8	4-8	<b>RFE</b>	4-8	4-8
<b>BISR</b>	4-8	4-8	<b>RFM</b>	4-8	4-8
<b>FCALL</b>	1	1	<b>FCALLA</b>	1	1
<b>FCALLI</b>	1	1	<b>FRET</b>	1	1

Access to DSPR require 4 cycles, accesses to cached external memory require 8 cycles.

**5.3.5.2.3 Load Instruction Timing**

Load instructions can produce two results if they use the pre-increment, post-increment, circular or bit-reverse addressing modes. Hence, in those cases there are two latencies that must be specified, the result latency for the value loaded from memory and the address latency for using the updated address register result.

- Each instruction is single issued.
- The memory references is naturally aligned.
- The memory accessed takes a single cycle to return a data item.
- Timing is best case; no cache misses, no pending stores.

**Table 120 Load Instruction Timing**

Instruction	Address Latency	Result Latency	Repeat Rate	Instruction	Address Latency	Result Latency	Repeat Rate
<b>Load Instructions</b>							
<b>LD.A</b>	1	3	1	<b>LD.Q</b>	1	2	1
<b>LD.B</b>	1	2	1	<b>LD.W</b>	1	2	1
<b>LD.BU</b>	1	2	1	<b>LDLCX</b>	5-9	5-9	5-9
<b>LD.D</b>	1	2	1	<b>LDUCX</b>	5-9	5-9	5-9
<b>LD.DA</b>	1	3	1	<b>SWAP.W</b>	2	3	6
<b>LD.H</b>	1	2	1	<b>LEA<sup>1)</sup></b>	-	1	1
<b>LD.HU</b>	1	2	1	<b>CMPSWAP.W</b>	2	3	6
<b>SWAPMSK.W</b>	2	3	6	<b>LHA</b>	-	1	1

1) The addressing mode returning an updated address is not relevant for this instruction.

**CPU Subsystem****5.3.5.2.4 Store Instruction Timing**

Cache and Store instructions similar to Load instructions will have a result for the pre-increment, post-increment, circular or bit-reverse addressing modes, but do not produce a ‘memory’ result.

- Each instruction is single issued.
- The memory references is naturally aligned.
- The memory accessed takes a single cycle to accept a data item.
- Timing is best case; no cache misses, no pending stores.

**Table 121 Cache and Store Instruction Timing**

<b>Instruction</b>	<b>Address Latency</b>	<b>Repeat Rate</b>	<b>Instruction</b>	<b>Address Latency</b>	<b>Repeat Rate</b>
<b>Cache Instructions</b>					
<b>CACHEA.I</b>	1	1	<b>CACHEA.W<sup>1)</sup></b>	1	1
<b>CACHEA.W<sup>1)</sup></b>	1	1	<b>CACHEI.W<sup>1)</sup></b>	1	1
<b>CACHEI.W<sup>1)</sup></b>	1	1	<b>CACHEI.I</b>	1	1
<b>Store Instructions</b>					
<b>ST.A</b>	1	1	<b>ST.T</b>	-	6
<b>ST.B</b>	1	1	<b>ST.W</b>	1	1
<b>ST.D</b>	1	1	<b>STLCX</b>	5-9	5-9
<b>ST.DA</b>	1	1	<b>STUCX</b>	5-9	5-9
<b>ST.H</b>	1	1	<b>LDMST</b>	1	6
<b>ST.Q</b>	1	1			

- 1) Repeat rate assumes that no memory writeback operation occurs. Otherwise the repeat rate will depend upon the time for the castout buffers to clear.

**CPU Subsystem****5.3.5.3 Floating Point Pipeline Timing**

Each instruction is single issued.

**Table 122 Floating Point Instruction Timing**

Instruction	Result Latency	Repeat Rate	Instruction	Result Latency	Repeat Rate
<b>Floating Point Instructions</b>					
<b>ADD.F</b>	2	1	<b>ITOF</b>	2	1
<b>CMP.F</b>	1	1	<b>MADD.F</b>	3	1

<b>FTOQ31Z</b>	2	1	<b>SUB.F</b>	2	1
<b>FTOU</b>	2	1	<b>UPDFL</b>	-	1
<b>FTOUZ</b>	2	1	<b>UTOF</b>	2	1
<b>FTOHP</b>	2	1	<b>HPTOF</b>	2	1

**5.3.6 Local Memory Details**

This chapter describes the features of the local memories of the TC1.6.2 processor.

The processor implementation includes the following local memories. The sizes of each of these memories is detailed in Section 1-2

- Data Scratch Pad Ram (DSPR) - Single cycle memory for local data operations, code access via bus
- Data Cache (DCache) - Single cycle memory for data operations
- Distributed LMU (DLMU) - Single cycle memory for local data operations, code access via bus. Contiguous with other LMU memory in the system.
  - The DLMU may be implemented as a standard SRAM or as a Standby SRAM. Where standby SRAM is indicated as implemented the entire local DLMU contents will be maintained during standby.
- Program Scratch Pad Ram (PSPR) - Single cycle memory for local code fetch, data access via bus.
- Program Cache (PCache) - Single cycle memory for code fetch
- Local PFlash Bank (LPB) - Multi cycle flash memory, Local code and data read operations are direct access but may optionally be performed via the bus (see FLASHCON4)

## CPU Subsystem

### 5.3.6.1 Memory Addressing

This chapter details the CPU specific addressing.

#### 5.3.6.1.1 Local and Global Addressing

The TriCore architecture supports closely coupled program and data SRAM memories known as Program Scratch Pad RAM (PSPR) and Data Scratch Pad RAM (DSPR). The local PSPR memory is always located at C0000000H. The local DSPR is always located at D0000000H. In a multiprocessor system the local scratch pad memories appear in the global address map in the following locations:-

**Table 123 Global Address Locations**

CORE_ID Value	PSPR_base	DSPR_base
0	70100000 <sub>H</sub>	70000000 <sub>H</sub>
1	60100000 <sub>H</sub>	60000000 <sub>H</sub>
2	50100000 <sub>H</sub>	50000000 <sub>H</sub>
3	40100000 <sub>H</sub>	40000000 <sub>H</sub>
4	30100000 <sub>H</sub>	30000000 <sub>H</sub>
6	10100000 <sub>H</sub>	10000000 <sub>H</sub>

The CPUs always use the global addresses for bus transactions. Thus a data load from C0000000<sub>H</sub> (a CPUs local PSPR) will result in a bus transaction with an address in the range 10100000<sub>H</sub> - 701FFFFF<sub>H</sub> dependent on the Core-ID value of the processor. Similarly a code fetch form D0000000H (a CPUs local DSPR) will result in a bus transaction with an address in the range 10000000<sub>H</sub> - 700FFFFF<sub>H</sub> dependent on the Core-ID value of the processor.

#### 5.3.6.1.2 CSFR and SFR base Locations

Each CPU has a dedicated set of control and status registers accessed at the addresses detailed in the following table. These registers are divided into Special Function Registers (SFRs) and Core Special Function Registers (CSFRs).

A CPU must access its own CSFR registers using MTCR and MFCR instructions. CSFR registers of other CPUs may be accessed using load and store instructions via the XBAR\_SRI. SFR registers of any CPU may only be accessed using load and store instructions via XBAR\_SRI. Currently the overlay control and the access protection registers of CPUx are mapped into CPUx SFR address range.

The base locations for the TC1.6.2P SFR and CSFR registers are as follows:-

**Table 124 CSFR and SFR Base Locations**

CORE_ID Value	CSFR Base Address	SFR Base Address
0	F881_0000 <sub>H</sub>	F880_0000 <sub>H</sub>
1	F883_0000 <sub>H</sub>	F882_0000 <sub>H</sub>
2	F885_0000 <sub>H</sub>	F884_0000 <sub>H</sub>
3	F887_0000 <sub>H</sub>	F886_0000 <sub>H</sub>
4	F889_0000 <sub>H</sub>	F888_0000 <sub>H</sub>
6	F88D_0000 <sub>H</sub>	F88C_0000 <sub>H</sub>

**CPU Subsystem****5.3.6.1.3 Cache Memory Access**

The cache and tag memories may be mapped into the CPUs address space. When mapped the cache memories are contiguous with the DSPR/PSPR memories as detailed in the following table. When mapped the cache memories behave identically to the PSPR/DSPR memories and may be used as standard memory.

The mapping of cache and tag memories to the TriCore address space is controlled by the MTU\_MEMMAP register. See the MTU chapter for details.

**Table 125 Cache Memory Locations when mapped**

<b>Memory</b>	<b>Local Address</b>	<b>Global Address</b>
Program Cache	C000_0000 <sub>H</sub> + PSPR_Memory_Size	PSPR_Base + PSPR_Memory_Size
Data Cache	D000_0000 <sub>H</sub> + DSPR_Memory_Size	DSPR_Base + DSPR_Memory_Size

When mapped the tag memories are available at the locations detailed in the following table. The mapping of the Tag memories is provided test purposes only. They may not be used as standard memory.

**Table 126 Tag Memory Locations when mapped**

<b>Memory</b>	<b>Local Address</b>	<b>Global Address</b>
Program Tag	C00C_0000 <sub>H</sub>	PSPR_Base + 000C_0000 <sub>H</sub>
Data Tag	D00C_0000 <sub>H</sub>	DSPR_Base + 000C_0000 <sub>H</sub>

The CACHEI.\* instructions require a way and index value to be supplied in a valid address. (i.e. an address that will pass memory protection and null pointer checks). The CACHEI.\* instructions also require an address to be cacheable. The local portion of DLMU (even when accessed via segment 0x9) is not cacheable. The local DSPR's global address (segment 0x[7-core\_id] is not cacheable either). The location of these bits in the 32-bit address is as follows.

**Table 127 Way and Index Location**

<b>Function</b>	<b>Address Bits</b>
Way	[0]
Index	[12:5]

**5.3.6.1.4 Customer-ID Numbering**

In circumstances where the Infineon defined Core identification numbering scheme is insufficient or incompatible with a customer numbering scheme, a customer ID value may be supplied via the CUS\_ID register. The implemented numbering scheme used in early device steps did not scale well across the derivatives and was changed for the latest steps. This old numbering scheme used a reverse encoding and is limited to only a few steps listed below. Affected devices can be identified by reading the version number at address 0xAF40\_0CB8.

- Example: the value 0x10 01 03 00 read from 0xAF40\_0CB8 translates to V1.0.1.3.0.

**Table 128 Customer ID old numbering scheme**

		<b>TC39xAA<sup>1)</sup>, BA<sup>2)</sup></b>	<b>TC38xAA<sup>1)</sup>, AB<sup>3)</sup></b>	<b>TC35xAA<sup>4)</sup></b>
<b>Core</b>	<b>CORE_ID</b>	<b>CUS_ID</b>	<b>CUS_ID</b>	<b>CUS_ID</b>
CPU0	0	5	3	2
CPU1	1	4	2	1

## CPU Subsystem

**Table 128 Customer ID old numbering scheme (cont'd)**

		<b>TC39xAA<sup>1)</sup>, BA<sup>2)</sup></b>	<b>TC38xAA<sup>1)</sup>, AB<sup>3)</sup></b>	<b>TC35xAA<sup>4)</sup></b>
<b>Core</b>	<b>CORE_ID</b>	<b>CUS_ID</b>	<b>CUS_ID</b>	<b>CUS_ID</b>
CPU2	2	3	1	0
CPU3	3	2	0	
CPU4	4	1		
CPU5	6	0		

- 1) TC39xAA/TC38xAA: All devices use old numbering scheme
- 2) TC39xBA: Version above V1.0.1.3.0 use the new numbering scheme
- 3) TC38xAB: Version above V1.0.1.2.1 use the new numbering scheme
- 4) TC35xAA: Version above V1.0.0.1.2 use the new numbering scheme

Further design steps use the latest numbering scheme documented in the table below.

**Table 129 Customer ID numbering**

		<b>TC39xB</b>	<b>TC3Ex TC38x TC3Ax</b>	<b>TC37xEXT TC37x TC35x</b>	<b>TC36x TC33xEXT</b>	<b>TC33x</b>

CPU3	3	3	3			
CPU4	4	4				
CPU5	6	5				

### 5.3.6.2 Memory Integrity Error Handling

The TriCore CPUs contain integrated support for the detection and handling of memory integrity errors. The handling of memory integrity errors for the various memory types in the CPU is as follows:

#### 5.3.6.2.1 Program Side Memories

The program side memories of the CPU consist of four memory structures:- The Program Scratchpad RAM (PSPR), the Program Cache (PCACHE), the Program TAG RAM (PTAG) and the local PFlash bank (LPB). All of these memory structures are ECC protected from memory integrity errors. Any sub-width write access to the PSPR from the Bus interface is converted to a Read-Modify-Write sequence by the PMI module.

##### Program Scratchpad RAM (PSPR)

The Scratchpad RAM of the CPU is protected from memory integrity errors on a 64bit basis. ECC protection of the PSPR is enabled via the SSH ECCS register.

For instruction fetch requests from the TriCore CPU to PSPR, the ECC bits are read along with the data bits and are passed to the CPU along with their corresponding instructions. Whenever an attempt is made to issue an instruction containing an uncorrectable memory integrity error a synchronous PIE trap is raised. The trap handler is then responsible for correcting the memory entry and re-starting program execution.

## CPU Subsystem

For PSPR read operations from the Bus interface, either from the DMI module or another Bus master agent, an access that results in the detection of an uncorrectable memory integrity error in the requested data causes an error to be returned for the bus transaction. Since the TriCore CPU may not be involved in the transaction, a separate error alarm is also flagged to the SMU module to optionally generate an NMI trap back to the CPU.

Writes to program scratchpad memory are only ever performed from the bus interface. For write operations less than the protection width of the PSPR the memory transaction is transformed into a read-modify-write sequence inside the PMI module. Such a write operation may result in the detection of an uncorrectable memory integrity errors during the read phase which are handled as standard read operations.

### Program Cache (PCACHE)

The program cache RAM of the CPU is protected from memory integrity errors on a 64bit basis. ECC protection of the PCACHE is enabled via the SSH ECCS register.

For instruction fetch requests from the TriCore CPU to PCACHE, the ECC bits are read along with the data bits of all cache ways, and an uncorrectable error signal generated for each cache way. In the case of a tag hit, the uncorrectable error signals for the corresponding cache way are passed to the CPU along with their corresponding instructions. Whenever an attempt is made to issue an instruction containing an uncorrectable error a synchronous PIE trap is raised. The trap handler is then responsible for checking the source of the memory integrity error.

### Program Tag (PTag)

ECC protection of the PTAG is enabled via the SSH ECCS register.

For instruction fetch requests from the TriCore CPU to PCACHE, the program tag ECC bits are read along with the data bits and an error flag is computed. A way hit is triggered only if the tag address comparison succeeds, the valid bit is set and no ECC error in the associated tag way is detected, any other result is considered a miss. In the normal case where no error is detected in either cache way then the cache line is filled/refilled as normal. In the case where an error is detected the cache controller replacement algorithm forces the way indicating an error to be replaced. In the case where one cache way flags a cache hit, and another cache way detects an uncorrectable ECC error, the error condition is masked and has no effect on the memory integrity error handling mechanisms.

### Local Pflash Bank (LPB)

The local Pflash bank returns data protected on a 64bit basis (This is different to the protection of the actually flash memory array itself). For instruction fetch requests from the TriCore CPU to LPB, the ECC bits are read along with the data bits and are passed to the CPU along with their corresponding instructions. Whenever an attempt is made to issue an instruction containing an uncorrectable memory integrity error a synchronous PIE trap is raised.

For LPB read operations from the Bus interface an access that results in the detection of an uncorrectable memory integrity error in the requested data causes a bus error to be returned for the bus transaction. Since the TriCore CPU may not be involved in the transaction, a separate error is also flagged to the SMU module to optionally generate an NMI trap back to the CPU.

### 5.3.6.2.2 Data Side Memories

The program side memories of the CPU consist of four memory structures:- The Data Scratchpad RAM (DSPR), the Data Cache (DCACHE), The data TAG RAM and the Distributed LMU (DLMU). All of these memory structures are ECC protected from memory integrity errors. Any byte write access to either DSPR or DCache is converted to a half-word Read-Modify-Write sequence. Any sub-double-word write to the DLMU is converted into a read-modify-write operation. In normal operation isolated write transactions to the data memories result in no additional stall cycles.

## CPU Subsystem

### Data Scratchpad Ram (DSPR)

The DSPR memory of the TC1.6.2P is protected from memory integrity errors on a per half-word basis. ECC protection of the DSPR is enabled via the SSH ECCS register.

For data load requests from the TriCore CPU to DSPR, the ECC bits are read along with the data bits and an uncorrectable error signal is generated for each half-word. If an error is detected associated with any of the data half-words passed to the CPU an error is flagged to the CPU. If such an error condition is detected an asynchronous DIE trap is raised. The trap handler is then responsible for correcting the memory entry, or for taking alternative action (such as system soft reset) if correction of the data is not possible.

For DSPR read operations from the Bus interface, either from the PMI module or another Bus master agent, an access that results in the detection of an uncorrectable error in the requested data half-words causes an error to be returned for the bus transaction. Since the TriCore CPU may not be involved in the transaction, a separate error is also flagged to the SMU module to optionally generate an NMI trap back to the CPU.

For write operations to DSPR of half-word size or greater, the ECC bits are pre-calculated and written to the memory in parallel with the data bits. For byte write operations the memory transaction is transformed into a half-word read-modify-write sequence inside the DMI module. As such, byte write operations may result in the detection of uncorrectable memory integrity errors, which are handled as per standard read operations.

### Data Cache (DCache)

ECC protection of the DCACHE is enabled via the SSH ECCS register.

For data load requests from the TriCore CPU to DCache, the ECC bits are read along with the data bits of both cache ways, and an uncorrectable error flag computed for each half-word of each cache way. In the case where an error is detected with any of the requested data half-words in a cache way which has a corresponding tag hit, an error is flagged to the CPU. If such an error condition is detected an asynchronous DIE trap is raised. The trap handler is then responsible for correcting the memory entry, or for taking alternative action (such as system soft reset) if correction of the data is not possible.

For write operations of half-word size or greater, the check bits are pre-calculated and written to the memory in parallel with the data bits. For byte write operations the memory transaction is transformed into a half-word read-modify-write sequence inside the DMI module. As such, byte write operations may result in the detection of uncorrectable memory integrity errors as for read operations.

For cache line writeback, uncorrectable error detection is performed as dirty data is transferred to the store buffers. In all cases (normal cache line eviction, cachex.xx instruction) where an error condition is detected in a valid cache line a DIE trap is raised. The trap handler is then responsible for taking corrective action (such as system soft reset) since correction of the data is not possible.

### Data Tag (DTag)

ECC protection of the DTAG is enabled via the SSH ECCS register.

For data load or store requests from the TriCore CPU to DCache, the data tag ECC bits are read along with the data bits and an uncorrectable error flag is computed. A way hit is triggered only if the tag address comparison succeeds, the tag location is valid and no uncorrectable error in the associated tag way is detected, any other result is considered a miss. In the normal case where no error is detected in either tag way then the cache line is filled/refilled as normal. In the case of a cache miss where an error is detected in one of the tag ways and the cache line does not contain dirty data the cache controller replacement algorithm forces the way indicating an error to be replaced when the refill operation returns. In the case where one cache way flags a cache hit, and the another way detects an uncorrectable error, the error condition is masked and has no effect on the memory integrity error handling mechanisms. If a cache miss occurs, with an uncorrectable error detected on the associated data tag way and dirty data detected, then an asynchronous DIE trap is signalled to the CPU and any writeback / refill sequence aborted. The trap handler is responsible for invalidating the cache line and processing any associated

---

## CPU Subsystem

dirty data if possible, or taking other corrective action. Similar action is taken for forced cache writeback using the cache manipulation instructions.

### Distributed LMU (DLMU)

The DLMU memory of the TC1.6.2P is protected from memory integrity errors on a double word (64bit) basis. ECC protection of the DLMU is enabled via the SSH\_ECCS register.

For data load requests from the TriCore CPU to DLMU, the ECC bits are read along with the data bits and an uncorrectable error signal is generated for each double word. If an error is detected associated with any of the data double-words passed to the CPU an error is flagged to the CPU. If such an error condition is detected an asynchronous DIE trap is raised. The trap handler is then responsible for correcting the memory entry, or for taking alternative action (such as system soft reset) if correction of the data is not possible.

For DLMU read operations from the Bus interface, either from the PMI module or another Bus master agent, an access that results in the detection of an uncorrectable error in the requested data double-words causes a bus error to be returned for the bus transaction. Since the TriCore CPU may not be involved in the transaction, a separate alarm is also flagged to the SMU module.

For write operations to DLMU of double-word size or greater, the ECC bits are pre-calculated and written to the memory in parallel with the data bits. For sub double word write operations the memory transaction is transformed into a read-modify-write sequence. Such operations may result in the detection of uncorrectable memory integrity errors, which are handled as per standard read operations.

#### 5.3.6.2.3 Memory Initialisation

To avoid the generation of spurious ECC errors the DLMU, DSPR, PSPR, LPB must be fully initialised prior to use. This may be done either by software or by automatically by hardware (see the DMU.HF\_PROCONRAM register for details). The entire physical memory as detailed in [Chapter 5.3.3](#) must be initialised irrespective of any memory size variants produced for derivative products.

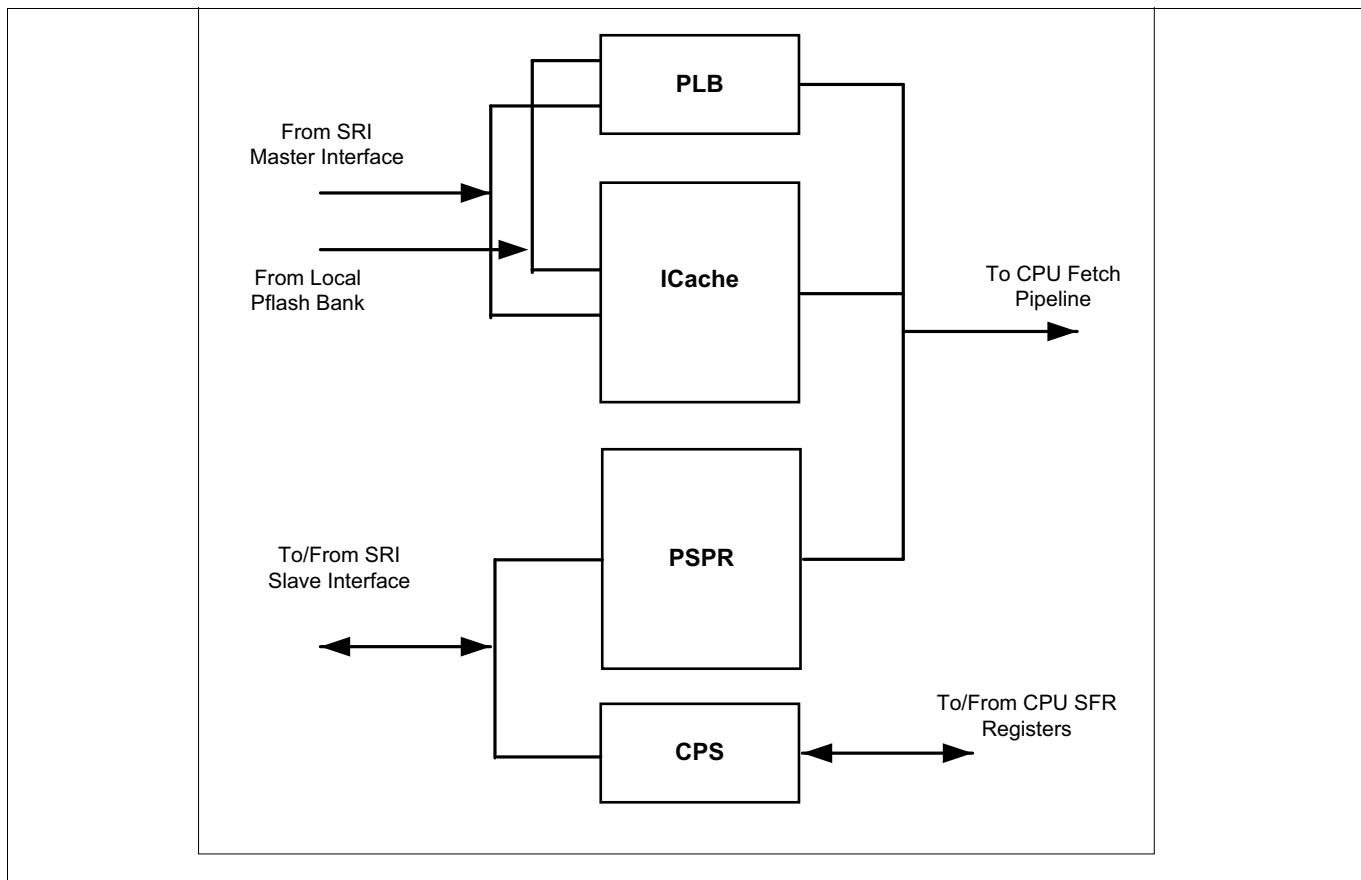

## CPU Subsystem

### 5.3.6.3 Program Memory Interface (PMI)

The program Memory Interface (PMI) provides the instruction stream to the CPU.

#### 5.3.6.3.1 TC1.6.2P PMI Description

**Figure 51** shows the block diagram of the Program Memory Interface (PMI) of the TC1.6.2P.

**Figure 51 PMI Block Diagram**

The Program Memory Interface (PMI) has the following features:

- Program Cache (PCACHE)
  - Two-way set associative cache
  - LRU (Least-Recently Used) replacement algorithm
  - Cache line size: 256 bits (4 double-words)
  - Validity granularity: One valid bit per cache line
  - Single cycle access for hit.
  - The PCACHE can be globally invalidated to provide support for software cache coherency (to be handled by the programmer)
  - The PCACHE can be bypassed to provide a direct fetch from the CPU to on-chip and off-chip resources
  - The PCACHE refill mechanism is critical word first with line wrap around, and direct streaming to the CPU
- Program Scratchpad memory (PSPR)
- CPU interface
  - Supporting 64bit aligned fetches.

## CPU Subsystem

- CPU Slave interface (CPS)
- Shared Resource Interconnect Bus (SRI) Master Interface
- Interface to the local PFlash Bank (LPB)
- Shared Resource Interconnect Bus (SRI) Slave Interface to PSPR and CPS.
- All PMI SRAMs (PSPR, PCACHE, and cache tag SRAM) are ECC protected
  - ECC is calculated on 64bit data for the PSPR and PCACHE

### Program Scratchpad RAM (PSPR)

The TC1.6.2P Program scratchpad RAM provides a fast, deterministic program fetch access from the CPU for use by performance critical code sequences.

- CPU program fetch accesses to scratchpad RAM are never cached in the program cache and are always directly targeted to the scratchpad RAM.

The CPU fetch interface will generate aligned accesses (64-bit), which will result in 64-bits of instruction being returned to the CPU.

Note that the CPU Fetch Unit can only read from the scratchpad RAM and can never write to it.

The scratchpad RAM may also be accessed from the SRI Slave interface by another bus master, such as the Data Memory Interface (DMI). The scratchpad RAM may be both read and written from the SRI. The SRI Slave interface supports all SRI transaction types.

The Program scratchpad RAM is ECC protected across 64-bit data. Writes to the PSPR that are less than 64 bits, or which are 64 bits but not naturally aligned will be performed as read-modify-write operations at the memory interface. Any read-modify-write operation that detects an error on the read phase will not perform the write phase of operation. (Sub-64 bit writes to un-initialised memory will always result in an ECC error being detected on the read phase and hence no data will be written to the memory).

### Program Cache

The program Cache is a two-way set-associative cache with a Least-Recently-Used (LRU) replacement algorithm. Each PCACHE line contains 256 bits of instruction and associated ECC bits.

CPU program fetch accesses which target a cacheable memory segment (and where the PCACHE is not bypassed) target the PCACHE. If the requested address and its associated instruction are found in the cache (Cache Hit), the instruction is passed to the CPU Fetch Unit without incurring any wait states. If the address is not found in the cache (Cache Miss), the PMI cache controller issues a cache refill sequence and wait states are incurred whilst the cache line is refilled. The fetch request always returns an aligned packet to the CPU.

The program cache is ECC protected on 64-bit data.

The program TAG Ram is ECC protected on 22-bit data.

Errors detected at the ECC decoders are signaled to the EMM via the SSH logic of the associated SRAM

### Program Cache Refill Sequence

Program Cache refills are performed using a critical double-word first strategy with cache line wrapping such that the refill size is always 4 double-words. PCACHE refills are always performed in 64-bit quantities. A refill sequence will always affect only one cache line. There is no prefetching of the next cache line.

PCACHE refills are therefore implemented using an SRI Burst Transfer 4 (BTR4) transfers. The program cache supports instruction streaming, meaning that it can deliver available instruction half-words to the CPU Fetch Unit whilst the refill operation is ongoing.

## CPU Subsystem

### Program Cache Bypass

The Program Cache may be bypassed, under control of PCON0.PCBYP, to provide a direct instruction fetch path for the CPU Fetch Unit. The default value of PCON0.PCBYP is such that the PCACHE is bypassed after reset.

Whilst PCACHE bypass is enabled, a fetch request by the CPU to a cacheable address will result in a forced cache miss, such that the cache controller issues a standard refill sequence and supplies instruction half-words to the CPU using instruction streaming, without updating the cache contents. Any valid cache lines within the PCACHE will remain valid and unchanged whilst the PCACHE is bypassed. As such, instruction fetch requests to cacheable addresses with PCACHE bypass enabled behave identically to instruction fetch requests to non-cacheable addresses.

The PCON0 register is CPUx endinit protected.

### Program Cache Invalidation

The PMI does not have automatic cache coherency support. Changes to the contents of memory areas external to the PMI that may have already been cached in the PCACHE are not detected. Software must provide the cache coherency in such a case. The PMI supports this via the cache invalidation function. The PCACHE contents may be globally invalidated by writing a '1' to PCON1.PCINV. The PCACHE invalidation is performed over 64 cycles by a hardware state machine which cycles through the PCACHE entries marking each as invalid. During an invalidate sequence the CPU may continue to fetch instructions from non-cacheable memory. Any attempt to fetch instructions from a cacheable memory location during an invalidation sequence will result in the CPU stalling until the sequence completes. The status of the PCACHE invalidation sequence may be determined by reading the PCON1.PCINV bit.

### Program Line Buffer (PLB)

The PMI module contains a 256-bit Program Line Buffer (PLB). Program fetch requests to non-cacheable addresses (or to cacheable addresses with the cache in bypass) utilize the PLB as a single line cache. A single valid bit is associated with the PLB, denoting that the PLB contents are valid. As such all fetch requests resulting in an update of the PLB, whether to a cacheable address or not, are implemented as SRI Burst Transfer 4 (BTR4) transactions, with the critical double-word of the PLB line being fetched first size. The PLB may be invalidated by writing PCON1.PBINV.

### CPU Slave Interface (CPS)

The CPU Slave Interface provides access from the SRI bus to the CPU CSFR and SFR registers.

## CPU Subsystem

### 5.3.6.3.2 PMI Registers

Three control registers are control the operation of the Program Memory Interface. These registers and their bits are described in this section.

#### PMI Register Descriptions

##### CPUx Program Control 0

**Application Reset Value:** 0000 0000<sub>H</sub>

Field	Bits	Type	Description
<b>FRE</b>	0	rwh	<b>Fetch Range Error</b> A Fetch Range Error occurs whenever an access to the Program Scratch is outside the range of the SRAM.
<b>RES</b>	1, 11:3, 13, 31:15	r	<b>Reserved</b>
<b>FBE</b>	2	rwh	<b>Fetch Bus Error</b> A Fetch bus error will be set whenever the SRI flags an error due a fetch from external memory. This will be set for both direct fetches from the bus and for cache refills.
<b>FPE</b>	12	rwh	<b>Fetch Peripheral Error</b> A Fetch peripheral error will be flagged whenever a fetch is attempted to peripheral space.
<b>FME</b>	14	rwh	<b>Fetch MSIST Error</b> During SIST mode, a fetch from the PTAG will cause a PSE trap to occur.

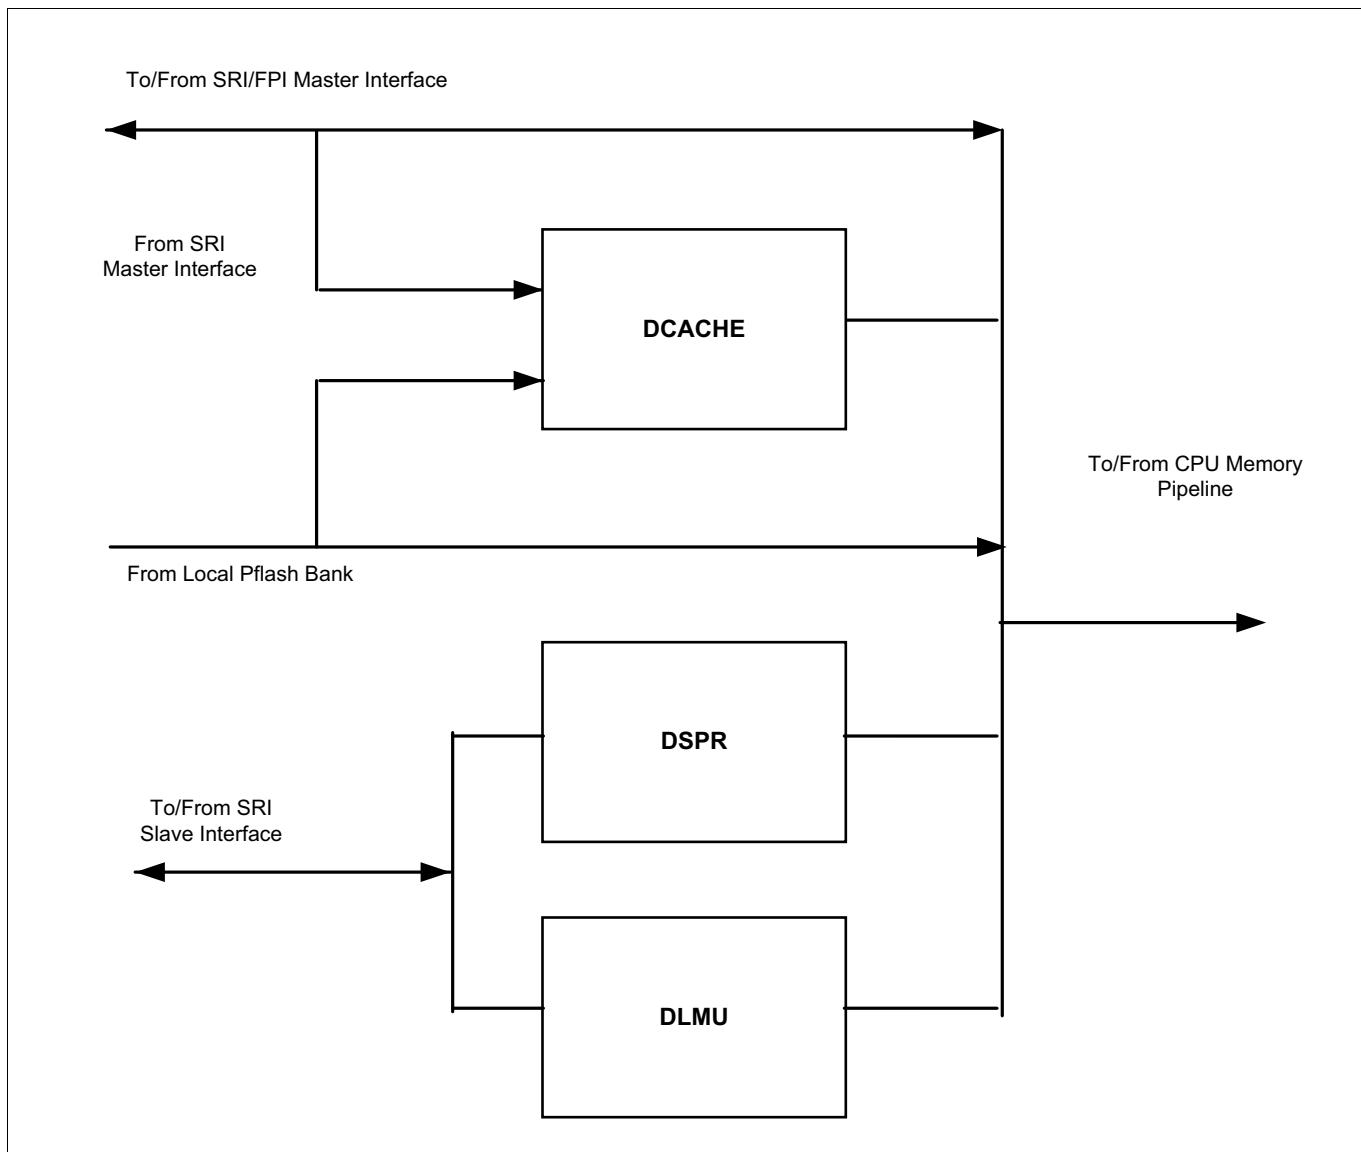

## CPU Subsystem

### 5.3.6.4 Data Memory Interface (DMI)

The Data Memory Interface (DMI) provides data values to the CPU and stores data values supplied by the CPU.

#### 5.3.6.4.1 DMI Description

This figure shows the block diagram of the Data Memory Interface (DMI) of the TC1.6.2P.

**Figure 52 DMI block diagram**

The Data Memory Interface (DMI) has the following features:

- Data Scratchpad Ram (DSPR)
  - Supporting unaligned access (16-bit aligned) with no penalty.
- Data Memory (DCACHE):
  - Two-way set associative cache, Least recently used (LRU) replacement algorithm
  - Cache line size: 256 bits
  - Validity granularity: One valid bit per cache line
  - Write-back Cache: Writeback granularity: 256 bits

## CPU Subsystem

- Refill mechanism: full cache line refill
- Single cycle access for hit.
- Distributed LMU SRAM (DLMU)
- CPU interface
- Shared Resource Interconnect Bus (SRI) Master interface
- Shared Resource Interconnect (SRI) Slave interface to DSPR
- Interface to local PFlash bank (LPB)
- Flexible Peripheral Interconnect Bus (FPI) Master interface for fast access to peripherals
- All DMI SRAMs (DSPR, DCACHE, and cache tag SRAM) are ECC protected

### Data Scratchpad RAM (DSPR)

The DSPR provides fast, deterministic data access to the CPU for use by performance critical code sequences.

The DSPR is organised as multiple memory “towers”. This organisation allow the CPU to access 64bits of data from any 16bit aligned address

The DSPR may also be accessed from the SRI Slave interface by another bus master, with both read and write transactions supported. The DSPR may be accessed by the SRI Slave interface using any SRI transaction type, including burst transfers. In accordance with the SRI protocol, accesses to the SRI Slave interface must be naturally aligned.

Errors detected at the ECC decoders are signaled to the EMM via the SSH logic of the associated SRAM.

The data scratchpad RAM is ECC protected across 16-bit data. Bytes Writes to the DSPR will be performed as read-modify-write operations at the memory interface. Any read-modify-write operation that detects an error on the read phase will not perform the write phase of operation. (Byte writes to un-initialised memory will always result in an ECC error being detected on the read phase and hence no data will be written to the memory).

### Data Cache (DCACHE)

The DCache is a Two-way set-associative cache with a Least-Recently-Used (LRU) replacement algorithm. Each line contains 256 bits of data along with ECC bits. A single valid bit and a single dirty bit are associated with each line.

CPU data accesses to a cacheable memory segment target the DCache. If the requested address and its associated data are found in the cache (Cache Hit), the data is passed to/from the CPU Load-Store Unit without incurring any wait states. If the address is not found in the cache (Cache Miss), the DMI cache controller issues a cache refill sequence and wait states are incurred whilst the cache line is refilled. The CPU load-store interface will generate unaligned accesses (16-bit aligned), which will result in up to 64-bits of data being transferred to or from the CPU (for non-context operations). If the data access is made within a DCACHE line, no matter the alignment, and a cache hit is detected then the requested data is returned to the CPU in a single cycle. If the data access is made to the end of a DCACHE line, such that the requested data would span two DCACHE lines, a single wait cycle is incurred (if both cache lines are present in the cache, otherwise a refill sequence is required for the missing cache line(s)).

The data cache is of the writeback type. When the CPU writes to a cacheable location the data is merged with the corresponding cache line and not written to main memory immediately. Associated with each cache line is a single ‘dirty’ bit, to denote that the data in the cache line has been modified. Whenever a CPU load-store access results in a cache miss, and each of the potential cache ways that could hold the requested cache line are valid, one of the cache lines is chosen for eviction based upon the LRU replacement algorithm. The line selected for eviction is then checked to determine if it has been modified using its dirty bit. If the line has not been modified the line is discarded and the refill sequence started immediately. If the line has been modified then the dirty data

## CPU Subsystem

is first written back to main memory before the refill is initiated. Due to the single dirty bit per cache line, 256 bits of data will always be written back, resulting in a SRI Burst-4 Transfer (BTR4) transactions.

Data Cache refills always result in the full cache line being refilled, with the critical double-word of the DCache line being fetched first. A refill sequence will always affect only one cache line. There is no prefetching of the next cache line. Due to the uniform size of DCache refill sequences, such refills are always implemented using SRI Burst Transfer 4 (BTR4) transactions.

All Cache SRAMs are ECC protected.

All TAG SRAMs are ECC protected

Errors detected at the ECC decoders are signaled to the EMM via the SSH logic of the associated SRAM

### Data Cache Bypass

The Data Cache may be bypassed, under control of DCON0.DCBYP, to provide a direct data access path to memory. The default value of DCON0.DCBYP is such that the data cache is bypassed after reset.

Whilst the data cache bypass is enabled, a data access request by the CPU to a cacheable address will result in a forced cache miss. Any valid cache lines within the data cache will remain valid and unchanged whilst the data cache is bypassed. As such data accesses to cacheable addresses with the data cache bypass enabled behave identically to data accesses to non-cacheable addresses.

The DCON0 register is CPUx endinit protected.

### 5.3.6.4.2 Distributed LMU (DLMU)

The DLMU is a contiguous portion of the global LMU SRAM. The DLMU provides fast, deterministic data access to a segment of the global LMU, ideally for use by the local CPU for global data.

The DLMU is organised as a 64 bit wide memory with ECC protection implemented on a 64bit granularity. Sub double word write accesses are performed as read-modify-write operations.

The DLMU may also be accessed from the SRI Slave interface by another bus master, with both read and write transactions supported. The DSPR may be accessed by the SRI Slave interface using any SRI transaction type, including burst transfers.

**The DLMU is uncacheable for data accesses from the local CPU. (The same as the DSPR)**

Errors detected at the ECC decoders are signaled to the SMU via the SSH logic of the associated SRAM.

The DLMU is ECC protected across 64-bit data. Writes to the DLMU that are less than 64 bits, or which are 64 bits but not naturally aligned will be performed as read-modify-write operations at the memory interface. Any read-modify-write operation that detects an error on the read phase will not perform the write phase of operation. (Sub-64 bit writes to un-initialised memory will always result in an ECC error being detected on the read phase and hence no data will be written to the memory).

### 5.3.6.4.3 DMI Trap Generation

CPU data accesses to the DMI may encounter one of a number of potential error conditions, which result in one of the following trap conditions being reported by the DMI.

#### ALN Trap

An ALN trap is raised for the following conditions:

- An access whose effective address does not conform to the alignment rules
- An access where the length, size or index of a circular buffer is incorrect

Whenever an ALN trap occurs, the DSTR (Data Synchronous Trap Register) and the DEADD (Data Error Address Register) CSFRs are updated.

## CPU Subsystem

### MEM Trap

A MEM trap is raised for the following conditions:

- An access whose effective address has a different segment to that of the base address (Segment Difference Error)
- An access whose effective address causes the data to span two segments (Segment Crossing Error)
- A memory address is used to access a CSFR area (CSFR Access Error)

Whenever a MEM trap occurs, the DSTR (Data Synchronous Trap Register) and the DEADD (Data Error Address Register) CSFRs are updated.

### DSE Trap

A DSE trap is raised for the following conditions:

- An access outside the range of the DSPR (Scratch Range Error)
- An error on the bus for an external accesses due to a load (Load Bus Error)
- An error from the bus during a cache refill (Cache Refill Error)
- An error during a load whilst in SIST mode (Load MSIST Error)
- An error generated by the overlay system during a load.

Whenever a DSE trap occurs, the DSTR (Data Synchronous Trap Register) and the DEADD (Data Error Address Register) CSFRs are updated.

### DAE Trap

A DAE trap is raised for the following conditions:

- An error on the bus for an external accesses due to a store (Store Bus Error)
- An error on the bus due to a cache writeback (Cache writeback Error)
- An error from the bus due to a cache flush (Cache Flush Error)
- An error due to a store whilst in SIST mode (Store MSIST Error)
- An error generated by the overlay system during a store.

Whenever a non-inhibited DAE trap occurs, the DATR (Data Asynchronous Trap Register) and the DEADD (Data Error Address Register) CSFRs are updated. DAE traps are inhibited if the DATR register is non-zero.

### Data Memory Protection Traps

Data memory protection traps (MPW, MPR, MPP, MPN) are raised by the memory protection system when a protection violation occurs. Whenever a data memory protection trap occurs the DSTR (Data synchronous trap register) and the DEADD (Data Error Address Register) are updated.

### 5.3.6.4.4 DMI Registers

Two control registers and three trap flag registers control the operation of the DMI. These registers and their bits are described in this section.

## CPU Subsystem

### DMI Register Descriptions

Note: There is no DCON1 register in this implementation.

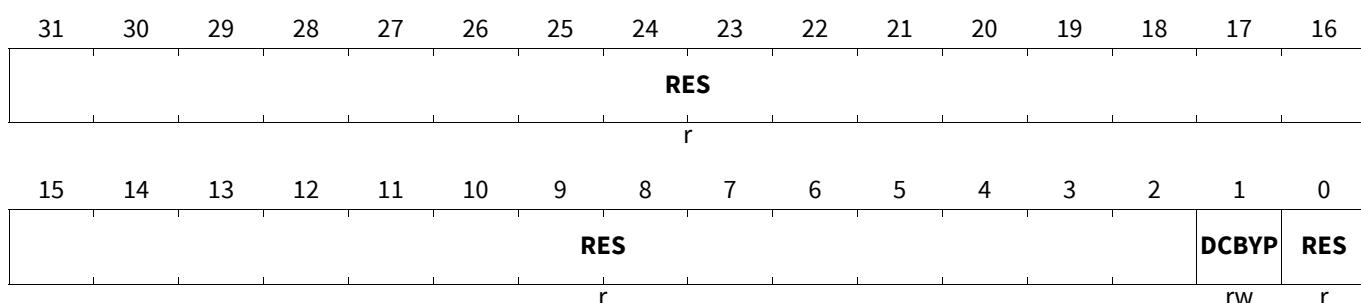

#### CPUx Data Memory Control Register

<b>ALN</b>	24	rwh	<b>Alignment Error</b> Data access causing alignment error.

### CPUx Data Asynchronous Trap Register

The DATR contains asynchronous trap information for the data memory system. The register is updated with trap information for DAE traps to aid the localisation of faults.

The register is updated whenever a valid trap is detected and the register has no bits already set. It is cleared by a write (independent of data value).

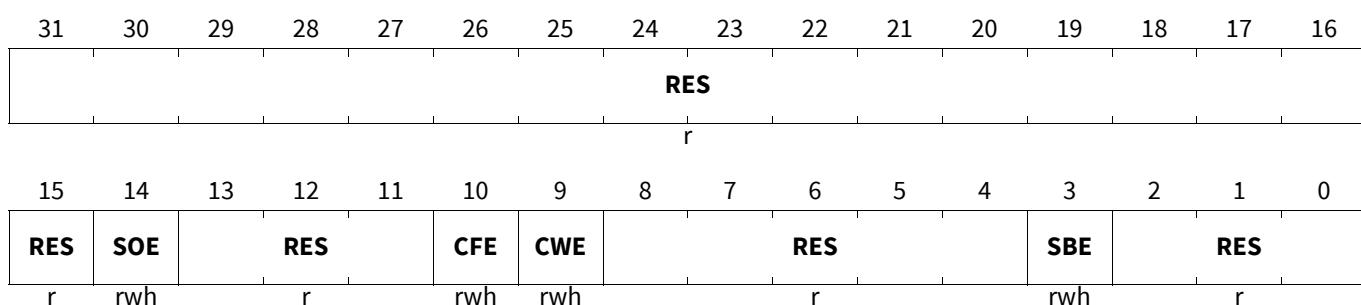

DAE traps are inhibited if the DATR register is non-zero.

#### DATR

## CPU Subsystem

### CPUx Data Error Address Register

DEADD contains trap address information for the Data memory system. The register is updated with trap information for MEM, ALN, DSE or DAE traps to aid the localisation of faults.

The register is only set whenever a trap is detected and either the DATR or DSTR registers have no bits already set.

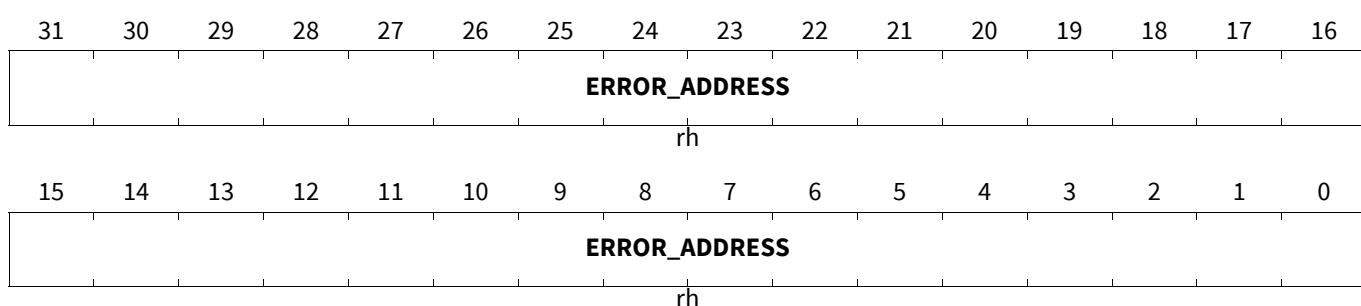

The register contents are only valid when either the DATR or DSTR register is non-zero and hence should be read prior to clearing these registers.

#### DEADD

<b>ERROR_ADDR</b>	31:0	rh	<b>Error Address</b>
<b>ESS</b>			

### 5.3.7 Miscellaneous

This chapter documents miscellaneous features that do not have any other logical place to be documented.

#### 5.3.7.1 Boot Halt

Following a system reset Core-0 will start its boot sequence, all other cores will be placed in the boot-halt state. In this state the core is halted, and the instruction fetch system stalled. All traps and interrupts are ignored by a core in the boot-halt state. All memories and registers associated with the core are available for access via the bus system in the boot-halt state. A core in boot-halt has SYSCON.BHALT set. **The core will remain halted until the SYSCON.BHALT bit is written to "0" when it will start to fetch from the PC defined in the PC CSFR (This will be the boot PC unless otherwise updated). A write to "1" of the SYSCON.BHALT will be ignored.**

#### 5.3.7.2 SSH usage recommendations

The following usage of the CPU SRAM SSH system is recommended.

- When any one of the CPU local data memories (DSPR/DCACHE or DTAG) is in SSH test mode (MEMTEST enabled), then other CPU local data memories will be not be accessible. It is therefore recommended to enable DSPR/DCACHE SSH mode and DTAG memory SSH mode together.
- When any one of the CPU local program memories (PSPR/PCACHE or PTAG) is in SSH test mode (MEMTEST enabled), then other CPU local program memories will be not be accessible. It is therefore recommended to enable PSPR/PCACHE SSH mode and PTAG memory SSH mode together.

---

## CPU Subsystem

### 5.3.7.3 Debug restrictions

For context operations and operations using circular addressing the base address of the operation is used for debug range comparison not the effective address.

When the pcache is mapped into address space pcache operation can only be enabled when debug is enabled. When the dcache is mapped into address space dcache operation can only be enabled when debug is enabled.

External writes to the processor's GPR registers are not supported unless the processor is in Boot-Halt, Debug-Halt or idle.

External writes to the processor's PSW and PC registers are not supported unless the processor is in Boot-Halt, Debug-Halt or idle.

### 5.3.7.4 Local Pflash Bank Configuration Registers

## CPU Subsystem

## 5.3.7.4.1 Registers

## Flash Configuration Registers

## CPUx Flash Configuration Register 0

Software may program a Flash Prefetch Buffer with a master tag identifier stored in Flash Configuration Register 0.

If a CPU instance does not have a local PFlash bank then the FLASHCON0 register associated with that instance will have no functionality.

## FLASHCON0

CPUx Flash Configuration Register 0 (01100<sub>H</sub>) Reset Value: [Table 130](#)

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
<b>RES</b>								<b>RES</b>							<b>TAG3</b>

Field	Bits	Type	Description
<b>TAG1</b>	5:0	rw	<b>Flash Prefetch Buffer 1 Configuration</b> FPB is assigned to on chip bus master with master tag id equal to TAG1.
<b>RES</b>	7:6, 15:14, 23:22, 31:30	r	<b>Reserved</b> Always read as 0; should be written with 0.
<b>TAG2</b>	13:8	rw	<b>Flash Prefetch Buffer 2 Configuration</b> FPB is assigned to on chip bus master with master tag id equal to TAG2.
<b>TAG3</b>	21:16	rw	<b>Flash Prefetch Buffer 3 Configuration</b> FPB is assigned to on chip bus master with master tag id equal to TAG3.
<b>TAG4</b>	29:24	rw	<b>Flash Prefetch Buffer 4 Configuration</b> FPB is assigned to on chip bus master with master tag id equal to TAG4.

Table 130 Reset Values of FLASHCON0

Reset Type	Reset Value	Note
Application Reset	3F3F 3F3F <sub>H</sub>	
CFS Value	0000 0000 <sub>H</sub>	

## CPUx Flash Configuration Register 1

The Flash Configuration Register 1 controls the stall response.

If a CPU instance does not have a local PFlash bank then the FLASHCON1 register associated with that instance will have no functionality.

## CPU Subsystem

### FLASHCON1

#### CPUX Flash Configuration Register 1

(01104<sub>H</sub>)

Application Reset Value: 0202 0000<sub>H</sub>

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
RES				RES1		RES				MASKUECC					
r					rw					r					rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RES												STALL			
								r							rw

Field	Bits	Type	Description
STALL	0	rw	<b>Stall Bus Request</b> This field must not be changed while any bank is busy. The results are unpredictable. It is strongly recommended to configure this field once and avoid changing it during operation. Reading a flash bank, erase counter, or status register, in Sleep Mode must result in a bus error independent of this field (although it reports "busy"). 0 <sub>B</sub> <b>Error</b> , Reading local PFlash bank, erase counter, or status registers, when DMU_STATUS.PxBUSY is set, generates a bus error. 1 <sub>B</sub> <b>Stall</b> , Reading local PFlash bank, erase counter, or status registers when DMU_HF_STATUS.PxBUSY is set delays the response by inserting additional wait cycles until PxBUSY is cleared.
RES	15:1, 23:18, 31:26	r	<b>Reserved</b> Always read as 0; should be written with 0.
MASKUECC	17:16	rw	<b>Mask PFLASH Uncorrectable ECC Bit Error</b> No value other than 01 <sub>B</sub> or 10 <sub>B</sub> shall be programmed in the register bitfields. The system will behave as specified for 10 <sub>B</sub> if 00 <sub>B</sub> or 11 <sub>B</sub> is programmed. 01 <sub>B</sub> If a local PFLASH uncorrectable ECC error occurs, then the error is globally disabled for any requesting master reading the local PFLASH. 10 <sub>B</sub> If a PFLASH uncorrectable ECC error occurs then an uncorrectable ECC error is reported to the CPU.
RES1	25:24	rw	<b>Reserved - RES</b> Always read as 2; should be written with 2.

### CPUX Flash Configuration Register 2

The Flash Configuration Register 2 controls the recording of ECC errors and margin control.

No value other than 01<sub>B</sub> or 10<sub>B</sub> shall be programmed in the register bitfields.

If a CPU instance does not have a local PFlash bank then the FLASHCON2 register associated with that instance will have no functionality.

## CPU Subsystem

### 5.3.8 Lockstep Comparator Logic (LCL)

The Lockstep Comparator Logic module provides access to the control and self test functions of the processor lockstep comparators.

#### 5.3.8.1 Feature List

An overview of the features implemented in the LCL follows:

- Monitoring the core comparators for the lockstep core and its shadow and flagging any detected differences
- Running background, continuous self test on the lockstep comparators to validate the correct operation of the logic.

## CPU Subsystem

### 5.3.8.2 Lockstep Control

The lockstep control function is enabled by the LSEN bitfield in a control register in the SCU. Each core capable of lockstep has its own instance of the control register.

These registers are only initialised by a cold power-on reset. In this initialisation state, all lockstepped processors in the system will have lockstep enabled. The lockstep function can only be disabled by the system initialisation software writing a  $0_B$  to the LSEN bitfield. Application software cannot enable or disable the lockstep function.

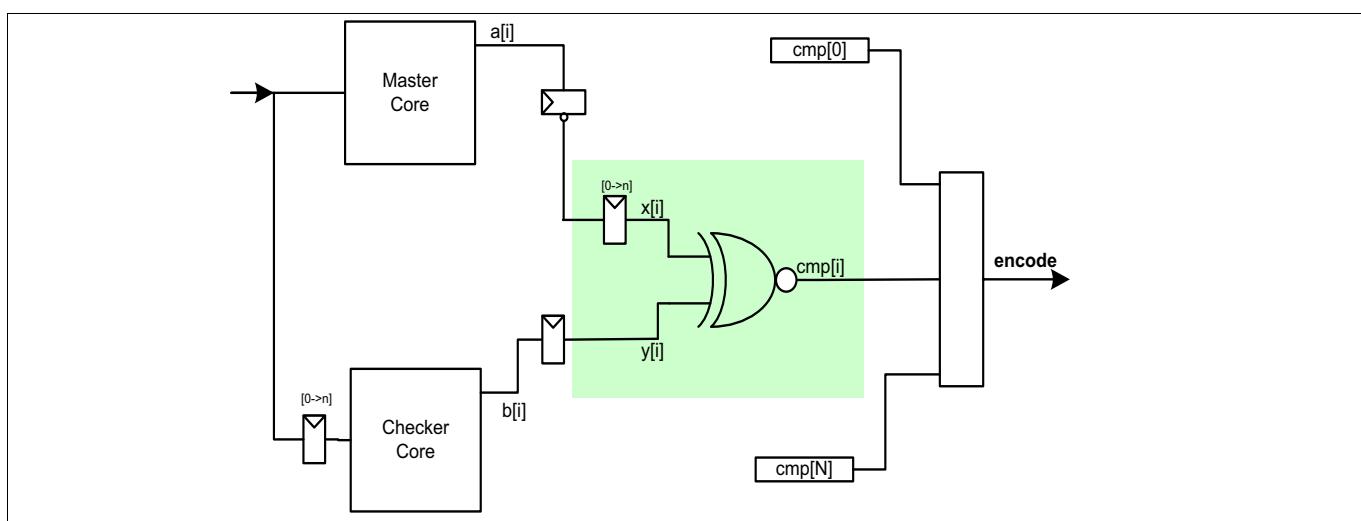

The current mode of the lockstep logic can be monitored by reading the lockstep status bit, LS, in the associated LCLCON register.

Writes to the control registers will be subject to the protection mechanisms of the SCU.

### 5.3.8.3 Lockstep Monitoring

The lockstep monitoring function will compare the outputs from the master and checker cores and report that a failure has occurred to the Safety Management Unit (SMU) for appropriate action.

The monitoring function temporally separates the cores by inserting synchronisation delays to re-align the signals being compared. To achieve this, the checker core inputs and the master core outputs fed to the comparators are delayed by two clock cycles.

**Figure 53 Node Comparator**

**Figure 53** above shows the equivalent circuit of an arbitrary node comparator,  $i$ , of 0 to  $N$  comparators. The comparator monitors two signals,  $\mathbf{a}$  and  $\mathbf{b}$ , which are connected to the same node in the master and checker cores. The signals can be synchronised in the relevant core using the core clock to minimise impact on the core timing.

After the optional synchronisation, the master core monitor point is inverted to reduce the risk of a common mode failure in the two monitored signals. Therefore,  $\mathbf{x}$  is equivalent to  $\mathbf{a}$  delayed by  $n$  clock cycles, where  $n=2$  in this implementation, to allow for the temporal shift between the master and checker cores and  $\mathbf{y}$  is equivalent to  $\mathbf{b}$ . If the nodes differ (i.e.  $\mathbf{x}$  and  $\mathbf{y}$  are the same), the CMP signal is set to  $1_B$ . This will cause the **encode** signal to flag the failing node and the failure will be detected. In the event that multiple nodes fail, the encode output will be the minimum and maximum values of all the indices,  $i$ , of the failing nodes. This has no impact on normal functioning but allows the self test logic to detect a real failure occurring in the same clock cycle that a fault is injected for test purposes.

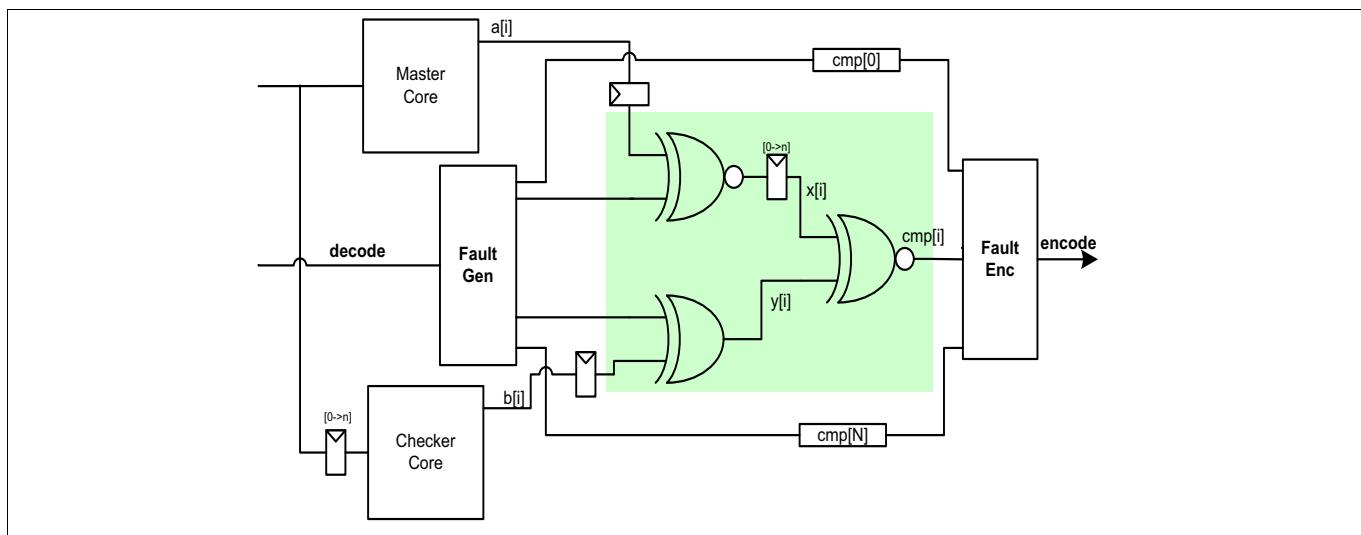

## CPU Subsystem

### 5.3.8.4 Lockstep Self Test

Each core capable of lockstep also has a continuously running background self test of the lockstep comparator. The self test function will inject faults into both inputs of each of the monitored nodes and verify that the fault is correctly detected by the monitoring logic.

In the event of a self test failure being detected, the failure will be reported to the Safety Management Unit for an appropriate response.

An equivalent circuit of a node comparator showing the fault injection logic is shown in [Figure 54](#)

**Figure 54 Node Comparator with Fault Injection**

Faults are injected using the **Fault Gen** block. This will use a binary number, **decode**, to calculate which node is to be tested. **decode** will be generated from a free running, binary counter using gray code number representation (the **input counter**). The Self test circuit will test every node once every 8192 clock cycles. Alternate test cycles will inject faults into either the **a** or **b** side of the comparator node. The complete self test cycle will therefore repeat every 16384 clock cycles.

Injecting a fault into either side of the comparator node will cause that node to fail unless a real fault occurs in the same clock cycle in which case the two faults will cancel out.

The node failing is processed by the **Fault Enc** block to generate a binary representation of the failing node, **encode**. This contains two numbers, the node index of the first node found to be failing counting up from the lowest minimum node index and the node index of the first node found to be failing counting down from the maximum node index.

If the lockstep block is functioning correctly, both values in **encode**, will either be 0 if no failures have been detected or the number of the node which has had a fault induced by the self test logic.

The values in **encode** are checked against a second, independent binary counter (the **monitor counter**). The **monitor counter** is also compared against the value of the **input counter**. In the event that either of the values in **encode** or the **input counter** fails to match the value of the monitor counter, a failure condition will be flagged to the SMU.

With this implementation, any of the following conditions will cause a self test fail:

- an actual fault occurring on any of the **a** or **b** nodes
- a stuck at  $0_B$  fault occurring on any of the **cmp** nodes
- a stuck at  $1_B$  fault occurring on any of the **cmp** nodes
- a failure in the **Fault Gen** block causing an incorrect or no fault to be injected

## CPU Subsystem

- a failure in the **Fault Enc** block causing an incorrect detection or no fault to be detected
- a stuck at fault on **x** (assuming that an injected fault does not always coincide with a masking pulse on **b**)
- a stuck at fault on **y** (assuming that an injected does not always coincide with a masking pulse on **a**)
- an actual fault on any of the **a** or **b** nodes coinciding with an injected fault
- a soft error occurring on either the **input counter** or **monitor counter**.

### 5.3.8.5 Lockstep Failure Signalling Test

The lockstep comparator allows a failure to be injected into one of the comparator nodes to allow the signalling of failures to be verified. A failure can be injected by writing  $1_B$  to the LCLT bitfield of the LCLTEST register. The failure will be injected for a single cycle of the SPB clock. It is not necessary to write a  $0_B$  to clear the test.

### 5.3.8.6 Functional Redundancy

All registers in the lockstep block which are not capable of being directly monitored for correct operation by the self test function will be duplicated. In the event of the duplicated registers not storing the same state, an error will be flagged to the SMU.

---

**CPU Subsystem**

### 5.3.9 Data Access Overlay (OVC)

The data overlay provides the capability to redirect selected data accesses to the Overlay memory. Data accesses made by the TriCore to Program Flash, Online Data Acquisition space, or EBU space (if present) can be redirected. Overlay memory may be located in the Local Memory (if present), in the Emulation Memory (Emulation Device only), in the EBU space, or in the DPSR/PSPR memory. Overlay functionality makes it possible, for example, to modify the application's test and calibration parameters (which are typically stored in Flash memory) during run time of a program. Note that only read and write data accesses are redirected. The access redirection is executed without performance penalty.

**Attention:** As the address translation is implemented in the DMI it is only effective for data accesses by the TriCore. Instruction fetches by the TriCore or accesses by any other master (including the debug interface) are not effected!

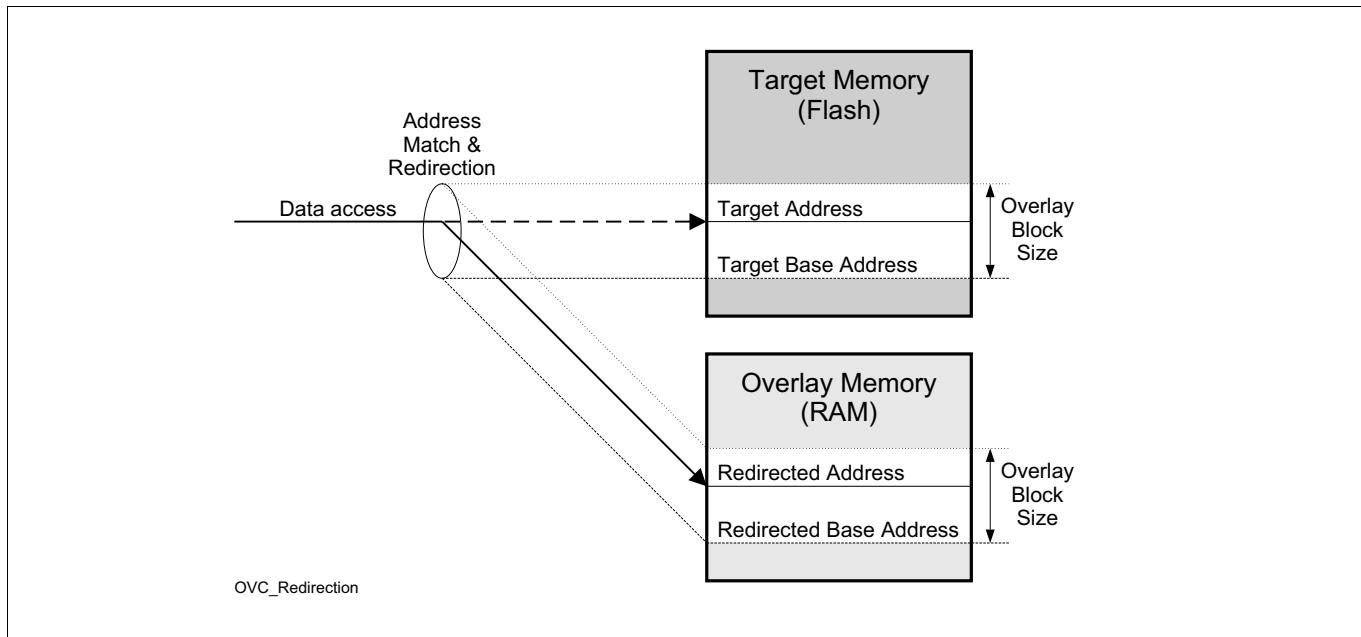

#### Summary of Features and Functions

- Redirecting data accesses addressed to Program Flash, OLDA or External EBU Space.
- Support redirection to Overlay memory located in:
  - Local Memory (LMU) (if present)
  - Emulation Memory (Emulation Device only)
  - EBU space (if present)
  - DPSR or PSPR memory
- Support of up to 4 MB overlay memory address range;
- Up to 32 overlay ranges ("blocks") available in each TriCore instance;
- Overlay block size from 32 byte to 128 Kbyte;
- Overlay memory location and block size selected individually for every overlay block;
- Multiple overlay blocks can be enabled or disabled with one register write access;
- Programmable flush (invalidate) control for data cache in DMI.
- Overlay start/stop synchronised against data load.
- Individual Overlay system per processor core.

## CPU Subsystem

### 5.3.9.1 Data Access Redirection

The principle of redirecting data access from the original target memory (“Target Address”) to overlay memory (“Redirected Address”) is shown below.

**Figure 55 Data Access Redirection**

Data access overlay is defined using overlay ranges (“overlay blocks”). Each overlay block defines one continuous range of address space for which the accesses are redirected. Each overlay block is configured with the following parameters:

- Overlay Block Target Base Address - the start address for the range of the target addresses to be redirected;
- Overlay Block Size - the size of the range of the addresses to be redirected;
- Overlay Block Redirection Base Address - the start address for redirection.

In AURIX™ up to 32 overlay ranges can be used in each TriCore instance.

Each overlay block has 3 associated registers for independent configuration of these parameters. The overlay parameters are configured as follows:

- Target Base Address is configured with OTARx register,
- Overlay Block Size is configured with OMASKx register,
- Redirection Base Address is configured with RABRx register.

The size of the overlay memory blocks can be  $2^n \times 32$  bytes, with  $n = 0$  to 12. This gives the block size range from 32 bytes to 128 Kbytes. The start address of the block can only be an integer multiple of the programmed block size (natural alignment boundary). If OTAR register value, or RABR register value is not aligned with the block size, the least significant bit values are ignored and treated as zero.

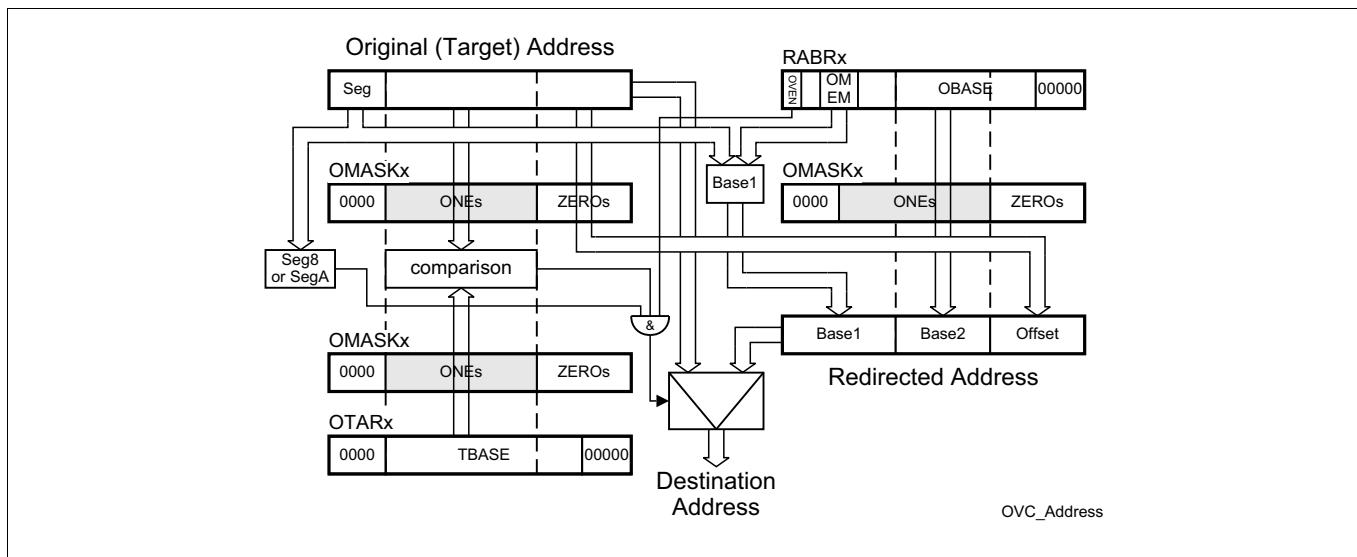

The Redirection Base Address is determined by two fields in RABRx register:

- RABRx.OMEM selecting the Overlay Memory, and
- RABRx.OBASE selecting the base address within this memory.

Each overlay block can be activated or deactivated with its RABRx.OVEN bit. Overlay blocks can be activated and deactivated independently, by directly accessing RABRx register, or in groups, where multiple configured blocks are activated or deactivated concurrently. For information on concurrent block activation see [Chapter 5.3.9.4.1](#).

The address redirection process is shown in the following figure.

## CPU Subsystem

**Figure 56 Address Redirection Process**

Any data access to segment  $8_H$  or segment  $A_H$  is checked against all the activated overlay blocks. For each activated overlay block, address bits 27..5 are compared with the target base address (OTARx), and this bit-wise comparison is qualified by the content of OMASKx register. Address bits participate in the comparison if the corresponding OMASKx bits are set to one. The access is redirected, if all the address bits selected by OMASKx equal to the corresponding bits in OTARx register.

The address for redirection is constructed as follows:

- Address bits 31..22 are set according to the overlay memory selection (RABRx.OMEM) and the cache-ability of the original address.
- For address bits 21..5:
  - If the corresponding OMASKx bit is set, the address bit value is taken from RABRx.OBASE field;
  - If the corresponding OMASKx bit is cleared, the address bit value is taken from the original address.
- Address bits 4..0 are always taken directly from the original address.

If there is no redirection, the original address is used to perform the access.

Target address ranges for activated overlay blocks should not overlap or an exception may occur, see [Chapter 5.3.9.6](#).

### 5.3.9.2 Target Memories

Data access to any memory within the segment  $8_H$  or segment  $A_H$  may be redirected to overlay memory. In particular, access to the following memories may be redirected:

- Program Flash;
- Data Flash;
- OLDA space;
- External EBU space.

#### 5.3.9.2.1 Online Data Acquisition (OLDA) Space

Calibration is additionally supported by virtual OLDA memory range. The base address of the virtual OLDA memory range is  $A/8FE7\ 0000_H$ .

## CPU Subsystem

### 5.3.9.3 Overlay Memories

In the following, all the supported overlay memories are described. Note, that depending on the device type only a subset of the listed overlay memories is available. Overlay memory is selected independently for each block by RABRx.OMEM field value.

#### 5.3.9.3.1 Local Memory

If present, the Local Memory (LMU) can be selected for overlay. The Local Memory is selected for overlay block x redirection, if RABRx.OMEM value is 8. The base address of the LMU is  $B/9000\ 0000_H$ . During address translation, the upper 10 address bits are set to  $B0_H00_B$  (for target segment  $A_H$ ) or to  $90_H00_B$  (for target segment  $8_H$ ).

#### 5.3.9.3.2 External Memory

If present, the External Memory (EBU space) can be selected for overlay. The EBU space is selected for overlay block x redirection, if RABRx.OMEM value is  $A_H$ . The base address of the EBU space is  $A/8100\ 0000_H$ . During address translation, the upper 10 address bits are set to  $A1_H00_B$  (for target segment  $A_H$ ) or to  $81_H00_B$  (for target segment  $8_H$ ).

#### 5.3.9.3.3 DSPR & PSPR Memory

Data Scratch Memory (DSPR) or Program Scratch Memory (PSPR) from any core can be selected for overlay by configuring the block RABRx.OMEM value. During address translation, the upper 10 address bits are set to the target PSPR or DSPR target address. Depending on the value set in RABRx.OBASE either DSPR memory (starting at offset  $0_H$ ) or PSPR memory (starting at offset  $10\ 0000_H$ ) can be used.

### 5.3.9.4 Global Overlay Control

Overlay can be disabled or enabled individually for each core with OVCENABLE register. If OVCENABLE.OVENn bit is cleared no address redirection is permitted on Core-n regardless of the remaining register settings. A write to OVCENABLE register does not change any of the remaining register values.

While each overlay block can be activated and deactivated individually by writing its RABRx.OVEN bit, a dedicated functionality is provided for concurrently activating and deactivating multiple blocks. This can be useful in maintaining data consistency across several memory regions. For the purpose of concurrent activation and deactivation overlay blocks are selected in two stages:

- The individual blocks for activation and deactivation are selected with OVCn\_OSEL registers, for each core-n independently;
- The set of cores is selected with OVCCON.CSEL field.

Multiple overlay blocks can be simultaneously activated or deactivated with OVCCON.OVSTRT bit. When OVCCON.OVSTRT bit is written with one:

- If OVCCON.CSELn bit is written with one, and OVCn\_OSEL.SHOVENx bit value is one, overlay block x in core-n is activated, and OVCn\_RABRx.OVEN bit is set;
- If OVCCON.CSELn bit is written with one, and OVCn\_OSEL.SHOVENx bit value is zero, overlay block x in core-n is deactivated, and OVCn\_RABRx.OVEN bit is cleared;
- If OVCCON.CSELn bit is written with zero, the overlay configuration in core-n is not effected.

The actions listed above are executed concurrently. The overlay configuration is not changed otherwise. With this function it is possible to switch directly from one set of overlay blocks to another set of overlay blocks.

Multiple overlay blocks can be simultaneously deactivated with OVCCON.OVSTP bit. When OVCCON.OVSTP is written with one:

## CPU Subsystem

- If OVCCON.CSELn bit is written with one, all the overlay blocks in core-n are deactivated, and all OVCn\_RABRx.OVEN bits are cleared;
- If OVCCON.CSELn bit is written with zero, the overlay configuration in core-n is not effected.

The actions listed above are executed concurrently. The overlay configuration is not changed otherwise.

**Note:** *Overlay should not be enabled or disabled using global OVCENABLE register if any of the blocks are enabled with RABRx.OVEN. Instead, OVSTRT or OVSTP should be used if concurrent block enabling or disabling is required.*

When OVCCON.DCINVAL is written with one, all the unmodified (clean) data cache lines in the selected cores are invalidated. The data cache lines containing modified (dirty) data are not effected. The cores not selected with OVCCON.CSEL field are not effected. Data Cache invalidation can be combined with OVSTRT or OVSTP action. This function helps to assure that the CPU can access the new data after the overlay blocks have been activated or deactivated.

**Note:** *OVCCON.CSEL field is written together with OVSTRT, OVSTP and DCINVAL bits in the same register, and only impacts any action triggered by the same write. CSEL, OVSTRT, OVSTP and DCINVAL do not retain the written value and always read as zero.*

The OVCCON.OVCONF user control flag is provided, together with its protection bit OVCCON.POVOCONF. These bits do not impact the overlay functionality.

When OVCCON register is written with CSELn set and either OVSTRT or OVSTP set, and at the same time OVCn\_RABRy register is written, the resulting value of OVCn\_RABRx.OVEN bit is not defined. Possibility of such simultaneous access should be avoided.

OVSTRT, OVSTP and DCINVAL actions are not performed when TriCore is in IDLE state.

### 5.3.9.4.1 Global Overlay Control Synchronisation

When OVSTRT, OVSTP or DCINVAL action is requested its execution may be delayed to prevent changing Overlay configuration during an ongoing data load.

Sufficient time should be allowed after an action request, before another action is requested. If a new action is requested while previous action is still pending (due to synchronisation with CPU loads) some actions may be lost.

### 5.3.9.5 Overlay Configuration Change

Overlay block should be disabled, by clearing its RABRx.OVEN bit, before any changes are made to OTARx, OMASKx or RABRy registers. Otherwise, unintended access redirections may occur. Overlay block should only be enabled, if the target address, the overlay memory selection, the redirection address and the mask have all been configured with intended values.

**Note:** *The Overlay Control does not prevent configuring the translation logic incorrectly. In particular, redirection to not implemented or forbidden address range is not prevented.*

Special care needs to be taken to synchronise Overlay redirection change to the executed instruction stream if data consistency is required.

External accesses may be buffered in the CPU. External accesses that have not been completed may still be affected by overlay configuration changes. Therefore, it is advised to ensure completion of all pending accesses (for example, by executing DSYNC instruction) before any overlay range is activated or deactivated.

---

## CPU Subsystem

When overlay block is enabled and the same memory location is written through the target address space and read through the redirected address space, or vice-versa, the access synchronisation need to be enforced (with DSYNC and data cache writeback if applicable).

### 5.3.9.6 Access Protection, Attributes, Concurrent Matches

When data access is redirected by Overlay, access protection is applied as follows:

- Target address is subject to CPU Memory Protection (MPU) validation;
- Redirected address is subject to Safety Protection validation.

Physical Memory Attributes for the redirected access are determined basing on the Target Address segment (see CPU Physical Memory Attributes chapter).

Concurrent matches in more than one enabled overlay block are not supported. When an address matches two, or more, of the enabled overlay blocks, an exception is raised and the memory access is not performed. A load operation with multiple matches on overlay ranges, raises a Data Access Synchronous Error (DSE) trap, and a store operation raises Data Access Asynchronous Error (DAE) trap. In such case, relevant trap information registers: Data Synchronous Trap Register (DSTR), Data Asynchronous Trap Register (DATR), and Data Error Address Register (DEADD) are updated, see DMI Registers chapter for more information.

## CPU Subsystem

### 5.3.9.7 Overlay Control Registers

OVC block control registers are located in each module that supports data access overlay. OVC global control registers are located in SCU. OVC register access can be restricted by Safety Register Protection.

#### Per Core Overlay register

- OVCn\_RABRx
- OVCn\_OTARx
- OVCn\_OMASKx
- OVCn\_OSEL

Where n is the core number and x is the block number.

#### Global Overlay Registers

- OVCENABLE
- OVCCON

Registers OVCENABLE and OVCCON are described in SCU Chapter.

**Table 131 Register Overview - OVERLAY\_BLOCK\_CONTROL (ascending Offset Address)**

Short Name	Long Name	Offset Address	Access Mode		Reset	Page Number
			Read	Write		
OSEL	CPUx Overlay Range Select Register	0FB00 <sub>H</sub>	U,SV,32	SV,32,P	Application Reset	<a href="#">111</a>
RABRI	CPUx Redirected Address Base Register i	0FB10 <sub>H</sub> +i *12	U,SV,32	SV,32,P	Application Reset	<a href="#">111</a>
OTARI	CPUx Overlay Target Address Register i	0FB14 <sub>H</sub> +i *12	U,SV,32	SV,32,P	Application Reset	<a href="#">112</a>
OMASKi	CPUx Overlay Mask Register i	0FB18 <sub>H</sub> +i *12	U,SV,32	SV,32,P	Application Reset	<a href="#">113</a>

#### 5.3.9.7.1 Block control registers

For each of the 32 overlay memory blocks (indicated by index x), three registers control the overlay operation and the memory selection:

- Redirected Address Base Register RABRx, which selects the overlay memory, holds the block base address within this memory, and contains block enable bit.
- Overlay Target Address Register OTARx, which holds the base address of the memory block being overlaid.
- Overlay Mask Register OMASKx, which determines which bits (from RABRx) are used for the base address (of overlay memory and block) and which bits (of original data address) are directly used as offset within the block.

Additionally, Overlay Range Select Registers OSEL determines which blocks are to be enabled and which blocks are to be disabled when OVCCON.OVSTRT bit is set.

All overlay block control registers are reset to their default values with the application reset. A special debug reset is not considered.

**CPU Subsystem****CPUX Overlay Range Select Register****OSEL**
**CPUX Overlay Range Select Register** **(0FB00<sub>H</sub>)** **Application Reset Value: 0000 0000<sub>H</sub>**

**CPU Subsystem**

### 5.3.9.8 Global overlay control registers

Two registers globally control the overlay operation for all the cores:

- Overlay Enable Register OVCENABLE can be used to disable or enable data access overlay individually for each core;
- Overlay Control Register OVCCON can be used to perform the following action on selected set of cores:
  - concurrently enable / disable selected overlay blocks,
  - concurrently disable overlay blocks,
  - invalidate data cache.

---

## CPU Subsystem

### 5.3.10 CPU Architecture registers

#### 5.3.10.1 Registers with architecturally defined reset values

Please refer to the Tricore Architecture Manual for the descriptions and reset values of the following registers.

- SYSCON
- CPU\_SYSCON
- ICR
- CPU\_ICR
- TRiEVT (i=0-7)
- CPU\_TRiEVT (i=0-7)
- TRiADR (i=0-7)
- CPU\_TRiADR (i=0-7)
- CCTRL
- CPU\_CCTRL
- CCNT
- CPU\_CCNT
- ICNT
- CPU\_ICNT
- M1CNT
- CPU\_M1CNT
- M2CNT
- CPU\_M2CNT
- M3CNT
- CPU\_M3CNT
- DBGSR
- CPU\_DBGSR
- EXEVT
- CPU\_EXEVT
- CREVT
- CPU\_CREVT
- SWEVT
- CPU\_SWEVT
- TRIG\_ACC
- CPU\_TRIG\_ACC
- DBGTMR
- CPU\_DBGTMR

#### 5.3.10.2 Program Counter (PC)

Please refer to the Tricore Architecture Manual for the description of the Program Counter (PC) register. The reset value of the PC is configured by the SSW. For details on the reset value please refer to the Firmware chapter (Boot Mode evaluation sequence)

## CPU Subsystem

- PC
- CPU\_PC

### 5.3.10.3 Registers with Implementation specific reset values

The reset values and description of CPU architecture registers with implementation specific reset values can be listed in this section.

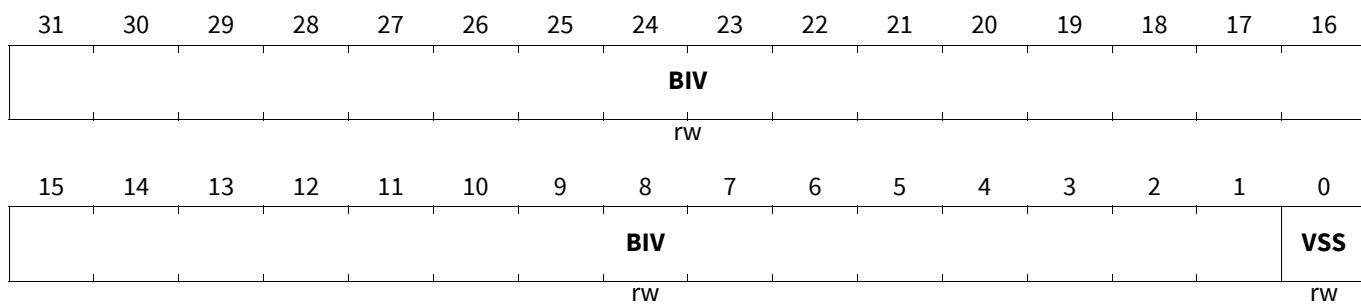

#### CPUX Base Interrupt Vector Table Pointer

**BIV**

**CPUX Base Interrupt Vector Table Pointer** (1FE20<sub>H</sub>) **Application Reset Value:** 0000 0000<sub>H</sub>

**CPU\_BIV**

**Short address for domain CSFR** (0FE20<sub>H</sub>) **Application Reset Value:** 0000 0000<sub>H</sub>

Field	Bits	Type	Description
<b>VSS</b>	0	rw	<b>Vector Spacing Select</b> 0: 32 byte vector spacing. 1: 8 Byte vector spacing.
<b>BIV</b>	31:1	rw	<b>Base Address of Interrupt Vector Table</b> The address in the BIV register must be aligned to an even byte address (halfword address). Because of the simple ORing of the left-shifted priority number and the contents of the BIV register, the alignment of the base address of the vector table must be to a power of two boundary, dependent on the number of interrupt entries used. For the full range of 256 interrupt entries an alignment to an 8 KByte boundary is required. If fewer sources are used, the alignment requirements are correspondingly relaxed.

## CPU Subsystem

### CPUx Base Trap Vector Table Pointer

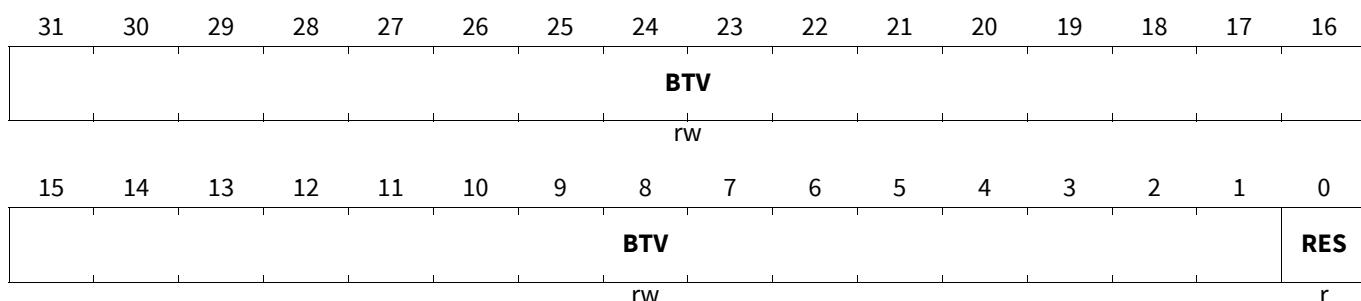

BTV

CPUx Base Trap Vector Table Pointer

(1FE24<sub>H</sub>)Application Reset Value: A000 0100<sub>H</sub>

CPU\_BTV

Short address for domain CSFR

(0FE24<sub>H</sub>)Application Reset Value: A000 0100<sub>H</sub>

Field	Bits	Type	Description
RES	0	r	<b>Reserved</b> Read as 0; should be written as 0.
BTW	31:1	rw	<b>Base Address of Trap Vector Table</b> The address in the BTV register must be aligned to an even byte address (halfword address). Also, due to the simple ORing of the left-shifted trap identification number and the contents of the BTV register, the alignment of the base address of the vector table must be to a power of two boundary. There are eight different trap classes, resulting in Trap Classes from 0 to 7. The contents of BTV should therefore be set to at least a 256 byte boundary (8 Trap Classes * 8 word spacing).

### CPUx Interrupt Stack Pointer

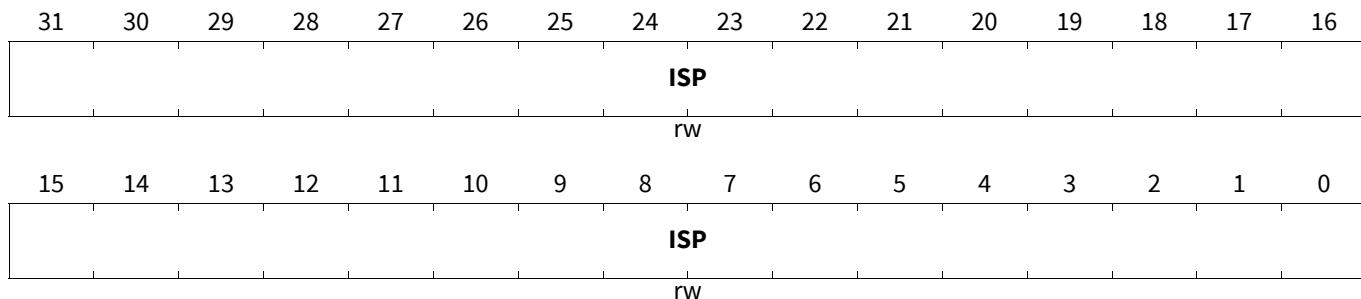

ISP

CPUx Interrupt Stack Pointer

(1FE28<sub>H</sub>)Application Reset Value: 0000 0100<sub>H</sub>

CPU\_ISP

Short address for domain CSFR

(0FE28<sub>H</sub>)Application Reset Value: 0000 0100<sub>H</sub>

Field	Bits	Type	Description
ISP	31:0	rw	<b>Interrupt Stack Pointer</b>

## CPU Subsystem

### CPUx Free CSA List Head Pointer

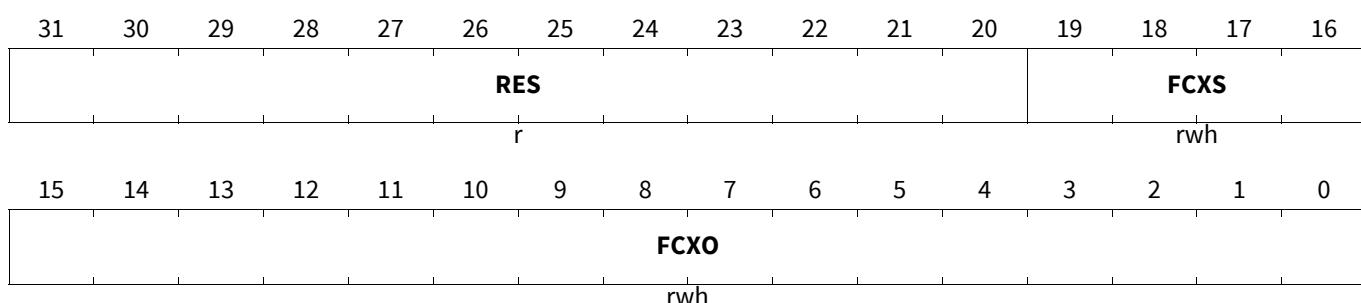

FCX

CPUx Free CSA List Head Pointer

**(1FE38<sub>H</sub>)****Application Reset Value: 0000 0000<sub>H</sub>**

CPU\_FCX

Short address for domain CSFR

**(0FE38<sub>H</sub>)****Application Reset Value: 0000 0000<sub>H</sub>**

Field	Bits	Type	Description
FCXO	15:0	rwh	<b>FCX Offset Address Field</b> The FCXO and FCXS fields together form the FCX pointer, which points to the next available CSA.
FCXS	19:16	rwh	<b>FCX Segment Address Field</b> Used in conjunction with the FCXO field.
RES	31:20	r	<b>Reserved</b> Read as 0; should be written as 0.

### CPUx Free CSA List Limit Pointer

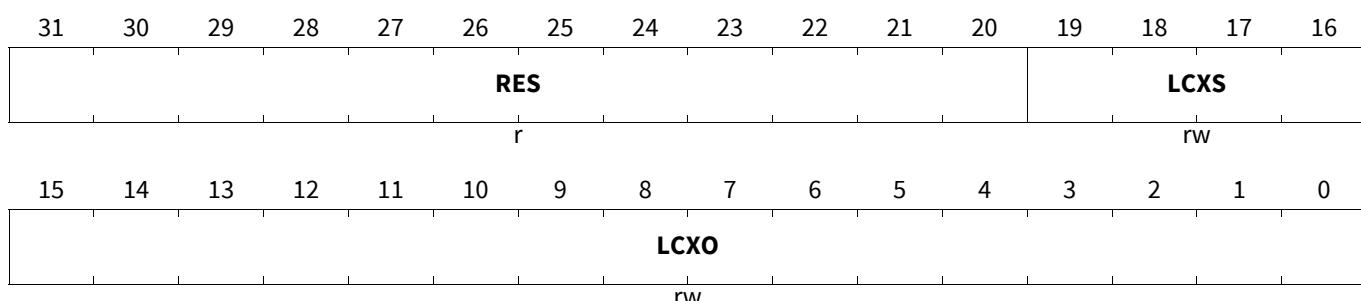

LCX

CPUx Free CSA List Limit Pointer

**(1FE3C<sub>H</sub>)****Application Reset Value: 0000 0000<sub>H</sub>**

CPU\_LCX

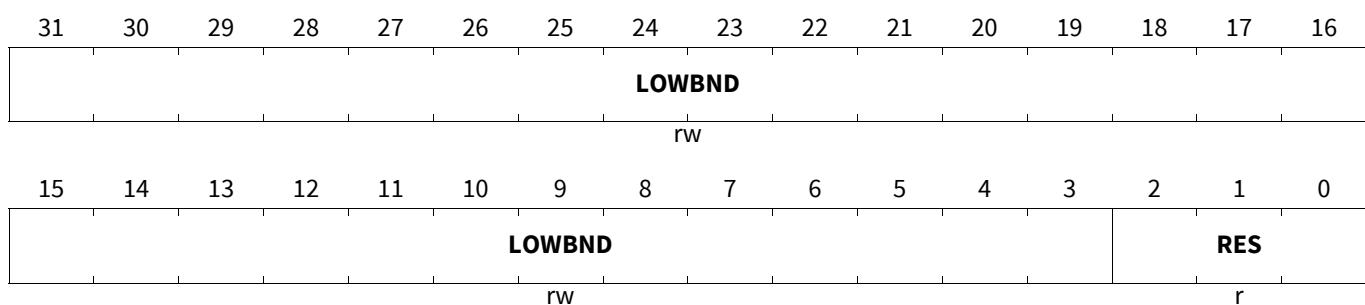

Short address for domain CSFR

**(0FE3C<sub>H</sub>)****Application Reset Value: 0000 0000<sub>H</sub>**

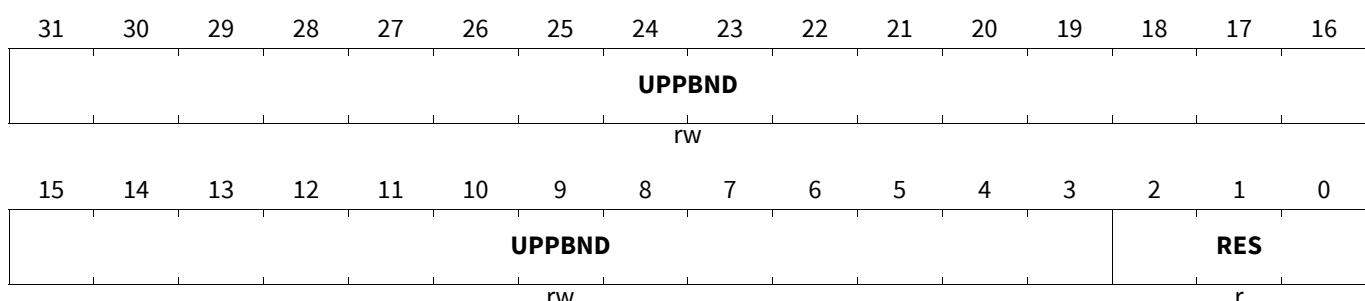

Field	Bits	Type	Description
LCXO	15:0	rw	<b>LCX Offset Field</b> The LCXO and LCXS fields form the pointer LCX, which points to the last available CSA.
LCXS	19:16	rw	<b>LCX Segment Address</b> This field is used in conjunction with the LCXO field.

**CPU Subsystem**

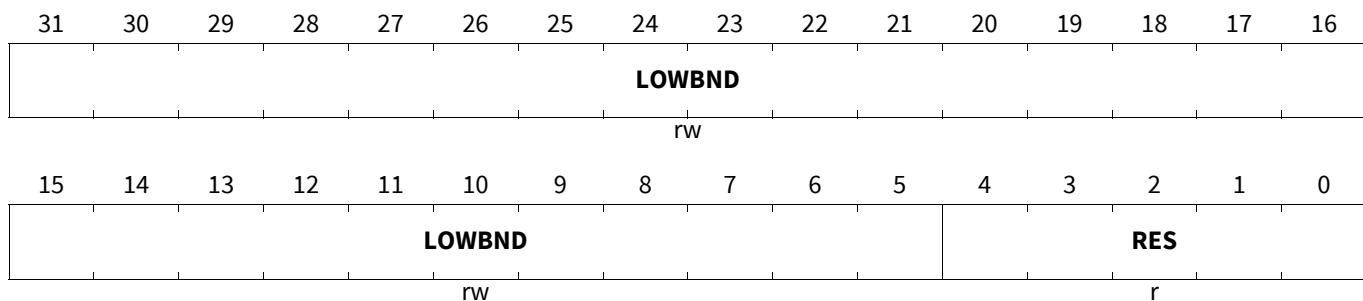

Field	Bits	Type	Description
<b>RES</b>	31:20	r	<b>Reserved</b> Read as 0; should be written as 0.

**CPUx Data Protection Range y, Lower Bound Register****DPRy\_L (y=0-17)****CPUx Data Protection Range y, Lower Bound Register( $1C000_H+y*8$ ) Application Reset Value: 0000 0000<sub>H</sub>****CPU\_DPRy\_L (y=0-17)****Short address for domain CSFR (0C000<sub>H</sub>+y\*8) Application Reset Value: 0000 0000<sub>H</sub>**

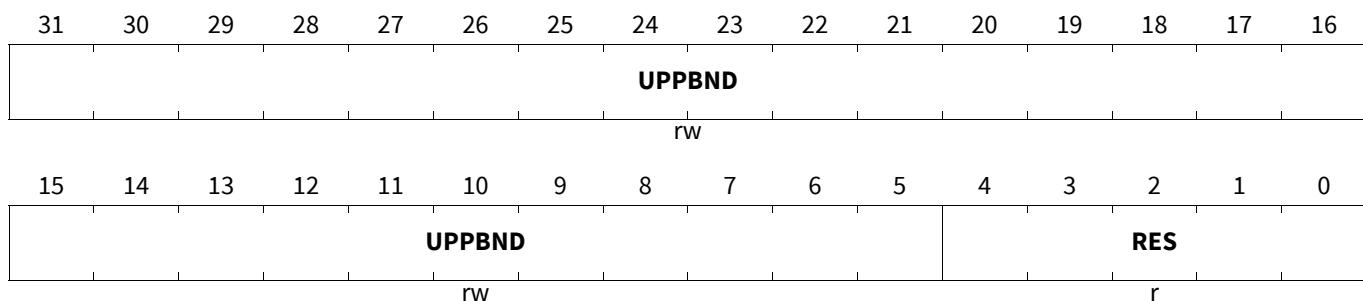

Field	Bits	Type	Description
<b>RES</b>	2:0	r	<b>Reserved</b> The three least significant bits are not writable and always return zero.
<b>LOWBND</b>	31:3	rw	<b>DPRy Lower Boundary Address</b>

**CPUx Data Protection Range y, Upper Bound Register****DPRy\_U (y=0-17)****CPUx Data Protection Range y, Upper Bound Register( $1C004_H+y*8$ ) Application Reset Value: 0000 0000<sub>H</sub>****CPU\_DPRy\_U (y=0-17)****Short address for domain CSFR (0C004<sub>H</sub>+y\*8) Application Reset Value: 0000 0000<sub>H</sub>**

Field	Bits	Type	Description
<b>RES</b>	2:0	r	<b>Reserved</b> The three least significant bits are not writable and always return zero.
<b>UPPBND</b>	31:3	rw	<b>DPRy Upper Boundary Address</b>

**CPUx Debug Monitor Start Address**

The DMS reset value is {20'hA0000,3'B0001,CORE\_ID,6'B000000}.

**DMS****CPUx Debug Monitor Start Address (1FD40<sub>H</sub>)**      **Debug Reset Value: A000 0XX0<sub>H</sub>****CPU\_DMS****Short address for domain CSFR (0FD40<sub>H</sub>)**      **Debug Reset Value: A000 0XX0<sub>H</sub>**

## CPU Subsystem

Field	Bits	Type	Description
<b>RES</b>	0	r	<b>Reserved</b>
<b>DMSValue</b>	31:1	rw	<b>Debug Monitor Start Address</b> The address at which monitor code execution begins when a breakpoint trap is taken.

### CPUx Debug Context Save Area Pointer

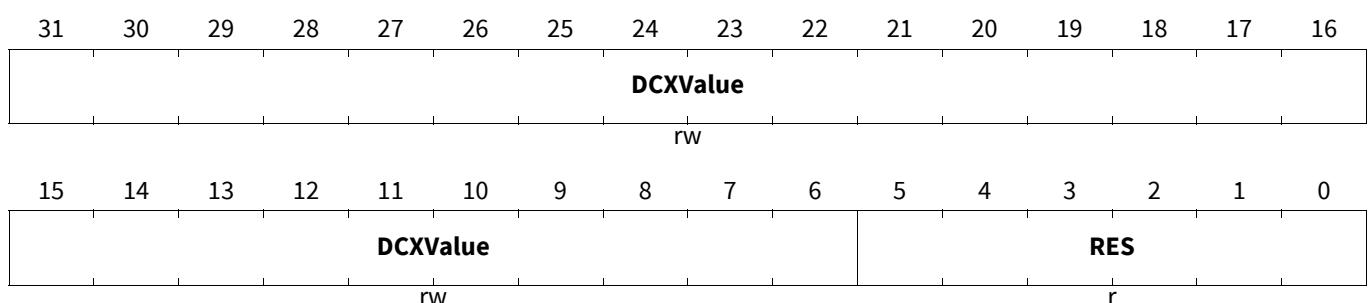

The reset value of the DCX register is {20'hA0000,3'b010,CORE\_ID,6'b000000}.

#### DCX

**CPUx Debug Context Save Area Pointer** **(1FD44<sub>H</sub>)** **Debug Reset Value: A000 0XX0<sub>H</sub>**

**CPU\_DCX**

**Short address for domain CSFR** **(0FD44<sub>H</sub>)** **Debug Reset Value: A000 0XX0<sub>H</sub>**

Field	Bits	Type	Description
<b>RES</b>	5:0	r	<b>Reserved</b>
<b>DCXValue</b>	31:6	rw	<b>Debug Context Save Area Pointer</b> Address where the debug context is stored following a breakpoint trap.

## CPU Subsystem

### 5.4 Safety Measures

The CPUs implements a number of safety concepts These are detailed in the following sections.

#### 5.4.1 SRI Bus Master Address Phase Error Injection

To allow the SRI address phase error detection system to be tested it is necessary to inject errors during the address phase of an SRI transaction. This is done by the TC1.6.2P SRI bus master for data accesses only. The SRI master selectively inverts individual bits of the address phase of an SRI data read or write phase ECC packet and is controlled using the SEGEN register. The SEGEN register contains three fields:- an enable (AE), an error descriptor (ADTYPE) and a bit flip (ADFLIP) field. When enabled for an address phase error the address ECC bits indicated by the flip field are inverted for the next SRI data read or write bus transaction performed. Following the transaction the enable bit is cleared by hardware. This mechanism allows selected bits of the SRI address ECC to be corrupted for a single transaction. The SEGEN register is CPUx ENDINIT protected.

#### 5.4.2 SRI Bus Master Write Phase Error Injection

To allow the SRI data phase error detection system to be tested it is necessary to inject errors during the data phase of an SRI write transaction. This is done by the TC1.6.2P SRI bus master. The SRI bus master selectively inverts individual bits of the SRI write phase ECC packet and is controlled using the SEGEN register. The SEGEN register contains three fields:- an enable (AE), an error descriptor (ADTYPE) and a bit flip (ADFLIP) field. When enabled for a data phase error the data phase ECC bits indicated by the flip field are inverted for the next SRI write bus transaction performed. Following the transaction the enable bit is cleared by hardware. This mechanism allows selected bits of the SRI data ECC to be corrupted for a single transaction. The SEGEN register is CPUx ENDINIT protected.

#### 5.4.3 SRI bus Slave Read Phase Error Injection

To allow the SRI data phase error detection system to be tested it is necessary to inject errors during the data phase of an SRI read transaction. This is done by the TC1.6.2P SRI bus slave interface. The slave selectively inverts individual bits of the SRI read phase ECC packet and is controlled using the SEGEN register. The SEGEN register contains three fields:- an enable (AE), an error descriptor (ADTYPE) and a bit flip (ADFLIP) field. When enabled for a data phase error the data phase ECC bits indicated by the flip field are inverted for the next SRI read bus transaction performed by the DMI. Following the transaction the enable bit is cleared by hardware. This mechanism allows selected bits of the SRI data ECC to be corrupted for a single transaction. The SEGEN register is CPUx ENDINIT protected.

#### 5.4.4 SRI Error Capture

The SRI master and slave interfaces of the CPU implement the standard SRI ECC system. Error information detected during SRI transactions at the SRI master and slave interfaces is captured in the PIETR and PIEAR, or DIETR and DIEAR registers. On detection of an error the error information is captured and the relevant IED bit is set. No further error information is captured until this bit is cleared by software.

Error conditions at the SRI program interfaces are notified to the Safety Management Unit via the pbus\_err\_o output from the CPU.

Error conditions at the SRI data interfaces are notified to the Safety Management Unit via the dbus\_err\_o output from the CPU.

If an error is detected at an SRI slave interface during a write operation then the erroneous data will not be written.

## CPU Subsystem

### 5.4.5 SRI Safe Data Master tag

In order to differentiate between data accesses from safe and regular tasks a new safe task identification bit is introduced into the PSW register (PSW.S).

An SRI data access performed by a task when the PSW.S bit is set uses the safe data master tag. When this bit is not set the regular data master tag is used for the access. There is only one program master tag. This is used for SRI program fetches by both safe and regular tasks.

The initial value of the PSW.S bit for interrupt handlers is defined by the SYSCON.IS bit. The initial value of the PSW.S bit for trap handlers is defined by the SYSCON.IT bit.

On a trap the save of the current context is performed using the data master tag defined by SYSCON.TS

On an interrupt the save of the current context is performed using the data master tag defined by SYSCON.IS

### 5.4.6 Safety Protection System

The safety protection system provides protection against illegal or unintended bus accesses to the local memory system and control registers. The system comprises of two elements:- A bus MPU to gate accesses to the local PSPR, DSPR, DLMU SRAMs and the local Pflash Bank (LPB), and an register access enable system to gate write access to the local control registers.

#### 5.4.6.1 Bus MPU

The Bus MPU comprises of:-

- Eight read and write protected regions of scratch pad memory (PSPR, DSPR) with enables for reads and writes on a per bus master basis.
- Eight read and write protected regions of DLMU with enables for reads and writes on a per bus master basis.
- Individual master read enables for accesses to the local PFlash Bank (LPB)

The protection scheme is based on the use of SRI tags to identify the master attempting the access and allows for a six bit tag individually identifying up to 64 masters.

#### General operation

A read-modify-write operation requires both read and write permissions to be enabled.

All safety protection registers are protected from modification by the safety\_endinit signal.

After reset the Safety Protection System will be enabled for access from all masters.

When altering protection settings, it should be noted that, due to access pipelining and resynchronization delays in the register block, a write to a memory address affected by the protection change occurring immediately after the register write initiating the change may, or may not, be affected by the changed settings.

Whenever a Safety Memory Protection violation occurs the event is notified to the Safety Management Unit via the tc16\_safe\_prot\_err\_o output signal from the CPU. The PIETR/DIETR and PIEAR/DIEAR registers are updated to aid localisation of the error

The following masters are allowed read access to all memories under all circumstances:- Cerburus, HSM, IOM

*Note:* Additional information can be found in the On-Chip Bus chapter under SRI Errors.

#### Scratch Pad SRAMs

Each scratchpad region is defined using the registers, SPR\_SPROT\_RGNLAI (i=0-7) to define the lower address of the region, SPR\_SPROT\_RGNUAI (x=0-7) to define the upper address of the region.

Each region may be enabled for writes on a per bus master basis using the register SPR\_SPROT\_RGNACCENAI\_W (Masters 31-0) and SPR\_SPROT\_RGNACCENBi\_W (Masters 63-32),

## CPU Subsystem

Each region may be enabled for reads on a per bus master basis using the register SPR\_SPROT\_RGNACCENAi\_R (Masters 31-0) and SPR\_SPROT\_RGNACCENBi\_R (Masters 63-32),

A write access to the PSPR/DSPR memory is seen as valid if the master tag of the access is enabled in the SPR\_SPROT\_RGNACCENi\_W register and the address of the access satisfies the following relationship:-

$\text{SPR\_SPROT\_RGNLAI} \leq \text{address} < \text{SPR\_SPROT\_RGNUAI}$

A read access to the PSPR/DSPR is seen as valid if the master tag of the access is enabled in the SPR\_SPROT\_RGNACCENi\_R register and the address of the access satisfies the following relationship:-

$\text{SPR\_SPROT\_RGNLAI} \leq \text{address} < \text{SPR\_SPROT\_RGNUAI}$

If any of these conditions are not satisfied, the access is seen as invalid.

Access from all masters to the local DSPR (excluding data access from the local CPU) are checked by the SPR safety mechanism.

Access from all masters to the local PSPR (excluding fetch access from the local CPU) are checked by the SPR safety mechanism.

## DLMU SRAMs

Each DLMU region is defined using the registers, DLMU\_SPROT\_RGNLAI (i=0-7) to define the lower address of the region, DLMU\_SPROT\_RGNUAx (i=0-7) to define the upper address of the region.

Each region may be enabled for writes on a per bus master basis using the register DLMU\_SPROT\_RGNACCENAi\_W (Masters 31-0) and DLMU\_SPROT\_RGNACCENBi\_W (Masters 63-32),

Each region may be enabled for reads on a per bus master basis using the register DLMU\_SPROT\_RGNACCENAi\_R (Masters 31-0) and DLMU\_SPROT\_RGNACCENBi\_R (Masters 63-32),

A write access to the local DLMU memory is seen as valid if the master tag of the access is enabled in the DLMU\_SPROT\_RGNACCENi\_W register and the address of the access satisfies the following relationship:-

$\text{DLMU\_SPROT\_RGNLAI} \leq \text{address} < \text{DLMU\_SPROT\_RGNUAI}$

A read access to the local DLMU memory is seen as valid if the master tag of the access is enabled in the DLMU\_SPROT\_RGNACCENi\_R register and the address of the access satisfies the following relationship:-

$\text{DLMU\_SPROT\_RGNLAI} \leq \text{address} < \text{DLMU\_SPROT\_RGNUAI}$

If any of these conditions are not satisfied, the access is seen as invalid.

Accesses from all masters to the local DLMU (including those from the local CPU) are checked by the DLMU safety protection mechanism.

## Local Pflash Bank

The local PFlash bank is protected from read accesses on a per master basis. The individual masters allowed to read the LPB are selected by the LPB\_SPROT\_ACCENA\_R (master31-0) and LPB\_SPROT\_ACCENB\_R (master 63-31) registers.

Accesses from all masters to the LPB (including those from the local CPU) are checked by the LPB safety protection mechanism.

### 5.4.6.2 Register Access Enable Protection

The CPUs implement the standard memory protection scheme for peripheral registers using the SFR\_SPROT\_ACCENA\_W (masters 31-0) and SFR\_SPROT\_ACCENB\_W (masters 63-32) register. This allows all CPU CSFR and SFR registers to be protected from write access by untrusted masters.

The SFR\_SPROT\_ACCENA\_W and SFR\_SPROT\_ACCENB\_W registers define which masters may write the SFR and CSFR registers via bus access through the SRI slave interface.

The SFR\_SPROT\_ACCENA\_W and SFR\_SPROT\_ACCENB\_W registers are protected by the safety\_endinit signal.

---

**CPU Subsystem**

In all cases the master is identified using the SRI tag of the access. See On Chip Bus chapter for the product's TAG ID to master peripheral mapping.

Whenever a Safety Register Protection violation occurs the event is notified to the Safety Management Unit via the safe\_prot\_err\_o output signal from the CPU. The PIETR and PIEAR registers are updated to aid localisation of the error.

The safety protection registers themselves are not subject to safety protection but are protected by the safety\_endinit signal.

#### **5.4.7 Registers Implementing Safety Features**

## CPU Subsystem

### 5.4.7.1 SRI safety registers

#### CPUx SRI Error Generation Register

The SEGEN register controls the injection of SRI errors from the DMI.

##### SEGEN

###### CPUx SRI Error Generation Register

( $11030_H$ )

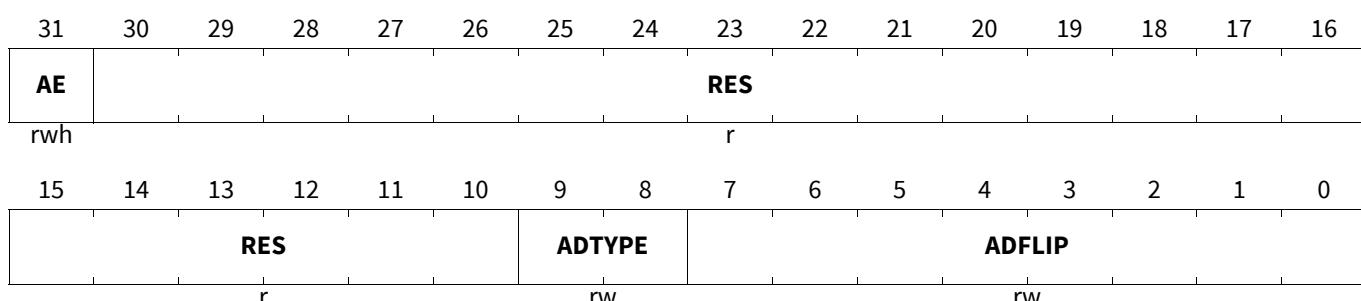

**Application Reset Value:** 0000 0000 $_H$

###### CPU\_SEGEN

###### Short address for domain CSFR

( $01030_H$ )

**Application Reset Value:** 0000 0000 $_H$

Field	Bits	Type	Description
<b>ADFLIP</b>	7:0	rw	<b>Address ECC Bit Flip</b> SRI address ECC Bits to be flipped on the next read or write transaction from the DMI when enabled by AE. 00 $_H$ No Flip 01 $_H$ Flip
<b>ADTYPE</b>	9:8	rw	<b>Type of error</b> 00 $_B$ Data Master Address Phase 01 $_B$ Data Master Write Data 10 $_B$ Data Slave Read Data 11 $_B$ Reserved
<b>RES</b>	30:10	r	<b>Reserved</b>
<b>AE</b>	31	rwh	<b>Activate Error Enable</b> Enabled the selective inverting of SRI ECC packet bits defined by ADFLIP. This bit will be cleared by hardware after the next SRI read or write transaction from the DMI. 0 $_B$ Not Enabled 1 $_B$ Enabled

## CPU Subsystem

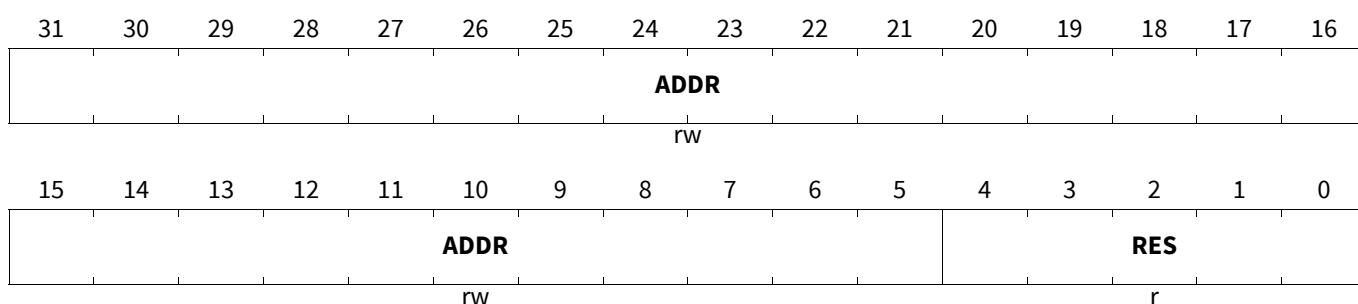

### 5.4.7.2 Safety Protection registers

#### CPUx Safety Protection SPR Region Lower Address Register i

The SPR\_SPROT\_RGNLAI defines the lower address of a region of PSPR/DSPR memory, SPR\_SPROT\_RGNUAi defines the upper address and the SPR\_SPROT\_RGNACCENi\_R/W registers define the SRI tags allowed access to the region. Address ranges can be set to be larger than the SPR SRAM address space but only accesses to the SPR SRAM are affected by these registers. The minimum resolution of the comparison logic is 32<sub>D</sub> bytes so address bits 4<sub>D</sub> down to 0<sub>D</sub> are not used

##### SPR\_SPROT\_RGNLAI (i=0-7)

**CPUx Safety Protection SPR Region Lower Address Register i(0E000<sub>H</sub>+i\*10<sub>H</sub>) Application Reset Value: 0000 0000<sub>H</sub>**

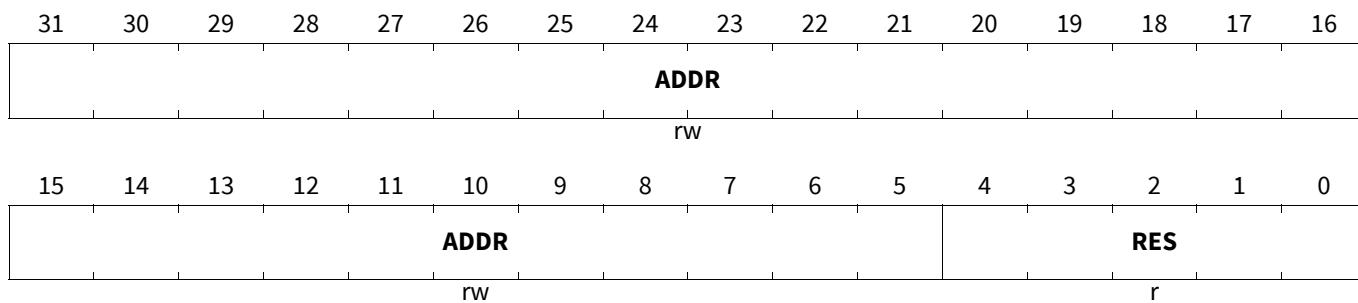

Field	Bits	Type	Description
<b>RES</b>	4:0	r	<b>Reserved</b>
<b>ADDR</b>	31:5	rw	<b>Region Lower Address</b> Bits 31 to 5 of the address which is the lower bound of the defined memory region

#### CPUx Safety Protection SPR Region Upper Address Register i

The SPR\_SPROT\_RGNUAi defines the upper address of a region of PSPR/DSPR memory. The minimum resolution of the comparison logic is 32<sub>D</sub> bytes so address bits 4<sub>D</sub> down to 0<sub>D</sub> are not used

##### SPR\_SPROT\_RGNUAi (i=0-7)

**CPUx Safety Protection SPR Region Upper Address Register i(0E004<sub>H</sub>+i\*10<sub>H</sub>) Application Reset Value: FFFF FFE0<sub>H</sub>**

Field	Bits	Type	Description
<b>RES</b>	4:0	r	<b>Reserved</b> Unused bits will always read as 0 <sub>B</sub> . Written value will be ignored

## CPU Subsystem

Field	Bits	Type	Description
<b>ADDR</b>	31:5	rw	<b>Region Upper Address</b> Bits 31 to 5 of the address which is the upper bound of the defined memory region

### CPUx Safety Protection SPR Region Write Access Enable Register Ai

The Write Access Enable Register A controls write access for transactions to the SPR safety protected memory region with the on chip bus master TAG ID 000000B to 011111B (see On Chip Bus chapter for the products TAG ID <-> master peripheral mapping).

#### SPR\_SPROT\_RGNACCENAi\_W (i=0-7)

## Non Volatile Memory (NVM) Subsystem

# 6 Non Volatile Memory (NVM) Subsystem

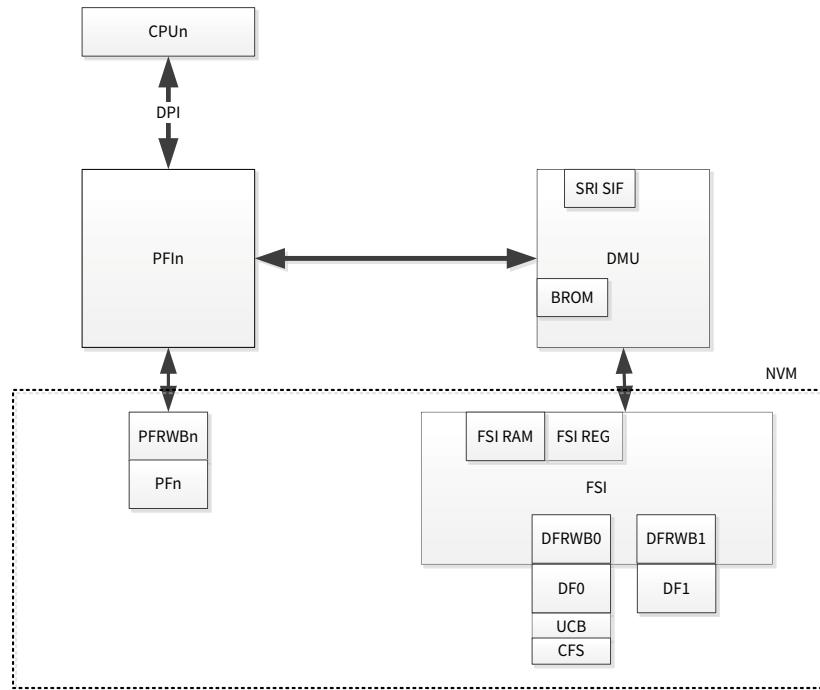

## 6.1 Overview

The Non Volatile Memory (NVM) Subsystem comprises of the Data Memory Unit (DMU), Program Flash Interface (PFI), and Non Volatile Memory module (comprising of the Flash Standard Interface (FSI), Program and Data Flash memories and Program Flash Read Write buffer (PFRWB)).

- Data Memory Unit (DMU): Controls command sequences executed on all program and data flash memories.
- Flash Standard Interface (FSI): Executes erase, program and verify operations on all flash memories.
- Program Flash (PFLASH): Divided into one or more banks each connected to a CPU. It is used by the application to store program code and data constants. Compute performance is optimized by using a point-to-point interface to minimize latency and maximize bandwidth. Each PFLASH is connected to a PFlash Read Write Buffer (PFRWB) that performs the ECC correction and detection and provides the read data to the system.
- Program Flash Interface (PFI): Each PFLASH bank has a unique point-to-point fast connection to a CPU provided by a PFI. The PFI interfaces between the CPU and the PFRWB and contains the Prefetch Buffers for storing speculative data.
- Data Flash (DFLASH): The Data Flash Module is used to emulate EEPROM and store data and divided into two banks. DFLASH read accesses are relatively slow compared to PFLASH accesses. The DFlash Read Write Buffer (DFRWB) in the FSI interfaces to the DFLASH to provide the read data. Data Flash Module also contains regions to store configuration data - User Configuration Blocks (UCBs), and Configuration Sector (CFS) which is not accessible by user.
- Boot ROM (BROM): Connected to the system via the DMU SRI port.
  - Tuning protection (commonly called the “Secure Watchdog”) to protect user software and data from malfunctions.

**Attention:** *The ‘Non Volatile Memory Subsystem’ chapter is the AURIX PMU chapter re-structured for closer alignment to AURIXTC3XX product architecture. It comprises of the DMU, PFI, NVM and UCB Chapters. Please note that the application accessible registers located in the FSI, and the PFLASH read status and control registers are described in the NVM chapter.*

## Non Volatile Memory (NVM) Subsystem

**Figure 57 Non Volatile Memory (NVM) Subsystem**

The purpose of the PFLASH NVM is:

- One or more PFLASH banks stores program code and data constants.
- Implementation of Erase Counters.

The purpose of the DFLASH NVM is:

- Emulation of Electrically Erasable Programmable Read Only Memory (EEPROM):
  - CPU-EEPROM used by the user application.
  - HSM-EEPROM used by the security application.
- Multiple User Configuration Blocks (UCB) used for:
  - Password based read protection combined with write protection.
  - Read-only UCB configured by IFX with unique chip identifier and trimming data.
- Configuration Sector (CFS) stores system set-up data not accessible by the user.

Data stored in the NVM is protected by ECC checksum.

- An ECC decoder at the output of the NVM corrects and detects faults in the NVM array.
- The NVM is fault tolerant and supports system operation in the presence of a number of NVM bit errors.
- For Program Flash the calculation of the ECC checksum is extended across the address to provide read protection against addressing faults.

If the Flash is not operating in the application then the NVM may be programmed and erased by command sequences executed by the FSI micro controller. All read accesses to Flash are memory mapped reads. Margin read levels may be used to check how completely a cell is programmed or erased.

The Non Volatile Memory interface micro architecture includes a security layer and a safety layer.

### Security Layer (provided by DMU and PFI)

- Read protection is enabled/disabled globally for the whole Flash Module.

## Non Volatile Memory (NVM) Subsystem

- Write protection is enabled/disabled with a Flash Module sector based granularity.

### Safety Layer

- Master specific read access protection to each Flash Module (Bank).
- Master specific read and write access control to individual Special Function Registers (SFRs).
- Integrity of data stored in the NVM is ensured by an ECC checksum
- Integrity of PFlash read path is ensured by monitoring of read parameters in the FSI (MISR, redundant Flip Flops etc.), PFI partial lockstep mechanism, protection of PFlash wait cycles with ECC checksum, protection of data from PFI to CPU by ECC checksum and an additional safety mechanism to ensure that the local PFlash is not being programmed/erased when not expected by PFI.

## 6.2 Functional Description

### 6.2.1 Definition of Terms

The Non Volatile Memory modules use the following terminology:

#### Flash Operation Terms

- **Erasing:** The erased state of a Flash cell is logical ‘0’. Forcing a cell to this state is called “erasing”. Complete Flash sectors are erased. All Flash cells in this area incur one “cycle” that counts for the “endurance”.
- **Programming:** The programmed state of a Flash cell is logical ‘1’. Changing an erased Flash cell to this state is called “programming”. Programming bits within a page to a logic ‘1’ occurs concurrently.
- **Retention:** This is the time during which the data of a flash cell can be read reliably. The retention time is a statistical figure that depends on the operating conditions of the device (e.g. temperature profile) and is affected by operations on other Flash cells in the same wordline and physical sector. With an increasing number of program/erase cycles (see endurance) the retention is lowered.
- **Endurance:** As described above the data retention is reduced with an increasing number of program/erase cycles. The maximum number of program/erase cycles of each Flash cell is called “endurance”. As for retention it is a statistical figure that depends on operating conditions, the use of the flash cells and the required quality level.

#### Flash Structure Terms

- **Flash Module:** A module that contains a Non Volatile Memory (NVM) with its own digital control logic.
- **Bank:** A “Flash module” contains separate “banks”. In the PFLASH there are one or more PFp banks and in the DFLASH there are one or more banks. “Banks” support concurrent operations with some limitations due to common logic.
- **Non Volatile Memory (NVM):** The physical memory used to store information. It is split into sectors:
  - Physical Sectors: One physical area of memory is isolated from another area of memory.
  - Logical Sectors: A physical sector is further separated into logical sectors. A logical sector is a group of wordlines for PFLASH and DFLASH, and a single wordline for UCB. A logical sector can be erased with a single operation. The plain term “sector” means “logical sector”.
  - Mini Sectors: A group of logical sectors in UCB.
- **Page:** A page is an aligned group of data double words plus an ECC extension. It is the smallest unit that can be programmed.

## Non Volatile Memory (NVM) Subsystem

- PFLASH: 4 data double words (32 bytes) plus 22-bit ECC extension.
- DFLASH: 1 data double word (8 bytes) plus 22-bit ECC extension.
- **Wordline:** An aligned group of bytes:
  - PFLASH: 1024 bytes.
  - DFLASH: 512 bytes in single ended mode and 256 bytes in complement sensing mode.
- **Program Burst:** The maximum amount of data that can be programmed with one command. The programming throughput is higher than for programming single pages.
  - PFLASH: 8 pages (256 bytes).
  - DFLASH: 4 pages (32 bytes).
- **Flash Interface:** The digital control logic to control read accesses and program and erase operations to the NVM.

### 6.2.2 Major changes from Aurix to AURIXTC3XX

- Dedicated performance interface for PFLASH read (PFI)
- New Flash structure and Flash sizes
- HSM PCODE sectors in PF0 increased
- Configuration Sector (CFS) moved to DFLASH
- Erase Counter moved to the respective PFLASH
- All Flash banks, CFS, UCB, Erase Counters and registers have separate system addresses
- Complement Sensing mode for DFLASH0/1 EEPROM
- New UCBs and Dual UCB concept
- Protection configuration in UCB updated to match new Flash structure
- New command sequences
- New power mode - Cranking mode
- New registers, and re-organisation of existing registers to accomodate architecture changes
- No legacy ECC for PFLASH, only safe ECC
- Requested Read feature removed
- DFLASH1 register access protection - change in definition of access term 'H'
- Support for Software update Over the Air (SOTA)
  - Enabling HSM PCODE sector configuration in more than one PFLASH
  - Individual PFLASH bank protection disable
  - Disabling Safety Endinit protection for PFLASH banks not used for code execution by the running application.
- High and Low priority Erase Counter regions
- New functional safety features

### 6.2.3 Flash Structure

The NVM contains the following Flash banks. The offset address of each sector is relative to the base address of its bank which is given in the device Memory Map.

## Non Volatile Memory (NVM) Subsystem

### 6.2.3.1 Program Flash Banks

All PFLASH Banks PFp are based on the same sector structure.

PFp banks may vary in size and implement the following logical sector structure:

- 3 Mbyte Program Flash Bank PFp implements logical sectors S0 to S191.
- 2 Mbyte Program Flash Bank PFp implements logical sectors S0 to S127.
- 1 Mbyte Program Flash Bank PFp implements logical sectors S0 to S63.

**Table 133 Sector Structure of PFp**

Logical Sector	Physical Sector	Offset Address	Size	Total
S0	PS0	00'0000 <sub>H</sub>	16 Kbyte	16 Kbyte
S1		00'4000 <sub>H</sub>	16 Kbyte	32 Kbyte
S2		00'8000 <sub>H</sub>	16 Kbyte	48 Kbyte
...		...	...	...
S61		0F'4000 <sub>H</sub>	16 Kbyte	992 Kbyte
S62		0F'8000 <sub>H</sub>	16 Kbyte	1008 Kbyte
S63		0F'C000 <sub>H</sub>	16 Kbyte	1024 Kbyte
S64	PS1	10'0000 <sub>H</sub>	16 Kbyte	1040 Kbyte
S65		10'4000 <sub>H</sub>	16 Kbyte	1056 Kbyte
S66		10'8000 <sub>H</sub>	16 Kbyte	1072 Kbyte
...		...	...	...
S125		1F'4000 <sub>H</sub>	16 Kbyte	2016 Kbyte
S126		1F'8000 <sub>H</sub>	16 Kbyte	2032 Kbyte
S127		1F'C000 <sub>H</sub>	16 Kbyte	2048 Kbyte
S128	PS2	20'0000 <sub>H</sub>	16 Kbyte	2064 Kbyte
S129		20'4000 <sub>H</sub>	16 Kbyte	2080 Kbyte
S130		20'8000 <sub>H</sub>	16 Kbyte	2096 Kbyte
...		...	...	...
S189		2F'4000 <sub>H</sub>	16 Kbyte	3040 Kbyte
S190		2F'8000 <sub>H</sub>	16 Kbyte	3056 Kbyte
S191		2F'C000 <sub>H</sub>	16 Kbyte	3072 Kbyte

#### 6.2.3.1.1 PFLASH Tuning Protection (TP) and HSM Support

AURIXTC3XX must support simultaneous TP and HSM operation. The lower logical sectors of PFLASH bank 0 (at [Figure 58](#)) may be configured to support TP and HSM Program Code (PCODE).

## Non Volatile Memory (NVM) Subsystem

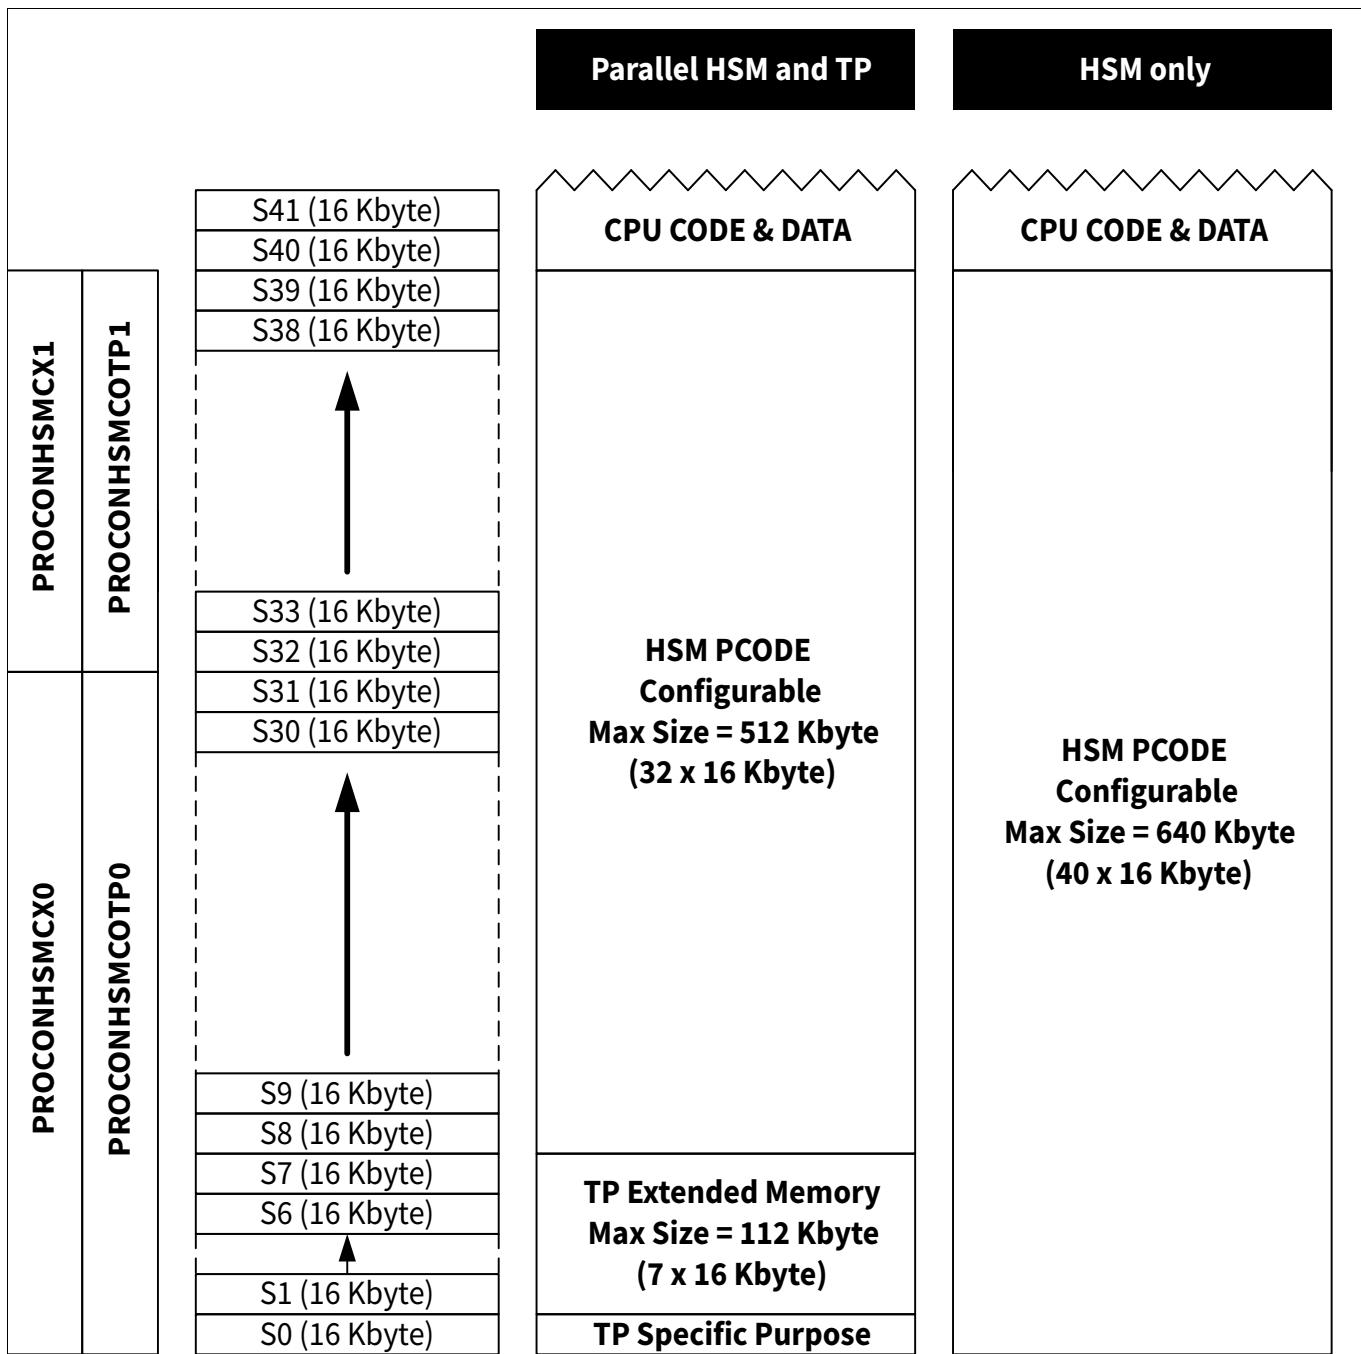

Figure 58 PFLASH TP and HSM PCODE Configuration.

### PFLASH TP Configuration

If TP is enabled (DMU\_HF\_PROCONTP.TP = 1<sub>B</sub>) then PFLASH PF0 S0 has a specific TP purpose and S0 must not be configured as “HSM\_exclusive”.

The PFLASH logical sectors above PF0 S0 may be configured to implement TP extended memory.

In addition, another PFLASH bank can have S0 configured for TP and other sectors configured to implement TP extended memory depending on the DMU\_HF\_PROCONTP.SWAPEN bit. This secondary PFLASH bank number is device dependent, and is the PFLASH bank with the lowest system address in the alternate address map provided in the MEMMAP chapter.

## Non Volatile Memory (NVM) Subsystem

### PFLASH HSM PCODE Configuration

PFLASH PF0 logical sectors S0 to S39 may be configured as “HSM\_exclusive” to support the placement of HSM PCODE at S0 or above TP sectors. HSM PCODE sectors may be configured as HSM locked forever.

### Configuration Options

If parallel TP and HSM operation are required then PF0 S0 to S39 may be configured for TP and HSM PCODE as follows:

- PF0 S0: specific TP purpose.
- PF0 S1 to S7: TP extended memory
- PF0 S8 to S39: HSM PCODE

TP, HSM PCODE and CPU address ranges must be contiguous.

### Multiple PFLASH TP and HSM PCODE configuration

In order to support “Software update Over the Air (SOTA)”, another PFLASH bank can have sectors S0 to S39 configured for TP or HSM PCODE, in addition to PFLASH0. This secondary PFLASH bank number is device dependent, and is the PFLASH bank with the lowest system address in the alternate address map provided in the MEMMAP chapter.

The same registers, DMU\_SP\_PROCONHSMCX0-1 and DMU\_SP\_PROCONHSMCOTP0-1 are used to configure the sectors in this secondary PFLASH used for HSM PCODE. The sectors not used for HSM PCODE in the secondary PFLASH bank, can be used for TP similar to PF0 and protected by enabling sectorwise protection in DMU\_HP\_PROCONOTP/DMU\_HP\_PROCONWOP/DMU\_HP\_PROCONP registers of the secondary PFLASH bank.

#### 6.2.3.1.2 Erase Counters

An Erase Counter(EC) is a dedicated 16 Kbyte logical sector within each PFLASH(PFp) bank. The erase counter may be accessed by every bus master and is read-only in the application.

##### Erase Logging

For every call of an “Erase Logical Sector Range” command sequence the FSI automatically records the logical sector start address (this is not the system address, but the address of the selected local PFLASH bank) and number of logical sectors in a 256-bit log in the corresponding Erase Counter (ECp).

**Table 134 256-bit Erase Counter Logging Entry Structure**

Bits	Description
[31:0]	Marker.
[63:32]	Start address of the first PFp logical sector.
[71:64]	Number of logical sectors erased.
[255:72]	Reserved.

The ECp 16 Kbyte erase counter supports the recording of 2 X 255 X 256-bit log entries. The Erase Counter area in each PFLASH is divided into two areas supporting 256 entries each - of which the first entry is pre-programmed and the remaining 255 entries are used to record erase operations. The first 256 entries from the Erase Counter base address is the Low priority area and the remaining is the High priority area. The user can assign priority to a logical sector in the PFLASH using the UCB\_ECPRI0. When an erase encompassing at least one high priority logical sector is triggered, it is recorded in the high priority area of the Erase Counter. Otherwise, the erase is recorded in the low priority area. The first entry of each area is a pre-programmed ECC valid entry, and cannot be used for Erase Counter entries. Each EC entry (including the first pre-programmed entry) has a 4 byte log marker.

## Non Volatile Memory (NVM) Subsystem

The marker is used to indicate the last valid EC entry. If the marker value of the entry is not equal to 0x00000000, the next EC entry is valid and can be read. If the marker value of entry is equal to 0x00000000, the last valid EC entry is reached. Thus, the next entry on address is empty (erased state) and generates ECC MBE fails when read.

### Erase Counter access

Erase counters can be read by any bus master that has the rights to read the associated PFLASH bank. All reads are performed by the local CPU through the connected PFI. All other flash operations on the Erase Counter regions fail with an SQER (See DMU Chapter for more details).

### 6.2.3.2 EEPROM Emulation with DFLASH

The term “EEPROM Emulation” designates an algorithm with the following features:

- It increases the effective endurance by spreading the EEPROM write accesses over a larger range of Flash memory.
- It ensures that all Flash cells incur a similar number of cycles independent of the update frequency of the EEPROM data (“wear levelling”).
- It manages the allocation of EEPROM data to Flash ranges so that stale data can be erased.

### Aborts and Startup

A specific requirement for the EEPROM emulation algorithm is resistance against aborts during its operation. After startup the device must be able to recover the active data without data loss and resume operation.

#### 6.2.3.2.1 DFLASH Emulation Modes

The DFLASH supports multi sector EEPROM emulation.

The DFLASH banks DFLASH0 and DFLASH1 must be operated in the same mode (i.e. single ended or complement sensing).

#### 6.2.3.2.2 Robust EEPROM Emulation

A key requirement for an EEPROM emulation algorithm is the reliability of the stored data. The DFLASH with its TECQED ECC algorithm protects perfectly against bit or bit-line oriented failures.

The ECC mechanism does not protect against wordline oriented failures. Wordline failure modes may result in a complete wordline which can no longer be programmed or erased and the data within the failed wordline may not be able to be read correctly. Wordline failures are most likely to occur during the high voltage conditions present during programming or erase operations. A robust EEPROM emulation algorithm must tolerate wordline failures and must protect against data loss in case the wordline fails during an erase or programming operation.

The following steps should be followed to achieve the necessary robustness:

- Before programming a page save the content of all other pages on the same wordline that contain active data to SRAM.
- Program the new page and compare the content of this page and of the saved pages with their reference data. This can be done with normal read margins. Ignore correctable bit-errors.
- If the data comparison fails or the programming returned with PVER error program this page and the saved content of the other pages to a different wordline.
- This procedure can be repeated if the data comparison fails again. The number of repetitions should be limited (e.g. to 3) in case the programming fails because of out-of-spec operating conditions.

## Non Volatile Memory (NVM) Subsystem

- Wordline oriented fails can also have the effect that the affected wordlines can not be erased anymore, yet the contents of the wordline data could still be read without any error indication. Sequence counters for the data blocks or other means must be used to identify old data blocks in wordlines with this type of failure mode.

Due to the specificity of each application the appropriate usage and implementation of these measures must be chosen according to the context of the application.

### 6.2.3.3 Data Flash Bank DFLASH0

DFLASH0 includes DFLASH0\_EEPROM (single ended mode at [Table 135](#) and complement sensing mode at [Table 136](#)), DFLASH0\_UCB (at [Table 137](#)) and DFLASH0\_CFS (at [Table 138](#)).

#### DFLASH0\_EEPROM Erase Operations and Erase Disturb

The number of erase operations over lifetime is limited by the parameter  $N_{ERDO}$  ( $N_{ERDOS}$  for single ended and  $N_{ERDOC}$  for complement sensing). All sectors must be used round-robin in order to prevent the accumulation of erase disturbs in static sectors<sup>1)</sup>. In derivatives with a reduced amount of DFLASH all sectors in this reduced DFLASH range must be used round-robin.

**Table 135 Sector Structure of DFLASH0\_EEPROM in Single Ended Mode**

Logical Sector	Physical Sector	Offset Address <sup>1)</sup>	Size	Total
EEPROM0	DFLASH0_EEPROM	00'0000 <sub>H</sub>	4 Kbyte	4 Kbyte

1) System Address = DFLASH0 Base Address (see Memory Map) + Offset Address

1) The parameter  $N_{DFD}$  (see Data Sheet) documents the erase disturb limit. It is chosen higher than needed for pure round-robin usage to cover also error cases (e.g. repetition of erase commands on the same range due to power failures during operation).

## Non Volatile Memory (NVM) Subsystem

**Attention:** For DFLASH0\_EEPROM configured in single ended mode the minimum erase size is 4 Kbyte aligned to the logical sector address boundary.

**Table 136 Sector Structure of DFLASH0\_EEPROM in Complement Sensing Mode**

Logical Sector	Physical Sector	Offset Address <sup>1)</sup>	Size	Total

### 6.2.3.4 Data Flash Bank DFLASH1

DFLASH1 includes DFLASH1\_EEPROM (single ended mode at [Table 139](#) and complement sensing mode at [Table 140](#)).

## Non Volatile Memory (NVM) Subsystem

### DFLASH1\_EEPROM Erase Operations and Erase Disturb

The number of erase operations over lifetime is limited by the parameter  $N_{ERD1}$  ( $N_{ERD1S}$  for single ended and  $N_{ERD1C}$  for complement sensing). All sectors must be used round-robin in order to prevent the accumulation of erase disturbs in static sectors<sup>1)</sup>. In derivatives with a reduced amount of DFLASH all sectors in this reduced DFLASH range must be used round-robin.

**Table 139 Sector Structure of DFLASH Bank 1 in Single Ended Mode**

Logical Sector	Physical Sector	Offset Address	Size	Total
EEPROM0	DFLASH1_EEPROM	00'0000 <sub>H</sub>	4 Kbyte	4 Kbyte
EEPROM1		00'1000 <sub>H</sub>	4 Kbyte	8 Kbyte
EEPROM2		00'2000 <sub>H</sub>	4 Kbyte	12 Kbyte
EEPROM3		00'3000 <sub>H</sub>	4 Kbyte	16 Kbyte
...		...	...	...
EEPROM28		01'C000 <sub>H</sub>	4 Kbyte	116 Kbyte
EEPROM29		01'D000 <sub>H</sub>	4 Kbyte	120 Kbyte
EEPROM30		01'E000 <sub>H</sub>	4 Kbyte	124 Kbyte
EEPROM31		01'F000 <sub>H</sub>	4 Kbyte	128 Kbyte

**Attention:** For DFLASH1\_EEPROM configured in single ended mode the minimum erase size is 4 Kbyte aligned to the logical sector address boundary.

**Table 140 Sector Structure of DFLASH Bank 1 in Complement Sensing Mode**

Logical Sector	Physical Sector	Offset Address	Size	Total
EEPROM0	DFLASH1_EEPROM	00'0000 <sub>H</sub>	2 Kbyte	2 Kbyte
EEPROM1		00'0800 <sub>H</sub>	2 Kbyte	4 Kbyte
EEPROM2		00'1000 <sub>H</sub>	2 Kbyte	6 Kbyte
EEPROM3		00'1800 <sub>H</sub>	2 Kbyte	8 Kbyte
...		...	...	...
EEPROM28		00'E000 <sub>H</sub>	2 Kbyte	58 Kbyte
EEPROM29		00'E800 <sub>H</sub>	2 Kbyte	60 Kbyte
EEPROM30		00'F000 <sub>H</sub>	2 Kbyte	62 Kbyte
EEPROM31		00'F800 <sub>H</sub>	2 Kbyte	64 Kbyte

**Attention:** For DFLASH1\_EEPROM configured in complement sensing mode the minimum erase size is 2 Kbyte aligned to the logical sector address boundary.

### 6.2.4 Program Flash (PFLASH) Features

- PFLASH Non Volatile Memory (NVM)
- Low latency safe instruction fetch path to support high performance:

1) The parameter  $N_{DFD}$  (see Data Sheet) documents the erase disturb limit. It is chosen higher than needed for pure round-robin usage to cover also error cases (e.g. repetition of erase commands on the same range due to power failures during operation).

## Non Volatile Memory (NVM) Subsystem

- DPI point-to-point interface between local CPU and local PFLASH.
- Flash prefetch buffers for linear speculative code fetches.
- Flash read access:
  - Read margins to check for sub optimal logic 0's and 1's.
- Command interface to support the following operations:
  - NVM program and erase operations.
  - Fast programming of 32 byte pages for PFLASH
  - High throughput burst programming of 256 byte units for PFLASH
  - High throughput erase by multi-sector erase commands.
  - Suspend and resume operations to interrupt on-going NVM operation.
  - Fast suspend to read command.
  - End of erase and program operations reported by interrupt.
- Password based read and write protection.
- Erase counters.
- Interrupt service requests to signal:
  - Indication of end of busy
  - Indication of an operation error
  - Indication of a protection error
  - Indication of a command sequence error
  - Indication of a program or erase verify error
- ECC Detection and Correction
  - DECTED: single-bit and double-bit error correction and triple-bit error detection.
  - Error reporting to the Safety Management Unit (SMU).
- Low power Standby Mode.
- Delivery in erased state.

### 6.2.5 Data Flash (DFLASH) Features

- DFLASH Bank 0 (DFLASH0) NVM instances
  - Multiple EEPROMx sectors commonly used for EEPROM emulation for run time application data storage.
  - User Configuration Blocks (UCBs) for protection data.
  - Configuration Sector (CFS) is a logical sector not directly accessible by the user.
- DFLASH Bank 1 (DFLASH1) NVM instances
  - Multiple EEPROMx sectors
  - In devices with HSM, they are used by the HSM for EEPROM emulation protected from application access.
- Flash read access:
  - Unique 64-bit read access to DFLASH arrays.
  - Read margins to check for sub optimal logic 0's and 1's.
- Command interface to support the following operations:
  - NVM program and erase operations.
  - Fast programming of 8 byte pages for DFLASH

## Non Volatile Memory (NVM) Subsystem

- High throughput burst programming of 32 byte units for DFLASH
- High throughput erase by multi-sector erase commands.
- Suspend and resume operations to interrupt on-going NVM operation.
- Fast suspend to read command.
- End of erase and program operations reported by interrupt.
- Password based read and write protection.
- Interrupt service requests to signal:
  - Indication of end of busy
  - Indication of an operation error
  - Indication of a protection error (DFLASH0 only)
  - Indication of a command sequence error
  - Indication of a program or erase verify error
- ECC Detection and Correction
  - TECQED: dynamic correction of single-bit, double-bit and triple-bit errors and detection of quad-bit errors.
- Pad supply voltage used for program and erase.
- Low power Standby Mode.
- Delivery of all user area in erased state.

### 6.2.6 Boot ROM (BROM) Features

- Startup SoftWare (SSW) executed at every reset.
- Test firmware to support IFX product test routines.
- Tuning Protection (TP) code to implement the “Secure Watchdog”.

## Non Volatile Memory (NVM) Subsystem

### 6.3 Safety Measures

The Flash Interface modules include the following functional safety features:

- Safety ENDINIT protection of relevant DMU configuration registers and Command Sequences modifying PFLASH content.
- Master specific access control of DMU control and configuration registers.
- Master specific access control of PFLASH read.
- Protection of safety relevant configuration registers against Single Event Effects (SEE).
- Integrity of read data stored in the NVM is ensured by an ECC checksum.
- Integrity of PFLASH read path is ensured by the following means: (For more details on the below safety mechanisms, please refer PFI chapter)
  - PFI partial lockstep mechanism
  - Protection of PFLASH wait cycles with ECC checksum
  - Protection of read data from PFI to CPU by ECC checksum
  - Additional safety mechanism to check that there is no NVM operation in the local PFLASH when it is not expected by PFI/DMU.
  - Monitoring of read parameters in the FSI (MISR, redundant Flip Flops)

#### 6.3.1 Safety Endinit protection

All command sequences that can modify PFLASH content are protected by Safety Endinit. A PROER is generated if there is an access to the PFLASH without removal of Safety Endinit protection.

In order to support “Software update Over the Air (SOTA)”, if DMU\_HP\_PROCONTP.SWAPEN is “Enabled”, then DMU removes Safety Endinit protection of the inactive PFLASHes, i.e., those PFLASHES that are not currently used for code execution by the running application. DMU uses the SCU\_SWAPCTRL bits to determine whether the system is in the standard or alternate address map, and from it, derives which are the ‘active’ and ‘inactive’ PFLASH banks. The alternate address map is described in the MEMMAP chapter. The ‘active’ banks in the standard or alternate address map mode are the PFLASH banks with the physical address (as described in the standard address map) of PFLASH0, PFLASH1 and PFLASH 4 for the AURIXTC39x and AURIXTC38x derivatives. The remaining banks are the ‘inactive’ banks. For the other derivatives, the ‘active’ bank is the one with the physical address of PFLASH0.

If an illegal value of SCU\_SWAPCTRL is detected, DMU generates a SQER when the next program/erase of any PFLASH bank is requested.

#### 6.3.2 Access Control

The Flash Module Registers located in the DMU are accessed through the SRI DFLASH slave interface. The DMU register set includes access protection registers and NVM configuration, control and status registers. The register access modes are described in the Introduction chapter.

**Table 141 Functional Safety Features of registers and PFLASH Bank**

	PFLASH Bank	Registers
Master Specific Access Control in DMU <sup>1)</sup>	–	Restricts Write Accesses
Master Specific Access Control in CPU	Restricts reads	-
ENDINIT	–	Restricts Write Accesses

## Non Volatile Memory (NVM) Subsystem

**Table 141 Functional Safety Features of registers and PFLASH Bank (cont'd)**

	PFLASH Bank	Registers
Safety ENDINIT	Restricts Command Sequences	Restricts Write Accesses
Supervisor Mode	-	Restricts Write Accesses

- 1) The master specific access control is configured and controlled by the registers DMU\_HF\_ACCENO and DMU\_HF\_ACCEN1. The ACCEN registers determine which master is allowed to perform writes to the protected DMU registers. The SRI slave interface is protected by this mechanism. Write accesses that are blocked by this mechanism create a bus error as response.

**Note:** *It is convention to use short register names (e.g. "ID") in the chapter that defines these registers. In all other chapters and in the development tools long register names are used that are a concatenation of the module instance (e.g. "DMU"), an underscore and the short register name, i.e. "DMU\_HF\_ID". This document uses for clarification also mostly the short register names.*

### 6.3.3 Data Reliability and Integrity

The data is stored in Flash with error correcting codes "ECC" in order to protect against data corruption. The reliability of Flash data can be checked with margin checks.

The following measures ensure the integrity for reading from Flash is a single point failure metric of >99% and a latent fault metric of >90%.

#### 6.3.3.1 PFLASH ECC

The ECC checksum is calculated over 256 data bits and the address bits. The ECC has the following features:

- Correction of 1-bit and 2-bit errors.
- Detection of 100% of 1-bit, 2-bit and 3-bit errors.
- Detection of >99% of all error vectors in the white noise error model.
- Detection of >99% of all-0 and all-1 cases.
- Detection of addressing errors.

As side effect of the all-0 error detection an erased Flash range can't be read without ECC errors. Also over-programming of Flash ranges with all-1 would create entries with ECC errors.

The ECC is automatically generated when programming the Flash when this is not disabled with bit field DMU\_HF\_ECCW.PECENCDIS.

The ECC is automatically evaluated when reading data. Errors are only reported for 256-bit data blocks for which at least one byte is read by the CPU port.

An errored internal prefetch data is discarded and is not stored in the prefetch buffer. The reported error is not recorded in the status registers, and will not trigger a SMU alarm.

The flash interface does not know if the master uses the requested data or discards it (e.g. due to speculatively fetching code). Therefore speculatively fetched data gets the same error response.

Error reporting and ECC disabling:

- Single-bit error:
  - Is noted in Flash bit field PFIz\_ECCS.ERR1.
  - Single Bit Error (SBER) alarm is generated.
  - If CPUx\_FLASHCON2.RECDIS = 10<sub>B</sub> then the affected address is stored uniquely in the SBAB and safety alarm is generated on SBAB full. No alarm is generated if CPUx\_FLASHCON2.RECDIS = 01<sub>B</sub>.
  - Data and ECC value are corrected if this is not disabled with Flash CPUx\_FLASHCON2.ECCCORDIS<sup>1)</sup>.

## Non Volatile Memory (NVM) Subsystem

- Double-bit error:
  - Is noted in Flash bit field PFIz\_ECCS.ERR2.
  - Double Bit Error (DBER) alarm is generated.
  - If CPUx\_FLASHCON2.RECDIS = 10<sub>B</sub> then the affected address is stored uniquely in the DBAB and safety alarm generated on DBAB full.
  - Data and ECC value are corrected if this is not disabled with Flash bit field CPUx\_FLASHCON2.ECCCORDIS.
- Multi-bit error and not All-0 error:
  - Is noted in Flash bit field PFIz\_ECCS.ERRM by the MULTIFAIL status.
  - Causes a bus error.
  - If CPUx\_FLASHCON2.RECDIS = 10<sub>B</sub> then the affected address is stored uniquely in the MBAB and safety alarm is generated.
  - An address error will be reported as multi-bit error when found.
- Multi-bit error and All-0 error:
  - Is noted in Flash bit field PFIz\_ECCS.ERRM by the MULTIFAIL status.
  - Causes a bus error.
  - If CPUx\_FLASHCON2.RECDIS = 10<sub>B</sub> then the affected address is stored uniquely in MBAB and ZBAB and safety alarm is generated. Safety alarm is also generated on ZBAB full.
  - An address error will be reported as multi-bit error when found.

### 6.3.3.2 DFLASH ECC

The ECC is calculated only over 64 data bits. Therefore addressing faults (correct data is read from an incorrect address) can not be detected.

The algorithm has the following advantages:

- An erased Flash range delivers ECC correct 0 data in the single ended sensing mode (default option). If the complement sensing mode is selected, then an erased section contains cell pairs (erased/erased) which are not compliant to complement data structure (prog/erased or erased/prog) and may result in an arbitrary read data result together with any possible ECC correction (e.g. wrong correction or multibit error).
- Over-programming with all-1 delivers an ECC correct result for both sensing modes. However, in complement sensing mode, the all-1 read data may not have the full retention specified in the datasheet because in most cases, it would not be well defined complement data pattern (prog/prog instead of prog/erase).

### 6.3.4 Integrity of PFlash read data wait cycles

Wait cycle configured in DMU\_HF\_PWAIT register is protected by ECC check sum. This ECC is transported along with wait cycle information from DMU to each of the PFIs. The PFI performs an ECC check on the received data every cycle and reports an error to CPU (resulting in PFLASH read path monitor alarm to SMU). This ECC provides detection of 1-bit and 2-bit errors.

### 6.3.5 Alarms

The Flash Interface modules provide the following alarms to the SMU:

- PFRWB corrected Single Bit error Address Buffer (SBAB) full: OR'ed for all PFRWB instances.
- PFRWB corrected Double Bit error Address Buffer (DBAB) full: OR'ed for all PFRWB instances.

1) Disabling the correction of errors with CPUx\_FLASHCON2.ECCCORDIS is a test feature. During application run-time the correction must be enabled.

## Non Volatile Memory (NVM) Subsystem

- PFRWB uncorrected Multi Bit error Address Buffer (MBAB) full: OR'ed for all PFRWB instances.
- PFRWB uncorrected all Zeros Bits error Address Buffer (ZBAB) full: OR'ed for all PFRWB instances.
- PFRWB Single Bit Error (SBER) : OR'ed for all PFRWB instances.
- PFRWB Double Bit Error (DBER) : OR'ed for all PFRWB instances.
- NVM Configuration Error (NVMCERR) : OR'ed for all FSI and PFRWB instances.
- PFRWB EDC error detected in the EDC checker: OR'ed for all PFRWB instances.
- PFRWB ECC error detected in on-line ECC checker : OR'ed for all PFRWB instances.
- PFRWB FLASHCON error (FLCONERR) - Illegal FLASHCON register values detected by PFRWB : OR'ed for all PFRWB instances
- PFLASH read path monitor error : All errors in PFI are OR'ed and sent via its local CPU to SMU.
- DMU SRI slave interface address phase error (see [Chapter 6.3.5.1](#)).
- DMU SRI slave interface write data phase error (see [Chapter 6.3.5.2](#)).

### 6.3.5.1 SRI Access Address Phase Error

If an ECC error occurs during the address phase of an SRI access then the DMU\_HF\_ERRSR.ADER bit will be set and an error will be signalled to the SMU. The SRI access will terminate with an error.

### 6.3.5.2 SRI Access Write Data Phase Error

If an ECC error occurs on the data phase of an SRI write access then an error will be signalled to the SMU.

## Non Volatile Memory (NVM) Subsystem

## 6.5 Data Memory Unit (DMU)

### 6.5.1 Overview

The DMU (in [Figure 59](#)) facilitates reads of DFLASH0, DFLASH1, UCB and CFS and facilitates all operations executed on the PFLASH and DFLASH memories. DMU also contains the BootROM, all reads of which are through the SRI interface. DMU interfaces to the FSI and PFI for all flash operations, and PFlash read respectively.

**Figure 59 Block diagram of DMU module**

The DMU supports the following features:

- Support of [Command Sequences](#) to perform flash operations to all PFLASH and DFLASH banks and UCBs.
- Facilitates DFLASH0, DFLASH1, UCB and CFS reads
- Functions as the security layer over the flash - controls access to all the flash banks based on the protection installed in the UCBs. Performs password based protection of the UCBs and Flash banks. Has two separate channels for Host and HSM programming of DFLASH1
- Performs HSM exclusivity checks and controls access to DFLASH1 based on the HSM configuration programmed in the UCBs

## 6.5.2 Functional Description

### 6.5.2.1 Flash Read Access

If the Flash banks are in Read Mode then all flash read accesses are memory mapped reads. Read protection can be used to block a read.

#### 6.5.2.1.1 Transaction Types

##### Program Flash

The transaction types for local CPU (at [Table 143](#)) and remote CPU (at [Table 144](#)) read accesses to a PFLASH are as follows:

**Table 143 Local CPU Read Accesses to PFLASH**

Local CPU access	Bus	Code Fetch	Data Constant
Cacheable address	DPI	Block Transfer 4 (BTR4)	Block Transfer 4 (BTR4)
Non-cacheable address	DPI	Block Transfer 4 (BTR4)	Minimum width

**Table 144 Remote CPU Read Accesses to PFLASH**

CPU access	Bus	Code Fetch	Data Constant
Cacheable address	SRI	Block Transfer 4 (BTR4)	Block Transfer 4 (BTR4)
Non-cacheable address	SRI	Block Transfer 4 (BTR4)	Minimum width

##### Data Flash

Read accesses to DFLASH must be single transfers made across the SRI and are available only in the non-cacheable address range. A Block Transfer will result in a bus error.

#### 6.5.2.1.2 Configuring Flash Read Access Cycles

The Flash read path including the ECC decoders uses the  $f_{SRI}$  clock. The minimum number of cycles can be calculated based on the delays given in the Data Sheet or the Electrical Specification.

**Attention:** In case of using the FM-PLL the maximum frequency of the  $f_{SRI}$  clocks has to enter the calculation.

##### Configuring Program Flash Read Access Cycles

Read accesses to the PFLASH have two delay settings counted with the  $f_{SRI}$  clock. The settings are defined in the [HF\\_PWAIT](#) register for:

- [Operation Mode](#) including [Error Mode](#)
- [Cranking Mode](#)

**Table 145 PFLASH Read Access Cycle Calculation**

	<b>Minimum Value<sup>1)</sup></b>
PFLASH read cycles	Ceiling( $t_{PF} * f_{SRI}$ )
ECC cycles	Ceiling( $t_{PF ECC} * f_{SRI}$ )

1) The Ceiling(r) function rounds up a real number, i.e., the result is the smallest integer not less than the real argument.

**Attention:** Note that the wait cycles to be programmed in the DMU\_HF\_PWAIT register is ‘PFLASH read cycles’ - 1, and ‘ECC cycles’ - 1 as shown in the example below.

### Program Flash Example

Example configuration for  $t_{PF} = 30$  ns and  $t_{PF ECC} = 10$  ns, with  $f_{SRI} = 200$  MHz in **Operation Mode**. The number of PFLASH read cycles equals 6 and the number of error correction cycles equals 2 therefore the wait cycle values to be programmed are:

- **HF\_PWAIT.RFLASH** = 5<sub>D</sub>
- **HF\_PWAIT.RECC** = 1<sub>D</sub>

### Configuring Data Flash Read Access Cycles

Read accesses to the DFLASH have one delay setting counted with the  $f_{FSI}$  clock. The settings are defined in the **HF\_DWAIT** register.

**Table 146 DFLASH Read Access Cycle Calculation**

	<b>Minimum Value<sup>1)</sup></b>
DFLASH read cycles	Ceiling( $t_{DF} * f_{FSI}$ )
ECC cycles	Ceiling( $t_{DF ECC} * f_{FSI}$ )

1) The Ceiling(r) function rounds up a real number, i.e., the result is the smallest integer not less than the real argument.

**Attention:** Note that the wait cycles to be programmed in the DMU\_HF\_DWAIT register is ‘DFLASH read cycles’ - 1, and ‘ECC cycles’ - 1 as shown in the example below.

### Data Flash Example

Example configuration for  $t_{DF} = 100$  ns and  $t_{DF ECC} = 20$  ns, with  $f_{FSI} = 100$  MHz. The number of DFLASH read cycles equals 10 and the number of error correction cycles equals 2 therefore the wait cycle values to be programmed are:

- **HF\_DWAIT.RFLASH** = 9<sub>D</sub>
- **HF\_DWAIT.ECC** = 1<sub>D</sub>

### 6.5.2.2 Flash Operations

All Flash operations except memory mapped reads are performed with command sequences. Write accesses are treated as follows:

- Write accesses to the PFLASHp memory range are refused with bus error.
- Write accesses to the DFLASH0 and DFLASH1 memory ranges are interpreted as a command cycles belonging to the respective command sequences.

The DMU has a Command Sequence Interpreter (CSI) to process command sequences.

In devices with HSM, the DMU supports two Command Sequence Interpreters (CSIs):

- Host Command Sequence Interpreter
  - The DMU executes command sequences on all PFLASH banks, DFLASH0 and DFLASH1 when DFLASH1 is not HSM exclusive.
  - The Host command sequence interpreter decodes write accesses to the DFLASH0 address range in the memory map segment A.
  - Any on chip bus master can perform command sequences via the Host Command Sequence Interpreter.
- HSM Command Sequence Interpreter
  - The DMU executes command sequences on DFLASH1 when DFLASH1 is HSM exclusive.
  - The HSM command sequence interpreter decodes write accesses to the DFLASH1 address ranges in the memory map segments A and F.
  - Only on chip bus masters marked with the Access Term Symbol H can perform command sequences via the HSM Command Sequence Interpreter.

### 6.5.2.2.1 Page Mode

A Command Sequence Interpreter must be in **Page Mode** to:

- Load write data into the Assembly Buffer (ASB).
- Initiate a write command to program data into PLFLASH or DFLASH.

### 6.5.2.2.2 Command Sequences

Command sequences consist of 1 to 9 command cycles. The command sequence interpreter checks that a command cycle is correct in the current state of command interpretation else a **Sequence Error (SQER)** is reported.

The DMU includes a Host Command Interface (see [Chapter](#)) and a HSM Command Interface (see [Chapter](#)). Both interfaces are completely independent. They can issue command sequences independently to the FSI and they see only the results, errors and busy signals of their own commands<sup>1)</sup>. The FSI arbitrates between the commands from both interfaces. Common resources in FSI and Flash are shared in time slices.

Command sequences to PFLASH are blocked by the Safety Endinit protection. See ‘Functional Safety Features’ section in NVM Subsystem chapter for more details on this protection.

Register read and write accesses are not affected by active commands.

#### Host Command Sequence Interpreter

The Host command sequence interpreter:

- Interprets writes to the DFLASH0 EEPROM memory range as command cycles.
- Reports status and errors in **HF\_STATUS** and **HF\_ERRSR** registers.
- Uses its own assembly buffer for programming data.
- Can be used to perform operations on PFLASH, DFLASH0, UCBs and DFLASH1<sup>2)</sup>.

Triggering an NVM operation using the command sequences takes the DMU into Command Mode. During its execution the Flash bank reports BUSY in DMU\_HF\_STATUS. In this mode read accesses to a Flash bank are refused with a bus error or the ready is suppressed until BUSY clears. The read access response is configured as follows:

- PFLASH response is configured on a bank granularity by CPUX\_FLASHCON1.STALL

1) If however the DFLASH1 is busy with a command received from the Host command interface (possible as long DFLASH1 is not HSM\_exclusive) commands from the HSM command interface are refused with a bus error.

2) DFLASH1 operations are controlled by “HSMDX” and “BLKFLAN”.

At the end of a flash operation the Flash bank clears the BUSY bit and read accesses are enabled. Only flash operations with a significant duration (shown in the command documentation) set BUSY.

**Attention:** *Using CPUx\_FLASHCON1.STALL = “STALL” is not recommended because the stalled CPU is inoperable. This feature should be only used under controlled conditions by a Flash loader.*

**Attention:** *Using CPUx\_FLASHCON1.STALL = “STALL” together with Flash sleep is prohibited as it might lead to device hang-up.*

If a command is executing then further command sequences to this command sequence interpreter are not allowed. Any writes to the command sequence interpreter are refused with a bus error. Generally when the command sequence interpreter detects an error it reports a sequence error by setting **HF\_ERRSR.SQER** or a protection error by setting **HF\_ERRSR.PROER**. Then the command sequence interpreter is reset and a **Page Mode** is left. The next command cycle must be the 1st cycle of a command sequence. The only exception is “Enter Page Mode” when a Flash is already in **Page Mode**.

### HSM Command Sequence Interpreter

The HSM command sequence interpreter:

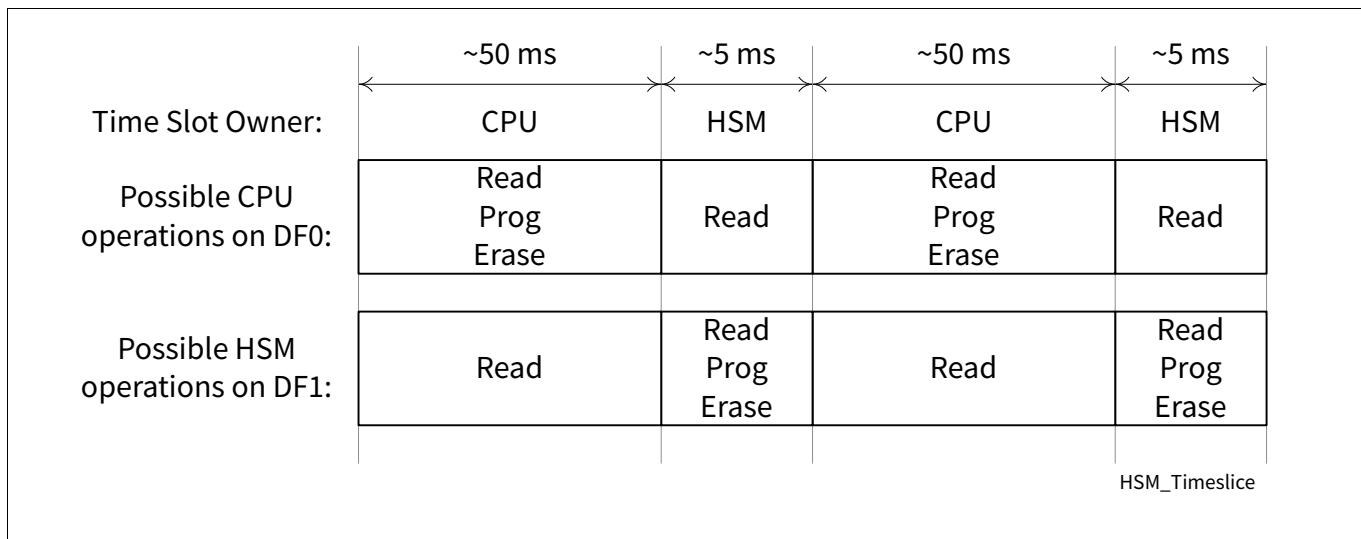

- Interprets writes to the DFLASH1 EEPROM memory range as command cycles.
- Writes by any other master than HSM (and Cerberus when HSM debugging is enabled) are refused with a bus error.
- Reports status and errors in **SF\_STATUS** and **SF\_ERRSR** registers.
- Uses its own assembly buffer for programming data.
- Can be used to perform operations on DFLASH1.

The HSM has a dedicated command interface. If a command is executing then further command sequences to this command sequence interpreter are not allowed. Any writes to the command sequence interpreter are refused with a bus error.

### Time Slice Control

The FSI performs Flash commands by the CPU and HSM in time slices (see [Figure 60](#)):

- CPU time slice of 50 ms.
- HSM time slice of 5 ms.

**Figure 60 Time Slice Control Overview**

Time slicing starts automatically when two requests (one HSM and one CPU) compete for resources. The first request starts execution immediately. The second request then triggers the time slice handling. During the CPU time slice phase the command from Host command sequence interpreter is executed and in HSM time slice phase the command from HSM. Switching between the time slice phases is done by firmware. Busy is high also for the inactive phase in time slice, so the functionality is not visible from outside.

In the HSM time slice an HSM command is executed. The roles of HSM and CPU are interchanged.

The following examples describe how conflicts are handled. The examples show a DFLASH0 access on Host CSI and it is to be noted that the same examples are valid for any PFLASH accesses on Host CSI.

DFLASH0 busy with erase:

- DFLASH0 can be only read after suspending the erase with **HF\_SUSPEND.REQ**
- Also for programming in DFLASH0 the erase has to be suspended or finished.
- The DFLASH1 can be read by HSM.
- A program/erase job in DFLASH1 is performed for 5 ms after the CPU time slice of 50 ms has expired.

DFLASH1 busy with HSM erase:

- DFLASH1 can be only read after suspending the erase with **SF\_SUSPEND.REQ**
- Also for programming in DFLASH1 the erase has to be suspended or finished.
- The DFLASH0 can be read by the CPU.
- A program/erase job in DFLASH0 is performed for 50 ms after the HSM time slice of 5 ms has expired.

DFLASH0 busy with programming:

- DFLASH0 can be only read after the programming has finished or has been suspended.
- Also for erasing in DFLASH0 the programming job has to finish or has to be suspended.
- A DFLASH0 programming job received during HSM time slice is started after the HSM time slice expired.
- The DFLASH1 can be read by HSM.
- A program/erase job in DFLASH1 is performed for 5 ms after the CPU time slice of 50 ms has expired.

DFLASH1 busy with HSM programming:

- DFLASH1 can be only read after the programming has finished or has been suspended.
- Also for erasing in DFLASH1 the programming job has to finish or has to be suspended.
- A DFLASH1 programming job received during the CPU time slice is started after the CPU time slice expired.

- The DFLASH0 can be read by the CPU.
- A program/erase job in DFLASH0 is performed for 50 ms after the HSM time slice of 5 ms has expired.

### Time Slice Control and Flash Parameters

The duration of program and erase commands is described in the data sheet.

The DFLASH erase times ( $t_{ERD}$ ,  $t_{MERD}$ ) are documented for the case that only one operation is executed uninterrupted by the time slicing. In the case of two concurrent operations (i.e. active time slicing) the duration increases, about 15% for CPU erase commands and by a factor of about 15 for HSM erase commands.

The programming durations of DFLASH operations ( $t_{PRD}$  and  $t_{PRDB}$ ) are also given for commands running unaffected by the time slice operation. The execution of programming commands issued by the CPU can be shifted by up to 5 ms and for those issued by the HSM can be shifted by up to 50 ms. From outside this appears as prolonged busy times by 5 ms or 50 ms.

#### 6.5.2.2.3 Command Sequence Definitions

The command sequence descriptions use the following nomenclature (symbolic assembly language):

**ST addr, data:** Symbolic representation of a command cycle moving “data” to “addr”.

The parameter “addr” is defined as followed:

- **CCCC<sub>H</sub>:** The “addr” must point into any of the address regions of the Command Sequence Interpreter used. The last 16 address bits must match CCCC<sub>H</sub>.

The parameter “data” can be one of the following:

- **PA:** Absolute start address of the Flash page. Must be aligned to burst size for “Write Burst” or to the page size for “Write Page”.
- **WA:** Absolute start address of the Flash wordline.
- **SA:** Absolute start address of a Flash sector. Allowed are the PFLASH sectors Sx and the DFLASH sectors EEPROMx and UCBx.
- **WD:** 64-bit or 32-bit write data to be loaded into the page assembly buffer.
- **xxYY:** 8-bit write data as part of a command cycle. Only the byte “YY” is used for command interpretation. The higher order bytes “xx” are ignored.
  - **xx5y:** Specific case for “YY”. The “y” can be “0<sub>H</sub>” for selecting the PFLASH or “D<sub>H</sub>” to select the DFLASH.
  - **xxww:** Specific case for “YY”. The “ww” defines the number of pages and must not cross a wordline border.
  - **xxnn:** Specific case for “YY”. The “nn” defines the number of logical sectors that are erased or verified. This number underlies certain restrictions (see [Erase Logical Sector Range](#)).
- **UC:** Identification of the UCBx for which the password checking shall be performed:
  - xx00<sub>H</sub> for UCB\_BMHxDn\_ORIG and UCB\_BMHxDn\_COPY (n=0 - 3)
  - xx10<sub>H</sub> for UCB16 = UCB\_PFLASH\_ORIG and UCB24 = UCB\_PFLASH\_COPY to disable global read and write protection for all PFLASHes
  - xx11<sub>H</sub> for UCB17 = UCB\_DFLASH\_ORIG and UCB25 = UCB\_DFLASH\_COPY
  - xx12<sub>H</sub> for UCB18 = UCB\_DBG\_ORIG and UCB26 = UCB\_DBG\_COPY
  - xx16<sub>H</sub> for UCB22 = UCB\_ECPRIOR\_ORIG and UCB30 = UCB\_ECPRIOR\_COPY
  - xx17<sub>H</sub> for UCB23 = UCB\_SWAP\_ORIG and UCB31 = UCB\_SWAP\_COPY
  - xx0F<sub>H</sub> for UCB15 = UCB\_RETEST
  - xx20<sub>H</sub> for UCB16 = UCB\_PFLASH\_ORIG and UCB24 = UCB\_PFLASH\_COPY to disable global read protection, and sector specific write protection for PFLASH0

- $\text{xx21}_H$  for UCB16 = UCB\_PFLASH\_ORIG and UCB24 = UCB\_PFLASH\_COPY to disable global read protection, and sector specific write protection for PFLASH1
- $\text{xx22}_H$  for UCB16 = UCB\_PFLASH\_ORIG and UCB24 = UCB\_PFLASH\_COPY to disable global read protection, and sector specific write protection for PFLASH2
- $\text{xx23}_H$  for UCB16 = UCB\_PFLASH\_ORIG and UCB24 = UCB\_PFLASH\_COPY to disable global read protection, and sector specific write protection for PFLASH3
- $\text{xx24}_H$  for UCB16 = UCB\_PFLASH\_ORIG and UCB24 = UCB\_PFLASH\_COPY to disable global read protection, and sector specific write protection for PFLASH4
- $\text{xx25}_H$  for UCB16 = UCB\_PFLASH\_ORIG and UCB24 = UCB\_PFLASH\_COPY to disable global read protection, and sector specific write protection for PFLASH5

- **PWx:** 32-bit word of a 256-bit password.

When using for command cycles 64-bit transfers the “data” is expected in the correct 32-bit word as indicated by the address “addr”.

### Command Sequence Overview Table

The following sections describe each command sequence (at [Table 147](#)) in detail.

**Table 147 Command Sequences for Flash Control**

Command Sequence		1. Cycle	2./6. Cycle	3./7. Cycle	4./8. Cycle	5./9. Cycle	6. Cycle
<b>Reset to Read</b>	Address Data	.5554 .xx <b>F0</b>					
<b>Enter Page Mode</b>	Address Data	.5554 .xx <b>5y</b>					
<b>Load Page</b>	Address Data	.55F0 <b>WD</b>					
<b>Write Page</b>	Address Data	.AA50 <b>PA</b>	.AA58 .xx <b>00</b>	.AAA8 .xx <b>A0</b>	.AAA8 .xx <b>AA</b>		
<b>Write Page Once</b>	Address Data	.AA50 <b>PA</b>	.AA58 .xx <b>00</b>	.AAA8 .xx <b>A0</b>	.AAA8 .xx <b>A8</b>		
<b>Write Burst</b>	Address Data	.AA50 <b>PA</b>	.AA58 .xx <b>00</b>	.AAA8 .xx <b>A0</b>	.AAA8 .xx <b>A6</b>		
<b>Write Burst Once</b>	Address Data	.AA50 <b>PA</b>	.AA58 .xx <b>00</b>	.AAA8 .xx <b>A0</b>	.AAA8 .xx <b>A4</b>		
<b>Replace Logical Sector</b>	Address Data	.AA50 <b>PA</b>	.AA58 .xx <b>00</b>	.AAA8 .xx <b>A0</b>	.AAA8 .xx <b>AC</b>		
<b>Verify Erased Page</b>	Address Data	.AA50 <b>PA</b>	.AA58 .xx <b>00</b>	.AAA8 .xx <b>80</b>	.AAA8 .xx <b>56</b>		
<b>Verify Erased WL</b>	Address Data	.AA50 <b>WA</b>	.AA58 .xx <b>00</b>	.AAA8 .xx <b>80</b>	.AAA8 .xx <b>58</b>		
<b>Verify Erased Logical Sector Range</b>	Address Data	.AA50 <b>SA</b>	.AA58 .xx <b>nn</b>	.AAA8 .xx <b>80</b>	.AAA8 .xx <b>5F</b>		
<b>Erase Logical Sector Range</b>	Address Data	.AA50 <b>SA</b>	.AA58 .xx <b>nn</b>	.AAA8 .xx <b>80</b>	.AAA8 .xx <b>50</b>		

**Table 147 Command Sequences for Flash Control (cont'd)**

<b>Command Sequence</b>		<b>1. Cycle</b>	<b>2./6. Cycle</b>	<b>3./7. Cycle</b>	<b>4./8. Cycle</b>	<b>5./9. Cycle</b>	<b>6. Cycle</b>
<b>Resume NVM Operation</b>	Address Data	.AA50 <b>PA/SA</b>	.AA58 .xxnn	.AAA8 .xx <b>70</b>	.AAA8 .xx <b>CC</b>		
<b>Disable Protection</b>	Address Data	.553C <b>UC</b>	.553C <b>PW0/4</b>	.553C <b>PW1/5</b>	.553C <b>PW2/6</b>	.553C <b>PW3/7</b>	
<b>Resume Protection</b>	Address Data	.5554 .xx <b>F5</b>					
<b>Clear Status</b>	Address Data	.5554 .xx <b>FA</b>					

**Reset to Read****Calling**

- ST 5554<sub>H</sub>, xxF0<sub>H</sub>

**Function**

This function resets the addressed command sequence interpreter to its initial state (i.e. the next command cycle must be the 1st cycle of a sequence). A **Page Mode** is aborted.

This command is the only one that is accepted without **Sequence Error (SQER)** when the command sequence interpreter has already received command cycles of a different sequence. Thus **Reset to Read** can cancel every command sequence before its last command cycle has been received.

A system reset will re-initialize the NVM control circuits.

**Host Command Sequence Interpreter**

Host command sequence interpreter is reset. The following flags are cleared:

- Command sequence error flag: DMU\_HF\_ERRSR.SQER
- Protection error flag: DMU\_HF\_ERRSR.PROER
- **Page Mode** flags: DMU\_HF\_STATUS.DFPAGE and DMU\_HF\_STATUS.PFPAGE

**HSM Command Sequence Interpreter**

HSM command sequence interpreter is reset. The following flags are cleared:

- Command sequence error flag: DMU\_SF\_ERRSR.SQER
- **Page Mode** flags: DMU\_SF\_STATUS.DFPAGE

**Enter Page Mode****Calling**

- ST 5554<sub>H</sub>, xx5y<sub>H</sub>

**Function**

The PFLASH or the DFLASH assembly buffer enter **Page Mode** selected by the parameter "y".

The write pointer of the page assembly buffer is set to 0, its previous content is maintained.

If a new **Enter Page Mode** command sequence is received while any Flash is already in **Page Mode** then **Sequence Error (SQER)** is set, the existing **Page Mode** is aborted, and the new **Enter Page Mode** sequence is correctly executed (i.e. in this case the command sequence interpreter is not reset).

**Page Mode** is exited when the next command sequence terminates.

### Host Command Sequence Interpreter

**Page Mode** is signalled by the flags DMU\_HF\_STATUS.PFPAGE and DMU\_HF\_STATUS.DFPAGE for PFLASH and DFLASH respectively.

### HSM Command Sequence Interpreter

**Page Mode** is signalled by the flag DMU\_SF\_STATUS.DFPAGE.

If the DMU is in **Cranking Mode** or **Error Mode** then the command fails with an **Sequence Error (SQER)**.

### Load Page

#### Calling

- ST 55F0<sub>H</sub>, WD (Note: offset 55F4<sub>H</sub> is used for the higher order 32-bit transfers).

#### Function

Loads the data “WD” into the page assembly buffer and increments the write pointer to the next position.

All WD transfers for one page must have the same width (either all 32-bit or all 64-bit). Else the transfer is refused with SQER.

See **Chapter** for information on programming 32-bit Load Page from the CPU.

If **Load Page** is called more often than allowed by the available buffer space of 256 bytes PFLASH (32 byte DFLASH) then the overflow data is discarded and **Page Mode** is not left. This overflow is reported by the following Write Page/Burst command with **Sequence Error (SQER)**.

If the DMU is in **Cranking Mode** or **Error Mode** then the command fails with an **Sequence Error (SQER)**.

### Write Page

#### Calling

- ST AA50<sub>H</sub>, PA
- ST AA58<sub>H</sub>, xx00<sub>H</sub>
- ST AAA8<sub>H</sub>, xxA0<sub>H</sub>
- ST AAA8<sub>H</sub>, xxAH

#### Function

This function starts the programming process for one page with the data transferred previously by **Load Page** commands. Upon executing the command, **Page Mode** is exited (indicated by clearing the corresponding PAGE flag) and the BUSY flag of the bank is set.

This command is refused with **Sequence Error (SQER)** when the addressed Flash is not in **Page Mode**.

SQER is also issued when PA addresses an unavailable Flash range or when PA does not point to a legal page start address.

If after **Enter Page Mode** too few data, no data or too much data was transferred to the assembly buffer with **Load Page** then **Write Page** programs the page but sets **Sequence Error (SQER)**. Missing data is programmed with the previous content of the assembly buffer.

When the page “PA” is located in a sector with active write protection or the Flash module has an active global read protection the execution fails and **Protection Error (PROER)** is set.

When the programming process incurs an error the flag PVER is set.

The same applies to the HSM command sequence interpreter which maintains its own assembly buffer. After programming to the HSMx sectors the assembly buffer is automatically erased.

If the DMU is in **Cranking Mode** or **Error Mode** then the command fails with an **Sequence Error (SQER)**.

### Write Page Once

#### Calling

- ST AA50<sub>H</sub>, PA
- ST AA58<sub>H</sub>, xx00<sub>H</sub>
- ST AAA8<sub>H</sub>, xxA0<sub>H</sub>
- ST AAA8<sub>H</sub>, xxA8<sub>H</sub>

#### Function

This function starts the programming process for one page as the normal **Write Page** does. But before programming it checks if the page is erased. If the page is not erased (allowing correctable errors) the command fails with **Erase Verify Error (EVER)**.

When the programming itself incurs an error the flag **Program Verify Error (PVER)** is set.

On sectors with “write-once” protection only **Write Page Once** or **Write Burst Once** is accepted by DMU.

### Host Command Sequence Interpreter

The command is only supported for PFLASH.

When applied to DFLASH the command fails with DMU\_HF\_ERRSR.SQER.

### HSM Command Sequence Interpreter

The command is rejected by the HSM command sequence interpreter with DMU\_SF\_ERRSR.SQER.

If the DMU is in **Cranking Mode** or **Error Mode** then the command fails with an **Sequence Error (SQER)**.

### Write Burst

#### Calling

- ST AA50<sub>H</sub>, PA
- ST AA58<sub>H</sub>, xx00<sub>H</sub>
- ST AAA8<sub>H</sub>, xxA0<sub>H</sub>

- ST AAA8<sub>H</sub>, xxA6<sub>H</sub>

## Function

This function starts the programming process for an aligned group of pages. The programming process is more efficient than for a single page, achieving a significantly higher throughput (see data sheet).

In the PFLASH 8 pages (256 bytes) are programmed and in DFLASH 4 pages (32 bytes). The pages are programmed one after the other with increasing addresses.

## Host Command Sequence Interpreter

For disabled ECC generation:

- If DMU\_HF\_ECCW.PECENCDIS = '11<sub>B</sub>' then the user must not perform a Write Burst to PFLASH.
- If DMU\_HF\_ECCW.DECENCDIS = '11<sub>B</sub>' then the user must not perform a Write Burst to DFLASH.

## HSM Command Sequence Interpreter

For disabled ECC generation:

- If DMU\_SF\_ECCW.DECENCDIS = '11<sub>B</sub>' then the user must not perform a Write Burst to DFLASH.

If the DMU is in **Cranking Mode** or **Error Mode** then the command fails with an **Sequence Error (SQER)**.

For further details see "Write Page".

## Write Burst Once

### Calling

- ST AA50<sub>H</sub>, PA
- ST AA58<sub>H</sub>, xx00<sub>H</sub>
- ST AAA8<sub>H</sub>, xxA0<sub>H</sub>
- ST AAA8<sub>H</sub>, xxA4<sub>H</sub>

## Function

This function starts the programming process for an aligned group of pages as the normal "Write Burst" does. But before programming it checks if the pages are erased. If the pages are not erased (allowing correctable errors) the command fails with EVER.

When the programming itself incurs an error the flag PVER is set.

On sectors with "write-once" protection only **Write Page Once** or **Write Burst Once** is accepted by DMU.

For disabled ECC generation:

- If DMU\_HF\_ECCW.PECENCDIS = '11<sub>B</sub>' then the user must not perform a Write Burst Once to PFLASH.

## Host Command Sequence Interpreter

The command is only supported for PFLASH.

When applied to DFLASH the command fails with DMU\_HF\_ERRSR.SQER.

## HSM Command Sequence Interpreter

The command is rejected by the HSM command sequence interpreter with DMU\_SF\_ERRSR.SQER.

If the DMU is in **Cranking Mode** or **Error Mode** then the command fails with an **Sequence Error (SQER)**.

## Replace Logical Sector

### Calling

- ST AA50<sub>H</sub>, PA
- ST AA58<sub>H</sub>, xx00<sub>H</sub>
- ST AAA8<sub>H</sub>, xxA0<sub>H</sub>
- ST AAA8<sub>H</sub>, xxAC<sub>H</sub>

### Use Case

Replace Logical Sector is a command sequence that enables the replacement of a PFLASH logical sector with hard fails with an available redundant PFLASH logical sector. It can be used if a sector fails during an erase or program in order to meet the endurance of PFLASH (see datasheet parameter N<sub>E\_P</sub>).

There are two redundant logical sectors provided for every physical sector for the purpose of replacing a failing logical sector. These are available both for production test, and for the user. A failure in an already replaced logical sector cannot be repaired, i.e., this failing redundant logical sector cannot be mapped to an available redundant logical sector. If the command is successfully executed, UCB\_REDSEC is updated with the redundancy information. User can read UCB\_REDSEC to get information on the replaced sectors (both by user and by production test) and the available redundant sectors.

### Function

The argument “PA” is used to select a page address aligned to the start of the PFLASH logical sector to be re-mapped.

### Host Command Sequence Interpreter

The sequence error flag SQER (DMU\_HF\_ERRSR.SQER) is set when the PA is not aligned to the start address of a PFLASH logical sector page address or when PA addresses an unavailable Flash range.

The protection error flag(DMU\_HF\_ERRSR.PROER) is set when there is an attempt to re-map a logical sector with enabled **PFLASH Write Protection**.

Note that both DMU\_HF\_STATUS.PxBUSY and DMU\_HF\_STATUS.D0BUSY are set during the execution of this command.

### HSM Command Sequence Interpreter

This command is rejected by the HSM Command Sequence Interpreter with DMU\_SF\_ERRSR.SQER.

**Erase Verify Error (EVER)** is generated if there is no free entry available in UCB\_REDSEC.

**Program Verify Error (PVER)** is generated if there is a programming error during the programming of UCB\_REDSEC with the redundancy information.

If the DMU is in **Cranking Mode** or **Error Mode** then the command fails with an **Sequence Error (SQER)**.

A detailed application note is available on request.

## Verify Erased Page

### Calling

- ST AA50<sub>H</sub>, PA
- ST AA58<sub>H</sub>, xx00<sub>H</sub>
- ST AAA8<sub>H</sub>, xx80<sub>H</sub>
- ST AAA8<sub>H</sub>, xx56<sub>H</sub>

### Function

This command verifies if one page addressed by “PA” is correctly erased, i.e. contain 0 data and ECC bits. Upon executing the command, the BUSY flag of the corresponding bank is set.

As the PFLASH has Safety ECC, the PFLASH cannot be checked for “0” content by direct reads.

If the DFLASH is being operated in Complement Sensing Mode, this command verifies only that all read cells have sufficient high current that a program operation without prior erase is possible. After a certain operation history, a valid complement data entry may also appear as erased. Data qualifiers like headers or footers, which are usually used in EEPROM emulation, can be used to distinguish expected valid data from unknown data fields (see also [HF\\_ECCS.BLANKA](#) or [SF\\_ECCS.BLANKA](#)).

### Host Command Sequence Interpreter

The sequence error flag (DMU\_HF\_ERRSR.SQER) is set when the PA is not aligned to a page address.

The erase verify error flag (DMU\_HF\_ERRSR.EVER) is set to identify a found verification error.

See [Chapter 6.5.2.2.4](#) for Host Command Sequence Interpreter verify erase and analysis commands security.

### HSM Command Sequence Interpreter

The sequence error flag (DMU\_SF\_ERRSR.SQER) is set when the PA is not aligned to a page address.

The erase verify error flag (DMU\_SF\_ERRSR.EVER) is set to identify a found verification error.

If the DMU is in [Cranking Mode](#) or [Error Mode](#) then the command fails with an [Sequence Error \(SQER\)](#).

## Verify Erased WL

### Calling

- ST AA50<sub>H</sub>, WA
- ST AA58<sub>H</sub>, xx00<sub>H</sub>
- ST AAA8<sub>H</sub>, xx80<sub>H</sub>
- ST AAA8<sub>H</sub>, xx58<sub>H</sub>

### Function

This command verifies if one wordline addressed by “WA” is correctly erased, i.e. contain 0 data and ECC bits. Upon executing the command, the BUSY flag of the corresponding bank is set.

As the PFLASH has Safety ECC, the PFLASH cannot be checked for “0” content by direct reads.

If the DFLASH is being operated in Complement Sensing Mode, this command verifies only that all read cells have sufficient high current that a program operation without prior erase is possible. After a certain operation history, a valid complement data entry may also appear as erased. Data qualifiers like headers or footers, which are usually used in EEPROM emulation, can be used to distinguish expected valid data from unknown data fields (see also [HF\\_ECCS.BLANKA](#) or [SF\\_ECCS.BLANKA](#)).

### Host Command Sequence Interpreter

The sequence error flag (DMU\_HF\_ERRSR.SQER) is set when the WA is not aligned to a wordline address.

The erase verify error flag (DMU\_HF\_ERRSR.EVER) is set to identify a found verification error.

See [Chapter 6.5.2.2.4](#) for Host Command Sequence Interpreter verify erase and analysis commands security.

### HSM Command Sequence Interpreter

The sequence error flag (DMU\_SF\_ERRSR.SQER) is set when the WA is not aligned to a wordline address.

The erase verify error flag (DMU\_SF\_ERRSR.EVER) is set to identify a found verification error.

If the DMU is in [Cranking Mode](#) or [Error Mode](#) then the command fails with an [Sequence Error \(SQER\)](#).

### Verify Erased Logical Sector Range

#### Calling

- ST AA50<sub>H</sub>, SA
- ST AA58<sub>H</sub>, xxnn<sub>H</sub>
- ST AAA8<sub>H</sub>, xx80<sub>H</sub>
- ST AAA8<sub>H</sub>, xx5F<sub>H</sub>

#### Function

This command verifies if “nn” sectors starting at the sector addressed by “SA” are correctly erased, i.e. contain 0 data and ECC bits. Upon executing the command, the BUSY flag of the corresponding bank is set.

As the PFLASH has Safety ECC, the PFLASH cannot be checked for “0” content by direct reads.

If the DFLASH is being operated in Complement Sensing Mode, this command verifies only that all read cells have sufficient high current that a program operation without prior erase is possible. After a certain operation history, a valid complement data entry may also appear as erased. Data qualifiers like headers or footers, which are usually used in EEPROM emulation, can be used to distinguish expected valid data from unknown data fields (see also [HF\\_ECCS.BLANKA](#) or [SF\\_ECCS.BLANKA](#)).

### Host Command Sequence Interpreter

A sequence error (DMU\_HF\_ERRSR.SQER) is returned and the execution fails for the following conditions:

- The SA does not point to the base address of a correct sector or to an unavailable sector.
- The range of logical sectors is not contained in one physical sector.
- For DFLASH, if the range of logical sectors exceeds 256KByte addressable memory (256KByte physical memory in Single Ended mode, and 512KByte physical memory in Complement Sensing mode)
- For PFLASH, if the range of logical sectors exceeds 512KByte.
- For UCB, if the range of logical sectors exceeds 1.

The error flag (DMU\_HF\_ERRSR.EVER) is set to identify a found verification error.

See [Chapter 6.5.2.2.4](#) for Host Command Sequence Interpreter verify erase and analysis commands security.

### HSM Command Sequence Interpreter

A sequence error (DMU\_SF\_ERRSR.SQER) is returned and the execution fails for the following conditions:

- The SA does not point to the base address of a correct sector or to an unavailable sector.

The error flag (DMU\_SF\_ERRSR.EVER) is set to identify a found verification error.

If the DMU is in **Cranking Mode** or **Error Mode** then the command fails with an **Sequence Error (SQER)**.

### Erase Logical Sector Range

#### Calling

- ST AA50<sub>H</sub>, SA
- ST AA58<sub>H</sub>, xxnn<sub>H</sub>
- ST AAA8<sub>H</sub>, xx80<sub>H</sub>
- ST AAA8<sub>H</sub>, xx50<sub>H</sub>

#### Function

This command erases “nn” logical sectors starting at the sector addressed by “SA”. Upon executing the command, the BUSY flag of the corresponding bank is set.

A **Sequence Error (SQER)** is returned and the execution fails for the following conditions:

- The range of logical sectors is not contained in one physical sector.
- For PFLASH, if the range of logical sectors exceeds 512KByte.
- For DFLASH, if the range of logical sectors exceeds 256KByte addressable memory (256KByte physical memory in Single Ended mode, and 512KByte physical memory in Complement Sensing mode)
- For UCB, if the range of logical sectors exceeds 1.
- If SA does not align to the start address of a logical sector.
- If SA aligns to an unavailable sector.
- If “nn” logical sectors is set to 0.
- If the DMU is in **Cranking Mode** or **Error Mode**.

A **Protection Error (PROER)** is returned and the execution fails for the following conditions:

- If SA or any of the following nn-1 logical sectors has an active write protection.
- The Flash module has an active global read protection set.

The error flag EVER is set to indicate an error during the erase process.

The flag PVER is set when the erase counter programming incurs an error.

**Note:** *The duration of an erase command can be much shorter than documented ( $t_{ERD}$ ,  $t_{MERD}$ ,  $t_{ERP}$ ,  $t_{MERP}$ ) when the range is already erased or partly erased.*

### Resume NVM Operation

### **Calling**

- ST AA50<sub>H</sub>, PA/SA
- ST AA58<sub>H</sub>, xxnn<sub>H</sub>
- ST AAA8<sub>H</sub>, xx70<sub>H</sub>
- ST AAA8<sub>H</sub>, xxCC<sub>H</sub>

### **Function**

A suspended command may be resumed.

### **Disable Protection**

### **Calling**

- ST 553C<sub>H</sub>, UC
- ST.W 553C<sub>H</sub>, PW0
- ST.W 553C<sub>H</sub>, PW1
- ST.W 553C<sub>H</sub>, PW2
- ST.W 553C<sub>H</sub>, PW3
- ST.W 553C<sub>H</sub>, PW4
- ST.W 553C<sub>H</sub>, PW5
- ST.W 553C<sub>H</sub>, PW6
- ST.W 553C<sub>H</sub>, PW7

### **Function**

The password protection of the selected UCB (if this UCB offers this feature) is temporarily disabled by setting DMU\_HF\_PROTECT.PRODISx (with “x” indicating the UCB) or DMU\_HF\_PROTECT.SRT when all the passwords PW0–PW7 match their configured values in the corresponding UCB.

The command fails by setting PROER when any of the supplied PWs does not match. In this case until the next application reset all further calls of **Disable Protection** fail with PROER independent of the supplied password.

### **Host Command Sequence Interpreter**

The protection handling has to use the Host command interface.

### **HSM Command Sequence Interpreter**

This command is rejected by the HSM command sequence interpreter with DMU\_SF\_ERRSR.SQER.

### **Resume Protection**

### **Calling**

- ST 5554<sub>H</sub>, xxF5<sub>H</sub>

## Function

This command clears all DMU\_HF\_PROTECT.PRODISx and DMU\_HF\_PROTECT.SRT effectively enabling again the Flash protection as it was configured.

### Host Command Sequence Interpreter

The protection handling has to use the Host command interface.

### HSM Command Sequence Interpreter

This command is rejected by the HSM command sequence interpreter with DMU\_SF\_ERRSR.SQER.

## Clear Status

### Calling

- ST 5554<sub>H</sub>, xxFA<sub>H</sub>

### Function

Clear operation and error flags.

Clearing of error flags will not solve the underlying problem that caused the error flag.

### Host Command Sequence Interpreter

The following flags are cleared:

- Operation flags: DMU\_HF\_OPERATION.PROG, DMU\_HF\_OPERATION.ERASE.
- Error flags: DMU\_HF\_ERRSR.SQER, DMU\_HF\_ERRSR.PROER, DMU\_HF\_ERRSR.PVER and DMU\_HF\_ERRSR.EVER.

### HSM Command Sequence Interpreter

The following flags are cleared:

- Operation flags: DMU\_SF\_OPERATION.PROG, DMU\_SF\_OPERATION.ERASE.
- Error flags: DMU\_SF\_ERRSR.SQER, DMU\_SF\_ERRSR.PVER and DMU\_SF\_ERRSR.EVER.

## 6.5.2.2.4 Protection for Verify Command Sequences

For the Host Command Sequence Interpreter, the command sequence function may be limited by configuring DMU\_SP\_PROCONHSMCFG.BLKFLAN = 1<sub>B</sub>:

If DMU\_SP\_PROCONHSMCFG.BLKFLAN = 0<sub>B</sub> then function is enabled for every address.

If DMU\_SP\_PROCONHSMCFG.BLKFLAN = 1<sub>B</sub> then function is blocked as follows:

- PFLASH PF0 logical sector analysis is blocked if DMU\_SP\_PROCONHSMCX0.HSMxX = 1<sub>B</sub> or DMU\_SP\_PROCONHSMCX1.HSMxX = 1<sub>B</sub> for the corresponding PFLASH HSM code logical sector "s".
- DFLASH1 analysis is blocked if DMU\_SP\_PROCONHSMCFG.HSMDX = 1<sub>B</sub>.
- UCB\_HSMCFG analysis is blocked if DMU\_HF\_CONFIRM0.PROINHSMCFG = **CONFIRMED** or **ERRORED**.
- UCB\_RETEST analysis is blocked if DMU\_HF\_CONFIRM0.PROINSRT = **CONFIRMED** or **ERRORED**.
- UCB\_PFLASH\_ORIG and UCB\_PFLASH\_COPY analysis is blocked if one of the following conditions is true:
  - The UCB\_PFLASH confirmation state is **CONFIRMED** and **Disable Protection** has not been activated.
  - The UCB\_PFLASH confirmation state is **ERRORED**.

- UCB\_DFLASH\_ORIG and UCB\_DFLASH\_COPY analysis is blocked if one of the following conditions is true:
  - The UCB\_DFLASH confirmation state is **CONFIRMED** and **Disable Protection** has not been activated.
  - The UCB\_DFLASH confirmation state is **ERRORED**.
- UCB\_DBG\_ORIG and UCB\_DBG\_COPY is blocked if one of the following conditions is true:
  - The UCB\_DBG confirmation state is **CONFIRMED** and **Disable Protection** has not been activated.
  - The UCB\_DBG confirmation state is **ERRORED**.
- UCB\_ECPPIO\_ORIG and UCB\_ECPPIO\_COPY analysis is blocked if one of the following conditions is true:
  - The UCB\_ECPPIO confirmation state is **CONFIRMED** and **Disable Protection** has not been activated.
  - The UCB\_ECPPIO confirmation state is **ERRORED**.
- UCB\_BMHDX\_ORIG and UCB\_BMHDX\_COPY analysis is blocked if one of the following conditions is true:
  - The UCB\_BMHDX confirmation state is **CONFIRMED** and **Disable Protection** has not been activated.
  - The UCB\_BMHDX confirmation state is **ERRORED**.

If this function is blocked the command fails by setting DMU\_HF\_ERRSR.PROER

### 6.5.2.2.5 DMU Commands

The DMU implements the following commands:

- **Reset to Read**
- **Clear Status**
- **Disable Protection**
- **Resume Protection**

### 6.5.2.2.6 Suspend and Resume Operations

The following operations may be suspended:

- **Write Page, Write Page Once, Write Burst, Write Burst Once.**
  - For **Write Page** and **Write Page Once**, the write operation may be suspended between the end of the programming and the start of the verification. Therefore the programming process itself is not suspended
  - For **Write Burst** and **Write Burst Once**, the burst operation in PFLASH may be suspended during the programming process. In DFLASH it is only suspended after end of the programming and before the start of verification.
- **Erase Logical Sector Range.**
- **Verify Erased Page, Verify Erased WL, Verify Erased Logical Sector Range.**
- **Replace Logical Sector**

There can be at most one operation in the suspended state in the **Host Command Interface** and one in the **HSM Command Interface**.

Erroneous suspend and resume requests are detected and prevented by the DMU.

The target range of a suspend program or erase operation is in an undefined state. Reading this range delivers unpredictable results.

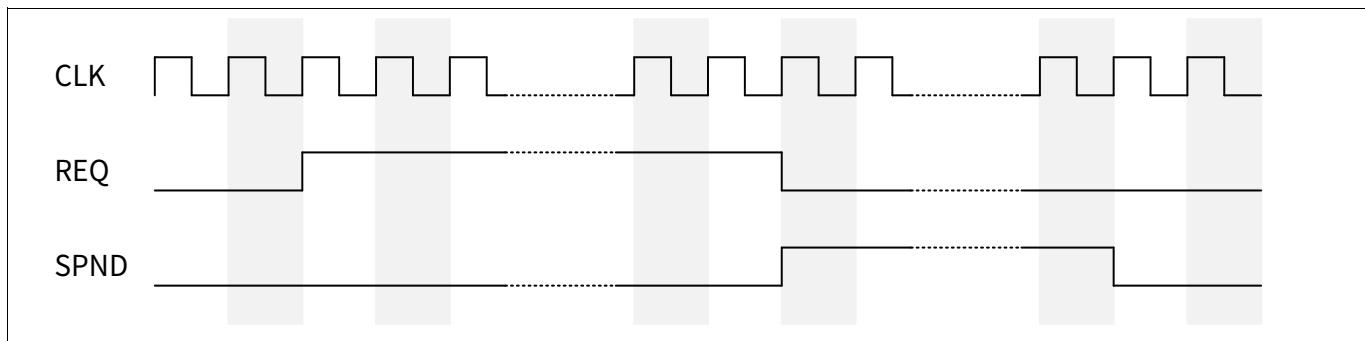

#### Host Command Interface

The Host Command Interface may suspend one flash operation (at [Figure 62](#)).

#### Suspend

Software may suspend a flash operation by writing  $1_B$  to DMU\_HF\_SUSPEND.REQ.

- The **Host Command Interface** checks if there is a flash operation requested or ongoing
  - If not then the suspend request is ignored and DMU\_HF\_SUSPEND.REQ is cleared.
- The **Host Command Interface** checks if the ongoing flash operation is suspendable.
  - If not then the DMU waits for the flash operation to complete and then clears DMU\_HF\_SUSPEND.REQ
  - If suspendable, the **Host Command Interface** checks if there is already a suspended operation. If true then a suspend error is reported (DMU\_HF\_SUSPEND.ERR = 1<sub>B</sub>) and the request is cleared (DMU\_HF\_SUSPEND.REQ = 0<sub>B</sub>).
- Else the **Host Command Interface** suspend request is serviced by the DMU.
- The DMU waits for the flash operation to reach an interruptible state and then clears the busy flag. The **Host Command Interface** reports the following (at **Figure 61**):
  - Operation suspended: DMU\_HF\_SUSPEND.SPND is set and DMU\_HF\_SUSPEND.REQ is cleared. The DMU stores which process was suspended and its arguments.
  - Operation finished: DMU\_HF\_SUSPEND.REQ is cleared.

**Figure 61 Operation Suspended and Operation Finished**

## Resume

A suspended operation may be resumed with the command sequence **Resume NVM Operation**.

- The DMU checks if there is a suspended operation.
  - If not then a **Sequence Error (SQER)** is reported.
- The arguments “PA” or “SA” and “nn” of the **Resume NVM Operation** must be identical to the argument of the suspended command. Using a different argument is detected by the DMU and lets the resume fail with a **Sequence Error (SQER)** and DMU\_HF\_SUSPEND.SPND remains set.
- Else for a valid **Resume NVM Operation** the DMU sets corresponding bank busy flag, clears the suspend flag (DMU\_HF\_SUSPEND.SPND = 0<sub>B</sub>) and sets appropriate status flag DMU\_HF\_OPERATION.{PROG/ERASE}.

**Attention:** Please ensure that between the start or resume of a Flash operation and the suspend request normally at least ~3ms execution time can pass. This is especially important for Erase and Erase Verify Operations. Shorter execution durations are possible but the erase/verify process will not advance at all. To avoid a high number of repetitions and very long total execution timings it is recommended to wait at least in average ~10ms. Timings mentioned above are valid for f(FSI) = 100 MHz and need to be scaled up accordingly when using a lower FSI frequency.

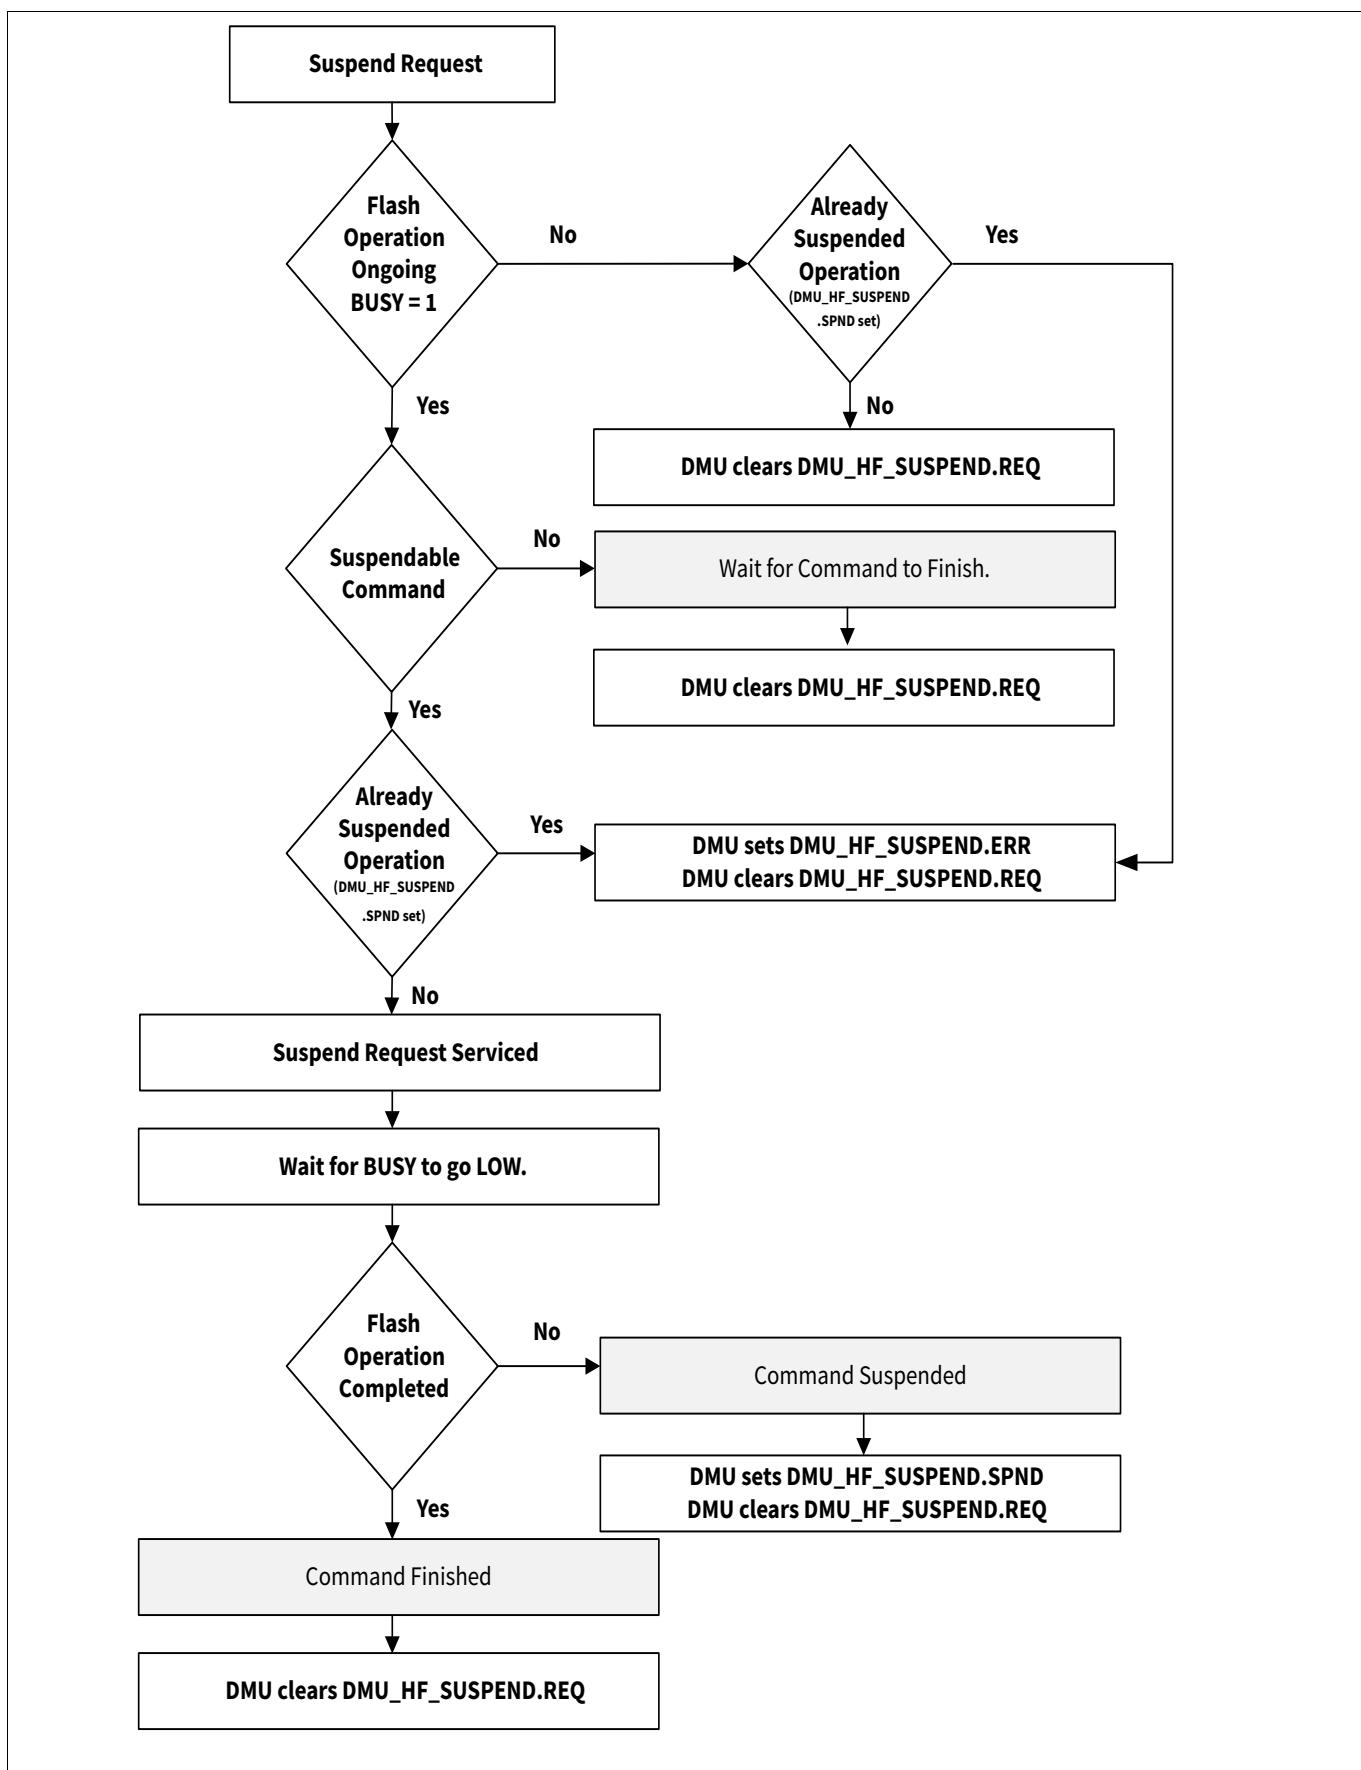

Figure 62 Suspend

## HSM Command Interface

The HSM Command Interface suspend and resume operation is like that of the [Host Command Interface](#).

The DMU\_SF\_SUSPEND register is used to control and monitor suspend operations.

## Suspended States

### Suspended Programming State

In the suspended programming state:

- Reading Flash is allowed.
- New programming commands are rejected with SQER:
  - [Enter Page Mode](#).
  - [Write Page](#), [Write Page Once](#), [Write Burst](#), [Write Burst Once](#).
  - [Replace Logical Sector](#)
- New erase and verify commands are rejected with SQER:
  - [Erase Logical Sector Range](#).
  - [Verify Erased Page](#), [Verify Erased WL](#), [Verify Erased Logical Sector Range](#).

### Suspended Erase State

In the suspended erase state:

- Reading Flash is allowed.
- New programming commands may be performed on any bank:
  - [Enter Page Mode](#).
  - [Write Page](#), [Write Page Once](#), [Write Burst](#), [Write Burst Once](#).
  - [Replace Logical Sector](#)
- However programming in the target range of the suspended erase fails with SQER.
- New erase and verify commands are rejected with SQER:
  - [Erase Logical Sector Range](#).
  - [Verify Erased Page](#), [Verify Erased WL](#), [Verify Erased Logical Sector Range](#).

### Suspended Verify State

In the suspended [Verify Erased Page](#), [Verify Erased WL](#) or [Verify Erased Logical Sector Range](#) state:

- Reading Flash is allowed.
- New programming commands may be performed on any bank:
  - [Enter Page Mode](#).
  - [Write Page](#), [Write Page Once](#), [Write Burst](#), [Write Burst Once](#).
  - [Replace Logical Sector](#)
- New erase and verify commands are rejected with SQER:
  - [Erase Logical Sector Range](#).
  - [Verify Erased Page](#), [Verify Erased WL](#), [Verify Erased Logical Sector Range](#).

## Suspend-Resume application note for Host Command Interface

The following notes provide guidance in using the suspend and resume feature for Host Command Interface

In the case of a request for suspending an ongoing NVM operation:

- Please ensure that there is a delay between start or resume of an erase process and the suspend request. For further details on the delay, please refer to the ‘Attention’ section of [Chapter](#).
- Check if the corresponding BUSY flag has already been cleared. If yes, no suspend is necessary.
- Check DMU\_HF\_SUSPEND.SPND bit. If this is ‘1’, then there is already a suspended operation and the ongoing operation cannot be suspended.
- Request suspend with the control flag DMU\_HF\_SUSPEND.REQ.
- Wait until the corresponding BUSY flag clears.
- After that, check the DMU\_HF\_SUSPEND.SPND bit. If this is ‘1’, then the operation was suspended and needs to be resumed later. If this is ‘0’, the operation has already finished, therefore, no resume is necessary.
- Now, new Flash operations are allowed with the restrictions documented in [Chapter](#).

The resume of the NVM operation is done in these steps:

- Check if DMU\_HF\_SUSPEND.SPND is set. If this is ‘1’, there is an operation suspended that can be resumed.
- Resume the operation with the command sequence “Resume NVM Operation”.
- Wait until the DMU\_HF\_SUSPEND is ‘0’.
- After that, wait for the end of operation signalled by the corresponding BUSY flag going to ‘0’.

The same guidance is applicable for HSM Command Interface using the DMU\_SF\_SUSPEND register.

### 6.5.2.2.7 Programming Voltage Selection

If a device supports an external 5V supply via  $V_{EXT}$  then DMU\_HF\_PCONTROL.PR5V may be used to select an external supply as the source of the programming voltage:

- DMU\_HF\_PCONTROL.PR5V set to “P5V”
  - The programming voltage is sourced directly from the external supply  $V_{EXT}$  supplied with a nominal 5V.
  - See data sheet for supply voltage tolerances.
- DMU\_HF\_PCONTROL.PR5V set to “P3V”
  - The programming voltage is internally generated from  $V_{DDP3}$  supplied with a nominal 3.3 V.
  - The allowed range of  $V_{EXT}$  is much larger in this configuration.

For the PFLASH the P5V mode offers significantly shorter programming times (see data sheet).

### 6.5.2.2.8 Performing Flash Operations

This section offers advice for using command sequences.

#### General Advice

- Please remember to disable the Safety ENDINIT protection before executing program, erase and user commands for the PFLASH.
- Code that performs PFLASH programming or erasing should not be executed from the same PFLASH.

- Command cycles shall address the non-cached address range of the Flash (otherwise the data may stay in the cache or could be received by the DMU in an incorrect order).
- The prefetch buffers and data line buffer used for PFLASH reads are automatically invalidated after changing PFLASH content by erasing or programming. The prefetch buffers can additionally be invalidated by writing **HF\_PCONTROL.DEMAND** to '11', disabling prefetch. All buffers are invalidated by a reset.
- The NVM Subsystem works with the SRI, FSI and FSI2 clocks. When changing the divider values of these clocks in SCU\_CCUCON0 the following rules apply:
  - The only allowed DMU/Flash “operation” when switching is reading from Flash memory. Any other operation on the Flash is forbidden.
  - It must be ensured that before, during and after the divider change the configured number of Flash wait-cycles is sufficient for the selected clock frequency. Remember that the wait-cycles are counted with fFSI2 for PFlash and fFSI for DFlash.
  - fFSI2 must not be programmed slower than fSRI.
  - After System Resets and Power-On Resets the wait cycle values are configured to a value only sufficient for the clock frequencies used during startup (i.e. 100 MHz). So basically always changes to the clock configuration must be preceded by changes to the wait cycles.

### Flushing the CPU buffer when using NVM commands

The NVM **Load Page** command requires that all write data transfers for one page must have the same width (either all 32-bit or all 64-bit). If 32-bit **Load Page** commands are used there would be pairs of two writes as follows:

```
ST 0x55F0
ST 0x55F4
```

```
ST 0x55F0
ST 0x55F4
```

```
ST 0x55F0
ST 0x55F4
```

If the CPU Store function is active, some of these 32-bit writes might be merged into a 64-bit write. In order to prevent this and have all **Load Page** commands in the same order it is necessary to place a DSYNC instruction after every 32-bit write (or a register read, for example to **HF\_ID**, which would have the same effect). This ensures that all data is written to the memory prior to the execution of the next ST write instruction. Thus the above program sequence would become (with an additional DSYNC at the start of the sequence to ensure there is no residual operation lying around in the store buffer):

```
DSYNC
ST 0x55F0
DSYNC
ST 0x55F4
DSYNC
```

```
DSYNC
ST 0x55F0
DSYNC
ST 0x55F4
DSYNC
```

```
DSYNC
```

```
ST 0x55F0
DSYNC
ST 0x55F4
DSYNC
```

It is recommended to insert a DSYNC (or register read) after each program command sequence to ensure the correct sequencing of commands to the DMU.

### Sequence for Programming

The following sequence is the most defensive one for programming a page. It is however acceptable to skip some checks when the programmed data is later verified:

- “Clear Status” to clear flags.
- “Enter Page Mode”.
- DSYNC.
- Wait until **HF\_STATUS.PFPAGE** = ‘1’ or **HF\_STATUS.DFPAGE** = ‘1’ depending upon the Flash target, or fail if **HF\_ERRSR.SQER** = ‘1’ or **HF\_ERRSR.PROER** = ‘1’.
- Repeat “Load Page” until the page is filled.
- “Write Page”.
- DSYNC.
- Wait until **HF\_OPERATION.PROG** = ‘1’ or fail if (**HF\_ERRSR.SQER** = ‘1’ or **HF\_ERRSR.PROER** = ‘1’).
- Wait for 2\*1/fFSI ns (DFlash) or 3\*1/fFSI + 8\*1/fSRI ns (PFlash).
- Wait until **HF\_STATUS.xBUSY** = ‘0’ or enable the interrupt.
  - While **HF\_STATUS.xBUSY** is ‘1’ the flags **HF\_ERRSR.OPER** can be checked for ‘1’ as abort criterion to protect against hardware failures causing BUSY to stay ‘1’.
- Check for **HF\_ERRSR.PVER** flag.
- Fail if **HF\_ERRSR.OPER** = ‘1’.
- Recommended: check programmed content, evaluate **HF\_ECCS** for DFlash accesses, and possibly count correctable errors.
- Clear error flags either with “Clear Status” or by directly writing to **HF\_CLRE**.

### Sequence for Erasing

The following sequence is the most defensive one for erasing a range of sectors. It is however acceptable to skip some checks when the programmed data is verified after programming (or the flag **HF\_ERRSR.PVER** is checked as described above):

- “Clear Status” to clear flags
- “Erase Logical Sector Range”.
- DSYNC.
- Wait until **HF\_OPERATION.ERASE** = ‘1’ or fail if (**HF\_ERRSR.SQER** = ‘1’ or **HF\_ERRSR.PROER** = ‘1’).
- Wait for 2\*1/fFSI ns (DFlash) or 3\*1/fFSI + 8\*1/fSRI ns (PFlash).
- Wait until **HF\_STATUS.xBUSY** = ‘0’ or enable the interrupt.
  - While **HF\_STATUS.xBUSY** is ‘1’ the flags **HF\_ERRSR.OPER** can be checked for ‘1’ as abort criterion to protect against hardware failures causing BUSY to stay ‘1’.
- Check for **HF\_ERRSR.PVER** and **HF\_ERRSR.EVER** flags.
- Fail if **HF\_ERRSR.OPER** = ‘1’.

- Clear error flags either with “Clear Status” or by directly writing to **HF\_CLRE**.

An analog sequence can be used for “Verify Erased Logical Sector Range”.

### Resets during Flash Operation

A reset or power failure during an ongoing Flash operation (i.e. program or erase) must be considered as a violation of stable operating conditions. However, the Flash was designed to prevent damage to non-addressed Flash ranges when the reset is applied as defined in the data sheet. The addressed Flash range is left in an undefined state.

### General advice

When an erase operation is aborted the previously programmed bits ('1') in the addressed Flash range can be in any state between '0' and '1'. When reading this range all-0 can be returned, the old data, or something in between. The result can be unstable. Due to the ECC correction there may even appear '1' bits at positions which contained '0' bits before erase start.

When a page programming operation is aborted the page can still appear as erased (but contain slightly programmed bits), it can appear as being correctly programmed (but the data has a lowered retention) or the page contains garbage data. It is also possible that the read data is unstable so that depending on the operating conditions different data is read.

For the detection of an aborted Flash process the flags **HF\_OPERATION.PROG**, **HF\_OPERATION.ERASE** and **HF\_OPERATION.USER** could be used as an indicator, but only when the reset was an application reset. When Flash processes are aborted by power-on resets, this is not indicated by any flags. It is not possible to detect an aborted operation simply by reading the Flash range (please note that the ECC is not a reliable means to detect an aborted Flash operation). Even the margin reads don't offer a reliable indication. When erasing or programming the PFlash usually an external instance can notice the reset and restart the operation by erasing the Flash range and programming it again.

### Advice for EEPROM Emulation

However for the case of EEPROM emulation in the DFlash this external instance is not existing. A common solution is detecting an abort by performing two operations in sequence and determine after reset from the correctness of the second the completeness of the first operation, for example, after erasing a DFlash sector a page is programmed. After reset the existence of correct data in this page proves that the erase process was performed completely. The detection of aborted programming processes can be handled similarly. After programming a block of data an additional page is programmed as marker. When after reset the block of data is readable and the marker is existent it is ensured that the block of data was programmed without interruption. In very specific cases it is allowed to repair data left from an aborted programming operation: if the algorithm can detect that an abort occurred and the algorithm knows which data must be present in the page it is possible to simply redo the programming by programming the same data again. In the AURIX2G family the probability of aborting a programming process can be minimized by the following means:

- In case of a reset with stable power supply (“warm resets”) the Flash gets automatically a request to enter shutdown state before the reset is applied. Due to their short duration, single “Write Page” operations are finished correctly by this process. “Write Burst” operations however are interrupted after the current page programming has finished.
- The voltage monitoring can be used to get an under voltage warning early enough that an ongoing programming process can be finished and no new one is started.
- By selecting an internally generated programming voltage, the needed voltage at VEXT is reduced giving more headroom for an early warning by the voltage monitors.

### 6.5.2.3 Traps

Generally the DMU peripherals report fatal errors by issuing a bus error which is translated by the CPU into a trap.

The conditions for reporting a bus error are:

- Uncorrectable ECC error.
- Write access to read-only register.
- Write access to Boot ROM (BROM).
- Write access to an access controlled register or Flash address range by a master without allowance by the register access protection.
- Not allowed write access to protected register (e.g. SV, Endinit or Safety Endinit).
- Not allowed Flash read access with active read protection.
- Read and write access to the FSI when the DMU is in sleep mode.
- Read access to not available Flash memory.
- Write access to not available Flash memory.
- Read-modify-write access to the Flash memory.
- Read access to a busy PFLASH bank (if not disabled by with CPUx\_FLASHCON1.STALL).
- Read access to a busy DFLASH bank (DFLASH0/1 EEPROM, CFS or UCB)
- Block Transfer to a DFLASH bank.
- Write access to the DFLASH0 address range when the Host Command Interface is busy with a command.
- Write access to the DFLASH1 address range when the HSM Command Interface is busy with a command.
- Read or write access to unoccupied register address.

### 6.5.2.4 Interrupts

#### 6.5.2.4.1 Host Command Interface

The following events can trigger an interrupt service request to the Interrupt Router (IR):

- End of BUSY: if DMU\_HF\_EER.EOBM = 1<sub>B</sub> and one of the DMU\_HF\_STATUS flags D0BUSY, D1BUSY or PFLASH flags transitions from ‘1’ to ‘0’ then an interrupt service request is triggered (e.g. wake-up, erase sequences or program sequences).
- **Operation Error (OPER):** if DMU\_HF\_EER.OPERM = 1<sub>B</sub> and DMU\_HF\_ERRSR.OPER flag is set.
- **Protection Error (PROER):** if DMU\_HF\_EER.PROERM = 1<sub>B</sub> and DMU\_HF\_ERRSR.PROER flag is set.
- **Sequence Error (SQER):** if DMU\_HF\_EER.SQERM = 1<sub>B</sub> and DMU\_HF\_ERRSR.SQER flag is set.
- **Erase Verify Error (EVER):** if DMU\_HF\_EER.EVERM = 1<sub>B</sub> and DMU\_HF\_ERRSR.EVER flag is set.
- **Program Verify Error (PVER):** if DMU\_HF\_EER.PVERM = 1<sub>B</sub> and DMU\_HF\_ERRSR.PVER flag is set.

The event that triggered the interrupt can be determined from the DMU\_HF\_STATUS and DMU\_HF\_ERRSR registers.

An interrupt event must be triggered when the event appears again and the corresponding status flag is still set. End of BUSY interrupts are only generated after completion of startup.

#### 6.5.2.4.2 HSM Command Interface

The following events can trigger an application interrupt to the HSM module:

- End of BUSY: if DMU\_SF\_EER.EOBM = 1<sub>B</sub> and HSM flag D1BUSY transitions from ‘1’ to ‘0’ then an interrupt service request is triggered (e.g. wake-up, erase sequences or program sequences).
- **Operation Error (OPER)**: if DMU\_SF\_EER.OPERM = 1<sub>B</sub> and DMU\_SF\_ERRSR.OPER flag is set.
- **Sequence Error (SQER)**: if DMU\_SF\_EER.SQERM = 1<sub>B</sub> and DMU\_SF\_ERRSR.SQER flag is set.
- **Erase Verify Error (EVER)**: if DMU\_SF\_EER.EVERM = 1<sub>B</sub> and DMU\_SF\_ERRSR.EVER flag is set.
- **Program Verify Error (PVER)**: if DMU\_SF\_EER.PVERM = 1<sub>B</sub> and DMU\_SF\_ERRSR.PVER flag is set.

The event that triggered the interrupt can be determined from the DMU\_SF\_STATUS and DMU\_SF\_ERRSR registers.

An end of BUSY interrupt is only generated after completion of startup.

### 6.5.2.5 Error Handling

Customer software should handle errors during startup and operation as follows:

#### 6.5.2.5.1 Handling Errors During Startup

The status flags are not only used to inform about the success of Flash command sequences but they are also used to inform (1) the startup software and (2) the user software about special situations incurred during startup. In order to react on this information these flags must be evaluated after reset and before performing any flag clearing sequences such as **Reset to Read** or **Clear Status**.

The following two levels of situations are separated:

- Fatal level: the user software is not started. A WatchDog Timer (WDT) reset is performed.
- Warning level: the user software is started but a warning is issued.

##### Fatal Level (WDT Reset)

These error conditions are evaluated by the startup software which decides that the Flash is not operable and thus waits for a WDT reset. The application sees only a longer startup time followed by a WDT reset.

The reason for a failed Flash startup can be a hardware error or damaged configuration data.

##### Warning Level

These conditions inform the user software about an internally corrected or past error condition.

Leftover OPER: FSI\_ERR.OPERERR

Status bits set: DMU\_HF\_ERRSR.OPER

The OPER flag is only cleared by a system reset. After any other reset a OPER flag is still set when the user software is started.

#### 6.5.2.5.2 Handling Errors During Operation

During operation (i.e. after issuing command sequences) error conditions are handled as follows:

##### Sequence Error (SQER)

Fault conditions:

- Improper command cycle address or data, i.e. incorrect command sequence.
- New **Enter Page Mode** in **Page Mode**.
- **Load Page** and not in **Page Mode**.
- **Load Page** with mixed 32/64-bit transfers.

- **Load Page** with invalid operation code - operation code must be SDTD or SDTW.
- For a 32-bit transfer the first **Load Page** addresses the upper 32-bit word.
- Write commands with incorrect buffer sizes.
- Write commands not in **Page Mode**.
- All commands to unavailable Flash range (e.g. Flash range does not physically exist).
- Command sequence with address not aligned to a legal start address (e.g. page, UCB or sector).
- Command sequence not pointing to a PFLASH, DFLASH0\_EEPROM, DFLASH0\_UCB or DFLASH1\_EEPROM address.
- **Write Page Once** targeting DFLASH.
- **Write Burst Once** targeting DFLASH.
- **Erase Logical Sector Range** or **Verify Erased Logical Sector Range** with range leaving a physical sector.
- **Resume NVM Operation** with arguments not matching the suspended command.
- **Resume NVM Operation** when there is no suspended operation.
- Any programming or erase command when there is a suspended programming command.
- Any erase command when there is a suspended erase command, including **Verify Erased WL** and **Verify Erased Logical Sector Range**.
- Programming to the target range of a suspended erase command.
- Unsupported command sequence for **Error Mode**.
- Unsupported command sequence for **Cranking Mode**.
- Unsupported command sequence for the HSM command sequence interpreter.
- Illegal value of SCU\_SWAPCTRL bits when DMU\_HP\_PROCONTP.SWAPEN is “Enabled” and a write or erase command is requested.

New state:

The command interface enters the idle state with following exceptions:

- **Enter Page Mode** in **Page Mode** re-enters **Page Mode**.
- **Write Page**, **Write Page Once**, **Write Burst** or **Write Burst Once** with buffer underflow is executed.
- After **Load Page** causing a buffer overflow the **Page Mode** is not left, a following **Write Page**, **Write Page Once**, **Write Burst** or **Write Burst Once** is executed.

Proposed handling by software:

Usually this bit is only set due to a bug in the software. Therefore in development code the responsible error tracer should be notified. In production code this error will not occur. It is however possible to clear this flag with **Clear Status** or **Reset to Read** and simply issue the corrected command sequence again.

## Operation Error (OPER)

Fault conditions:

The FSI may report an OPER at any time. Possible causes include:

- Double-bit ECC error detected while executing microcode out of FSI SRAM.
- Transient event due to alpha-particles or illegal operating conditions.
- Permanent error due to a hardware defect

New state:

The Flash operation is aborted and **Error Mode** is entered.

Proposed handling by software:

The last operation can be determined from the PROG and ERASE flags. The PROG or ERASE flag should be cleared with **Clear Status**. In case of an erase operation the affected physical sector must be assumed to be in an invalid state, in case of a program operation only the affected page. Other physical sectors can still be read. New program or erase commands must not be issued before the next reset.

A system reset must be applied to perform a new Flash startup with initialization of the FSI SRAM and clear the OPER flag. The application must determine from the context which operation failed and react accordingly. Mostly erasing the addressed sector and re-programming its data is most appropriate. If a **Write Page**, **Write Page Once**, **Write Burst** or **Write Burst Once** command was affected and the sector can not be erased (e.g. in Flash EEPROM emulation) the wordline could be invalidated if needed by marking it with all-one data and the data could be programmed to another empty wordline.

Only in case of a defective FSI SRAM the next program or erase operation will incur again this error.

**Note:** *Although an OPER indicates a failed operation it is possible to ignore it and rely on a data verification step to determine if the Flash memory has correct data. Before re-programming the Flash the flow must ensure that a new reset is applied.*

### Protection Error (PROER)

Fault conditions:

- Password failure.
- Erase/Write to protected sector.
- Replace Logical Sector command to a protected sector.
- **Erase Logical Sector Range** of UCB with active protection.
- Write commands to UCB with active protection.
- Verify commands to blocked addresses:
  - **Verify Erased Page**, **Verify Erased WL**, **Verify Erased Logical Sector Range**.
- Program, erase and replace logical sector commands targeting PFLASH with active Safety ENDINIT protection.
- During rampup if for single and dual UCB both the ORIG and COPY confirmation codes are **ERRORED**.

New state:

The command interface enters the idle state. The protection violating command is not executed.

Proposed handling by software:

Usually this bit is only set during runtime due to a bug in the software. In case of a password failure or UCB error a reset must be performed in the other cases the flag can be cleared with **Clear Status**. After that the corrected sequence can be executed.

### Erase Verify Error (EVER)

Fault conditions:

This flag is set by the erase commands when they don't achieve an optimum result. This is also set if a verification error is found by the verify erase commands or if there is no free entry available when performing **Replace Logical Sector**.

New state:

No state change. Just the bit is set.

Proposed handling by software:

This bit should be cleared with **Clear Status**.

The operating conditions should be checked. The following advice assumes correct operating conditions and a correctly configured device.

In the PFLASH an EVER indicates a fail in a logical sector. The command **Replace Logical Sector** can be used to replace that logical sector with a free redundant logical sector.

In the DFLASH an EVER indicates a potential fail at a wordline. It is recommended to repeat the erase once, however, if the EVER still persists, the robust EEPROM emulation has to “jump” over this wordline and program its data to the next wordline.

**Note:** *Even when this flag is ignored it is recommended to clear it at the end of the command, including suspend or resume of the command. Otherwise all following operations – including “sleep” – could trigger an interrupt even when they are successful.*

### **Program Verify Error (PVER)**

Fault conditions:

This flag is set by the program commands when they don't achieve an optimum result. This is also set during the execution of an erase command when the erase counter programming encounters an error or if there is a failure during the programming of the redundancy information while performing **Replace Logical Sector**.

New state:

No state change. Just the bit is set.

Proposed handling by software:

This bit should be cleared with **Clear Status**.

The operating conditions should be checked. The following advice assumes correct operating conditions and a correctly configured device.

In the PFLASH a PVER could indicate a fail in a logical sector. The command **Replace Logical Sector** can also be used to replace a failing logical sector with a free redundant logical sector.

In the DFLASH a PVER is a signal for the robust EEPROM emulation that programming on the current wordline failed. It is recommended to repeat the programming once, however, if the PVER still persists, the algorithm has to “jump” over this wordline and program its data to the next wordline.

**Note:** *Even when this flag is ignored it is recommended to clear it at the end of the command, including suspend or resume of the command. Otherwise all following operations – including “sleep” – could trigger an interrupt even when they are successful.*

### **Original Error (ORIER)**

Fault conditions:

This flag is set when a UCB ORIG confirmation code is **ERRORED** in a UCB containing both ORIG and COPY confirmation codes.

Proposed handling:

This bit should be cleared with application reset.

### **6.5.2.6 DMU Modes**

The DMU functions in one of the following modes (**Figure 63**)

### 6.5.2.6.1 Operation Mode

The PFLASH and DFLASH modules are powered up. The NVM may be read and the DMU must interpret command sequences. If a flash operation is performed then the response to a read access to a busy PFLASH bank is determined by the stall function:

- Error response ( $\text{STALL} = 0_B$ ): bus error.
- Stall response ( $\text{STALL} = 1_B$ ): ready is suppressed until BUSY clears.

Read access to any section of a busy DFLASH bank (either EEPROM, UCB or CFS) always generates a bus error.

Control of the power sub-modes is:

- **Demand Mode:** flash prefetch buffer accesses may be disabled by software.
- **Dynamic Idle Mode:** may be configured by software.

The following programming program sub-mode is supported:

- **Page Mode:** flash modules enabled to received data for programming.

The PFLASH read cycles are calculated from DMU\_HF\_PWAIT.RFLASH and DMU\_HF\_PWAIT.RECC

### 6.5.2.6.2 Error Mode

If the FSI has reported an **Operation Error (OPER)** in **Operation Mode** or **Cranking Mode** then the DMU is also in **Error Mode**. An on-going flash operation is aborted and the BUSY flag is cleared. Flash reads are not impaired.

Only the **DMU Commands** and FSI ROM Commands (see FSI chapter for details) are supported. The remaining commands fail with **Sequence Error (SQER)**.

The PFLASH read cycles are inherited from mode prior to entering **Error Mode**:

- **Operation Mode:** DMU\_HF\_PWAIT.RFLASH and DMU\_HF\_PWAIT.RECC
- **Cranking Mode:** DMU\_HF\_PWAIT.CFLASH and DMU\_HF\_PWAIT.CECC

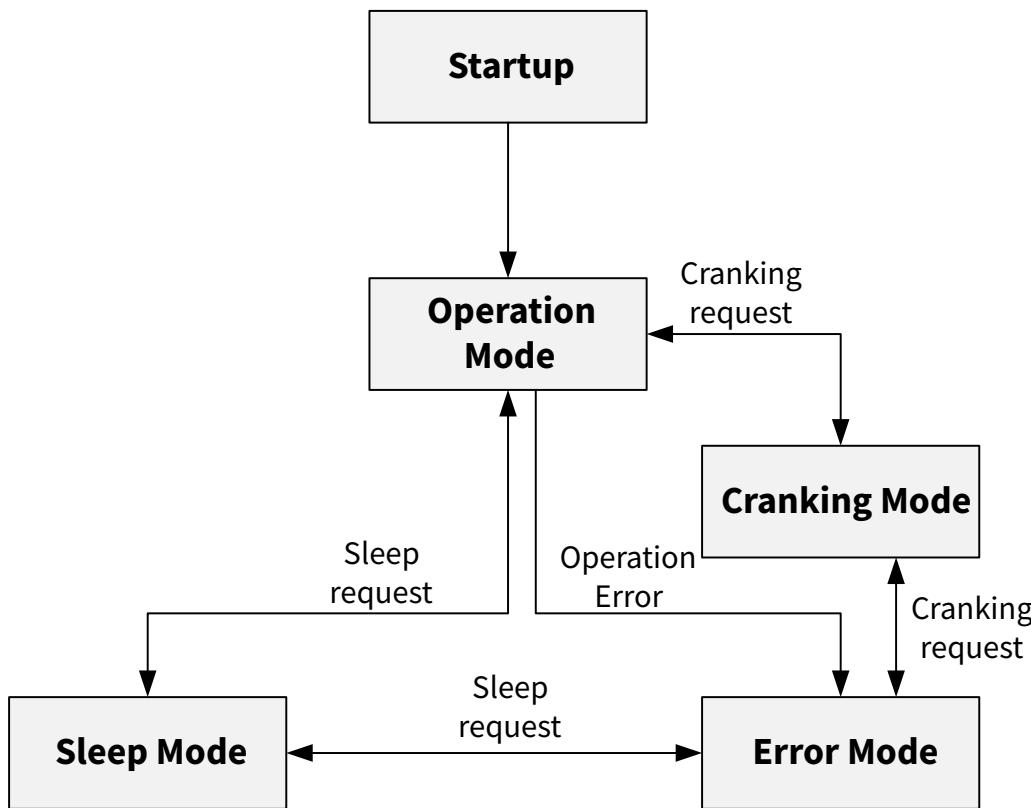

**Cranking Mode, Demand Mode** and **Dynamic Idle Mode** are inherited from the mode prior to entering **Error Mode** and can also be programmed by software while in **Error Mode**.

A system reset must be applied to exit **Error Mode**.

A sleep request is not acted upon by the DMU.

### 6.5.2.6.3 Power modes

For power reduction, DMU can be programmed to be in **Sleep Mode** or **Cranking Mode**.

**Figure 63 Modes**

### 6.5.2.7 Internal Connections

#### 6.5.2.7.1 Clocks

**Table 148 Clocks of Flash Interfaces**

Clock Name	Description of Use in Module
$f_{SRI}$	SRI clock (used in PFI and DMU)
$f_{BROM}$	BROM clock
$f_{FSI}$	FSI clock (used in FSI, PFI and DMU)
$f_{FSI2}$	FSI PFlash read clock (used in PFRWB), must be greater than or equal to $f_{SRI}$ for correct PFLASH operations

#### 6.5.2.7.2 Interrupts and Service Requests

The DMU peripheral generates an interrupt service request.

**Table 149 Interrupt /Service Request Sources of DMU**

Service Request Name	Description of Interrupt Source
DMUHOST	<p>Host Command Interface interrupt service request supports</p> <ul style="list-style-type: none"> <li>• Indication of end of busy</li> <li>• Indication of an operation error</li> <li>• Indication of a protection error</li> <li>• Indication of a command sequence error</li> <li>• Indication of a program or erase verify error</li> </ul>
DMUHSM	<p>HSM Command Interface interrupt service request supports (routed to HSM)</p> <ul style="list-style-type: none"> <li>• Indication of end of busy</li> <li>• Indication of an operation error</li> <li>• Indication of a command sequence error</li> <li>• Indication of a program or erase verify error</li> </ul> <p><i>Note:</i> <i>HSM command interface does not generate an “end of busy” interrupt for the falling edge of BUSY after startup.</i></p>
DMUFSI	FSI interrupt enabled for test purposes.

### 6.5.2.7.3 Cross Triggers

The DMU peripheral has no cross triggers.

### 6.5.2.8 Power Modes

Power consumption may be controlled by the following means:

#### 6.5.2.8.1 Flash Prefetch Buffers

Individual flash prefetch buffers are disabled by programming the respective CPUX\_FLASHCON0 bit field to the reserved Master Tag Identifier value. If prefetch accesses are disabled by changing mode or by disabling individual prefetch buffers then it does not prevent the delivery of existing prefetch data.

#### 6.5.2.8.2 Demand Mode

When in Demand Mode, PFLASH prefetch accesses to the local PFLASH bank by the flash prefetch buffers are disabled. Demand Mode can be requested by writing  $1_B$  to DMU\_HF\_PCONTROL.DEMAND. Demand Mode is also sub-mode of **Cranking Mode** and is entered when DMU\_HF\_CCONTROL.CRANKING =  $11_B$ .

#### 6.5.2.8.3 Dynamic Idle Mode

When there is no flash access the wordline decoder is switched off.

- DFLASH: dynamic idle is automatically enabled by hardware when no read access is performed.
- PFLASH: dynamic idle is enabled by software.

#### 6.5.2.8.4 Sleep Mode

Switching the DMU to Sleep Mode is requested by software. The 1.2V and 3.3V supply voltages to all flash modules (banks) are powered up. The regulators and charge pumps are powered down. The clock is switched off.

The sleep request can have two sources:

- Global sleep mode requested by SCU. Only executed by DMU when DMU\_HF\_PCONTROL.ESLDIS =  $00_B$
- Writing  $11_B$  to DMU\_HF\_PCONTROL.SLEEP

After receiving a sleep request, the Flash starts to ramp down and becomes idle, i.e. none of the banks are in command mode and no reads are executed anymore. An ongoing read burst is finished completely. During ramp down to sleep mode, all the BUSY status bits in the DMU registers are set.

The sleep mode is indicated in DMU\_HF\_PSTATUS.SLEEP. All the BUSY status bits in the DMU registers remain set.

**Note:** Requesting sleep mode does not disable automatically an enabled end-of-busy interrupt. When requesting sleep mode during an ongoing Flash operation with enabled end-of-busy interrupt, the operation finishes, the interrupt is issued and then the Flash enters sleep mode. However, this end-of-busy interrupt will wake-up the CPU again.

#### 6.5.2.8.5 Cranking Mode

The 3.3V supply voltage to all PFLASH and DFLASH banks is reduced, the 5V supply is not reliable. The read access time to all flash modules is increased. Flash prefetch buffer accesses are disabled. **Cranking Mode** is enabled by software writing DMU\_HF\_CCONTROL.CRANKING.

Control of the power sub-modes is:

- **Demand Mode:** flash prefetch buffer accesses are disabled by hardware.
- **Dynamic Idle Mode:** may be configured by software.

Only the **DMU Commands** and FSI ROM Commands (see FSI chapter for details) are supported. The remaining commands fail with **Sequence Error (SQER)**.

Before entering **Cranking Mode** software must suspend all on-going flash operations. On exiting **Cranking Mode** and after entering **Operation Mode** suspended flash operations may be resumed with **Resume NVM Operation**.

The PFLASH read cycles are calculated from DMU\_HF\_PWAIT.CFLASH and DMU\_HF\_PWAIT.CECC

### 6.5.2.8.6 Standby Mode

Device wide mode. The 1.2V supply voltage to all flash modules (banks) is powered down. Standby mode shall be entered only if the DMU is in sleep or read mode (i.e., none of the flash banks are in command mode, and performing any flash operations).

### 6.5.2.9 Boot ROM (BROM)

#### 6.5.2.9.1 Read Accesses

Both address ranges of the BROM (i.e. the cached and the non-cached) support SRI single and burst transfers.

#### 6.5.2.9.2 Data Integrity

The data in the BROM is ECC protected.

### 6.5.3 Registers

**Table 150 Flash Interface SFR Naming Convention**

Module Name	Group Name	Description
PMU	N/A	PMU SFR - PMU does not exist as a hardware module or chapter (replaced with DMU, PFI and separate NVM modules and chapters), but the name is retained for the Flash ID, BootROM and Tuning Protection registers for backward compatibility of software to TC39x-A Step. • BROM Control
PFI0		Flash Flash Interface 0
PFI1		Flash Flash Interface 1 (if PFI1 exists).
PFI2		Flash Flash Interface 2 (if PFI2 exists).
PFI3		Flash Flash Interface 3 (if PFI3 exists).
PFI4		Flash Flash Interface 4 (if PFI4 exists).
PFI5		Flash Flash Interface 5 (if PFI5 exists).
DMU	HF	Host Command Interface • Host Command Sequence Interpreter
DMU	HP	Host Protection Configuration
DMU	SF	HSM Command Interface • HSM Command Sequence Interpreter
DMU	SP	HSM Protection Configuration
FSI	N/A	FSI SFR

### 6.5.3.1 Flash ID and BootROM Registers (PMU)

**Table 151 Register Address Space - PMU**

Module	Base Address	End Address	Note
PMU	F8038000 <sub>H</sub>	F803FFFF <sub>H</sub>	sri slave interface

**Table 152 Register Overview - PMU (ascending Offset Address)**

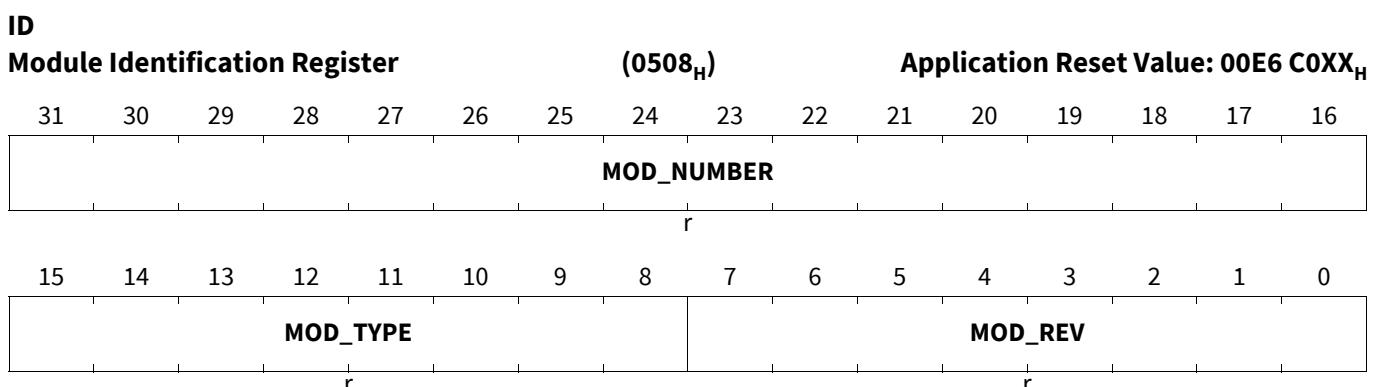

Short Name	Long Name	Offset Address	Access Mode		Reset	Page Number
			Read	Write		
ID	Module Identification Register	0508 <sub>H</sub>	U,SV	BE	Application Reset	58

#### 6.5.3.1.1 PMU Identification

The PMU\_ID register identifies the DMU and its version.

##### Module Identification Register

This module identification register identifies the DMU module

Field	Bits	Type	Description
<b>MOD_REV</b>	7:0	r	<b>Module Revision Number</b> MOD_REV defines the module revision number.
<b>MOD_TYPE</b>	15:8	r	<b>Module Type</b> This bit field is C0 <sub>H</sub> . It defines the module as a 32-bit module.
<b>MOD_NUMBE R</b>	31:16	r	<b>Module Number Value</b> This bit field defines the module identification number.

### 6.5.3.2 DMU Registers

**Table 153 Register Address Space - DMU**

Module	Base Address	End Address	Note
(DMU)	8FFF0000 <sub>H</sub>	8FFFFFFF <sub>H</sub>	Boot ROM (BROM)
	AF000000 <sub>H</sub>	AF0FFFFF <sub>H</sub>	Data Flash 0 EEPROM (DF0) and Host Command Sequence Interpreter
	AFC00000 <sub>H</sub>	AFC1FFFF <sub>H</sub>	Data Flash 1 EEPROM (DF1) and HSM Command Sequence Interpreter
	AFFF0000 <sub>H</sub>	AFFFFFFF <sub>H</sub>	Boot ROM (BROM)
DMU	F8040000 <sub>H</sub>	F807FFFF <sub>H</sub>	SRI slave interface - Register Address Space
(DMU)	FFC00000 <sub>H</sub>	FFC1FFFF <sub>H</sub>	Data Flash 1 EEPROM (DF1) and HSM Command Sequence Interpreter

**Table 154 Register Overview - DMU (ascending Offset Address)**

Short Name	Long Name	Offset Address	Access Mode		Reset	Page Number
			Read	Write

### 6.5.3.2.1 DMU Identification

#### Module Identification Register

The module identification register identifies the Flash module.

Field	Bits	Type	Description
<b>MOD_REV</b>	7:0	r	<b>Module Revision Number</b> This bit field defines the module revision number reflecting major changes in the module.
<b>MOD_TYPE</b>	15:8	r	<b>Module Type</b> The bit field is set to C0 <sub>H</sub> which defines the module as a 32-bit module.
<b>MOD_NUMBE R</b>	23:16	r	<b>Module Number Value</b> This bit field defines the module identification number.
<b>FLASH_REV</b>	31:24	r	<b>Flash Revision</b> This bit field defines the flash revision number.

### 6.5.3.2.2 Host Command Interface

#### Flash Status Register

The Flash Status Register reflects the status of the Flash Banks after reset.

**Note:** The DxBUSY and PxBUSY flags cannot be cleared with the “Clear Status” command or with the “Reset to Read” command. These flags are controlled by HW.

**Note:** After every reset, the busy bits are set while the Flash module is busy with startup (until the operation mode is entered). Also the protection installation bits are always set until end of startup.

HF STATUS

## **Flash Status Register**

(0000010<sub>H</sub>)

## **Application Reset Value: 0000 00FF**

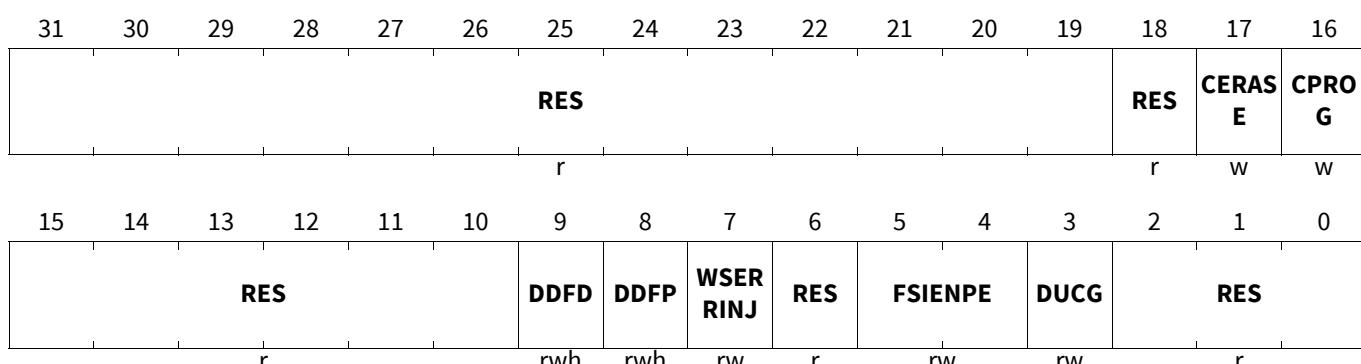

Field	Bits	Type	Description
<b>D0BUSY</b>	0	rh	<p><b>Data Flash Bank 0 Busy</b>            HW-controlled status flag.            Indication of busy state of DFLASH bank 0 because of active execution of an operation; DF0 busy state is also indicated during Flash startup after reset or in sleep mode; while in busy state the DF0 does not allow read access.</p> <p><math>0_B</math> DF0 ready, not busy; DF0 in operation mode.  <math>1_B</math> DF0 busy; DF0 not in operation mode.</p>
<b>D1BUSY</b>	1	rh	<p><b>Data Flash Bank 1 Busy</b>            HW-controlled status flag.            Indication of busy state of DFLASH bank 1 because of active execution of an operation; DF1 busy state is also indicated during Flash startup after reset or in sleep mode; while in busy state the DF1 does not allow read access.</p> <p>Bit is not set for program/erase operations initiated by the HSM interface.</p> <p><math>0_B</math> DF1 ready, not busy; DF1 in operation mode.  <math>1_B</math> DF1 busy; DF1 not in operation mode.</p>
<b>PxBUSY (x=0-5)</b>	x+2	rh	<p><b>Program Flash PFxBUSY</b>            HW-controlled status flag.            Indication of busy state of PFx because of active execution of an operation; PFx busy state is also indicated during Flash startup after reset or in sleep mode; while in busy state the PFx does not allow read access.</p> <p><math>0_B</math> PFx ready, not busy; PFx in operation mode.  <math>1_B</math> PFx busy; PFx not in operation mode.</p>

Field	Bits	Type	Description
<b>RES</b>	15:8, 23, 31:26	r	<b>Reserved</b> Always read as 0; should be written with 0.
<b>RES</b>	16, 17, 18, 19, 22, 25:24	rX	<b>Reserved</b> Undefined.
<b>DFPAGE</b>	20	rh	<b>Data Flash in Page Mode</b> HW-controlled status flag. Set with Enter Page Mode for DFLASH, cleared with Write Page command. This bit is not set by “Enter Page Mode” initiated by the HSM interface.  Note: <i>Read accesses are allowed while in page mode.</i>  0 <sub>B</sub> Data Flash not in page mode 1 <sub>B</sub> Data Flash in page mode
<b>PFPAGE</b>	21	rh	<b>Program Flash in Page Mode</b> HW-controlled status flag. Set with Enter Page Mode for Flash, cleared with Write Page command This bit is not set by “Enter Page Mode” initiated by the HSM interface.  Note: <i>Read accesses are allowed while in page mode.</i>  0 <sub>B</sub> Flash not in page mode. 1 <sub>B</sub> Flash in page mode.

## Flash Control Register

### HF\_CONTROL

#### Flash Control Register

(00000014<sub>H</sub>)Application Reset Value: 0000 0320<sub>H</sub>

Field	Bits	Type	Description
<b>RES</b>	2:0, 6, 15:10, 18, 31:19	r	<b>Reserved</b>
<b>DUCG</b>	3	rw	<b>DFLASH User Command Granularity</b> Granularity configuration of User commands for DFLASH0 $0_B$ Wordline granularity. $1_B$ Page granularity.
<b>FSIENPE</b>	5:4	rw	<b>Enable Program/Erase</b> The field prevents any Flash program or erase directly in the FSI. It is set to “Enabled” by the SSW upon finishing the startup.  <i>Note:</i> Once in the “enabled” state this field cannot be changed.  $00_B$ <b>Disabled</b> , Program/Erase are disabled in the FSI. $01_B$ <b>Enabled</b> , Program/Erase are enabled in the FSI. $10_B$ <b>Disabled</b> , Program/Erase are disabled in the FSI. $11_B$ <b>Disabled</b> , Program/Erase are disabled in the FSI.
<b>WSERRINJ</b>	7	rw	<b>PFlash Wait State ECC error injection</b> Error injection into the ECC logic protecting PFlash Wait states. $0_B$ No error injection requested $1_B$ An error is injected into the ECC protecting PFlash wait states
<b>DDFP</b>	8	rwh	<b>Disable Read from PFLASH</b> This bit enables/disables the read access to PFLASH. <b>DMU ramp up and SSW start up</b> This bit is automatically set with reset and is cleared during startup, if no Read Protection installed, and during startup SSW in case of internal start out of Flash. <b>User Software: Clearing PFLASH Read Protection</b> Once set, <b>HF_CONTROL.DDFP</b> can only be cleared when <b>HF_PROTECT.PRODISP</b> or <b>HF_PROTECT.PRODISP0-5</b> or not <b>HF_PROCONPF.RPRO</b> <b>User Software: Setting PFLASH Read Protection</b> Software must write <b>HF_CONTROL.DDFP</b> to $1_B$ $0_B$ Read access from the PFLASH memory area is allowed. $1_B$ Read access from the PFLASH memory area is not allowed.

Field	Bits	Type	Description
<b>DDFD</b>	9	rwh	<p><b>Disable Data Fetch from DF0_EEPROM</b>  This bit enables/disables the data fetch from DF0_EEPROM.</p> <p><b>DMU ramp up and SSW start up</b>  This bit is automatically set with reset and is cleared during startup, if no Read Protection installed, and during startup (BROM SW) in case of internal start out of Flash.</p> <p><b>User Software: Clearing DF0_EEPROM Read Protection</b>  Once set, <b>HF_CONTROL.DDFD</b> can only be cleared when <b>HF_PROTECT.PRODISD</b> or not <b>HF_PROCONDF.RPRO</b></p> <p><b>User Software: Setting DF0_EEPROM Read Protection</b>  Software must write <b>HF_CONTROL.DDFD</b> to 1<sub>B</sub></p> <p>0<sub>B</sub> Read access from the DF0_EEPROM memory area is allowed.  1<sub>B</sub> Read access from the DF0_EEPROM memory area is not allowed.</p>
<b>CPROG</b>	16	w	<p><b>Clear Programming State</b>  0<sub>B</sub> No action.  1<sub>B</sub> Clear the Programming State Flag DMU_HF_OPERATION.PROG</p>
<b>CERASE</b>	17	w	<p><b>Clear Erase State</b>  0<sub>B</sub> No action.  1<sub>B</sub> Clear the Erase State Flag DMU_HF_OPERATION.ERASE</p>

### PFLASH and DFLASH Read Protection

After DMU ramp up the SSW will set the following read protection values:

- Start not in internal Flash:
  - **HF\_CONTROL.DDFP** is set to **HF\_PROCONPF.RPRO**
  - **HF\_CONTROL.DDFD** is set to **HF\_PROCONDF.RPRO**
- Start in internal Flash:
  - **HF\_CONTROL.DDFP** is cleared to 0<sub>B</sub>
  - **HF\_CONTROL.DDFD** is cleared to 0<sub>B</sub>

Before disabling read access by setting **HF\_CONTROL.DDFP** or **HF\_CONTROL.DDFD** all pending read accesses to the affected Flash ranges should have finished.

### Flash Operation Register

The Flash Operation Register reflects the overall status of the Flash after reset.

#### HF\_OPERATION

### Error Status Register

#### HF\_ERRSR

##### Error Status Register

(0000034<sub>H</sub>)

Application Reset Value: 0000 0000<sub>H</sub>

Field	Bits	Type	Description
<b>OPER</b>	0	rh	<b>Flash Operation Error</b>  Note: Cleared with system reset.  $0_B$ No operation error. $1_B$ Flash array operation aborted, because of a Flash array failure, e.g. an ECC error in FSI SRAM.

Field	Bits	Type	Description
SQER	1	rh	<p><b>Command Sequence Error</b>            A sequence error is not indicated if the Reset to Read command aborts a command sequence.</p> <p><b>Note:</b> Cleared with application reset, commands “Reset to Read” and “Clear Status” or writing <a href="#">HF_CLRE.CSQER = 1<sub>B</sub></a>.</p> <p>0<sub>B</sub> No sequence error.            1<sub>B</sub> Command state machine operation unsuccessful because of improper address or command sequence.</p>
PROER	2	rh	<p><b>Protection Error</b>            A Protection Error is reported e.g. because of a not allowed command, for example an Erase or Write Page command addressing a locked sector, or because of wrong password(s) in a protected command sequence such as “Disable Read Protection”.</p> <p><b>A Protection Error is also reported if the safety protection prevented a program/erase operation in Flash.</b></p> <p><b>Note:</b> Cleared with application reset, with the command “Clear Status” or writing <a href="#">HF_CLRE.CPROER = 1<sub>B</sub></a>.</p> <p>0<sub>B</sub> No protection error.            1<sub>B</sub> Protection error.</p>
PVER	3	rh	<p><b>Program Verify Error</b>            A verify error was reported on completion of a Flash program operation</p> <p><b>Note:</b> Cleared with application reset, with the command “Clear Status” or writing <a href="#">HF_CLRE.CPVER = 1<sub>B</sub></a>.</p> <p>0<sub>B</sub> The page is correctly programmed. All bits have full expected quality.            1<sub>B</sub> A program verify error has been detected. Full quality of all bits cannot be guaranteed.</p>
EVER	4	rh	<p><b>Erase Verify Error</b>            A verify error was reported on completion of a Flash erase operation.</p> <p><b>Note:</b> Cleared with application reset, with the command “Clear Status” or writing <a href="#">HF_CLRE.CEVER = 1<sub>B</sub></a>.</p> <p>0<sub>B</sub> The sector is correctly erased. All erased bits have full expected quality.            1<sub>B</sub> An erase verify error has been detected. Full quality erased bits cannot be guaranteed.</p>

Field	Bits	Type	Description
<b>ADER</b>	5	rh	<p><b>SRI Bus Address ECC Error</b>            This flag is set when the DMU detects an ECC error in the address phase bus transaction on the SRI bus.</p> <p><i>Note:</i> Cleared with application reset or writing <b>HF_CLRE.CADER</b> = <math>1_B</math>.</p> <p><math>0_B</math> No SRI address error detected.  <math>1_B</math> SRI address error detected.</p>
<b>ORIER</b>	6	rh	<p><b>Original Error</b>            If a UCB contains both ORIG and COPY confirmation codes and during startup an ERRORED value or an uncorrectable ECC error is detected in the ORIG confirmation code then the original error flag is set by hardware.</p> <p><i>Note:</i> Cleared with application reset.</p> <p><math>0_B</math> No original error detected.  <math>1_B</math> Original error detected.</p>
<b>RES</b>	7, 31:8	r	<b>Reserved</b>

#### **6.5.3.2.4 Data Flash Bank 0 ECC Registers**

## DF0 ECC Read Register

The ECC Read Register must store the ECC checksum read during the last DF0 (including CFS and UCB) and DF1 (when DF1 is configured as not HSM\_exclusive) NVM read access when the read is initiated via the DMU SRI slave interface.

HF ECCR

<b>Field</b>	<b>Bits</b>	<b>Type</b>	<b>Description</b>
<b>RCODE</b>	21:0	rh	<b>Error Correction Read Code</b> ECC checksum read during the last NVM read access.
<b>RES</b>	23:22, 31:24	r	<b>Reserved</b>

## DF0 ECC Status Register

The ECC Status Register must capture ECC errors detected during the last DF0 (including CFS and UCB) and DF1 (when DF1 is configured as not HSM\_exclusive) NVM read access when the read is initiated via the DMU SRI slave interface.

### DF0 ECC Write Register

The ECC Write Register contains bits for disabling the ECC encoding for PFLASH Banks and DF0.

When disabling the ECC encoding for a PFLASH Bank with **HF\_ECCW.PECENCDIS** = ' $11_B$ ' the ECC code for the next 256-bit data block transferred from DMU to the Flash assembly buffer is taken from **HF\_ECCW.WCODE**.

When disabling the ECC encoding for DF0 with **HF\_ECCW.DECENCDIS** = ' $11_B$ ' the ECC code for the next 64-bit data block transferred from DMU to the Flash assembly buffer is taken from **HF\_ECCW.WCODE**.

If **HF\_ECCW.PECENCDIS** or **HF\_ECCW.DECENCDIS** is set to ' $11_B$ ' then the "Write Burst" command sequence will cause unpredictable results and must not be used.

**Attention:** After reading data with disabled ECC correction data buffers it is recommended to perform a reset to resume normal operation with ECC correction

**Attention:** Software should only set one of **HF\_ECCW.PECENCDIS** or **HF\_ECCW.DECENCDIS** to ' $11B$ '.

### 6.5.3.2.12 Access Protection Registers

The master specific access control is configured and controlled by the registers **HF\_ACCEN1** and **HF\_ACCENO**.

#### Access Enable Register 0

The Access Enable Register 0 controls access for transactions with the on chip bus master TAG ID  $000000_B$  to  $011111_B$  (see On Chip Bus chapter for the products TAG ID <-> master peripheral mapping).

**HF\_ACCENO** provides one enable bit for each 6-bit On Chip Bus Master TAG ID encoding.

Mapping of TAG IDs to **HF\_ACCENO**.ENx: EN0 -> TAG ID  $000000_B$ , EN1 -> TAG ID  $000001_B$ , ..., EN31 -> TAG ID  $011111_B$ .

For modules connected to SRI bus the **HF\_ACCENO** register controls write accesses.

:

Note: Please see also chapter *On-Chip System Buses and Bus Bridges*, table 'On Chip Bus Master TAG Assignments'

EN28	28	rw	<b>Access Enable for Master TAG ID 28</b> This bit enables write access to the module kernel addresses for transactions with the Master TAG ID 28 $0_B$ Write access will not be executed $1_B$ Write access will be executed

Field	Bits	Type	Description
<b>EN29</b>	29	rw	<b>Access Enable for Master TAG ID 29</b> This bit enables read / write access to the module kernel addresses for transactions with the Master TAG ID 29 $0_B$ Read / Write access will not be executed $1_B$ Read / Write access will be executed
<b>EN30</b>	30	rw	<b>Access Enable for Master TAG ID 30</b> This bit enables write access to the module kernel addresses for transactions with the Master TAG ID 30 $0_B$ Write access will not be executed $1_B$ Write access will be executed
<b>EN31</b>	31	rw	<b>Access Enable for Master TAG ID 31</b> This bit enables read / write access to the module kernel addresses for transactions with the Master TAG ID 30 $0_B$ Read / Write access will not be executed $1_B$ Read / Write access will be executed

### Access Enable Register 1

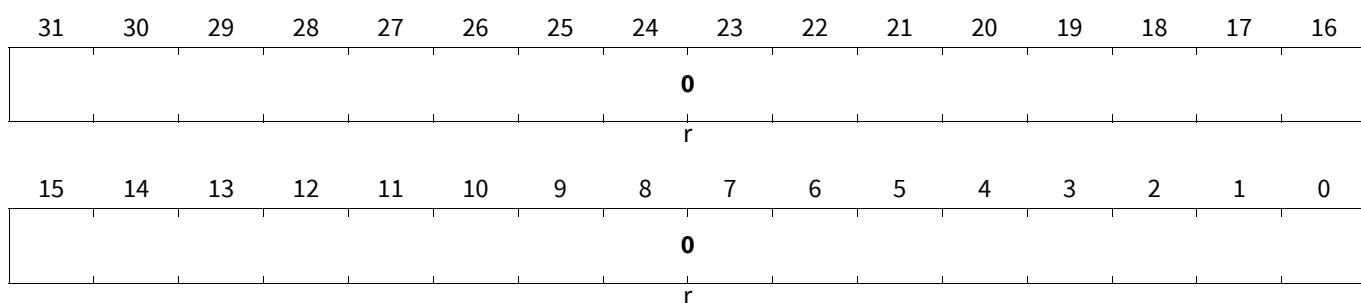

The Access Enable Register 1 controls write access for transactions with the on chip bus master TAG ID  $100000_B$  to  $111111_B$  (see On Chip Bus chapter for the products TAG ID <-> master peripheral mapping).

**HF\_ACCE1** is not implemented with register bits as the related On Chip Bus Master TAG IDs are not used.

Mapping of TAG IDs to **HF\_ACCE1**.ENx: EN0 -> TAG ID  $100000_B$ , EN1 -> TAG ID  $100001_B$ , ..., EN31 -> TAG ID  $111111_B$ .  
Access Enable Register 1 is safe endinit protected.

#### HF\_ACCE1

**Access Enable Register 1** **(00000F8<sub>H</sub>)** **Application Reset Value: 0000 0000<sub>H</sub>**

Field	Bits	Type	Description
<b>0</b>	31:0	r	<b>Reserved</b> Read as 0; should be written with 0.

### 6.5.3.2.13 Protection Configuration

#### PFLASH Protection Configuration

The configuration of PFLASH read protection is indicated by the PFLASH protection configuration registers.

## PFLASH Bank i Protection Configuration 0

### 6.5.3.2.14 HSM Command Interface

The following registers constitute the HSM command interface together with its reserved address range for command sequences.

#### HSM Flash Status Register

Note: *The DxBUSY flags cannot be cleared with the “Clear Status” command or with the “Reset to Read” command. These flags are controlled by HW.*

Note: *After every reset, the busy bits are set while the Flash module is busy with startup (until operation mode is entered). Also the protection installation bits are always set until end of startup.*

#### SF\_STATUS

HSM Flash Status Register (0020010 <sub>H</sub> ) Application Reset Value: 0000 0002 <sub>H</sub>															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

RES												D1BU SY	RES		

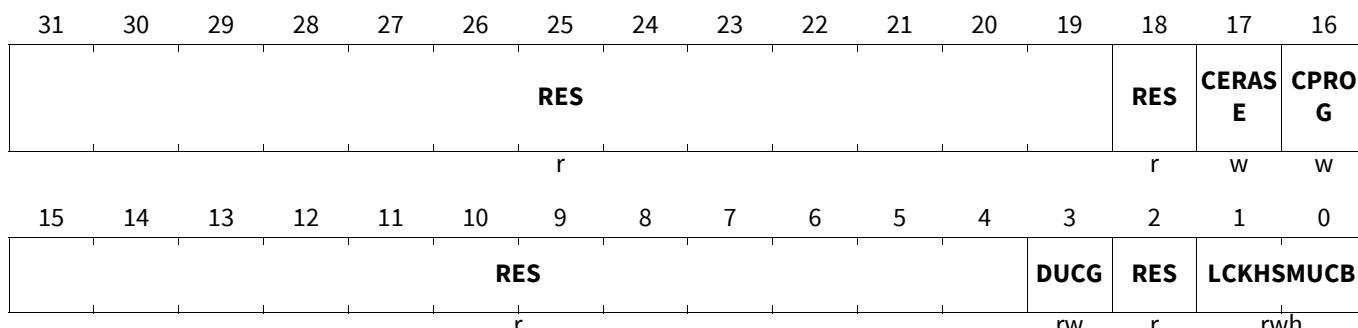

Field	Bits	Type	Description
RES	0, 19:2, 31:21	r	<b>Reserved</b> Always read as 0; should be written with 0.

Field	Bits	Type	Description
D1BUSY	1	rh	<p><b>Data Flash Bank 1 Busy</b>            HW-controlled status flag.            Indication of busy state of DFLASH bank 1 because of active execution of an operation; DF1 busy state is also indicated during Flash startup after reset or in sleep mode; while in busy state the DF1 does not allow read access.</p> <p>0<sub>B</sub> DF1 ready, not busy; DF1 in operation mode.             1<sub>B</sub> DF1 busy; DF1 not in operation mode.</p>
DFPAGE	20	rh	<p><b>Data Flash in Page Mode</b>            HW-controlled status flag.            Set with Enter Page Mode for DFLASH, cleared with Write Page command.</p> <p><i>Note:</i> <i>Read accesses are allowed while in page mode.</i></p> <p>0<sub>B</sub> Data Flash not in page mode             1<sub>B</sub> Data Flash in page mode</p>

### HSM Flash Configuration Register

#### SF\_CONTROL

#### HSM Flash Configuration Register

(0020014<sub>H</sub>)Application Reset Value: 0000 0001<sub>H</sub>

Field	Bits	Type	Description
LCKHSMUCB	1:0	rwh	<p><b>Lock Access to UCB_HSMCFG</b>            Trap door register. This field can only be written to the “Locked” state. Other writes are ignored.</p> <p>00<sub>B</sub> <b>Locked</b>, Reads to UCB_HSMCFG forbidden.             01<sub>B</sub> <b>Unlocked</b>, Reads by HSM to UCB_HSMCFG allowed.             10<sub>B</sub> <b>Locked</b>, Reads to UCB_HSMCFG forbidden.             11<sub>B</sub> <b>Locked</b>, Reads to UCB_HSMCFG forbidden.</p>
RES	2, 15:4, 18, 31:19	r	<b>Reserved</b>

Field	Bits	Type	Description
<b>DUCG</b>	3	rw	<b>DFLASH User Command Granularity</b> Granularity configuration of User commands for DFLASH1 $0_B$ Wordline granularity. $1_B$ Page granularity.
<b>CPROG</b>	16	w	<b>Clear Programming State</b> $0_B$ No action. $1_B$ Clear the Programming State Flag DMU_SF_OPERATION.PROG
<b>CERASE</b>	17	w	<b>Clear Erase State</b> $0_B$ No action. $1_B$ Clear the Erase State Flag DMU_SF_OPERATION.ERASE

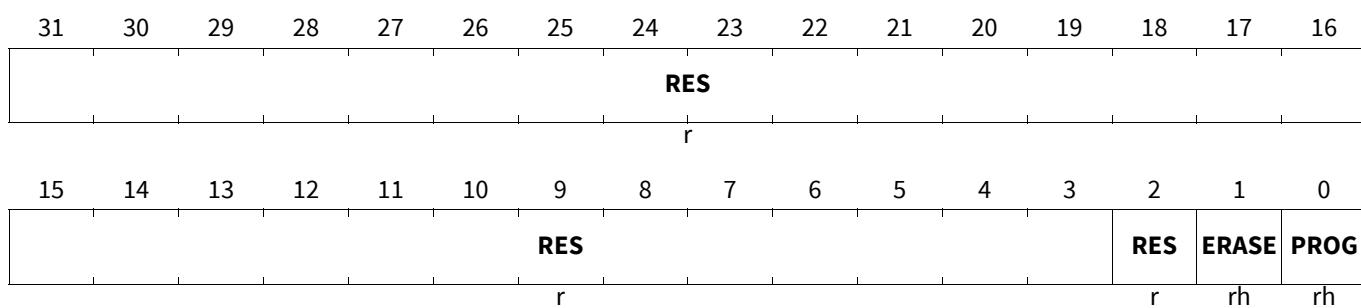

### HSM Flash Operation Register

#### SF\_OPERATION

##### HSM Flash Operation Register

(0020018<sub>H</sub>)

System Reset Value: 0000 0000<sub>H</sub>

Field	Bits	Type	Description
<b>PROG</b>	0	rh	<b>Programming State</b> HW-controlled status flag. Set with last cycle of Write Page/Burst command sequence. If one BUSY flag is coincidentally set, PROG indicates the type of busy state. If OPER is coincidentally set, PROG indicates the type of erroneous operation. Otherwise, PROG indicates, that operation is still requested or finished. Can be also cleared by writing '11' to <b>SF_CONTROL.CPROG</b> . This bit is not set for by program operations initiated by the Host interface.  <i>Note:</i> Cleared with command "Clear Status".  $0_B$ There is no program operation requested or in progress or just finished. $1_B$ Programming operation requested or in action or finished.

Field	Bits	Type	Description
<b>ERASE</b>	1	rh	<p><b>Erase State</b>            HW-controlled status flag.            Set with last cycle of Erase/Verify command sequence.            Indications are analogous to PROG flag.            Can be also cleared by writing '11' to <b>SF_CONTROL.CERASE</b>.            This bit is not set for by erase operations initiated by the Host interface.</p> <p><i>Note:</i> Cleared with command "Clear Status".</p> <p>0<sub>B</sub> There is no erase operation requested or in progress or just finished            1<sub>B</sub> Erase/Verify operation requested or in action or finished.</p>
<b>RES</b>	2, 31:3	r	<b>Reserved</b>

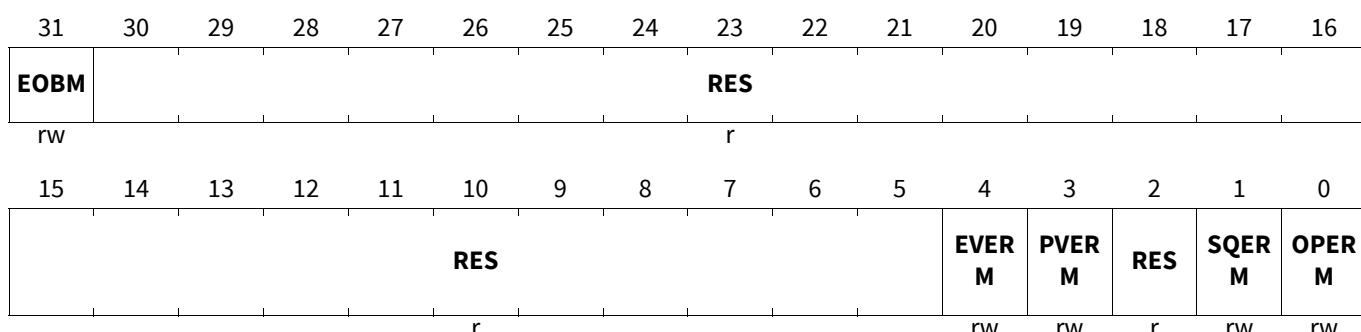

### 6.5.3.2.15 HSM Flash Error Registers

# HSM DF1 ECC Write Register

The HSM ECC Write Register contains bits for disabling the ECC encoding separately for DF1. When disabling the ECC encoding with **SF\_ECCW.ECCENCDIS** = '11<sub>B</sub>' the ECC code for the next 256-bit data block transferred from DMU to the Flash assembly buffer is taken from **SF\_ECCW.WCODE**. When **SF\_ECCW.ECCENCDIS** is set to '11<sub>B</sub>' the "Write Burst" command sequence must not be used as it may result in unpredictable results.

**Attention:** After reading data with disabled ECC correction data buffers it is recommended to perform a reset to resume normal operation with ECC correction

Field	Bits	Type	Description
<b>WCODE</b>	21:0	rw	<b>Error Correction Write Code</b> 22-bit ECC code for the current 64-bit (for DFLASH) or 256-bit (for PFLASH) write buffer to be written into the assembly buffer instead of a generated ECC.
<b>RES</b>	29:22	r	<b>Reserved</b> Always read as 0.
<b>ECCENCDIS</b>	31:30	rw	<b>ECC Encoding Disable</b>  00 <sub>B</sub> The ECC code is automatically calculated. ... 10 <sub>B</sub> The ECC code is automatically calculated. 11 <sub>B</sub> The ECC code is taken from WCODE.

## 6.5.4 Security

The security protection ensures that the PFLASH banks cannot be disturbed by software crashes or accesses by “unsafe” masters. This is achieved by the following features:

- Safety ENDINIT protection of ACCEN registers.
- Master specific protection of Flash relevant control and configuration registers.

The security protection prevents unauthorized PFLASH read and write accesses from internal masters or from external masters:

- Flash read protection: protected Flash sections can only be read when booting from Flash.
- Flash write protection: protected Flash sections can only be changed after authentication.
- Flash OTP (One-Time Programmable) protection: these Flash sections can't be changed anymore.
- HSM specific protection: it ensures that the HSM can protect its private data from access by other software. Additionally selected data can only be read during HSM boot phase.
- HSM debug protection: when the HSM allows internal debugging, accesses by the debug master (Cerberus) have the same privileges as the HSM itself.
- Device debug protection: depending on the boot mode and the configuration of debug protection and the Flash read protection and further controlled by HSM the debug access to the device is enabled.

The following security protection guards the Flash against mal-operation including software crashes (even of “safe” masters):

- ENDINIT and SV mode protection of configuration registers.
- Command sequences that can change Flash content need more command cycles. DMU\_HF\_ERRSR.SQER stops command interpretation.
- The separate HSM command interface enables main CPUs and HSM to share the DFLASH without disturbing each other and without the need for coordinating the software drivers.

The security protection supplements the Functional Safety Features because Flash data protected by the write protection is also safe against software crashes.

The following table gives an overview of all protection features and for which resources they are effective.

**Table 196 Security Protection**

	PFLASH	DFLASH
Flash Write Protection	Restricts Command Sequences	Restricts Command Sequences
Flash Read Protection	Restricts Reads	Restricts Reads

Any access to these resources has to pass all checks before the operation is performed.

### 6.5.4.1 Effective Flash Read Protection

The Flash read protection depends on the master and the Flash address range.

The following Flash ranges have separate read protections:

- PFLASH:
  - PFLASH Banks PFp including Erase Counters ECp
  - HSM Code exclusive sectors
- DFLASH:
  - CPU EEPROM
  - UCBs

- CFS
- HSM EEPROM

#### **6.5.4.1.1 PFLASH Read Protection**

All read accesses to a PFLASH bank are routed via the local CPU. Master specific access control (including local CPU PMBI and DMBI accesses) is configured and controlled by the CPUx ACCEN1 and ACCEN0 registers.

A read access to PFLASH (with the exception of HSM\_exclusive sectors) fails with bus error under the following conditions:

- DMU\_HF\_CONTROL.DDFP is 1<sub>B</sub>

Activating Read Protection:

- DMU\_HF\_CONTROL.DDFP is initialized by SSW depending on the startup mode and configured protection.
- DMU\_HF\_CONTROL.DDFP can be directly modified by user software under conditions noted in the description of DMU\_HF\_CONTROL

#### **HSM Code Read Protection**

The read access to the PFLASH Bank logical sector configured as an HSM code sectors depends on the setting of DMU\_SP\_PROCONHSMCX0.HSMxX or DMU\_SP\_PROCONHSMCX1.HSMxX which defines the “HSM\_exclusive” attribute of these sectors.

If DMU\_SP\_PROCONHSMCX0.HSMxX or DMU\_SP\_PROCONHSMCX1.HSMxX is set for such a sector then:

- HSM: full read access.
- Cerberus: with enabled HSM debug same access rights as HSM itself, with disabled HSM debug access rights as all other masters.
- All other masters except HSM and Cerberus with HSM debug access rights: a read fails with a bus error.

If DMU\_SP\_PROCONHSMCX0.HSMxX or DMU\_SP\_PROCONHSMCX1.HSMxX is cleared for such a sector then:

- The same rules as for the other PFLASH sectors based on CPU access enable as described above are valid.

#### **6.5.4.1.2 DFLASH Read Protection**

A read access to DFLASH0\_EEPROM fails with bus error under the following conditions:

- DMU\_HF\_CONTROL.DDFD is 1<sub>B</sub>

Activating Read Protection:

- DMU\_HF\_CONTROL.DDFD is initialized by SSW depending on the startup mode and configured protection.
- DMU\_HF\_CONTROL.DDFD can be directly modified by user software under conditions noted in the description of DMU\_HF\_CONTROL

#### **HSM EEPROM Read Protection**

The read access to the HSM data sectors HSMx depends on the configuration of DMU\_SP\_PROCONHSMCFG.HSMDX.

If DMU\_SP\_PROCONHSMCFG.HSMDX is set:

- HSM: full read access.
- Cerberus: with enabled HSM debug same access rights as HSM itself, with disabled HSM debug access rights as all other masters.
- All other masters except HSM and Cerberus with HSM debug access rights: a read fails with a bus error.

If DMU\_SP\_PROCONHSMCFG.HSMDX is cleared read access is allowed for all masters.

### 6.5.4.2 Effective Flash Write Protection

A range of Flash can be write protected by several means that are all configured in the UCBs.

#### 6.5.4.2.1 PFLASH Write Protection

Programming, erasing and replacing (using Replace Logical Sector command sequence) of a group of PFLASH logical sectors (with the exception of “HSM\_exclusive” code sectors) fails with PROER if any of the following conditions is true:

- DMU\_HF\_PROCONPF.RPRO and not (DMU\_HF\_PROTECT.PRODISP (global write protection disable) or DMU\_HF\_PROTECT.PRODISP0-5 (sector specific write protection disable)).
- DMU\_HP\_PROCONPp.SxL and not (DMU\_HF\_PROTECT.PRODISP or DMU\_HF\_PROTECT.PRODISP0-5).
- DMU\_HP\_PROCONOTPp.SxROM (sector specific OTP protection).
  - A set DMU\_HP\_PROCONOTPp.SxROM prohibits write and erase commands. These fail with DMU\_HF\_ERRSR.PROER.
- DMU\_HP\_PROCONWOPp.SxWOP (sector specific write-once protection).
  - A set DMU\_HP\_PROCONWOPp.SxWOP prohibits “Write Page”, “Write Burst”, “Replace Logical Sector” and erase commands. These fail with DMU\_HF\_ERRSR.PROER.
  - Only “Write Page Once” or “Write Burst Once” is accepted by the DMU. The FSI checks if the addressed Flash range is erased. If this is not the case the FSI reports a PVER and doesn’t start programming.
- Writes to PFLASH are Safety Endinit protected.

#### HSM Code Write Protection

Programming, erasing and replacing (using Replace Logical Sector command sequence) of the HSM exclusive logical sectors depends on the setting of the “HSM\_exclusive” attribute of these sectors and which master performs the access.

The above mentioned operations on “HSM\_exclusive” sectors fails if any of the following conditions is true:

- For all masters except HSM: DMU\_SP\_PROCONHSMCX0.HSMxX or DMU\_SP\_PROCONHSMCX1.HSMxX
- HSM specific OTP protection: DMU\_SP\_PROCONHSMCOTP0.HSMxROM or DMU\_SP\_PROCONHSMCOTP1.HSMxROM
- Writes to PFLASH are Safety Endinit protected.

For Cerberus the following rules apply: with enabled HSM debug same access rights as HSM itself, with disabled HSM debug access rights as all other masters.

#### 6.5.4.2.2 DFLASH Write Protection

Programming and erasing of the DFLASH0\_EEPROM fails with PROER when any of the following conditions is true:

- DMU\_HF\_PROCONDF.RPRO and not DMU\_HF\_PROTECT.PRODISD.
- DMU\_HF\_PROCONDF.L and not DMU\_HF\_PROTECT.PRODISD.

#### HSM EEPROM Write Protection

Programming and erasing of the HSM data sectors depends on DMU\_SP\_PROCONHSMCFG.HSMDX which defines their “HSM\_exclusive” attribute.

If DMU\_SP\_PROCONHSMCFG.HSMDX is set:

- HSM: full write access.
- All masters except HSM: programming and erasing fails.

- Cerberus: with enabled HSM debug same access rights as HSM itself, with disabled HSM debug access rights as all other masters.

If DMU\_SP\_PROCONHSMCFG.HSMDX is cleared:

- All master can program and erase without restriction.

### 6.5.4.3 Configuring Protection in the UCB

The effective protection is determined by the content of the PROCONx registers. These are loaded during startup from the UCBs. A UCB is erased with the command “Erase Logical Sector Range”. Its pages can be programmed with “Write Page” or “Write Burst”. Each UCB has its own access control. When programming or erasing fail because of this access control PROER is set. When reading fails a bus error is returned.

#### 6.5.4.3.1 UCB Confirmation

The state of a UCB is determined by the confirmation code:

**Table 197 UCB States**

State	Value	Description
UNLOCKED	4321 1234 <sub>H</sub>	<b>Delivery State</b> The UCB confirmation code is programmed with the UNLOCKED value.
CONFIRMED	57B5 327F <sub>H</sub>	<b>Operational State</b> The UCB confirmation code is programmed with the CONFIRMED value.  <i>Note: The UNLOCKED value can be over programmed with the CONFIRMED value.</i>
ERASED	0000 0000 <sub>H</sub>	<b>Erased State</b> Behavior as for the ERRORED state.
ERRORED	Others	<b>Errorred State</b> The UCB confirmation code stored is not the CONFIRMED or UNLOCKED value.

As also the erased state is considered as **ERRORED** the transition from **UNLOCKED** to **CONFIRMED** state can be done without erasing the UCB. For this the **UNLOCKED** code in the pages with the confirmation code and the copied confirmation code can be over-programmed with 57B5 327F<sub>H</sub>. It has to be ensured that the 4 bytes following the confirmation code (e.g. at offset 1F4<sub>H</sub>) are kept 0000 0000<sub>H</sub> in the unlocked state and in the over-programmed data. Only then the result after over-programming is ECC clean.

#### Dual UCB: Confirmation States

The UCB content is split across separate ORIG and COPY UCBs (e.g. UCB\_PFLASH\_ORIG and UCB\_PFLASH\_COPY). The UCB confirmation state is derived from the ORIG and COPY UCB confirmation codes.

The UCB confirmation is **UNLOCKED** if one of the following confirmation state conditions is true:

- ORIG UCB confirmation code is **UNLOCKED**.
- ORIG UCB confirmation code is **ERRORED** and the COPY UCB confirmation code is **UNLOCKED**.

The UCB confirmation is **CONFIRMED** if one of the following confirmation state conditions is true:

- ORIG UCB confirmation code is **CONFIRMED**.
- ORIG UCB confirmation code is **ERRORED** and the COPY UCB confirmation code is **CONFIRMED**.

The UCB confirmation is **ERRORED** if one of the following confirmation state conditions is true:

- ORIG UCB confirmation code is **ERRORED** and the COPY UCB confirmation code is **ERRORED**.

### **Single UCB: Errored State or ECC Error in the UCB Confirmation Codes**

If a UCB contains both ORIG and COPY confirmation codes (e.g. UCB\_SSW) then the following status is reported.

If the ORIG confirmation code is an **ERRORED** value or contains an uncorrectable ECC error then:

- The COPY confirmation code will be read to determine the UCB confirmation state and installation.
- Original error flag is set (DMU\_HF\_ERRSR.ORIER = 1<sub>B</sub>).

If both ORIG and COPY confirmation codes are an **ERRORED** value or contain uncorrectable ECC errors then:

- The UCB confirmation state is **ERRORED**
- Protection error flag is set (DMU\_HF\_ERRSR.PROER = 1<sub>B</sub>).

### **Dual UCB: Errored State or ECC Error in the UCB Confirmation Codes**

If the ORIG confirmation code is an **ERRORED** value or contains an uncorrectable ECC error then:

- The COPY confirmation code will be read to determine the UCB confirmation state and installation.

If the COPY confirmation code is an **ERRORED** value or contains an uncorrectable ECC error then:

- Protection error flag is set (DMU\_HF\_ERRSR.PROER = 1<sub>B</sub>).

### **ECC Error in the UCB Content**

If the UCB content contains an uncorrectable ECC error then:

- Protection error flag is set (DMU\_HF\_ERRSR.PROER = 1<sub>B</sub>).

### **UCB Evaluation Failure**

The device does not boot if any of the following error conditions are detected during startup:

- For single UCB: the ORIG and COPY confirmation code is **ERRORED**.
- For dual UCB: the ORIG and COPY confirmation code is **ERRORED**.
- The UCB content contains an uncorrectable ECC error.

For an errored UCB the default values are applied as shown in the Protection Configuration Register description.

### **Dual Password UCB ORIG and COPY Re-programming**

The data stored in the ORIG and COPY of a UCB pair should be identical. If there is a need to change the data then the following sequence should be followed:

- Confirm the ORIG and COPY UCB confirmation codes are **CONFIRMED**:
  - The configuration or protection installation will be installed from the ORIG UCB.
- Apply the password to **Disable Protection**. This disables protection for both ORIG and COPY UCBs.
- Erase COPY UCB - the confirmation code is erased prior to the content and treated as **ERRORED** for the installation.
- Program COPY UCB setting the confirmation code to **CONFIRMED**.
- Erase ORIG UCB - the confirmation code is erased prior to the content and treated as **ERRORED** for the installation.
  - The configuration or protection installation will be sourced from the COPY UCB.
- Program ORIG UCB setting the confirmation code to **CONFIRMED**.
  - The configuration or protection installation will be sourced from the ORIG UCB.
- Protection is re-enabled, either via command sequence or device reboot.

The ORIG is always evaluated. The above sequence ensures that the new data is confirmed in COPY before the ORIG is re-programmed. It avoids a scenario where the ORIG confirmation state is **ERRORED** and the COPY confirmation state is **UNLOCKED**.

#### 6.5.4.3.2 UCB\_BMHDx\_ORIG and UCB\_BMHDx\_COPY (x = 0-3)

Four Boot Mode Headers (BMHD) are evaluated by the SSW.

##### **UCB\_BMHDx\_ORIG and UCB\_BMHDx\_COPY (x = 0-3) Content**

The UCB content is described in the UCB chapter.

##### **UCB\_BMHDx\_ORIG (x = 0-3) Confirmation State**

The state of UCB\_BMHDx\_ORIG is indicated by DMU\_HF\_CONFIRM0.PROINBMHDxO.

##### **UCB\_BMHDx\_COPY (x = 0-3) Confirmation State**

The state of UCB\_BMHDx\_COPY is indicated by DMU\_HF\_CONFIRM0.PROINBMHDxC.

##### **Boot Mode Header Installation**

The BMHD installation is dependent on the confirmation states of UCB\_BMHDx\_ORIG and UCB\_BMHDx\_COPY. If the confirmation code of both ORIG and COPY is **ERRORED**, SSW does not evaluate the UCB.

**Table 198 Boot Mode Header 0 Installation**

<b>UCB_BMHD0_ORIG Confirmation State</b>	<b>UCB_BMHD0_COPY Confirmation State</b>	<b>Boot Mode Header Installation</b>
UNREAD	Don't Care	No evaluation.
<b>UNLOCKED</b>	Don't Care	SSW evaluates UCB_BMHD0_ORIG. Password installed from UCB_BMHD0_ORIG.
<b>CONFIRMED</b>	Don't Care	SSW evaluates UCB_BMHD0_ORIG. Password installed from UCB_BMHD0_ORIG.
<b>ERRORED</b>	<b>UNLOCKED</b>	SSW evaluates UCB_BMHD0_COPY. Password installed from UCB_BMHD0_COPY.
<b>ERRORED</b>	<b>CONFIRMED</b>	SSW evaluates UCB_BMHD0_COPY. Password installed from UCB_BMHD0_COPY.
<b>ERRORED</b>	<b>ERRORED</b>	No evaluation. No Password installed. SSW exits with error.

**Table 199 Boot Mode Header x Installation(x= 1 - 3)**

<b>UCB_BMHDx_ORIG Confirmation State</b>	<b>UCB_BMHDx_COPY Confirmation State</b>	<b>Boot Mode Header Installation</b>
UNREAD	Don't Care	No evaluation.
<b>UNLOCKED</b>	Don't Care	SSW evaluates UCB_BMHDx_ORIG.
<b>CONFIRMED</b>	Don't Care	SSW evaluates UCB_BMHDx_ORIG.
<b>ERRORED</b>	<b>UNLOCKED</b>	SSW evaluates UCB_BMHDx_COPY.

**Table 199 Boot Mode Header x Installation(x= 1 - 3) (cont'd)**

<b>UCB_BMHDx_ORIG Confirmation State</b>	<b>UCB_BMHDx_COPY Confirmation State</b>	<b>Boot Mode Header Installation</b>
<b>ERRORED</b>	<b>CONFIRMED</b>	SSW evaluates UCB_BMHDx_COPY.
<b>ERRORED</b>	<b>ERRORED</b>	No evaluation. SSW exits with error.

**BMHD Protection Disable**

If a password is installed and **Disable Protection** with matching PW is applied then

- DMU\_HF\_PROTECT.PRODISBMHD is set to 1<sub>B</sub>

If a password is not installed then protection may not be disabled.

**UCB\_BMHD0\_ORIG and UCB\_BMHD0\_COPY Access Protection**

UCB\_BMHD0\_ORIG and UCB\_BMHD0\_COPY are write protected if one of the following condition is true:

- UCB\_BMHD0 confirmation state is **CONFIRMED** and **Disable Protection** has not been activated using the password loaded from UCB\_BMHD0.
- UCB\_BMHD0 confirmation state is **ERRORED**.

UCB\_BMHD0\_ORIG and UCB\_BMHD0\_COPY content except for Password locations may be read by every on chip bus master. Password may be read by every on chip bus master only if UCB\_BMHD0 is **UNLOCKED** or **Disable Protection** has been activated.

**UCB\_BMHDx\_ORIG and UCB\_BMHDx\_COPY (x = 1-3) Access Protection**

UCB\_BMHDx\_ORIG and UCB\_BMHDx\_COPY (x = 1-3) are write protected if one of the following condition is true:

- UCB\_BMHDx confirmation state is **CONFIRMED** and **Disable Protection** has not been activated using the password loaded from UCB\_BMHD0.
- UCB\_BMHDx confirmation state is **ERRORED**.

UCB\_BMHDx\_ORIG and UCB\_BMHDx\_COPY may be read by every on chip bus master.

**6.5.4.3.3 UCB\_SSW**

UCB\_SSW contains data supplied by IFX during device production.

**UCB\_SSW Content**

The UCB content is described in the UCB chapter.

**UCB\_SSW Confirmation State**

The state of UCB\_SSW is indicated by DMU\_HF\_CONFIRM0.PROINSSW

**UCB\_SSW Content Installation**

The content installation is dependent on the ORIG and COPY confirmation states.

If ORIG confirmation code is **ERRORED** then an original error flag is set (DMU\_HF\_ERRSR.ORIER = 1<sub>B</sub>).

**UCB\_SSW Access Protection**

UCB\_SSW is read only and can be read by every on chip bus master.

#### 6.5.4.3.4 UCB\_USER

UCB\_USER contains data supplied by IFX during device production.

##### UCB\_USER Content

The UCB content is described in the UCB chapter.

##### UCB\_USER Unique Identifier

The Unique Identifier (UID) consists of 128 bits starting at UCB\_USER address offset 000<sub>H</sub>. It contains the following information:

- Lot number: “KKJWWNNNN” with sub-lot number “xy”.
- Date code: day, month, year.
- X and Y coordinate on the wafer.
- Wafer number.
- Constant identifiers for IFX, fab, Unique Identifier format.

The 6-bit characters 00<sub>H</sub> to 23<sub>H</sub> encode the digits and letters [0-9, A-Z].

**Table 200 Unique Identifier**

Bits	Type	Content
[7:0]	8-bit unsigned int	manufacturer ID (40 <sub>H</sub> )
[9:8]		unused
[14:10]	6-bit unsigned int	split lot char 2[bits 5:1]
[22:15]	8-bit unsigned int	Y coordinate on wafer
[30:23]	8-bit unsigned int	X coordinate on wafer
[31:31]		unused
[43:38]	6-bit unsigned int	split log char 1 [bit 5..0]
[44:44]	1-bit unsigned int	split lot char 2 [bit 0]
[45:45]	1-bit unsigned int	indicator for wafer test or blind assembly (0=wafer, 1=blind assembly)
[49:46]		unused
[59:50]	10-bit unsigned int	counter for serial lot numbers (001-999 <sub>D</sub> ) - NNN
[65:60]	6-bit unsigned int	Infineon logistic week during lot creation - WW
[69:66]	4-bit unsigned int	code number of Infineon financial year (last digit) - J
[74:70]	5-bit unsigned int	Facility code “19” = 7 (FabID) - KK
[79:75]	5-bit unsigned int	day of date code (range 1 to 31 <sub>D</sub> )
[83:80]	4-bit unsigned int	month of date code (range 1 to 12 <sub>D</sub> )
[91:84]	8-bit unsigned int	year of date code (add 2000 <sub>D</sub> )
[95:92]		constant 0100 <sub>B</sub> identifying the supplier
[127:96]		unused

##### UCB\_USER Confirmation State

The state of UCB\_USER is indicated by DMU\_HF\_CONFIRM0.PROINUSER.

### UCB\_USER Content Installation

The content installation is dependent on the ORIG and COPY confirmation states.

If ORIG confirmation code is **ERRORED** then an original error flag is set (DMU\_HF\_ERRSR.ORIER = 1<sub>B</sub>).

### UCB\_USER Access Protection

UCB\_USER is read only and can be read by every on chip bus master.

### 6.5.4.3.5 UCB\_TEST

UCB\_TEST contains test information supplied by IFX during device production.

#### UCB\_TEST Content

The UCB content is described in the Test specification.

#### UCB\_TEST Test Pass Marker

The 4 bytes starting at UCB\_TEST address offset 180<sub>H</sub> contain the “Test Pass Marker”. During test the Test Pass Marker is set to FFFFFFFF<sub>H</sub>. When all tests have passed the Test Pass Marker is programmed to 80658383<sub>H</sub>. A production device with a different value may be discarded.

#### UCB\_TEST Confirmation State

The state of UCB\_TEST is indicated by DMU\_HF\_CONFIRM0.PROINTEST.

#### UCB\_TEST Content Installation

The content installation is dependent on the ORIG and COPY confirmation states.

If ORIG confirmation code is **ERRORED** then an original error flag is set (DMU\_HF\_ERRSR.ORIER = 1<sub>B</sub>).

### UCB\_TEST Access Protection

UCB\_TEST is read only and can be read by every on chip bus master.

### 6.5.4.3.6 UCB\_HSMCFG

This UCB contains data supplied by Infineon during device production for the exclusive use of the HSM module.

#### UCB\_HSMCFG Content

If the HSM is configured then the HSM DLT routine has programmed the HSM keys and configuration data.

**Table 201 UCB\_HSMCFG Content**

Offset	Content	Range	Description
000 <sub>H</sub>	HSM Configuration		Defined in HSM ITS. It contains: <ul style="list-style-type: none"><li>• 128-bit Hash of the data.</li><li>• 128-bit AES key 0.</li><li>• 128-bit AES key 1.</li><li>• TRNG configuration</li><li>• Versioning.</li></ul>
1F0 <sub>H</sub>	ORIG Confirmation	4 Bytes	32-bit confirmation code.
1F8 <sub>H</sub>	COPY Confirmation	4 Bytes	32-bit confirmation code.

If the HSM is not configured then the UCB\_HSMCFG content should be programmed with all zeros.

#### **UCB\_HSMCFG Confirmation State**

The confirmed state of UCB\_HSMCFG is indicated by DMU\_HF\_CONFIRM0.PROINHSMCFG.

If ORIG confirmation code is **ERRORED** then an original error flag is set (DMU\_HF\_ERRSR.ORIER = 1<sub>B</sub>).

#### **UCB\_HSMCFG Write Access Protection**

UCB\_HSMCFG may be programmed and erased by all masters when all of the following conditions are true:

- UCB\_HSMCFG confirmation state is **UNLOCKED**.

#### **UCB\_HSMCFG Read Access Protection**

UCB\_HSMCFG may be read by all on chip masters if the following condition is true:

- UCB\_HSMCFG confirmation state is **UNLOCKED**.

UCB\_HSMCFG may be read only by the HSM on chip master if the following condition is true:

- UCB\_HSMCFG ORIG confirmation state is **CONFIRMED** or **ERRORED**.

The HSM can lock read access completely until the next application reset with DMU\_SF\_CONTROL.LCKHSMUCB. This locking is performed as part of the HSM startup by its firmware.

If HSM debug mode is enabled then the Cerberus has the same access rights as HSM else the Cerberus is treated as any other on chip bus master.

#### **6.5.4.3.7 UCB\_REDSEC**

This UCB contains the redundancy information for all the flash banks.

#### **UCB\_REDSEC**

The UCB content is described in the UCB chapter.

#### **UCB\_REDSEC Confirmation**

The confirmation state of UCB\_REDSEC is indicated by DMU\_HF\_CONFIRM0.PROINREDSEC.

If ORIG confirmation code is **ERRORED** then an original error flag is set (DMU\_HF\_ERRSR.ORIER = 1<sub>B</sub>).

#### **UCB\_REDSEC Access Protection**

UCB\_REDSEC is read only and can be read by every on chip bus master.

#### **6.5.4.3.8 UCB\_PFLASH\_ORIG and UCB\_PFLASH\_COPY**

Password protection of PFLASH banks is stored in UCB\_PFLASH\_ORIG and UCB\_PFLASH\_COPY.

#### **UCB\_PFLASH\_ORIG and UCB\_PFLASH\_COPY Content**

The UCB content is described in the UCB chapter.

#### **UCB\_PFLASH\_ORIG Confirmation State**

The confirmation state of UCB\_PFLASH\_ORIG is indicated by DMU\_HF\_CONFIRM1.PROINPO.

#### **UCB\_PFLASH\_COPY Confirmation State**

The confirmation state of UCB\_PFLASH\_COPY is indicated by DMU\_HF\_CONFIRM1.PROINPC.

## Program Flash Protection and Password Installation

The protection and password installation is dependent on the confirmation states of UCB\_PFLASH\_ORIG and UCB\_PFLASH\_COPY (at [Table 202](#)).

**Table 202 Program Flash Protection and Password Installation**

UCB_PFLASH_ORIG Confirmation State	UCB_PFLASH_COPY Confirmation State	Protection and Password Installation
UNREAD	Don't Care	Reset value. No password installed.
<b>UNLOCKED</b>	Don't Care	Protection installed from UCB_PFLASH_ORIG. Password installed from UCB_PFLASH_ORIG.
<b>CONFIRMED</b>	Don't Care	Protection installed from UCB_PFLASH_ORIG. Password installed from UCB_PFLASH_ORIG.
<b>ERRORED</b>	<b>UNLOCKED</b>	Protection installed from UCB_PFLASH_COPY. Password installed from UCB_PFLASH_COPY.
<b>ERRORED</b>	<b>CONFIRMED</b>	Protection installed from UCB_PFLASH_COPY. Password installed from UCB_PFLASH_COPY.
<b>ERRORED</b>	<b>ERRORED</b>	Default protection installed. No password installed. SSW exits with error.

## Program Flash Protection Disable

If a password is installed and **Disable Protection** with matching PW is applied then

- DMU\_HF\_PROTECT.PRODISP is set to 1<sub>B</sub>

If a password is not installed then protection may not be disabled.

## UCB\_PFLASH\_ORIG and UCB\_PFLASH\_COPY Access Protection

UCB\_PFLASH\_ORIG and UCB\_PFLASH\_COPY are read and write protected if one of the following conditions is true:

- The UCB\_PFLASH confirmation state is **CONFIRMED** and **Disable Protection** has not been activated.
- The UCB\_PFLASH confirmation state is **ERRORED**.

### 6.5.4.3.9 UCB\_DFLASH\_ORIG and UCB\_DFLASH\_COPY

Password protection of the DFLASH is stored in UCB\_DFLASH\_ORIG and UCB\_DFLASH\_COPY. The UCB is also used for configuring the memory initialization and contains an oscillator configuration.

#### UCB\_DFLASH\_ORIG and UCB\_DFLASH\_COPY Content

The UCB content is described in the UCB chapter.

#### UCB\_DFLASH\_ORIG Confirmation

The confirmation state of UCB\_DFLASH\_ORIG is indicated by DMU\_HF\_CONFIRM1.PROINDO.

#### UCB\_DFLASH\_COPY Confirmation

The confirmation state of UCB\_DFLASH\_COPY is indicated by DMU\_HF\_CONFIRM1.PROINDC.

### Data Flash Protection and Password Installation

The protection and password installation is dependent on the confirmation states of UCB\_DFLASH\_ORIG and UCB\_DFLASH\_COPY (at [Table 203](#)).

**Table 203 Data Flash Protection and Password Installation**

UCB_DFLASH_ORIG Confirmation State	UCB_DFLASH_COPY Confirmation State	Protection and Password Installation
UNREAD	Don't Care	Reset value. No password installed.
<b>UNLOCKED</b>	Don't Care	Protection installed from UCB_DFLASH_ORIG. Password installed from UCB_DFLASH_ORIG.
<b>CONFIRMED</b>	Don't Care	Protection installed from UCB_DFLASH_ORIG. Password installed from UCB_DFLASH_ORIG.
<b>ERRORED</b>	<b>UNLOCKED</b>	Protection installed from UCB_DFLASH_COPY. Password installed from UCB_DFLASH_COPY.
<b>ERRORED</b>	<b>CONFIRMED</b>	Protection installed from UCB_DFLASH_COPY. Password installed from UCB_DFLASH_COPY.
<b>ERRORED</b>	<b>ERRORED</b>	Default protection installed. No password installed. SSW exits with error.

### Data Flash Protection Disable

If a password is installed and **Disable Protection** with matching PW is applied then

- DMU\_HF\_PROTECT.PRODISD is set to 1<sub>B</sub>

If a password is not installed then protection may not be disabled.

### UCB\_DFLASH\_ORIG and UCB\_DFLASH\_COPY Access Protection

UCB\_DFLASH\_ORIG and UCB\_DFLASH\_COPY are read and write protected if one of the following conditions is true:

- The UCB\_DFLASH confirmation state is **CONFIRMED** and **Disable Protection** has not been activated.
- The UCB\_DFLASH confirmation state is **ERRORED**.

### 6.5.4.3.10 UCB\_DBG\_ORIG and UCB\_DBG\_COPY

This UCB configures the password protection for the debug interface.

#### UCB\_DBG\_ORIG and UCB\_DBG\_COPY Content

The UCB content is described in the UCB chapter.

#### UCB\_DBG\_ORIG Confirmation

The confirmation state of UCB\_DBG\_ORIG is indicated by DMU\_HF\_CONFIRM1.PROINDBGO.

#### UCB\_DBG\_COPY Confirmation

The confirmation state of UCB\_DBG\_COPY is indicated by DMU\_HF\_CONFIRM1.PROINDBGC.

### Debug Protection and Password Installation

The protection and password installation is dependent on the confirmation states of UCB\_DBG\_ORIG and UCB\_DBG\_COPY (at [Table 204](#)).

**Table 204 Debug Protection and Password Installation**

UCB_DBG_ORIG Confirmation State	UCB_DBG_COPY Confirmation State	Protection and Password Installation
UNREAD	Don't Care	Reset value. No password installed.
UNLOCKED	Don't Care	Protection installed from UCB_DBG_ORIG. Password installed from UCB_DBG_ORIG.
CONFIRMED	Don't Care	Protection installed from UCB_DBG_ORIG. Password installed from UCB_DBG_ORIG.
ERRORED	UNLOCKED	Protection installed from UCB_DBG_COPY. Password installed from UCB_DBG_COPY.
ERRORED	CONFIRMED	Protection installed from UCB_DBG_COPY. Password installed from UCB_DBG_COPY.
ERRORED	ERRORED	Default protection installed. No password installed. SSW exits with error.

### Debug Protection Disable

If a password is installed and **Disable Protection** with matching PW is applied then

- DMU\_HF\_PROTECT.PRODISDBG is set to 1<sub>B</sub>

If a password is not installed then protection may not be disabled.

### UCB\_DBG\_ORIG and UCB\_DBG\_COPY Access Protection

UCB\_DBG\_ORIG and UCB\_DBG\_COPY are read and write protected if one of the following conditions is true:

- The UCB\_DBG confirmation state is **CONFIRMED** and **Disable Protection** has not been activated.
- The UCB\_DBG confirmation state is **ERRORED**.
- Debug entry is destructive:
  - DMU\_SP\_PROCONHSMCFG.DESTDBG = 11<sub>B</sub> and (FDEST = 0<sub>B</sub> or SCU\_STCON.STP = 1<sub>B</sub>)
- Debug entered:
  - DMU\_HF\_PROCONDDBG.EDM = 11<sub>B</sub>

### 6.5.4.3.11 UCB\_HSM\_ORIG and UCB\_HSM\_COPY

UCB\_HSM\_ORIG and UCB\_HSM\_COPY configures the HSM interface protection and the content is only used in devices with activated HSM.

If HSM debug mode is enabled then the Cerberus has the same access rights as HSM else the Cerberus is treated as any other on chip bus master.

### UCB\_HSM\_ORIG and UCB\_HSM\_COPY Content

The UCB content is described in the UCB chapter.

### UCB\_HSM\_ORIG Confirmation

The confirmation state of UCB\_HSM\_ORIG is indicated by DMU\_HF\_CONFIRM1.PROINHSMO.

### UCB\_HSM\_COPY Confirmation

The confirmation state of UCB\_HSM\_COPY is indicated by DMU\_HF\_CONFIRM1.PROINHSMC.

### HSM Configuration Installation

The protection installation is dependent on the confirmation states of UCB\_HSM\_ORIG and UCB\_HSM\_COPY (at [Table 205](#)).

**Table 205 HSM Configuration Installation**

UCB_HSM_ORIG Confirmation State	UCB_HSM_COPY Confirmation State	Protection Installation
UNREAD	Don't Care	Reset value.
<b>UNLOCKED</b>	Don't Care	Protection installed from UCB_HSM_ORIG.
<b>CONFIRMED</b>	Don't Care	Protection installed from UCB_HSM_ORIG.
<b>ERRORED</b>	<b>UNLOCKED</b>	Protection installed from UCB_HSM_COPY.
<b>ERRORED</b>	<b>CONFIRMED</b>	Protection installed from UCB_HSM_COPY.
<b>ERRORED</b>	<b>ERRORED</b>	Default protection installed. SSW exits with error.

### UCB\_HSM\_ORIG and UCB\_HSM\_COPY Access Protection

UCB\_HSM\_ORIG and UCB\_HSM\_COPY are protected from programming and erasing by non-HSM bus masters if one of the following conditions is true:

- UCB\_HSM confirmation state is **CONFIRMED**.
- UCB\_HSM confirmation state is **ERRORED**.

UCB\_HSM\_ORIG and UCB\_HSM\_COPY may be read by every on chip bus master.

### 6.5.4.3.12 UCB\_HSMCOTP0/1\_ORIG and UCB\_HSMCOTP0/1\_COPY

HSMCOTP protection configures the HSM\_exclusive and OTP protection for the dedicated HSM flash sectors. It offers the possibility to add this type of protection to Flash sectors incrementally from two configuration sets:

- HSMCOTP0 configuration set derived from UCB\_HSMCOTP0\_ORIG and UCB\_HSMCOTP0\_COPY.
- HSMCOTP1 configuration set derived from UCB\_HSMCOTP1\_ORIG and UCB\_HSMCOTP1\_COPY.

### HSMCOTP Use Case

All masters can configure the HSMCOTP protection when both HSMCOTP0 and HSMCOTP1 configuration sets are **UNLOCKED**. If the HSMCOTP0 configuration set is **CONFIRMED** then only the HSM is allowed to program the HSMCOTP1 configuration set. If HSMCOTP1 is also **CONFIRMED** then the complete HSMCOTP configuration set is OTP protected.

### UCB\_HSMCOTP0/1\_ORIG and UCB\_HSMCOTP0/1\_COPY Content

The UCB content is described in the UCB chapter.

### **UCB\_HSMCOTP0\_ORIG Confirmation State**

The confirmation state of UCB\_HSMCOTP0\_ORIG is indicated by DMU\_HF\_CONFIRM1.PROINHSMCOTP00.

### **UCB\_HSMCOTP0\_COPY Confirmation State**

The confirmation state of UCB\_HSMCOTP0\_COPY is indicated by DMU\_HF\_CONFIRM1.PROINHSMCOTP0C.

### **UCB\_HSMCOTP1\_ORIG Confirmation State**

The confirmation state of UCB\_HSMCOTP1\_ORIG is indicated by DMU\_HF\_CONFIRM1.PROINHSMCOTP10.

### **UCB\_HSMCOTP1\_COPY Confirmation State**

The confirmation state of UCB\_HSMCOTP1\_COPY is indicated by DMU\_HF\_CONFIRM1.PROINHSMCOTP1C.

### **HSMCOTP0 Confirmation State**

The confirmation state of HSMCOTP0 is the confirmation state of UCB\_HSMCOTP0\_ORIG if **UNLOCKED** or **CONFIRMED**, else it is that of UCB\_HSMCOTP0\_COPY.

### **HSMCOTP1 Confirmation State**

The confirmation state of HSMCOTP1 is the confirmation state of UCB\_HSMCOTP1\_ORIG if **UNLOCKED** or **CONFIRMED**, else it is that of UCB\_HSMCOTP1\_COPY.

### **HSMCOTP Protection Configuration Installation**

The HSMCOTP protection configuration is installed as follows:

- Initial Protection
  - If the HSMCOTP0 confirmation state is **UNLOCKED** or **CONFIRMED** then the content of the DMU\_SP\_PROCONHSMCFG, DMU\_SP\_PROCONHSMCBS, DMU\_SP\_PROCONHSMCX0, DMU\_SP\_PROCONHSMCX1, DMU\_SP\_PROCONHSMCOTP0 and DMU\_SP\_PROCONHSMCOTP1 registers are initialized to HSMCOTP0.
- Subsequent Protection
  - If the HSMCOTP1 confirmation state is **CONFIRMED** then the HSMCOTP1 is OR'ed to the initial value.
  - If the confirmation state of either HSMCOTP0 or HSMCOTP1 is **ERRORED**, default protection is installed.

### **UCB\_HSMCOTP0/1\_ORIG and UCB\_HSMCOTP0/1\_COPY Erase Protection**

UCB\_HSMCOTP0\_ORIG, UCB\_HSMCOTP0\_COPY, UCB\_HSMCOTP1\_ORIG and UCB\_HSMCOTP1\_COPY are protected from erasing when the confirmation state of at least one of the HSMCOTP configuration sets is **CONFIRMED** or **ERRORED**.

### **UCB\_HSMCOTP0\_ORIG and UCB\_HSMCOTP0\_COPY Program Protection**

UCB\_HSMCOTP0\_ORIG and UCB\_HSMCOTP0\_COPY are protected from programming for all masters when one of the following conditions is true:

- HSMCOTP0 configuration set confirmation state is **CONFIRMED** or **ERRORED**.
- HSMCOTP1 configuration set confirmation state is **ERRORED**.

### **UCB\_HSMCOTP1\_ORIG and UCB\_HSMCOTP1\_COPY Program Protection**

UCB\_HSMCOTP1\_ORIG and UCB\_HSMCOTP1\_COPY are protected from programming for all masters except HSM when one of the following conditions is true:

- HSMCOTP0 configuration set confirmation state is **CONFIRMED**.

UCB\_HSMCOTP1\_ORIG and UCB\_HSMCOTP1\_COPY are protected from programming for all masters including the HSM when one of the following conditions is true:

- HSMCOTP0 configuration set confirmation state is **ERRORED**.
- HSMCOTP1 configuration set confirmation state is **CONFIRMED** or **ERRORED**.

#### **UCB\_HSMCOTP0/1\_ORIG and UCB\_HSMCOTP0/1\_COPY Read Protection**

UCB\_HSMCOTP0/1\_ORIG and UCB\_HSMCOTP0/1\_COPY are readable by all on chip bus masters.

#### **6.5.4.3.13 UCB\_ECPRIORIG and UCB\_ECPRIOCOPY**

UCB\_ECPRIORIG and UCB\_ECPRIOCOPY is used to set priority to the PFLASH logical sectors for use in recording of erase operations in the Erase Counter area.

#### **UCB\_HSMCOTP0/1\_ORIG and UCB\_HSMCOTP0/1\_COPY Content**

The UCB content is described in the UCB chapter.

#### **UCB\_ECPRIORIG Confirmation State**

The confirmation state of UCB\_ECPRIORIG is indicated by DMU\_HF\_CONFIRM1.PROINECPRIORO.

#### **UCB\_ECPRIOCOPY Confirmation State**

The confirmation state of UCB\_ECPRIOCOPY is indicated by DMU\_HF\_CONFIRM1.PROINECPRIOC.

#### **ECPRIOR Confirmation State**

The confirmation state of ECPRIOR is the confirmation state of UCB\_ECPRIORIG if **UNLOCKED** or **CONFIRMED**, else it is that of UCB\_ECPRIOCOPY.

#### **Priority and Password Installation**

The priority information and password installation is dependent on the confirmation states of UCB\_ECPRIORIG and UCB\_ECPRIOCOPY (at [Table 204](#)).

**Table 206 Priority and Password Installation**

<b>UCB_ECPRIORIG Confirmation State</b>	<b>UCB_ECPRIOCOPY Confirmation State</b>	<b>Protection and Password Installation</b>
UNREAD	Don't Care	Reset value. No password installed.
<b>UNLOCKED</b>	Don't Care	Priority installed from UCB_ECPRIORIG. Password installed from UCB_ECPRIORIG.
<b>CONFIRMED</b>	Don't Care	Priority installed from UCB_ECPRIORIG. Password installed from UCB_ECPRIORIG.
<b>ERRORED</b>	<b>UNLOCKED</b>	Priority installed from UCB_ECPRIOCOPY. Password installed from UCB_ECPRIOCOPY.

**Table 206 Priority and Password Installation (cont'd)**

UCB_ECPRIOR_ORIG Confirmation State	UCB_ECPRIOR_COPY Confirmation State	Protection and Password Installation
ERRORED	CONFIRMED	Priority installed from UCB_ECPRIOR_COPY. Password installed from UCB_ECPRIOR_COPY.
ERRORED	ERRORED	Default Priority installed. No password installed. SSW exits with error.

### Program Flash Protection Disable

If a password is installed and **Disable Protection** with matching PW is applied then

- DMU\_HF\_PROTECT.PRODISEC is set to 1<sub>B</sub>

If a password is not installed then protection may not be disabled.

### UCB\_ECPRIOR\_ORIG and UCB\_ECPRIOR\_COPY Access Protection

UCB\_ECPRIOR\_ORIG and UCB\_ECPRIOR\_COPY are read and write protected if one of the following conditions is true:

- The UCB\_ECPRIOR confirmation state is **CONFIRMED** and **Disable Protection** has not been activated.
- The UCB\_ECPRIOR confirmation state is **ERRORED**.

### 6.5.4.3.14 UCB\_SWAP\_ORIG and UCB\_SWAP\_COPY

UCB\_SWAP is evaluated by the SSW to determine the Pflashes used by the running application (referred to as 'SWAP' in this chapter). Refer to "Software Update Over the Air (SOTA) section of the User Manual for more details.

#### UCB\_SWAP\_ORIG and UCB\_SWAP\_COPY Content

The UCB content is described in the UCB chapter.

#### UCB\_SWAP\_ORIG Confirmation State

The state of UCB\_SWAP\_ORIG is indicated by DMU\_HF\_CONFIRM1.PROINSWAPO.

#### UCB\_SWAP\_COPY Confirmation State

The state of UCB\_SWAP\_COPY is indicated by DMU\_HF\_CONFIRM1.PROINSWAPC.

#### SWAP Installation

The SWAP installation is dependent on the confirmation states of UCB\_SWAP\_ORIG and UCB\_SWAP\_COPY. If the confirmation code of both ORIG and COPY is **ERRORED**, SSW does not evaluate the UCB.

**Table 207 SWAP Installation**

<b>UCB_SWAP_O RIG Confirmation State</b>	<b>UCB_SWAP_ COPY Confirmation State</b>	<b>SWAP confirmation</b>	<b>SWAP marker</b>	<b>SWAP installation</b>
<b>UNLOCKED/C ONFIRMED</b>	Don't Care	Valid in ORIG	Valid in ORIG	SWAP installed from ORIG after SSW evaluates the SWAP confirmation and SWAP marker.
<b>UNLOCKED/C ONFIRMED</b>	Don't Care	Invalid in ORIG	Don't care	SSW exits with error
<b>UNLOCKED/C ONFIRMED</b>	Don't Care	Don't care	Invalid in ORIG	SSW exits with error
<b>ERRORED</b>	<b>UNLOCKED/C ONFIRMED</b>	Valid in COPY	Valid in COPY	SWAP installed from COPY after SSW evaluates the SWAP confirmation and SWAP marker.
<b>ERRORED</b>	<b>UNLOCKED/C ONFIRMED</b>	Invalid in COPY	Don't care	SSW exits with error
<b>ERRORED</b>	<b>UNLOCKED/C ONFIRMED</b>	Don't care	Invalid in COPY	SSW exits with error
<b>ERRORED</b>	<b>ERRORED</b>	Don't care	Don't care	SSW exits with error

**SWAP Protection Disable**

If a password is installed and **Disable Protection** with matching PW is applied then

- DMU\_HF\_PROTECT.PRODISSWAP is set to 1<sub>B</sub>

If a password is not installed then protection may not be disabled.

**UCB\_SWAP\_ORIG and UCB\_SWAP\_COPY Access Protection**

UCB\_SWAP\_ORIG and UCB\_SWAP\_COPY are write protected if one of the following condition is true:

- UCB\_SWAP confirmation state is **CONFIRMED** and **Disable Protection** has not been activated using the password loaded from UCB\_SWAP.
- UCB\_SWAP confirmation state is **ERRORED**.

UCB\_SWAP\_ORIG and UCB\_SWAP\_COPY content except for Password locations may be read by every on chip bus master. Password may be read by every on chip bus master only if UCB\_SWAP is **UNLOCKED** or **Disable Protection** has been activated.

**6.5.4.3.15 UCB\_OTPy\_ORIG and UCB\_OTPy\_COPY (y = 0-7)**

UCB\_OTPy\_ORIG and UCB\_OTPy\_COPY configure sets of one-time programmable “OTP” and write-page once “WOP” protection. Each OTP and WOP configuration set supports the incremental addition of OTP and WOP protection to the PFLASH sectors. UCB\_OTP also contains the **HF\_PROCONT** register that is used to configure Tuning Protection and Software Update Over the Air (SOTA) in the device.

**UCB\_OTPy\_ORIG and UCB\_OTPy\_COPY Content**

The UCB content is described in the UCB chapter.

**Note:** *The memory size of the UCB\_OTPy\_ORIG and UCB\_OTPy\_COPY is fixed but the memory content will vary with the number of PFLASH banks.*

### **UCB\_OTPy\_ORIG Confirmation State**

The state of UCB\_OTPy\_ORIG is indicated by DMU\_HF\_CONFIRM2.PROINOTPyO.

### **UCB\_OTPy\_COPY Confirmation State**

The state of UCB\_OTPy\_COPY is indicated by DMU\_HF\_CONFIRM2.PROINOTPyC.

### **OTP Protection Installation**

The confirmation state of the complete set of the UCB\_OTP sets may be represented by PROINOTP.

PROINOTP = 1<sub>B</sub> when the following condition is true:

- For y = 0 - 7, if any one of the UCB\_OTPy confirmation states is **CONFIRMED** or **ERRORED**.

#### Initial Protection

- If UCB\_OTP0\_ORIG is **UNLOCKED** or **CONFIRMED** then
  - PROCONTP, PROCONOTP and PROCONWOP registers are initialized to the UCB\_OTP0\_ORIG configuration set.
- Else if UCB\_OTP0\_COPY is **UNLOCKED** or **CONFIRMED** then
  - PROCONTP, PROCONOTP and PROCONWOP registers are initialized to the UCB\_OTP0\_COPY configuration set.

#### Subsequent Protection

- If UCB\_OTP1\_ORIG is **CONFIRMED** then
  - PROCONTP, PROCONOTP and PROCONWOP registers are programmed to UCB\_OTP0 OR'ed UCB\_OTP1\_ORIG protection configuration sets.
- Else if UCB\_OTP1\_ORIG is **ERRORED** and UCB\_OTP1\_COPY is **CONFIRMED** then
  - PROCONTP, PROCONOTP and PROCONWOP registers are programmed to UCB\_OTP0 OR'ed UCB\_OTP1\_COPY protection configuration sets.
- If subsequent UCB\_OTPy are **CONFIRMED** then
  - PROCONTP, PROCONOTP and PROCONWOP registers are programmed to OR'ed protection configuration sets of all preceding confirmed UCBs.

#### Error

- If (for common y) UCB\_OTPy\_ORIG is **ERRORED** and UCB\_OTPy\_COPY is **ERRORED** then
  - All SxROM bits and SxWOP bits are activated for the complete OTP configuration set.

### **UCB\_OTPy\_ORIG and UCB\_OTPy\_COPY Erase Access Protection**

UCB\_OTPy\_ORIG and UCB\_OTPy\_COPY (for all y) are protected from erasing if PROINOTP = 1<sub>B</sub>

### **UCB\_OTPy\_ORIG and UCB\_OTPy\_COPY Program Access Protection**

If for any y UCB\_OTPy\_ORIG and UCB\_OTPy\_COPY the following condition is true:

- UCB\_OTPy\_ORIG confirmation state is **UNLOCKED**.

then UCB\_OTPy\_ORIG and UCB\_OTPy\_COPY may be programmed.

### **UCB\_OTPy\_ORIG and UCB\_OTPy\_COPY Read Access Protection**

UCB\_OTPy\_ORIG and UCB\_OTPy\_COPY are readable.

#### **6.5.4.3.16 Spare UCB**

A number of UCBs are currently not used (see UCB chapter).

##### **Spare UCB Content**

The content is undefined.

##### **Spare UCB Confirmation**

The confirmation state of spare UCBs is not supported.

##### **Spare UCB Access Protection**

Spare UCBs are read only and can be read by every on chip bus master.

#### **6.5.4.4 System Wide Effects of Flash Protection**

An active Flash read protection needs to be respected in the complete system.

The startup software “SSW” checks if the HSM is available.

If yes the HSM module is booted. During its boot process it can lock the device debug interface. This interface can be locked either by HSM (see below **HSM Booting**) or by setting OSTATE.IF\_LCK.

Additionally the customer can configure in UCB\_DBG\_ORIG/UCB\_DBG\_COPY that OCDS or the debug interface are disabled.

This results in the following lock conditions:

- OCDS disabled: DMU\_HF\_PROCONDBG.OCDSDIS and not DMU\_HF\_PROTECT.PRODISDBG.
- Debug interface locked: OSTATE.IF\_LCK<sup>1)</sup> or (HSM lock input) or (DMU\_HF\_PROCONDBG.DBGIFLCK and not DMU\_HF\_PROTECT.PRODISDBG).

The SSW performs the following operations:

- The SSW leaves the debug interface locked (OSTATE.IF\_LCK stays 1) if any Flash read protection is configured (DMU\_HF\_PROCONPF.RPRO or DMU\_HF\_PROCONPF.RPRO are 1).
- If the selected boot mode executes from internal PFLASH:
  - The SSW clears the DMU\_HF\_CONTROL.DDFP and DMU\_HF\_CONTROL.DDFD
- If the selected boot mode does not execute from internal PFLASH:
  - The SSW sets the DMU\_HF\_CONTROL.DDFP and DMU\_HF\_CONTROL.DDFD if their corresponding read protection is configured in DMU\_HF\_PROCONPF.RPRO or DMU\_HF\_PROCONDF.RPRO.

Full Flash analysis of an FAR device is only possible when the customer has removed all installed protections or delivers the necessary passwords with the device. As the removal of an OTP protection is not possible the OTP protection inevitably limits analysis capabilities.

For devices supporting HSM the FAR capabilities are generally limited to protect HSM configuration data.

#### **6.5.4.4.1 HSM Booting**

The SSW boots the HSM module (i.e. HSM executes its firmware) when the field DMU\_SP\_PROCONHSMCFG.HSMBOOTEN is set (i.e. HSM boot code is installed in the HSM code sectors).

First the HSM firmware checks DMU\_SP\_PROCONHSM.HSMDBGDIS. If this is cleared it enables HSM debug.

After that the HSM firmware checks DMU\_SP\_PROCONHSM.DBGIFLCK. If this is cleared it releases its lock of the system debug interface.

1) Only for illustration, this bit and its or-combination with the following signals is part of the OCDS not the DMU.

After execution of the HSM firmware the HSM executes from the HSM code sectors. Depending on DMU\_SP\_PROCONHSMCFG.SSWWAIT the SSW waits for an acknowledge from the HSM before leaving the Firmware.

#### 6.5.4.4.2 Destructive Debug Entry

As described before the debug interface can be opened by supplying the correct password to UCB\_DBG\_ORIG or UCB\_DBG\_COPY

This is under the condition that HSM doesn't lock this interface.

A special destructive debug entry can be configured with DMU\_SP\_PROCONHSMCFG.DESTDBG. When this is configured as "destructive" only the SSW can accept the UCB\_DBG\_ORIG or UCB\_DBG\_COPY password via debug interface (see BROM chapter). Additionally, read and write accesses are permitted to UCB\_DBG\_ORIG and UCB\_DBG\_COPY only if the device pin "FDEST" is logic '1' and the field DMU\_HF\_PROCONDDBG.EDM is "debug not entered". When all these conditions match the field DMU\_HF\_PROCONDDBG.EDM is programmed by the SSW to "debug entered" before opening the debug interface. When EDM is "debug entered", then automatically any communication via CAN or FlexRay is blocked.

## 6.5.5 Revision History

**Table 208 Revision History**

Reference	Change to Previous Version	Comment
<b>V2.0.9</b>		
Page 90	<b>HF_PWAIT</b> - Removed errant p in the RFLASH, RECC, CFLASH and CECC bit field descriptions.	
<b>V2.0.10</b>		
Page 31	<b>Write Burst Once</b> - Only an EVER is raised if the sequence is performed on an unerased area, not a PVER and EVER. Also changed wording to make clear that pages are effected, not a single page.	
Page 92	<b>HF_DWAIT</b> - In RECC description, changed PFLASH to DFLASH - header was correct.	
<b>V2.0.11</b>		
Page 63	Updated register <b>HF_STATUS</b> .	

## 6.6 Program Flash Interface (PFI)

### 6.6.1 Overview

The PFI (in [Figure 64](#)) contains two distinct signal paths that drive a PFI to CPU point-to-point connection:

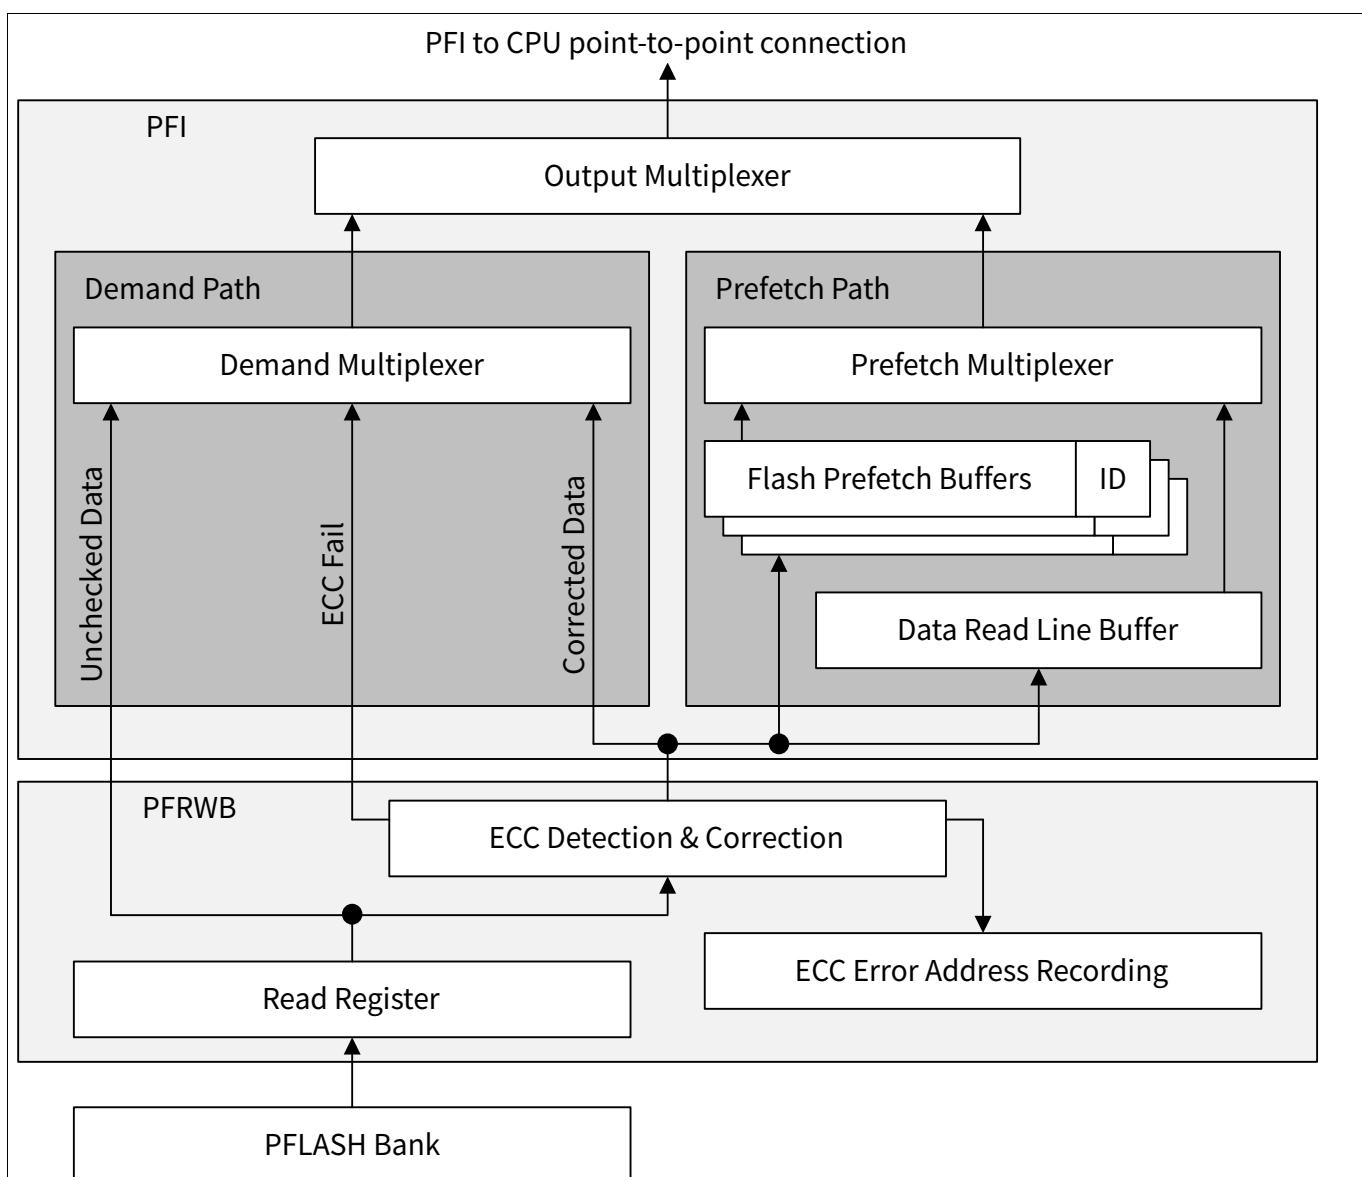

- Demand path to support early transmission of data.
- Prefetch path to support speculative fetch of data.

The PFLASH bank read data is available as follows:

- Uncorrected data is available at the read register output. ECC fail detects if the read data contains an ECC error.
- Corrected data is available after the ECC decoder has checked the data integrity.

ECC checksums protect the integrity of data as follows:

- Data programmed in the PFLASH bank is stored with an ECC checksum extension.
- Data transported across the PFI to CPU point-to-point connection is protected by an ECC sideband signal.

**Figure 64 Block Diagram of the PFI module.**

## 6.6.2 Functional Description

### 6.6.2.1 Demand Path

Local CPU PMBI program code fetches, local CPU DMBI Non Safe load data constants, local CPU DMBI Safe load data constants and SRI accesses requested by remote bus masters which cannot be serviced by a prefetch access (see [Chapter 6.6.2.3](#)) are serviced by a demand access direct to the PFLASH bank. PFLASH read data is transmitted after a number of read cycles determined by the configuration. If the access is a block transfer then the critical response (double word) must be transmitted first. If the block transfer is a BTR4 originating from the PMBI or the DMBI then the critical double word may be transmitted early using the uncorrected data. If an ECC failure is detected then the critical response is re-transmitted using corrected data.

### 6.6.2.2 Data Read Line Buffer (DRLB)

In order to improve the efficiency of SDTD and BTR2 accesses a DRLB stores the PFLASH page data and address. If a subsequent access hits the DRLB then the response is serviced by the DRLB.

### 6.6.2.3 Flash Prefetch Buffer (FPB)

The prefetch path instantiates prefetch buffer(s) to speculatively fetch data. If a BTR4 access hits the FPB then the response is serviced by the FPB.

#### FPB Configuration

The local CPU contains a set of FLASHCON registers for configuring its local PFI. Each PFI instantiates five FPBs. An FPB may be assigned to an on chip bus master (see [Table 209](#)) by software programming the 6-bit master tag identification number to the appropriate fields of the CPU\_FLASHCON0 register.

**Table 209 FPB Assignment**

FPB	Description
[0]	Permanently assigned to the local CPU PMBI master tag identification number.
[4:1]	Assigned to an on chip bus master by software programming the CPU_FLASHCON0 register with the appropriate 6-bit master tag identification number.  <i>Note:</i> To reduce power consumption prefetching from an individual FPB may be disabled by software assigning the FPB to the reserved 6-bit master tag identification number.

Performance may be optimized by assigning a maximum of two FPBs to one on chip bus master. If two FPBs are assigned then adjacent FPBs must be assigned, for example:

- Local CPU PMBI on chip bus master: FPB0 assigned by default and software may additionally assign FPB1 for optimal local CPU performance.
- Other on chip bus masters: software may assign FPB1 and FPB2, FPB2 and FPB3, or FPB3 and FPB4.

## 6.6.3 Erase Counter and Register Accesses

The PFI to CPU point-to-point connection may be used to read the erase counter and PFRWB registers.

The access size must be SDTD else the access will error.

### **6.6.3.1 Erase Counter**

If an erase counter is accessed from a system address then  $\text{addr}[27] = 1_B$  and  $\text{addr}[19] = 0_B$ .

### **6.6.3.2 User Registers**

If a user register is accessed from a system address then  $\text{addr}[27] = 1_B$ ,  $\text{addr}[19] = 1_B$  and  $\text{addr}[18] = 0_B$ .

## 6.6.4 Safety Measures

### 6.6.4.1 Access Enable

A CPU enables read access to its Local PFLASH Bank (LPB). Access by individual on chip bus masters is allowed by enabling the appropriate TAG ID bit in the CPU LPB\_SPROT\_ACCEN\_R register.

### 6.6.4.2 ECC encoding of read data to CPU

SRI data phase ECC is encoded on the PFLASH read data sent on the PFI to CPU point-to-point connection. This ECC is decoded in the CPU for a local PFLASH access, and by the requested master for an access via SRI.

### 6.6.4.3 ECC error detection of wait cycle configuration from DMU

ECC is encoded by the DMU on the PFLASH read wait cycle configuration (recorded in DMU\_HF\_PWAIT register and transmitted by DMU to all PFI instances) and decoded within the PFI. An error is reported to the local CPU which flags the PFlash read monitor alarm to SMU. The ECC used provides 1-bit and 2-bit error detection.

### 6.6.4.4 PFI Partial Lockstep (PPL)

Control logic in PFI is lockstepped in a manner similar to CPU lockstep mechanism. The lockstepped logic (master) and the shadow logic (checker) is temporarily separated by two clock cycles. A generic comparator module is used that checks the master and shadow logic and reports an error in case of mismatch. The lockstep error is reported to the local CPU, which flags the PFLASH read path monitor alarm.

Error injection to PPL is possible through the SCU\_LCLTEST register. A failure can be injected by writing  $1_B$  to the PLCLTx bitfield in SCU\_LCLTEST register. The failure will be injected for a single cycle of the SPB clock.

The PPL also has a continuously running background self test of the lockstep comparator. For more details on the self test mechanism, please refer CPU chapter (“Lockstep Comparator Logic”).

### 6.6.4.5 Busy checker

PFI performs a check to determine if there is an operation ongoing in its associated PFLASH that was not expected by DMU. For this purpose, it checks if FSI is performing an operation on its PFLASH when the corresponding DMU\_HF\_STATUS.PxBUSY flag is not set. If the check fails, an error is generated to the CPU, resulting in PFLASH read path monitor alarm from CPU to SMU.

## 6.6.5 Revision History

## 6.7 Non Volatile Memory (NVM)

### 6.7.1 Overview

The Non Volatile Memory component of the NVM Subsystem comprises the Program Flash (PFLASH), Data Flash (DFLASH) (including DFlash0, DFlash1, User Configuration Blocks (UCB) and Configuration Sector (CFS)), PFlash Read Write Buffer (PFRWB) and the Flash Standard Interface (FSI) modules.

- Program Flash (PFLASH): Stores program code and data constants. It is divided into one or more PFLASH banks depending on the configuration of the device. In addition to the Flash Arrays, it also contains the Analog Block with pumps and regulators. Each PFLASH has an associated PFlash Read Write Buffer (PFRWB) which provides the read data to the PFI.
- Program Flash Read Write Buffer (PFRWB): The PFRWB provides read access on the corresponding PFlash bank, status registers and Erase Counter. It performs ECC error detection, correction and flags safety alarms to SMU. PFRWB provides both uncorrected and corrected data to the PFI, which determines which one to use based on the type of access (more details in the PFI chapter).
- Data Flash (DFLASH): Utilized by user and security applications to store data. Interfaces with DFlash Read Write Buffer (DFRWB) in the FSI to provide DFlash read data. In addition to the Flash Arrays, there is an Analog Block containing pumps, regulators, reference.
- Flash Standard Interface (FSI): executes erase, program and verify operations on all flash memories.

Read accesses to the NVM are memory mapped reads. NVM programming and erase operations are sequenced by the Flash Standard Interface (FSI) micro controller.

**Figure 65 Block Diagram of the NVM module.**

## 6.7.2 Functional Description of the Flash Standard Interface (FSI)

The Flash Standard Interface (FSI) (in [Figure 65](#)) manages all maintenance tasks (start up, erasing, programming, verifying, analysis, etc.) of the PFLASH and DFLASH memories.

The FSI consists of the following hardware parts:

- FSI RAM
  - Shared SRAM for program code and Assembly Buffer (ASB) write data.
  - 64-bit read/write interface
- FSI ROM
  - Bootstrap program code.
  - Stable command sequences.
- Flash Processor (FLER)
  - 8-bit pipelined RISC processor
  - 8-bit read/write interface to Core Function Registers (CFR) and Special Function Registers (SFR)

### 6.7.2.1 FSI ROM

The FSI ROM stores bootstrap program code and stable firmware routines.

### 6.7.2.2 FSI SFR

The FSI is controlled by accesses to the FSI Special Function Registers.

#### 6.7.2.2.1 FSI SFR Access Control

FSI SFR access control is as follows:

##### FSI SFR Access Size

Only byte wide accesses are supported to the 8-bit FSI SFRs. Other access sizes generate a bus error.

Byte-size only access is fully supported by TriCore compilers. A register defined as volatile unsigned char is only ever accessed with byte-size load or byte-size store operations.

##### FSI SFR Accesses in Operation Mode

The following SFRs may be accessed via the DMU SRI slave interface:

- FSI Host communication SFRs
  - [COMM\\_1](#)
  - [COMM\\_2](#)
- FSI HSM communication SFRs
  - [HSMCOMM\\_1](#)
  - [HSMCOMM\\_2](#)

If the DMU is not in a Flash Test Mode then accesses to all other FSI SFRs generate a bus error.

##### FSI SFR Accesses in Sleep Mode

All accesses fail and generate a bus error.

*Note: Accesses after requesting Sleep Mode but before Sleep Mode is reached may result in erroneous behavior.*

### 6.7.2.3 Communication with FSI

The Host communicates with FSI via the Host Command Sequence Interpreter (Host CSI).

The HSM communicates with FSI via the HSM Command Sequence Interpreter (HSM CSI).

The HSM CSI interprets writes to the DF1 address range. DF1 access is controlled via DMU\_SP\_PROCONHSMCFG.HSMDX (at [Table 211](#)):

**Table 211 DF1 Access Control**

HSMDX	DF1 Access
0 <sub>B</sub>	DF1 is accessed via the Host CSI by all masters and via the HSM CSI by HSM master.
1 <sub>B</sub>	DF1 is accessed via the HSM CSI by HSM master only.

Control and status information is passed via the FSI communication SFRs:

- Host CSI: [COMM\\_1](#) and [COMM\\_2](#)
- HSM CSI: [HSMCOMM\\_1](#) and [HSMCOMM\\_2](#)

### 6.7.2.3.1 DMU Command Sequences

If a command is initiated by a DMU command sequence in Operation Mode then access to the FSI communication SFRs is blocked as follows:

- [COMM\\_1](#) and [COMM\\_2](#) accesses are blocked when any PFLASH or DFLASH BUSY reports a flash busy flag in the DMU\_HF\_STATUS register.
- [HSMCOMM\\_1](#) and [HSMCOMM\\_2](#) accesses are blocked when DF1 BUSY reports a flash busy flag in the DMU\_SF\_STATUS register.

## 6.7.3 Registers

### 6.7.3.1 FSI Registers

The FSI Registers are accessed through the DMU SRI slave interface. The register set includes access protection registers and NVM configuration, control and status registers.

#### Register Accesses

Only byte wide accesses are supported to the FSI Registers. Other access sizes generate a bus error on the DMU SRI slave interface.

**Table 212 Register Address Space - FSI**

Module	Base Address	End Address	Note
FSI	F8030000 <sub>H</sub>	F80300FF <sub>H</sub>	sri slave interface

### 6.7.3.2 PFRWB (PFI) Registers

The PFRWB User and Test Registers are accessed through the PFI. The local CPU can read the registers on the direct PFI to CPU point to point connection. A remote CPU can read these registers by triggering a request on the SRI SIF of the local CPU.

#### Access Protection

The PFRWB User and Test Registers are read-hardware.

**Table 214 Register Address Space - PFI**

Module	Base Address	End Address	Note

**Attention:** The Bitline Redundancy Registers, Sector Redundancy Registers and Test Registers do not down configure with PFLASH product configuration.

### 6.7.3.2.1 PFI ECC Registers

#### ECC Read Register

The ECC Read Register shall store the ECC checksum read during the last PFLASH Bank NVM read access.

ECCR															
ECC Read Register (0000000 <sub>H</sub> ) System Reset Value: 0000 0000 <sub>H</sub>															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

								ERRA NY	ALL1	ALLO	ERRA	ERRM	RES	ERR2	ERR1
					r			rh	rh	rh	rh	rh	r	rh	rh

Field	Bits	Type	Description
<b>ERR1</b>	0	rh	<b>Read Access Single Bit ECC Error</b> The flag reports a single bit ECC failure during the last NVM read access. 0 <sub>B</sub> No single bit ECC failure occurred. 1 <sub>B</sub> A single bit ECC failure occurred.
<b>ERR2</b>	1	rh	<b>Read Access Double Bit ECC Error</b> The flag reports a double bit ECC failure during the last NVM read access. 0 <sub>B</sub> No double bit ECC failure occurred. 1 <sub>B</sub> A double bit ECC failure occurred.
<b>RES</b>	2, 15:8, 18, 31:24	r	<b>Reserved</b> Always read as 0; should be written with 0.
<b>ERRM</b>	3	rh	<b>Read Access Multi-bit ECC Error</b> The flag reports multi bit ECC failure during the last NVM read access. 0 <sub>B</sub> No multi bit ECC failure occurred. 1 <sub>B</sub> Multi bit ECC failure occurred.
<b>ERRA</b>	4	rh	<b>Read Access ECC Error Within the Address</b> The flag reports an address error during the last NVM read access. 0 <sub>B</sub> No Address error detected. 1 <sub>B</sub> Address detected.
<b>ALLO</b>	5	rh	<b>Read Access All Zeros</b> The flag reports the All Zeros condition during the last NVM read access. 0 <sub>B</sub> No All Zeros detected. 1 <sub>B</sub> All zeros detected.
<b>ALL1</b>	6	rh	<b>All Ones</b> The flag reports the All Ones condition during the last NVM read access. 0 <sub>B</sub> No All Ones detected. 1 <sub>B</sub> All ones detected.
<b>ERRANY</b>	7	rh	<b>Any Read Access ECC Error</b> The flag reports any ECC failure during the last NVM read access. 0 <sub>B</sub> No ECC failure occurred. 1 <sub>B</sub> ECC failure occurred.

Field	Bits	Type	Description
<b>AER1</b>	16	rh	<b>Accumulated Single Bit ECC Errors</b> The flag accumulates single bit failures during NVM read operations. $0_B$ No single bit ECC failure occurred. $1_B$ At least one single bit ECC failure occurred.
<b>AER2</b>	17	rh	<b>Accumulated Double Bit ECC Errors</b> The flag accumulates double bit failures during NVM read operations. $0_B$ No double bit ECC failure occurred. $1_B$ At least one double bit ECC failure occurred.
<b>AERM</b>	19	rh	<b>Accumulated Multi-bit ECC Errors</b> The flag accumulates multi bit failures during NVM read accesses. $0_B$ No multi bit ECC failure occurred. $1_B$ Multi bit ECC failure occurred.
<b>ARRA</b>	20	rh	<b>Accumulated ECC Error Within the Address</b> The flag accumulates an address errors during NVM read accesses. $0_B$ No Address error detected. $1_B$ Address detected.
<b>AAL0</b>	21	rh	<b>Accumulated All Zeros</b> The flag accumulates the All Zeros condition during NVM read accesses. $0_B$ No All Zeros detected. $1_B$ All zeros detected.
<b>AAL1</b>	22	rh	<b>Accumulated All Ones</b> The flag accumulates the All Ones condition during NVM read accesses. $0_B$ No All Ones detected. $1_B$ All ones detected.
<b>AERANY</b>	23	rh	<b>Accumulated Any Read Access ECC Error</b> The status bit accumulates ECC failures during NVM read accesses. $0_B$ No ECC failure occurred. $1_B$ ECC failure occurred.

Note: An address error (ERRA) is also flagged as a multi bit error (ERRM). Only 1 or 2 bit address errors can be clearly identified as address errors. Greater than 2 bit address errors appear as multi bit error and might not be flagged as address error.

### 6.7.3.2.2 PFI Corrected Single Bits Address Buffer (SBAB)

When data is read from Flash NVM and the ECC decoder detects a correctable single bit error, then the local address is stored in the SBAB. Each local address is only entered once, and covers 256 bits of data. The bottom five reserved bits of the SBAB read as 0, and can be concatenated with the local address to give the local address as seen by the system (without the base offset).

When the SBAB becomes full the SMU is informed which can trigger an interrupt and the DBAB limit is changed to 1.

#### SBAB Record x

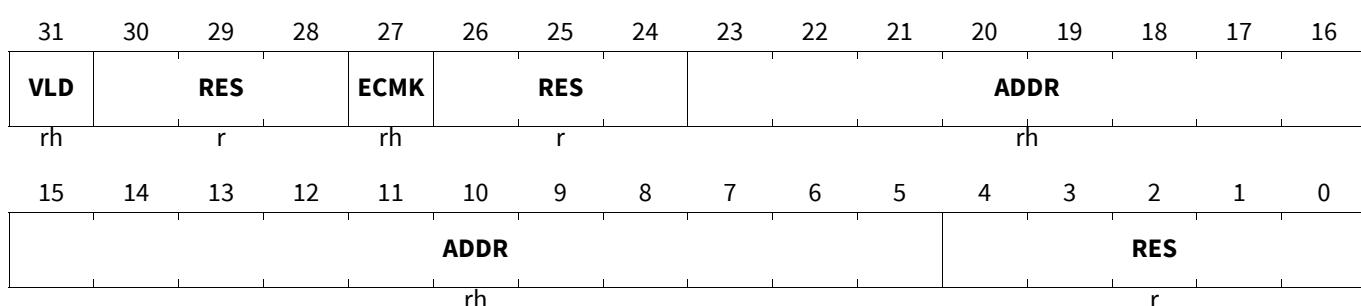

*Note:* All bits in this register are cleared when CPUx\_FLASHCON2.SBABCLR is written to 01<sub>B</sub>.

The address of the data with a detected error is stored in a SBAB Recorder Register.

Reset: system reset.

#### SBABRECORDx (x=0-16)

**SBAB Record x** (002000<sub>H</sub>+x\*20<sub>H</sub>) System Reset Value: 0000 0000<sub>H</sub>

Field	Bits	Type	Description
<b>RES</b>	4:0, 26:24, 30:28	r	<b>Reserved</b> Always read as 0; should be written with 0.
<b>ADDR</b>	23:5	rh	<b>Address</b> Captured local PFLASH bank address of the page with detected error.
<b>ECMK</b>	27	rh	<b>Erase Counter Marker</b> The captured address is from the Flash or Erase Counter. 0 <sub>B</sub> Erroneous page is in the PFLASH bank. 1 <sub>B</sub> Erroneous page is in the erase counter.
<b>VLD</b>	31	rh	<b>Valid</b> 0 <sub>B</sub> No entry recorded. 1 <sub>B</sub> Valid entry recorded.

### 6.7.3.2.3 PFI Corrected Double Bits Address Buffer (DBAB)

When data is read from Flash NVM and the ECC decoder detects a correctable double bit error, then the local address is stored in the DBAB. Each local address is only entered once, and covers 256 bits of data. The bottom five reserved bits of the DBAB read as 0, and can be concatenated with the local address to give the local address as seen by the system (without the base offset).

An alarm to SMU is generated when DBAB becomes full, which can trigger an interrupt.

The maximum number of DBAB records will change from two to one when SBAB becomes full.

#### DBAB Record x

Note: All bits in this register are cleared when  $CPUx\_FLASHCON2.DBABCLR$  is written to  $01_B$ .

The address of the data with a detected error is stored in a DBAB Recorder Register.

Reset: system reset.

#### DBABRECORD $x$ ( $x=0-1$ )

<b>DBAB Record x</b>															<b>(004000<sub>H</sub>+x*20<sub>H</sub>)</b>	<b>System Reset Value: 0000 0000<sub>H</sub></b>

Field	Bits	Type	Description
<b>RES</b>	4:0, 26:24, 30:28	r	<b>Reserved</b> Always read as 0; should be written with 0.
<b>ADDR</b>	23:5	rh	<b>Address</b> Captured address of local PFLASH bank with detected error.
<b>ECMK</b>	27	rh	<b>Erase Counter Marker</b> The captured address is from the Flash or Erase Counter. $0_B$ Erroneous page is in the PFLASH bank. $1_B$ Erroneous page is in the erase counter.
<b>VLD</b>	31	rh	<b>Valid</b> $0_B$ No entry recorded. $1_B$ Valid entry recorded.

### 6.7.3.2.4 PFI Uncorrected Multi Bits Address Buffer (MBAB)

When data is read from Flash NVM and the ECC decoder detects an uncorrected multi bit error (including all-0 and all-1 errors) then the local address is stored in the MBAB. Each local address is only entered once, and covers 256 bits of data. The bottom five reserved bits of the MBAB read as 0, and can be concatenated with the local address to give the local address as seen by the system (without the base offset).

When the MBAB becomes full the SMU is informed which can trigger an interrupt.

#### MBAB Record 0

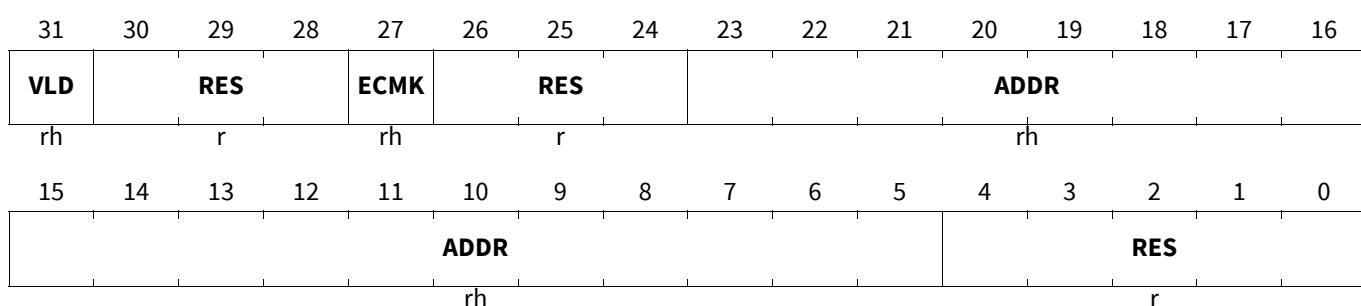

Note: *All bits in this register are cleared when CPUx\_FLASHCON2.MBABCLR is written to 01<sub>B</sub>.*

The address of the data with a detected error is stored in a MBAB Recorder Register.

Reset: system reset.

#### MBABRECORD0

**MBAB Record 0** **(008000<sub>H</sub>)** **System Reset Value: 0000 0000<sub>H</sub>**

Field	Bits	Type	Description
<b>RES</b>	4:0, 26:24, 30:28	r	<b>Reserved</b> Always read as 0; should be written with 0.
<b>ADDR</b>	23:5	rh	<b>Address</b> Captured address of local PFLASH bank with detected error.
<b>ECMK</b>	27	rh	<b>Erase Counter Marker</b> The captured address is from the Flash or Erase Counter. 0 <sub>B</sub> Erroneous page is in the PFLASH bank. 1 <sub>B</sub> Erroneous page is in the erase counter.
<b>VLD</b>	31	rh	<b>Valid</b> 0 <sub>B</sub> No entry recorded. 1 <sub>B</sub> Valid entry recorded.

### 6.7.3.2.5 PFI Uncorrected All Zeros Bits Address Buffer (ZBAB)

When data is read from Flash NVM and the ECC decoder detects an all-0 error, then the local address at the PFRWB is stored in the ZBAB. Each local address is only entered once, and covers 256 bits of data. The bottom five reserved bits of the ZBAB read as 0, and can be concatenated with the local address to give the local address as seen by the system (without the base offset).

When the ZBAB becomes full the SMU is informed which can trigger an interrupt.

#### ZBAB Record x

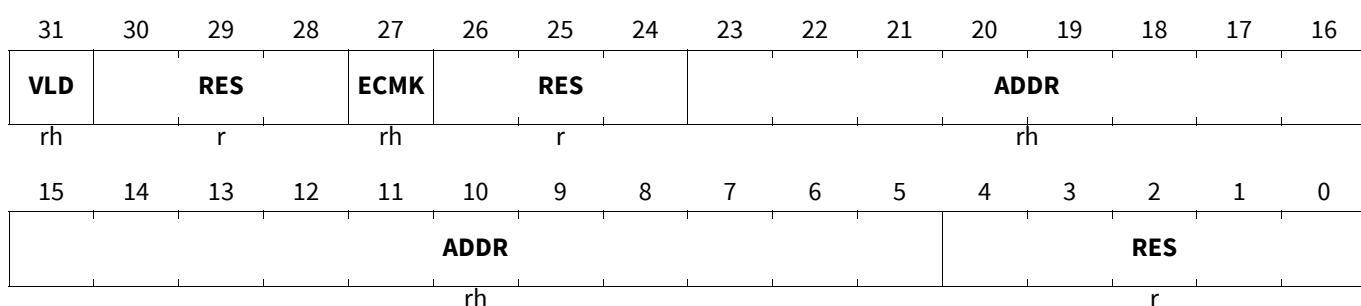

Note: *All bits in this register are cleared when CPUx\_FLASHCON2.ZBABCLR is written to 01<sub>B</sub>.*

The address of the data with a detected error is stored in a ZBAB Recorder Register.

Reset: system reset.

#### ZBABRECORDx (x=0-3)

**ZBAB Record x** (00C000<sub>H</sub>+x\*20<sub>H</sub>) System Reset Value: 0000 0000<sub>H</sub>

Field	Bits	Type	Description
<b>RES</b>	4:0, 26:24, 30:28	r	<b>Reserved</b> Always read as 0; should be written with 0.
<b>ADDR</b>	23:5	rh	<b>Address</b> Captured address of local PFLASH bank with detected error.
<b>ECMK</b>	27	rh	<b>Erase Counter Marker</b> The captured address is from the Flash or Erase Counter. 0 <sub>B</sub> Erroneous page is in the PFLASH bank. 1 <sub>B</sub> Erroneous page is in the erase counter.
<b>VLD</b>	31	rh	<b>Valid</b> 0 <sub>B</sub> No entry recorded. 1 <sub>B</sub> Valid entry recorded.

## 6.7.4 Revision History

<b>V2.0.5</b>		
<a href="#">Page 174</a>	<a href="#">ECC Status Register</a> - Corrected description of value 0 for AAL0 and AAL1, missing negation..	
<b>V2.0.6</b>		
<a href="#">Page 170</a>	<a href="#">Chapter 6.7.2.3</a> - Changed DMU_SF_PROCONHSM to DMU_SP_PROCONHSMCFG .	

## 6.8 User Configuration Block (UCB)

This chapter describes the content of the User Configuration Block (not the implementation of this storage area in Flash).

### 6.8.1 Overview

The User Configuration Block contains information used for configuration and protection installation. It is part of Data Flash 0.

### 6.8.2 UCB Address Map

All UCB offset address are given with reference to the following “Module” base address.

**Table 217 Register Address Space - UCB**

Module	Base Address	End Address	Note
UCB	AF400000 <sub>H</sub>	AF405FFF <sub>H</sub>	UCB Range

#### 6.8.2.1 List of Defined UCBs

The following overview table shows a list of all defined UCBs:

**Table 218 On Chip Bus Address Map of User Configuration Blocks**

Address Range	Size	Unit	Access Type	
			Read	Write
AF40 0000 <sub>H</sub> - AF40 01FF <sub>H</sub>	512 Byte	UCB00 (UCB_BMHD0_ORIG)	Access	SRIBE
AF40 0200 <sub>H</sub> - AF40 03FF <sub>H</sub>	512 Byte	UCB01 (UCB_BMHD1_ORIG)	Access	SRIBE
AF40 0400 <sub>H</sub> - AF40 05FF <sub>H</sub>	512 Byte	UCB02 (UCB_BMHD2_ORIG)	Access	SRIBE
AF40 0600 <sub>H</sub> - AF40 07FF <sub>H</sub>	512 Byte	UCB03 (UCB_BMHD3_ORIG)	Access	SRIBE
AF40 0800 <sub>H</sub> - AF40 09FF <sub>H</sub>	512 Byte	UCB04 (UCB_SSW)	Access	SRIBE
AF40 0A00 <sub>H</sub> - AF40 0BFF <sub>H</sub>	512 Byte	UCB05 (UCB_USER)	Access	SRIBE
AF40 0C00 <sub>H</sub> - AF40 0DFF <sub>H</sub>	512 Byte	UCB06 (UCB_TEST)	Access	SRIBE
AF40 0E00 <sub>H</sub> - AF40 0FFF <sub>H</sub>	512 Byte	UCB07 (UCB_HSMCFG)	Access	SRIBE
AF40 1000 <sub>H</sub> - AF40 11FF <sub>H</sub>	512 Byte	UCB08 (UCB_BMHD0_COPY)	Access	SRIBE
AF40 1200 <sub>H</sub> - AF40 13FF <sub>H</sub>	512 Byte	UCB09 (UCB_BMHD1_COPY)	Access	SRIBE
AF40 1400 <sub>H</sub> - AF40 15FF <sub>H</sub>	512 Byte	UCB10 (UCB_BMHD2_COPY)	Access	SRIBE
AF40 1600 <sub>H</sub> - AF40 17FF <sub>H</sub>	512 Byte	UCB11 (UCB_BMHD3_COPY)	Access	SRIBE
AF40 1800 <sub>H</sub> - AF40 19FF <sub>H</sub>	512 Byte	UCB12 (UCB_REDSEC)	Access	SRIBE
AF40 1A00 <sub>H</sub> - AF40 1BFF <sub>H</sub>	512 Byte	UCB13 (Reserved)	Access	SRIBE
AF40 1C00 <sub>H</sub> - AF40 1DFF <sub>H</sub>	512 Byte	UCB14 (Reserved)	Access	SRIBE
AF40 1E00 <sub>H</sub> - AF40 1FFF <sub>H</sub>	512 Byte	UCB15 (UCB_RETEST)	Access	SRIBE
AF40 2000 <sub>H</sub> - AF40 21FF <sub>H</sub>	512 Byte	UCB16 (UCB_PFLASH_ORIG)	Access	SRIBE
AF40 2200 <sub>H</sub> - AF40 23FF <sub>H</sub>	512 Byte	UCB17 (UCB_DFLASH_ORIG)	Access	SRIBE
AF40 2400 <sub>H</sub> - AF40 25FF <sub>H</sub>	512 Byte	UCB18 (UCB_DBG_ORIG)	Access	SRIBE
AF40 2600 <sub>H</sub> - AF40 27FF <sub>H</sub>	512 Byte	UCB19 (UCB_HSM_ORIG)	Access	SRIBE

**Table 218 On Chip Bus Address Map of User Configuration Blocks (cont'd)**

Address Range	Size	Unit	Access Type	
			Read	Write
AF40 2800 <sub>H</sub> - AF40 29FF <sub>H</sub>	512 Byte	UCB20 (UCB_HSMCOTP0_ORIG)	Access	SRIBE
AF40 2A00 <sub>H</sub> - AF40 2BFF <sub>H</sub>	512 Byte	UCB21 (UCB_HSMCOTP1_ORIG)	Access	SRIBE
AF40 2C00 <sub>H</sub> - AF40 2DFF <sub>H</sub>	512 Byte	UCB22 (UCB_ECPPIO_ORIG)	Access	SRIBE
AF40 2E00 <sub>H</sub> - AF40 2FFF <sub>H</sub>	512 Byte	UCB23 (UCB_SWAP_ORIG)	Access	SRIBE
AF40 3000 <sub>H</sub> - AF40 31FF <sub>H</sub>	512 Byte	UCB24 (UCB_PFLASH_COPY)	Access	SRIBE
AF40 3200 <sub>H</sub> - AF40 33FF <sub>H</sub>	512 Byte	UCB25 (UCB_DFLASH_COPY)	Access	SRIBE
AF40 3400 <sub>H</sub> - AF40 35FF <sub>H</sub>	512 Byte	UCB26 (UCB_DBG_COPY)	Access	SRIBE
AF40 3600 <sub>H</sub> - AF40 37FF <sub>H</sub>	512 Byte	UCB27 (UCB_HSM_COPY)	Access	SRIBE
AF40 3800 <sub>H</sub> - AF40 39FF <sub>H</sub>	512 Byte	UCB28 (UCB_HSMCOTP0_COPY)	Access	SRIBE
AF40 3A00 <sub>H</sub> - AF40 3BFF <sub>H</sub>	512 Byte	UCB29 (UCB_HSMCOTP1_COPY)	Access	SRIBE
AF40 3C00 <sub>H</sub> - AF40 3DFF <sub>H</sub>	512 Byte	UCB30 (UCB_ECPPIO_COPY)	Access	SRIBE
AF40 3E00 <sub>H</sub> - AF40 3FFF <sub>H</sub>	512 Byte	UCB31 (UCB_SWAP_COPY)	Access	SRIBE
AF40 4000 <sub>H</sub> - AF40 41FF <sub>H</sub>	512 Byte	UCB32 (UCB OTP0_ORIG)	Access	SRIBE
AF40 4200 <sub>H</sub> - AF40 43FF <sub>H</sub>	512 Byte	UCB33 (UCB OTP1_ORIG)	Access	SRIBE
AF40 4400 <sub>H</sub> - AF40 45FF <sub>H</sub>	512 Byte	UCB34 (UCB OTP2_ORIG)	Access	SRIBE
AF40 4600 <sub>H</sub> - AF40 47FF <sub>H</sub>	512 Byte	UCB35 (UCB OTP3_ORIG)	Access	SRIBE
AF40 4800 <sub>H</sub> - AF40 49FF <sub>H</sub>	512 Byte	UCB36 (UCB OTP4_ORIG)	Access	SRIBE
AF40 4A00 <sub>H</sub> - AF40 4BFF <sub>H</sub>	512 Byte	UCB37 (UCB OTP5_ORIG)	Access	SRIBE
AF40 4C00 <sub>H</sub> - AF40 4DFF <sub>H</sub>	512 Byte	UCB38 (UCB OTP6_ORIG)	Access	SRIBE
AF40 4E00 <sub>H</sub> - AF40 4FFF <sub>H</sub>	512 Byte	UCB39 (UCB OTP7_ORIG)	Access	SRIBE
AF40 5000 <sub>H</sub> - AF40 51FF <sub>H</sub>	512 Byte	UCB40 (UCB OTP0_COPY)	Access	SRIBE
AF40 5200 <sub>H</sub> - AF40 53FF <sub>H</sub>	512 Byte	UCB41 (UCB OTP1_COPY)	Access	SRIBE
AF40 5400 <sub>H</sub> - AF40 55FF <sub>H</sub>	512 Byte	UCB42 (UCB OTP2_COPY)	Access	SRIBE
AF40 5600 <sub>H</sub> - AF40 57FF <sub>H</sub>	512 Byte	UCB43 (UCB OTP3_COPY)	Access	SRIBE
AF40 5800 <sub>H</sub> - AF40 59FF <sub>H</sub>	512 Byte	UCB44 (UCB OTP4_COPY)	Access	SRIBE
AF40 5A00 <sub>H</sub> - AF40 5BFF <sub>H</sub>	512 Byte	UCB45 (UCB OTP5_COPY)	Access	SRIBE
AF40 5C00 <sub>H</sub> - AF40 5DFF <sub>H</sub>	512 Byte	UCB46 (UCB OTP6_COPY)	Access	SRIBE
AF40 5E00 <sub>H</sub> - AF40 5FFF <sub>H</sub>	512 Byte	UCB47 (UCB OTP7_COPY)	Access	SRIBE

The following detailed UCB tables contain a reference page number if the corresponding entries needs more explanation. Entries without page number are self explaining.

### 6.8.2.2 UCB\_BMHDx\_ORIG and UCB\_BMHDx\_COPY (x = 0 - 3)

The four UCB\_BMHDx\_ORIG (UCB00, UCB01, UCB02, UCB03) and UCB\_BMHDx\_COPY (UCB08, UCB09, UCB10, UCB11) are used by the customer to configure the Boot Mode Headers (BMHD). These are evaluated by the SSW.

In the following only the detailed offset tables for UCB00 and UCB01 are shown. UCB00 serves as example for a UCB\_BMHD with password (also UCB08) and UCB01 as example for UCB\_BMHD without password (also UCB02, UCB03, UCB09, UCB10, UCB11) are shown. The other UCBs have the same content just based on different offset addresses.

## Delivery State

The “CONFIRMATION” code entries contain the UNLOCKED value (see “DMU” chapter, section “UCB Confirmation”). All other addresses are delivered erased.

**Table 219 Register Overview - UCB00 (ascending Offset Address)**

Short Name	Long Name	Offset Address	Page Number
BMI_BMH DID	UCB_BMHD0_ORIG_DATA - Boot Mode Index (BMI) and Boot Mode Header ID (CODE) = B359H	0000 <sub>H</sub>	
STAD	UCB_BMHD0_ORIG_DATA - ABHMDx start address (in case BMI.HWCFG = ABM = 110B) or User Code start address (in case BMI.HWCFG = Flash start = 111B)	0004 <sub>H</sub>	
CRCBMHD	UCB_BMHD0_ORIG_DATA - Check Result for the BMI Header (offset 000H - 007H)	0008 <sub>H</sub>	
CRCBMHD_N	UCB_BMHD0_ORIG_DATA - Inverted Check Result for the BMI Header (offset 000H - 007H)	000C <sub>H</sub>	
PW0	UCB_BMHD0_ORIG_PW - 256-bit password protection, PW0 (least significant)	0100 <sub>H</sub>	
PW1	UCB_BMHD0_ORIG_PW - 256-bit password protection, PW1	0104 <sub>H</sub>	
PW2	UCB_BMHD0_ORIG_PW - 256-bit password protection, PW2	0108 <sub>H</sub>	
PW3	UCB_BMHD0_ORIG_PW - 256-bit password protection, PW3	010C <sub>H</sub>	
PW4	UCB_BMHD0_ORIG_PW - 256-bit password protection, PW4	0110 <sub>H</sub>	
PW5	UCB_BMHD0_ORIG_PW - 256-bit password protection, PW5	0114 <sub>H</sub>	
PW6	UCB_BMHD0_ORIG_PW - 256-bit password protection, PW6	0118 <sub>H</sub>	
PW7	UCB_BMHD0_ORIG_PW - 256-bit password protection, PW7	011C <sub>H</sub>	
CONFIRMATION	UCB_BMHD0_ORIG_CODE - 32-bit CODE	01F0 <sub>H</sub>	

**Table 220 Register Overview - UCB01 (ascending Offset Address)**

Short Name	Long Name	Offset Address	Page Number
BMI_BMH DID	UCB_BMHD1_ORIG_DATA - Boot Mode Index (BMI) and Boot Mode Header ID (CODE) = B359H	0200 <sub>H</sub>	
STAD	UCB_BMHD1_ORIG_DATA - ABHMDx start address (in case BMI.HWCFG = ABM = 110B) or User Code start address (in case BMI.HWCFG = Flash start = 111B)	0204 <sub>H</sub>	
CRCBMHD	UCB_BMHD1_ORIG_DATA - Check Result for the BMI Header (offset 000H - 007H)	0208 <sub>H</sub>	
CRCBMHD_N	UCB_BMHD1_ORIG_DATA - Inverted Check Result for the BMI Header (offset 000H - 007H)	020C <sub>H</sub>	
CONFIRMATION	UCB_BMHD1_ORIG_CODE - 32-bit CODE	03F0 <sub>H</sub>	

### 6.8.2.3 UCB\_SSW

The UCB\_SSW contains data supplied by Infineon and predominantly used by the SSW to configure the device. The single entries are not published with exception of the LBIST configuration and expected signature entries SCU\_LBISTCTRL\*. These can be also used by application SW when executing the LBIST.

**Table 221 Register Overview - UCB04 (ascending Offset Address)**

Short Name	Long Name	Offset Address	Page Number
SCU_LBISTCTRL3_BODY0	SCU_LBISTCTRL3_BODY0 - LBIST signature after execution of LBIST by SSW with LBISTCTRL1.BODY=0	08E8 <sub>H</sub>	
SCU_LBISTCTRL3_BODY1	SCU_LBISTCTRL3_BODY1 - LBIST signature after execution of LBIST by SSW with LBISTCTRL1.BODY=1	08EC <sub>H</sub>	
SCU_LBISTCTRL0	SCU_LBISTCTRL0 - Value used by SSW when executing LBIST (called "Configuration A")	0960 <sub>H</sub>	
SCU_LBISTCTRL1	SCU_LBISTCTRL1 - Value used by SSW when executing LBIST (called "Configuration A"). BODY determined by HWCFG[6].	0964 <sub>H</sub>	
SCU_LBISTCTRL2	SCU_LBISTCTRL2 - Value used by SSW when executing LBIST (called "Configuration A")	0968 <sub>H</sub>	
CONFIRMATION_ORIG	UCB_SSW_CODE_ORIG	09F0 <sub>H</sub>	
WORD125	RESERVED	09F4 <sub>H</sub>	
CONFIRMATION_COPY	UCB_SSW_CODE_COPY	09F8 <sub>H</sub>	
WORD127	RESERVED	09FC <sub>H</sub>	

### 6.8.2.4 UCB\_USER

This UCB contains data supplied by IFX to the customer application. The entries are documented in the respective chapters (e.g. EDSADC and RIF) or will be documented when necessary (e.g. UID and BOM).

**Table 222 Register Overview - UCB05 (ascending Offset Address)**

Short Name	Long Name	Offset Address	Page Number
UID	UCB_USER_UID - Unique Chip Identifier	0A00 <sub>H</sub>	
UID	UCB_USER_UID - Unique Chip Identifier	0A04 <sub>H</sub>	
UID	UCB_USER_UID - Unique Chip Identifier	0A08 <sub>H</sub>	
UID	UCB_USER_UID - Unique Chip Identifier	0A0C <sub>H</sub>	
BOM	UCB_USER_BOM - Bill of Materials: mold, bond wire material, ball material	0A10 <sub>H</sub>	
EVADC_G00_VDDK	EVADC_G00_VDDK - Device specific values G00: DVDDK/VDDKC	0A20 <sub>H</sub>	195
EVADC_G00_RES	EVADC_G00_RES - Device specific values G00: Reserved	0A24 <sub>H</sub>	
EVADC_G01_VDDK	EVADC_G01_VDDK - Device specific values G01: DVDDK/VDDKC	0A28 <sub>H</sub>	

**Table 222 Register Overview - UCB05 (ascending Offset Address) (cont'd)**

<b>Short Name</b>	<b>Long Name</b>	<b>Offset Address</b>	<b>Page Number</b>
EVADC_G01_RES	EVADC_G01_RES - Device specific values G01: Reserved	0A2C <sub>H</sub>	
EVADC_G02_VDDK	EVADC_G02_VDDK - Device specific values G02: DVDDK/VDDKC	0A30 <sub>H</sub>	
EVADC_G02_RES	EVADC_G02_RES - Device specific values G02: Reserved	0A34 <sub>H</sub>	
EVADC_G03_VDDK	EVADC_G03_VDDK - Device specific values G03: DVDDK/VDDKC	0A38 <sub>H</sub>

EDSADC_CH13_IRMS	EDSADC_CH13_IRMS - Device specific values CH13: IRMS	0AEC <sub>H</sub>	
RIF_LVDSCON1	RIF_LVDSCON1 - Trimming value in bits [2:0] for RIF0_LVDSCON1.RTERM and in bits [18:16] for RIF1_LVDSCON1.RTERM	0AFC <sub>H</sub>	196
CONFIRMATION_ORIG	UCB_USER_CODE_ORIG	0BF0 <sub>H</sub>	
CONFIRMATION_COPY	UCB_USER_CODE_COPY	0BF8 <sub>H</sub>	

### 6.8.2.5 UCB\_RETEST

Reserved by IFX, and not usable by customer.

### 6.8.2.6 UCB\_PFLASH\_ORIG and UCB\_PFLASH\_COPY

The UCB\_PFLASH (ORIG and COPY) contain the user defined PFlash protection. It is protected with the password PW0 to PW7. The protection configuration is transferred into the registers DMU\_HP\_PROCONPps (with “p” looping over the implemented PFlash banks and “s” looping over groups of 32 sectors) and DMU\_HF\_PROCONPF (see DMU chapter).

### Delivery State

The “CONFIRMATION” code entries contain the UNLOCKED value (see “DMU” chapter, section “UCB Confirmation”). All other addresses are delivered erased.

**Table 223 Register Overview - UCB16 (ascending Offset Address)**

Short Name	Long Name	Offset Address	Page Number
PROCONPp0	DMU_HP_PROCONPp0 - PFp protection for logical sectors S0 - S31	2000 <sub>H</sub> +p*20 <sub>H</sub>	
PROCONPp1	DMU_HP_PROCONPp1 - PFp protection for logical sectors S32 - S63	2004 <sub>H</sub> +p*20 <sub>H</sub>	
PROCONPp2	DMU_HP_PROCONPp2 - PFp protection for logical sectors S64 - S95	2008 <sub>H</sub> +p*20 <sub>H</sub>	
PROCONPp3	DMU_HP_PROCONPp3 - PFp protection for logical sectors S96 - S127	200C <sub>H</sub> +p*20 <sub>H</sub>	
PROCONPp4	DMU_HP_PROCONPp4 - PFp protection for logical sectors S128 - S159	2010 <sub>H</sub> +p*20 <sub>H</sub>	
PROCONPp5	DMU_HP_PROCONPp5 - PFp protection for logical sectors S160 - S191	2014 <sub>H</sub> +p*20 <sub>H</sub>	
PROCONPF	DMU_HF_PROCONPF	20C0 <sub>H</sub>	
PW0	UCB_PFLASH_ORIG_PW	2100 <sub>H</sub>	
PW1	UCB_PFLASH_ORIG_PW	2104 <sub>H</sub>	
PW2	UCB_PFLASH_ORIG_PW	2108 <sub>H</sub>	
PW3	UCB_PFLASH_ORIG_PW	210C <sub>H</sub>	
PW4	UCB_PFLASH_ORIG_PW	2110 <sub>H</sub>	
PW5	UCB_PFLASH_ORIG_PW	2114 <sub>H</sub>	
PW6	UCB_PFLASH_ORIG_PW	2118 <sub>H</sub>	
PW7	UCB_PFLASH_ORIG_PW	211C <sub>H</sub>	
CONFIRMATION	UCB_PFLASH_ORIG_CODE	21F0 <sub>H</sub>	

The layout of UCB24 is identical to UCB16 but on different offset addresses (see [Table 218](#)) and is therefore not shown here.

### 6.8.2.7 UCB\_DFLASH\_ORIG and UCB\_DFLASH\_COPY

The UCB\_DFLASH (ORIG and COPY) contain the user defined DFlash protection. It is protected with the password PW0 to PW7. The protection configuration is transferred into the registers DMU\_HF\_PROCONUSR, DMU\_HF\_PROCONDF and DMU\_HF\_PROCONRAM (see DMU chapter).

### Delivery State

The “CONFIRMATION” code entries contain the UNLOCKED value (see “DMU” chapter, section “UCB Confirmation”). All other addresses are delivered erased.

**Table 224 Register Overview - UCB17 (ascending Offset Address)**

Short Name	Long Name	Offset Address	Page Number
PROCONUSR	DMU_HF_PROCONUSR	2200 <sub>H</sub>	
PROCOND <sub>F</sub>	DMU_HF_PROCOND <sub>F</sub>	2204 <sub>H</sub>	
PROCONRAM	DMU_HF_PROCONRAM	2208 <sub>H</sub>	
PW0	UCB_DFLASH_ORIG_PW	2300 <sub>H</sub>	
PW1	UCB_DFLASH_ORIG_PW	2304 <sub>H</sub>	
PW2	UCB_DFLASH_ORIG_PW	2308 <sub>H</sub>	
PW3	UCB_DFLASH_ORIG_PW	230C <sub>H</sub>	
PW4	UCB_DFLASH_ORIG_PW	2310 <sub>H</sub>	
PW5	UCB_DFLASH_ORIG_PW	2314 <sub>H</sub>	
PW6	UCB_DFLASH_ORIG_PW	2318 <sub>H</sub>	
PW7	UCB_DFLASH_ORIG_PW	231C <sub>H</sub>	
CONFIRMATION	UCB_DFLASH_ORIG_CODE	23F0 <sub>H</sub>	

The layout of UCB25 is identical to UCB17 but on different offset addresses (see [Table 218](#)) and therefore not shown here.

### 6.8.2.8 UCB\_DBG\_ORIG and UCB\_DBG\_COPY

The UCB\_DBG (ORIG and COPY) contain the user defined debug protection. It is protected with the password PW0 to PW7. The protection configuration is transferred into the register DMU\_HF\_PROCOND<sub>BG</sub> (see DMU chapter).

#### Delivery State

The “CONFIRMATION” code entries contain the UNLOCKED value (see “DMU” chapter, section “UCB Confirmation”). All other addresses are delivered erased.

**Table 225 Register Overview - UCB18 (ascending Offset Address)**

Short Name	Long Name	Offset Address	Page Number
PROCOND <sub>BG</sub>	DMU_HF_PROCOND <sub>BG</sub>	2400 <sub>H</sub>	
PW0	UCB_DBG_ORIG_PW	2500 <sub>H</sub>	
PW1	UCB_DBG_ORIG_PW	2504 <sub>H</sub>	
PW2	UCB_DBG_ORIG_PW	2508 <sub>H</sub>	
PW3	UCB_DBG_ORIG_PW	250C <sub>H</sub>	
PW4	UCB_DBG_ORIG_PW	2510 <sub>H</sub>	
PW5	UCB_DBG_ORIG_PW	2514 <sub>H</sub>	
PW6	UCB_DBG_ORIG_PW	2518 <sub>H</sub>	
PW7	UCB_DBG_ORIG_PW	251C <sub>H</sub>	
CONFIRMATION	UCB_DBG_ORIG_CODE	25F0 <sub>H</sub>	

The layout of UCB26 is identical to UCB18 but on different offset addresses (see [Table 218](#)) and therefore not shown here.

### 6.8.2.9 UCB\_HSM\_ORIG and UCB\_HSM\_COPY

The UCB\_HSM (ORIG and COPY) contain the user defined HSM configuration. It is transferred into the register DMU\_SP\_PROCONHSM (see DMU chapter).

#### Delivery State

The “CONFIRMATION” code entries contain the UNLOCKED value (see “DMU” chapter, section “UCB Confirmation”). All other addresses are delivered erased.

**Table 226 Register Overview - UCB19 (ascending Offset Address)**

Short Name	Long Name	Offset Address	Page Number
PROCONHSM	DMU_SP_PROCONHSM	2600 <sub>H</sub>	
CONFIRMATION	UCB_HSM_ORIG_CODE	27F0 <sub>H</sub>	

The layout of UCB27 is identical to UCB19 but on different offset addresses (see [Table 218](#)) and therefore not shown here.

### 6.8.2.10 UCB\_HSMCOTP0/1\_ORIG and UCB\_HSMCOTP0/1\_COPY

The UCB\_HSMCOTP (two sets 0 and 1 each with ORIG and COPY) contain the OTP part of the user defined HSM protection and configuration. It is transferred into the registers DMU\_SF\_PROCONUSR, DMU\_SP\_PROCONHSMC\* (see DMU chapter).

#### Delivery State

The “CONFIRMATION” code entries contain the UNLOCKED value (see “DMU” chapter, section “UCB Confirmation”). All other addresses are delivered erased.

**Table 227 Register Overview - UCB20 (ascending Offset Address)**

Short Name	Long Name	Offset Address	Page Number
PROCONUSR	DMU_SF_PROCONUSR	2800 <sub>H</sub>	
PROCONHSMCBS	DMU_SP_PROCONHSMCBS	2804 <sub>H</sub>	
PROCONHSMCX0	DMU_SP_PROCONHSMCX0	2808 <sub>H</sub>	
PROCONHSMCX1	DMU_SP_PROCONHSMCX1	280C <sub>H</sub>	
PROCONHSMCOTP0	DMU_SP_PROCONHSMCOTP0	2810 <sub>H</sub>	
PROCONHSMCOTP1	DMU_SP_PROCONHSMCOTP1	2814 <sub>H</sub>	
PROCONHSMCFG	DMU_SP_PROCONHSMCFG	2818 <sub>H</sub>	
CONFIRMATION	UCB_HSMCOTP0_ORIG_CODE	29F0 <sub>H</sub>	

The layout of UCB21, UCB28 and UCB29 is identical to UCB20 but on different offset addresses (see [Table 218](#)) and therefore not shown here.

### 6.8.2.11 UCB\_ECPRIORIG\_ORIG and UCB\_ECPRIORIG\_COPY

The UCB\_ECPRIORIG (ORIG and COPY) contain the user defined erase counter configuration. It is protected with the password PW0 to PW7. The configuration is transferred into the registers DMU\_HP\_ECPRIOps (with “p” looping over the implemented PFlash banks and “s” looping over groups of 32 sectors, see DMU chapter).

#### Delivery State

The “CONFIRMATION” code entries contain the UNLOCKED value (see “DMU” chapter, section “UCB Confirmation”). All other addresses are delivered erased.

**Table 228 Register Overview - UCB22 (ascending Offset Address)**

Short Name	Long Name	Offset Address	Page Number
ECPRIOp0	DMU_HP_ECPRIOp0 - PFp Erase Counter priority for logical sectors S0 - S31	2C00 <sub>H</sub> +p*20 <sub>H</sub>	
ECPRIOp1	DMU_HP_ECPRIOp1 - PFp Erase Counter priority for logical sectors S32 - S63	2C04 <sub>H</sub> +p*20 <sub>H</sub>	
ECPRIOp2	DMU_HP_ECPRIOp2 - PFp Erase Counter priority for logical sectors S64 - S95	2C08 <sub>H</sub> +p*20 <sub>H</sub>	
ECPRIOp3	DMU_HP_ECPRIOp3 - PFp Erase Counter priority for logical sectors S96 - S127	2C0C <sub>H</sub> +p*20 <sub>H</sub>	
ECPRIOp4	DMU_HP_ECPRIOp4 - PFp Erase Counter priority for logical sectors S128 - S159	2C10 <sub>H</sub> +p*20 <sub>H</sub>	
ECPRIOp5	DMU_HP_ECPRIOp5 - PFp Erase Counter priority for logical sectors S160 - S191	2C14 <sub>H</sub> +p*20 <sub>H</sub>	
PW0	UCB_ECPRIORIG_PW	2D00 <sub>H</sub>	
PW1	UCB_ECPRIORIG_PW	2D04 <sub>H</sub>	
PW2	UCB_ECPRIORIG_PW	2D08 <sub>H</sub>	
PW3	UCB_ECPRIORIG_PW	2D0C <sub>H</sub>	
PW4	UCB_ECPRIORIG_PW	2D10 <sub>H</sub>	
PW5	UCB_ECPRIORIG_PW	2D14 <sub>H</sub>	
PW6	UCB_ECPRIORIG_PW	2D18 <sub>H</sub>	
PW7	UCB_ECPRIORIG_PW	2D1C <sub>H</sub>	
CONFIRMATION	UCB_ECPRIORIG_CODE	2DF0 <sub>H</sub>	

The layout of UCB30 is identical to UCB22 but on different offset addresses (see [Table 218](#)) and therefore not shown here.

### 6.8.2.12 UCB\_SWAP\_ORIG and UCB\_SWAP\_COPY

The UCB\_SWAP (ORIG and COPY) contain the user defined SWAP configuration. It is protected with the password PW0 to PW7. The SWAP configuration is evaluated by the SSW (see “Software update Over The Air (SOTA) chapter”).

**Delivery State**

The “CONFIRMATION” code entries (not CONFIRMATIONLx and CONFIRMATIONHx entries!) contain the UNLOCKED value (see “DMU” chapter, section “UCB Confirmation”). All other addresses are delivered erased.

**Table 229 Register Overview - UCB23 (ascending Offset Address)**

Short Name	Long Name	Offset Address	Page Number
MARKERLx	UCB_SWAP_ORIG_MARKERLx	2E00 <sub>H</sub> +x*10 <sub>H</sub>	<a href="#">196</a>
MARKERHx	UCB_SWAP_ORIG_MARKERHx	2E04 <sub>H</sub> +x*10 <sub>H</sub>	<a href="#">197</a>
CONFIRMATIONLx	UCB_SWAP_ORIG_CONFIRMATIONLx	2E08 <sub>H</sub> +x*10 <sub>H</sub>	<a href="#">197</a>
CONFIRMATIONHx	UCB_SWAP_ORIG_CONFIRMATIONHx	2E0C <sub>H</sub> +x*10 <sub>H</sub>	<a href="#">198</a>
PW0	UCB_SWAP_ORIG_PW	2F00 <sub>H</sub>	
PW1	UCB_SWAP_ORIG_PW	2F04 <sub>H</sub>	
PW2	UCB_SWAP_ORIG_PW	2F08 <sub>H</sub>	
PW3	UCB_SWAP_ORIG_PW	2F0C <sub>H</sub>	
PW4	UCB_SWAP_ORIG_PW	2F10 <sub>H</sub>	
PW5	UCB_SWAP_ORIG_PW	2F14 <sub>H</sub>	
PW6	UCB_SWAP_ORIG_PW	2F18 <sub>H</sub>	
PW7	UCB_SWAP_ORIG_PW	2F1C <sub>H</sub>	
CONFIRMATION	UCB_SWAP_ORIG_CODE	2FF0 <sub>H</sub>	

The layout of UCB31 is identical to UCB23 but on different offset addresses (see [Table 218](#)) and therefore not shown here.

**6.8.2.13 UCB\_OTPy\_ORIG and UCB\_OTPy\_COPY (y = 0 - 7)**

The UCB\_OTP (8 sets “y” with each ORIG and COPY) contain the user defined PFlash OTP and WOP protection. It is transferred into the registers DMU\_HP\_PROCONOTPps, DMU\_HP\_PROCONWOPps (with “p” looping over the implemented PFlash banks and “s” looping over groups of 32 sectors) and DMU\_HP\_PROCONTP.

**Delivery State**

The “CONFIRMATION” code entries contain the UNLOCKED value (see “DMU” chapter, section “UCB Confirmation”). All other addresses are delivered erased.

**Table 230 Register Overview - UCB32 (ascending Offset Address)**

Short Name	Long Name	Offset Address	Page Number
PROCONOTPp0	DMU_HP_PROCONOTPp0 - Set 0 of PFp OTP protection for logical sectors S0 - S31	4000 <sub>H</sub> +p*20 <sub>H</sub>	
PROCONOTPp1	DMU_HP_PROCONOTPp1 - Set 0 of PFp OTP protection for logical sectors S32 - S63	4004 <sub>H</sub> +p*20 <sub>H</sub>	
PROCONOTPp2	DMU_HP_PROCONOTPp2 - Set 0 of PFp OTP protection for logical sectors S64 - S95	4008 <sub>H</sub> +p*20 <sub>H</sub>	

**Table 230 Register Overview - UCB32 (ascending Offset Address) (cont'd)**

Short Name	Long Name	Offset Address	Page Number
PROCONOTPp3	DMU_HP_PROCONOTPp3 - Set 0 of PFp OTP protection for logical sectors S96 - S127	400C <sub>H</sub> +p*20 <sub>H</sub>	
PROCONOTPp4	DMU_HP_PROCONOTPp4 - Set 0 of PFp OTP protection for logical sectors S128 - S159	4010 <sub>H</sub> +p*20 <sub>H</sub>	
PROCONOTPp5	DMU_HP_PROCONOTPp5 - Set 0 of PFp OTP protection for logical sectors S160 - S191	4014 <sub>H</sub> +p*20 <sub>H</sub>	
PROCONWOPp0	DMU_HP_PROCONWOPp0 - Set 0 of PFp WOP protection for logical sectors S0 - S31	4100 <sub>H</sub> +p*20 <sub>H</sub>	
PROCONWOPp1	DMU_HP_PROCONWOPp1 - Set 0 of PFp WOP protection for logical sectors S32 - S63	4104 <sub>H</sub> +p*20 <sub>H</sub>	
PROCONWOPp2	DMU_HP_PROCONWOPp2 - Set 0 of PFp WOP protection for logical sectors S64 - S95	4108 <sub>H</sub> +p*20 <sub>H</sub>	
PROCONWOPp3	DMU_HP_PROCONWOPp3 - Set 0 of PFp WOP protection for logical sectors S96 - S127	410C <sub>H</sub> +p*20 <sub>H</sub>	
PROCONWOPp4	DMU_HP_PROCONWOPp4 - Set 0 of PFp WOP protection for logical sectors S128 - S159	4110 <sub>H</sub> +p*20 <sub>H</sub>	
PROCONWOPp5	DMU_HP_PROCONWOPp5 - Set 0 of PFp WOP protection for logical sectors S160 - S191	4114 <sub>H</sub> +p*20 <sub>H</sub>	
PROCONTp	DMU_HF_PROCONTp - Tuning Protection configuration set 0	41E8 <sub>H</sub>	
CONFIRMATION	UCB_OTP0_ORIG_CODE	41F0 <sub>H</sub>	

The layout of UCB33 to UCB47 is identical to UCB32 but on different offset addresses (see [Table 218](#)) and therefore not shown here.

### 6.8.2.14 UCB\_REDSEC

This UCB contains the redundancy activation for the Flash banks. In case certain redundancy is already used by IFX during the test flow these entries are marked as “USED”. Physically not available redundancy is marked as “FAILED”. The available entries can be used to extend the life time of the device. See DMU chapter for details.

#### Delivery State

The “CONFIRMATION\_ORIG” and “CONFIRMATION\_COPY” code entries contain the CONFIRMED value (see “DMU” chapter, section “UCB Confirmation”). As described above the remaining entries can be device specific.

**Table 231 Register Overview - UCB12 (ascending Offset Address)**

Short Name	Long Name	Offset Address	Page Number
REDSECPLps	UCB_REDSECPLps - Low Word of Wordline Redundancy for PFlash p Redundant Sector s	1800 <sub>H</sub> +p*40 <sub>H</sub> +s*8	<a href="#">198</a>
REDSECPHps	UCB_REDSECPHps - High Word of Wordline Redundancy for PFlash p Redundant Sector s	1804 <sub>H</sub> +p*40 <sub>H</sub> +s*8	<a href="#">199</a>
REDSECDL0s	UCB_REDSECDL0s - Low Word of Wordline Redundancy for DFlash0 Redundant Sector s	1980 <sub>H</sub> +s*8	<a href="#">199</a>

**Table 231 Register Overview - UCB12 (ascending Offset Address) (cont'd)**

Short Name	Long Name	Offset Address	Page Number
REDSECDH0s	UCB_REDSECDH0s - High Word of Wordline Redundancy for DFlash0 Redundant Sector s	1984 <sub>H</sub> +s*8	<a href="#">200</a>
REDSECDL1s	UCB_REDSECDL1s - Low Word of Wordline Redundancy for DFlash1 Redundant Sector s	19C0 <sub>H</sub> +s*8	<a href="#">201</a>
REDSECDH1s	UCB_REDSECDH1s - High Word of Wordline Redundancy for DFlash1 Redundant Sector s	19C4 <sub>H</sub> +s*8	<a href="#">201</a>
CONFIRMATION_ORIG	UCB_REDSEC_CODE_ORIG	19F0 <sub>H</sub>	
CONFIRMATION_COPY	UCB_REDSEC_CODE_COPY	19F8 <sub>H</sub>	

## 6.8.3 UCB Entries

UCB entries that relate directly to registers in hardware are not documented here as the register layout can be found in the respective module chapter. The following layouts are data structures without direct hardware match.

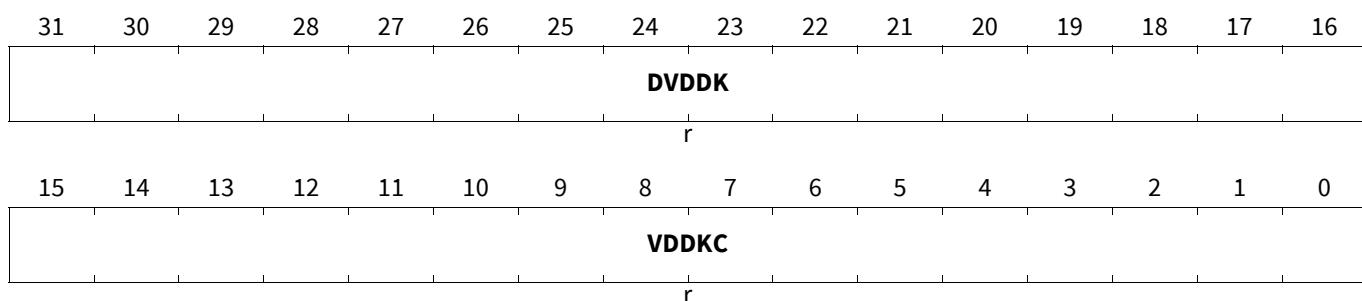

### 6.8.3.1 UCB\_USER

#### EVADC\_G00\_VDDK - Device specific values G00: DVDDK/VDDKC

See EVADC chapter for a detailed documentation of these UCB entries.

##### EVADC\_G00\_VDDK

**EVADC\_G00\_VDDK - Device specific values G00: DVDDK/VDDKC(0A20<sub>H</sub>)**      **Default Flash Value: 0000 0000<sub>H</sub>**

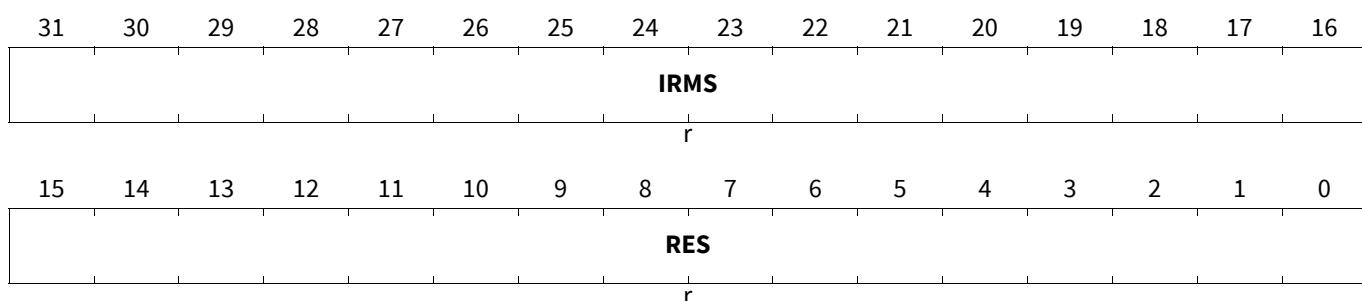

Field	Bits	Type	Description
<b>VDDKC</b>	15:0	r	<b>VDDKC</b> Value of $V_{DDK}$ measured at $-40^{\circ}\text{C}$ in [mV]
<b>DVDDK</b>	31:16	r	<b>DVDDK</b> Temperature deviation DVDDK in [ $\mu\text{V/K}$ ] measured at $V_{DDM}$ of 4.5 V

#### EDSADC\_CH00\_IRMS - Device specific values CH00: IRMS

See EDSADC chapter for a detailed documentation of these UCB entries.

##### EDSADC\_CH00\_IRMS

**EDSADC\_CH00\_IRMS - Device specific values CH00: IRMS(0A84<sub>H</sub>)**      **Default Flash Value: 0000 0000<sub>H</sub>**

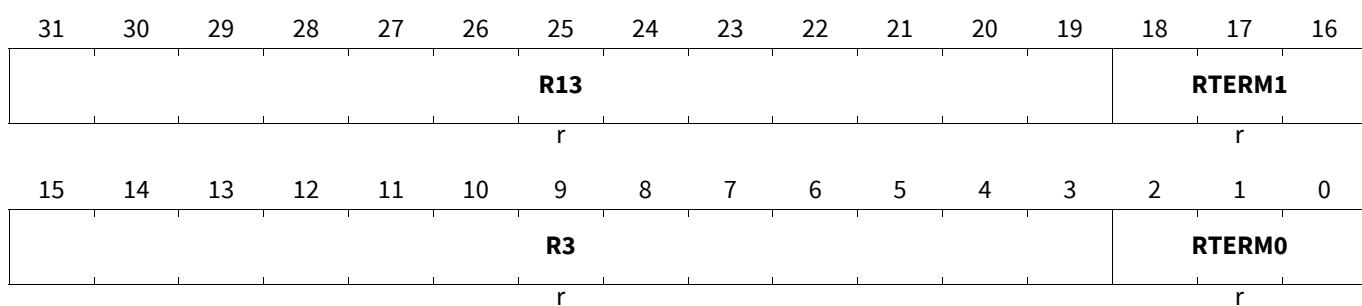

Field	Bits	Type	Description
<b>RES</b>	15:0	r	<b>Reserved</b>
<b>IRMS</b>	31:16	r	<b>IRMS</b> $I_{RMS}$ in [0.01 $\mu\text{A}$ ] measured at 5 V and $f_{MOD}$ of 26.67 MHz

**RIF\_LVDSCON1 - Trimming value in bits [2:0] for RIF0\_LVDSCON1.RTERM and in bits [18:16] for RIF1\_LVDSCON1.RTERM**

The trimming values for the RTERM bitfields of RIF0\_LVDSCON1 and RIF1\_LVDSCON1 are combined in this UCB entry.

**RIF\_LVDSCON1**

**RIF\_LVDSCON1 - Trimming value in bits [2:0] for RIF0\_LVDSCON1.RTERM and in bits [18:16] for RIF1\_LVDSCON1.RTERM** **(0AFC<sub>H</sub>)** **Default Flash Value: 0000 0000<sub>H</sub>**

Field	Bits	Type	Description
RTERM0	2:0	r	<b>RTERM - Termination resistor configuration for RIF0_LVDSCON1 register.</b> Value to be copied into RIF0_LVDSCON1.RTERM register field.
R3	15:3	r	<b>Reserved - RES</b>
RTERM1	18:16	r	<b>RTERM - Termination resistor configuration for RIF1_LVDSCON1 register.</b> Value to be copied into RIF1_LVDSCON1.RTERM register field.
R13	31:19	r	<b>Reserved - RES</b>

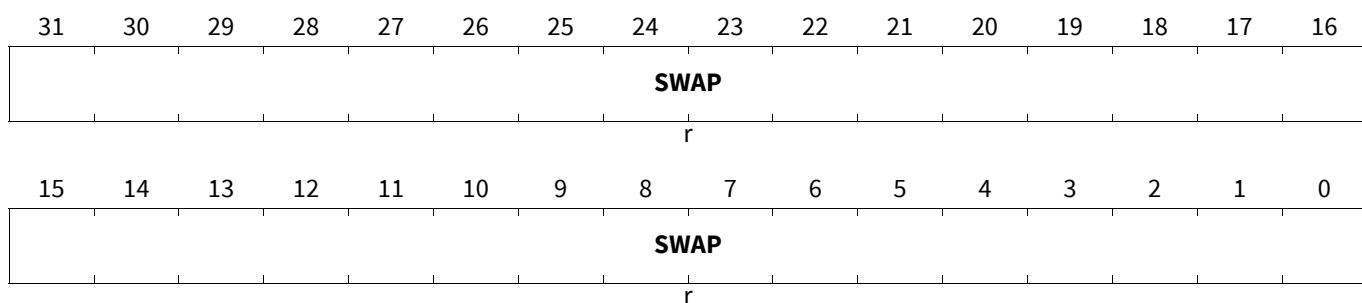

### 6.8.3.2 UCB\_SWAP\_ORIG and UCB\_SWAP\_COPY

**UCB\_SWAP\_ORIG\_MARKERLx**

Determines the system address map used by the current running application. For more details please refer to the "Software update Over The Air(SOTA)" chapter.

**MARKERLx (x=0-15)**

**UCB\_SWAP\_ORIG\_MARKERLx** **(2E00<sub>H</sub>+x\*10<sub>H</sub>)** **Default Flash Value: 0000 0000<sub>H</sub>**

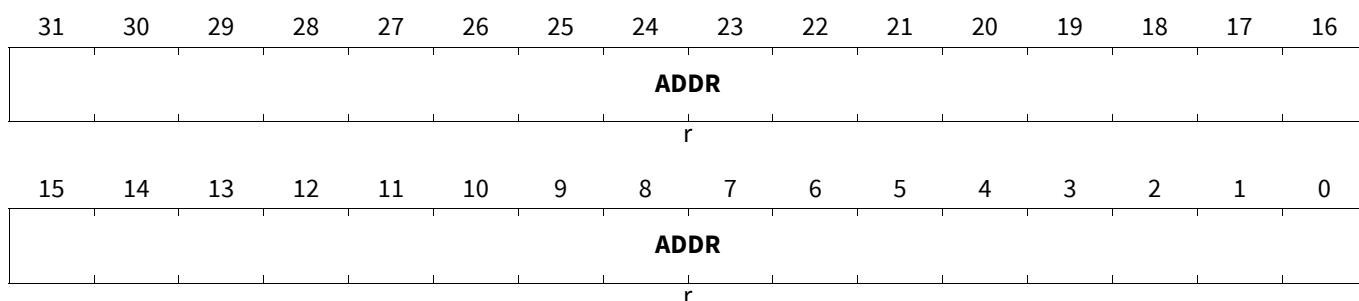

Field	Bits	Type	Description
<b>SWAP</b>	31:0	r	<b>SWAP</b> 00000000 <sub>H</sub> <b>ERASED</b> , Erased state 00000055 <sub>H</sub> <b>STD</b> , Selects standard address map 000000AA <sub>H</sub> <b>ALT</b> , Selects alternate address map

**UCB\_SWAP\_ORIG\_MARKERHx**

Holds the 32-bit system address of the corresponding MARKERLx.SWAP UCB\_SWAP entry confirming its validity. For safety purposes this is checked by the startup software before the address map is installed.

**MARKERHx (x=0-15)**

**UCB\_SWAP\_ORIG\_MARKERHx** **(2E04<sub>H</sub>+x\*10<sub>H</sub>)** **Default Flash Value: 0000 0000<sub>H</sub>**

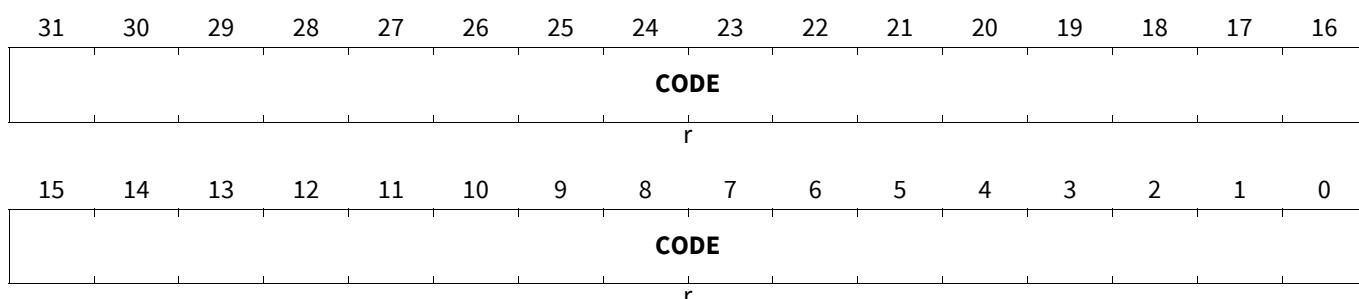

Field	Bits	Type	Description
<b>ADDR</b>	31:0	r	<b>Address of corresponding MARKERLx.SWAP entry as confirmation or erased</b>

**UCB\_SWAP\_ORIG\_CONFIRMATIONLx**

This holds the confirmation code of the address map configured in the previous SWAP MARKERL/H. A valid code indicates that the above configuration of the address map can be installed by the startup software in the SCU\_SWAPCTRL register.

**CONFIRMATIONLx (x=0-15)**

**UCB\_SWAP\_ORIG\_CONFIRMATIONLx** **(2E08<sub>H</sub>+x\*10<sub>H</sub>)** **Default Flash Value: 0000 0000<sub>H</sub>**

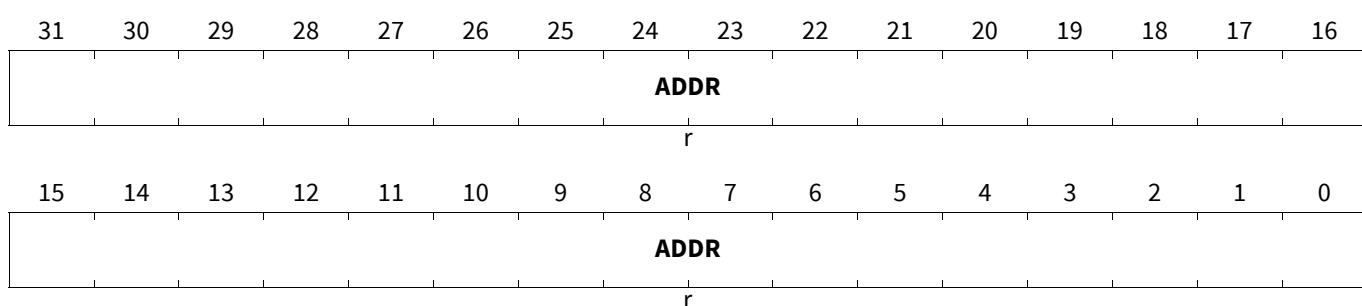

Field	Bits	Type	Description
<b>CODE</b>	31:0	r	<b>CODE</b> 00000000 <sub>H</sub> <b>ERASED</b> , Erased state 57B5327F <sub>H</sub> <b>CONFIRMED</b> , Confirmed code

**UCB\_SWAP\_ORIG\_CONFIRMATIONHx**

Holds the 32-bit system address of the corresponding CONFIRMATIONLx.CODE UCB\_SWAP entry confirming its validity. This is checked by startup software before the MARKER regions are read. The address map is installed only if this address matches the actual address of this location.

**CONFIRMATIONHx (x=0-15)**

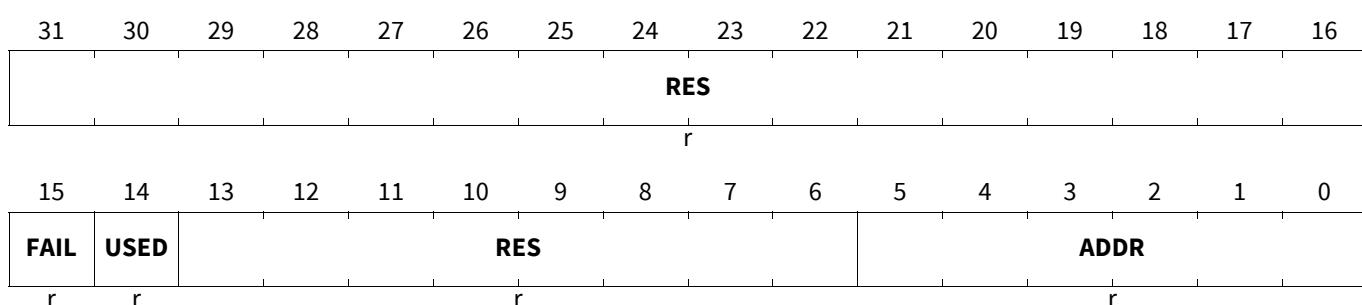

**UCB\_SWAP\_ORIG\_CONFIRMATIONHx**  $(2E0C_H + x * 10_H)$  **Default Flash Value: 0000 0000<sub>H</sub>**

Field	Bits	Type	Description
ADDR	31:0	r	Address of corresponding CONFIRMATIONLx.CODE entry as confirmation or erased

**6.8.3.3 UCB\_REDSEC****UCB\_REDSECPLps - Low Word of Wordline Redundancy for PFlash p Redundant Sector s****REDSECPLps (p=0-5;s=0-7)****UCB\_REDSECPLps - Low Word of Wordline Redundancy for PFlash p Redundant Sector s**

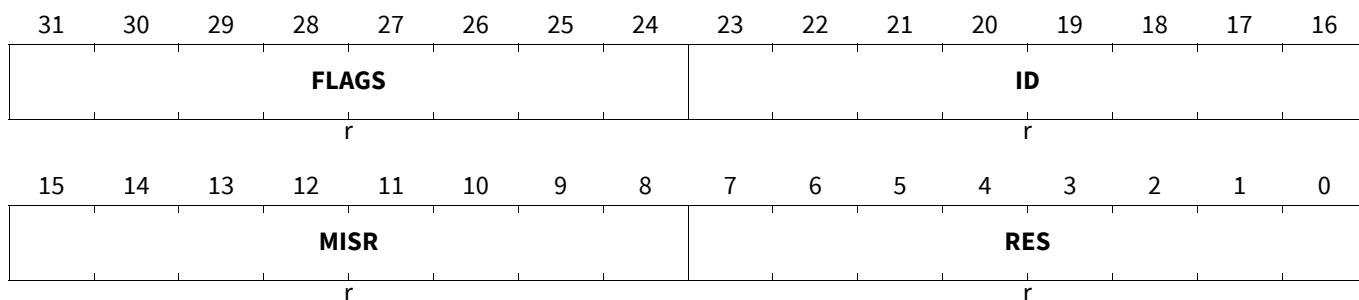

**(1800<sub>H</sub>+p\*40<sub>H</sub>+s\*8)** **Reset Value: Table 232**

Field	Bits	Type	Description
ADDR	5:0	r	Address of defective Sector in 1024KiB block.
RES	13:6, 31:16	r	Reserved
USED	14	r	Used State $0_B$ UNUSED, Entry free $1_B$ USED, Entry used
FAIL	15	r	Failed State $0_B$ OK, Entry available $1_B$ FAIL, Entry unavailable (redundancy not existing or unusable)

## Local Memory Unit (LMU)

# 7 Local Memory Unit (LMU)

The Local Memory Unit is an SRI peripheral providing access to volatile memory resources. Its primary purpose is to provide up to 256 KiB of local memory for general purpose usage. A product may contain multiple instances of the LMU. Refer to the system memory map for the configuration applicable to each product. Each instance of the LMU has its own set of configuration registers.

Data stored in the local memory is protected by ECC at all points within the LMU. Areas of local memory can be write protected by configuring up to sixteen address ranges using SFRs in the LMU. Each of these ranges can be sized in thirty-two byte increments and has its own, independent list of Master Tag IDs permitted write access. Read accesses are not protected.

## 7.1 Feature List

An overview of the features implemented in the LMU follows:

- Up to 256 KiB of SRAM
  - organized as 64 bit words
  - support for byte, half word and word accesses as well as double-word and burst accesses
  - memory can be used as overlay memory
- Protection of LMU SRAM contents
  - sixteen programmable address regions can be protected
  - each address range has a programmable list of bus masters permitted read or write access based on the Unique master Tag ID

## 7.2 Functional Description

### 7.2.1 Local Memory (LMU SRAM)

The LMU SRAM can be used for code execution, data storage or overlay memory. The address range of the memory is defined in the system memory map. As well as being accessed via cached (segment 9<sub>H</sub>), the memory can be accessed via non-cached (segment B<sub>H</sub>) memory addresses.

The memory implements memory integrity checking for error detection and correction. This means that the memory must be initialized before reads are attempted with the integrity checking enabled to avoid generating spurious data corruption errors. Initializing with the memory integrity logic disabled allows the LMU SRAM to support initialisation using word (32 bit) or smaller writes as well as 64 bit writes.

If memory integrity checking is enabled, a read access which fails the integrity check will cause an error condition to be flagged to the initiated bus master. This behaviour can be changed by setting the MEMCON.ERRDIS bit to 1<sub>B</sub>. If ERRDIS is set, the access will terminate normally.

An ECC error will also be reported to the SMU. The SMU will use this signal for error indication and triggering of an NMI trap (if enabled).

The LMU SRAM is internally organized as a 64 bit memory without the possibility of sub-word accesses. This means that any write access of less than 64 bits of data needs an internal Read-Modify-Write (iRMW) operation to correctly write the data and update the ECC data. This happens transparently to rest of the system unless an uncorrected ECC error is detected during the read phase of the iRMW. This ECC error will be flagged to the SMU in the same way as a data ECC error occurring during a normal read. In addition the MEMCON.RMWERR flag will be set. The write operation will not take place as this would write incorrect ECC data to the memory (the ECC would match the written data but the data would potentially contain an uncorrected error).

## Local Memory Unit (LMU)

LMU SRAM performance will be the same as, or better than, the performance of the embedded flash. This applies to both the initial latency of the first word returned and also the incremental latency for each word in the same cache line fetched.

If the CPU access cannot be handled by the LMU SRAM (e.g. an attempt has been made to access RAM with the LMU clock disabled), an SRI bus error is reported by the LMU. This will, for example, cause a CPU to take a DSE trap if the access is from a CPU and a DMA access to terminate with an error condition.

The ERRDIS bitfield of the MEMCON register is protected by MEMCON.PMIC bit. If the data written to the register has the bitfield set to 0<sub>B</sub>, no change will be made to ERRDIS (bit 9<sub>D</sub> of the register) regardless of the data written to the field.

### 7.2.2 Memory Protection

The LMU allows for the definition of sixteen protected regions of SRAM memory. The protection applies only to accesses to SRAM included in the LMU, not registers.

The protection scheme is based on the use of Unique Master Tag IDs to identify the master attempting the access and allows for a six bit tag individually identifying up to 64 masters.

Each region is defined using six registers:

- RGNLAX (x=0-15) to define the lower address of the region, RGNUAx (x=0-15) to define the upper address of the region
- two registers RGNACCENWAX (x=0-15) and RGNACCENWBx (x=0-15), to individually select the master tags permitted write access to the defined address range
- two registers RGNACCENRAx (x=0-15) and RGNACCENRBx (x=0-15) to individually select the master tags permitted read access to the defined address range.

The scheme is compatible with the Tricore implementation so RGNLAX (x=0-15) defines the first address in the region.

After reset, the region address registers will be set to include the whole of the LMU SRAM address space and read and write access by all masters will be enabled.

The registers implementing the memory protection scheme are protected by the “safety endinit” function.

If overlapping regions are defined, then an access only needs to be permitted by one of the overlapping regions for it to succeed.

When altering protection settings, it should be noted that, due to access pipelining in the LMU and resynchronization delays in the register block, an access to a memory address affected by the protection change occurring immediately after the register write initiating the change may, or may not, be affected by the changed settings.

For the Cerberus and HSM masters, if present in the product, access protection only applies to write accesses. Read accesses from these masters are always successful.

### 7.2.3 LMU Register Protection

The LMU implements the standard register protection scheme for peripheral registers using the ACCEN0 and ACCEN1 registers. This allows the LMU control registers to be protected from write accesses by untrusted masters. Masters are identified using the SRI tag of the access and, if the appropriate bit is not set in the access enable registers, write accesses will be disconnected with error acknowledge. See the On Chip Bus chapter for the product’s master Tag ID to master peripheral mapping. This protection scheme does not apply to the ACCEN0 and ACCEN1 themselves.

ACCEN0, ACCEN1 and SMCTRL are protected by Safe Endinit while all other registers are Endinit protected. The Endinit and Safe Endinit system status is defined by different Watchdog Units in the System Control Unit (SCU).

## Local Memory Unit (LMU)

### 7.2.4 Error Detection and Signalling

The LMU will detect several different classes of error which cannot necessarily be signalled on the SRI during the associated transaction. However, all errors will cause a trigger to be sent to the SMU for processing. Some will additionally cause a flag to be set in the MEMCON register. Unless explicitly stated below, the access will complete. The following list details the detected error conditions:

#### 7.2.4.1 SRI access address phase error

If an ECC error occurs on the address phase of an SRI access then the MEMCON.ADDERR bit will be set and an error will be signalled to the SMU. The SRI access will abort without attempting to modify RAM or SFR contents.

#### 7.2.4.2 SRI write access data phase error

If an ECC error occurs on the data phase of an SRI write access then the MEMCON.DATAERR bit will be set and an error will be signalled to the SMU. The write completes without signalling an SRI error.

#### 7.2.4.3 Uncorrected ECC Error

If an uncorrected ECC error is reported by the RAM during an SRAM read then an error will be signalled to the SMU.

#### 7.2.4.4 SRAM Data Correction ECC failure

The hardware used to check and correct the read data from the SRAM is replicated and the output from the two instances is compared. In the event of a difference between the two outputs, an error condition will be signalled to the SMU. The second instance will use inverted logic to eliminate common failure modes.

#### 7.2.4.5 Internal Data Transfer ECC Error

Internal registers used to transfer data between the RAM and the SRI interface are ECC protected. In the event of this ECC detecting an error, the MEMCON.INTERR bit will be set and an error will be signalled to the SMU.

#### 7.2.4.6 Access Protection Violation

If either the memory protection or register protection detect a protection violation, then the violating access will

- be terminated with an error if a read
- fail silently if a write

In both cases, the error will be signalled to the SMU.

#### 7.2.4.7 Internal SRAM Read Error

The LMU will perform a internal Read-Modify-Write (iRMW) access when a write of less than 64 bits of data is performed. An ECC error reported by the RAM on the read phase will cause the MEMCON.RMWERR bit to be set and an error will be signalled to the SMU. The write phase of the iRMW will not take place unless the MEMCON.ERRDIS bit is set.

#### 7.2.4.8 Control Logic Failure

The control logic of the LMU which is not suitable for protection by one of the ECC checks will be lockstepped (duplicated and compared). Any mismatch between the two copies of the logic will be detected and an alarm generated. This mechanism will be enabled after reset and can be disabled by writing  $01_B$  (OFF) to the SCTRL.LSEN bitfield. The current status of the lockstep is reported by SCTRL.LSSTAT. The alarm signal can be

## Local Memory Unit (LMU)

tested by writing  $10_B$  to SCTRL.LSTST. The lockstep block also runs a background self test which periodically checks the comparator functionality. A self test failure will trigger an SMU alarm.

The lockstep block also checks consistency of its own control state by maintaining all such information in redundant pairs of flip-flops where one flip-flop is the logical inverse of the other. Any of these pairs being in an inconsistent state (i.e.  $00_B$  or  $11_B$ ) will trigger a separate SMU alarm.

### 7.2.5 SRAM Data Correction ECC failure

The hardware used to check and correct the read data from the SRAM is replicated and the data output from the two instances is compared. In the event of a difference between the two data outputs, an error condition will be signalled to the SMU. The second instance will use inverted logic to eliminate common failure modes.

### 7.2.6 Internal Data Transfer ECC Error

Internal registers used to transfer data between the RAM and the SRI interface are ECC protected. In the event of this ECC detecting an error, the MEMCON.INTERR bit will be set and an error will be signalled to the SMU.

### 7.2.7 Internal SRAM Read Error

The LMU will perform a internal Read-Modify-Write (iRMW) access when a write of less than 64 bits of data is performed. An ECC error reported by the RAM on the read phase will cause the MEMCON.RMWERR bit to be set and an error will be signalled to the SMU. The write phase of the iRMW will not take place unless the MEMCON.ERRDIS bit is set.

### 7.2.8 Clock Control

The LMU contains a clock control register, CLC, which allows the LMU to be put into a power saving mode. If LMU \_CLC.DISR is set then the LMU will be disabled and all accesses will be errored unless they are addressed to a register.

## Local Memory Unit (LMU)

### 7.3 LMU Registers

The registers of each LMU instance are mapped into a 64 kByte address space. Accesses to unused register space will cause an SRI bus error.

### LMU Access Enable Register 0

The Access Enable Register 0 controls access for transactions to registers with the on chip bus master TAG ID 000000B to 011111B (see On Chip Bus chapter for the products TAG ID <-> master peripheral mapping). The LMU is prepared for an 6 bit TAG ID. The registers ACCEN0 / ACCEN1 are providing one enable bit for each possible 6 bit TAG ID encoding.

Mapping of TAG IDs to ACCEN0.ENx: EN0 -> TAG ID 000000B, EN1 -> TAG ID 000001B, ... ,EN31 -> TAG ID 011111B.

LMU Memory Control Register

This register provides software with the capability to monitor both the memory integrity error checking and the error signalling to the SMU.

MEMCON

LMU Memory Control Register

(00020..)

**Application Reset Value:** 0000 0000..

The diagram illustrates a 16-bit memory address bus. It consists of two parallel buses: a top bus and a bottom bus. The top bus has bits 31 through 17, followed by a central bit labeled 0, and then bits 16 through 1. The bottom bus has bits 15 through 1, followed by a central bit labeled 0. Between the two buses, there are several control signals: **ERRDI S**, **PMIC**, **ADDE RR**, **DATAE RR**, **RMWE RR**, and **INTER R**. The labels **r** and **rwh** are placed under the respective bus segments to indicate their function.

**Local Memory Unit (LMU)**

Field	Bits	Type	Description
<b>INTERR</b>	2	rwh	<b>Internal ECC Error</b> Flag set by hardware when the LMU detects an ECC error on the internal data path registers while accessing the RAM. $0_B$ No error has occurred $1_B$ An error has been observed during a RAM access.
<b>RMWERR</b>	4	rwh	<b>Internal Read Modify Write Error</b> Flag set by hardware when an uncorrected ECC error is reported by the RAM on the read phase of an internal RMW operation. $0_B$ No error has occurred $1_B$ An error has been observed during an iRMW operation.
<b>DATAERR</b>	6	rwh	<b>SRI Data Phase ECC Error</b> Flag set by hardware when the SRI interface detects an ECC error in the data phase of an incoming write transaction. This bit is cleared by writing $0_B$ but cannot be set by software. $0_B$ No error has occurred $1_B$ An ECC error has been observed on an SRI transaction addressed to the LMU
<b>ADDERR</b>	7	rwh	<b>SRI Address Phase ECC Error</b> Flag set by hardware when the SRI interface detects an ECC error in the address phase of an incoming transaction. This bit is cleared by writing $0_B$ but cannot be set by software. $0_B$ No error has occurred $1_B$ An ECC error has been observed on an SRI transaction addressed to the LMU
<b>PMIC</b>	8	rwh	<b>Protection Bit for Memory Integrity Control Bit</b> Will always return $0_B$ when read $0_B$ Bit Protection: Bit 9 remains unchanged after MEMCON write. $1_B$ Bit 9 will be updated by the current write to MEMCON
<b>ERRDIS</b>	9	rw	<b>ECC Error Disable</b> When set to $1_B$ SRI error reporting of ECC errors in data read from the SRAM will be disabled and an ECC error on the read phase of an iRMW will not cause the write phase to be aborted. $0_B$ Normal behavior. SRI error will occur on SRAM ECC errors. Default after reset $1_B$ Test or Initialisation Mode. SRI errors will not be generated on an SRAM ECC error. This does not affect the generation of alarms.
<b>0</b>	1:0, 3, 5, 31:10	r	<b>Reserved</b> Read as $0_H$ , must be written as $0_H$

**LMU Safety Control Register**

This register provides control of the user configurable safety mechanisms of the LMU. Writing one of the invalid values to any of the redundant control fields will cause an SMU alarm.

## Local Memory Unit (LMU)

### LMU Region Lower Address Register

In conjunction with the associated RGNUA and RGNACCENx registers, the RGNLA register provides control of a memory protection region. The register is cleared by an application (Class 3) reset. RGNLA defines the lower address of a region of memory, RGNUA defines the upper address and the RGNACCENx registers define the Unique Master Tag IDs allowed to access the region. Address ranges can be set to be larger than the LMU address space but only accesses to the LMU are affected by these registers.

### LMU Region Write Access Enable Register A

The Write Access Enable Register A controls write access for transactions to the protected memory region with the on chip bus master TAG ID 000000B to 011111B (see On Chip Bus chapter for the products TAG ID <-> master peripheral mapping). The LMU supports a 6 bit TAG ID. The registers RGNACCENWAI / RGNACCENWBi provide one enable bit for each possible 6 bit TAG ID encoding.

Mapping of TAG IDs to RGNACCENWAi.ENx: EN0 -> TAG ID 000000B, EN1 -> TAG ID 000001B, ... ,EN31 -> TAG ID 011111B.

## Default Application Memory (DAM)

### 8 Default Application Memory (DAM)

The Default Application Memory is an SRI peripheral providing access to volatile memory resources. Its primary purpose is to provide 64 kBytes or 32 kBytes of local memory for general purpose usage. The amount of memory available depends on the product.

Data stored in the local memory is protected by ECC. Areas of local memory can be write protected by configuring up to eight address ranges using SFRs in the DAM. Each of these ranges can be sized in thirty-two byte increments and has its own, independent list of Master Tag IDs permitted write access.

#### 8.1 Feature List

An overview of the features implemented in the DAM follows:

- 64 KiB of SRAM depending on the product
  - organized as 64 bit words
  - support for byte, half word and word accesses as well as double-word and burst accesses
- Protection of DAM SRAM contents
  - eight programmable address regions can be protected
  - each address range has a programmable list of bus masters permitted read or write access based on the Unique master Tag ID

#### 8.2 Functional Description

##### 8.2.1 Local Memory (DAM SRAM)

The DAM SRAM can be used for code execution or data storage but it does not have hardware safety mechanisms in place to support use in ASIL B, ASIL C or ASIL D applications. The address range of the memory is defined in the system memory map. As well as being accessed via cached (segment 9<sub>H</sub>), the memory can be accessed via non-cached (segment B<sub>H</sub>) memory addresses.

The SRAM can also be configured to emulate ROM by setting the ROM bit in the MEMCON register. In this mode, all write accesses from the SRI are terminated with an SRI error without changing the memory contents.

The memory implements memory integrity checking for error detection and correction. This means that the memory must be initialized before reads are attempted with the integrity checking enabled to avoid generating spurious data corruption errors. Initializing with the memory integrity logic disabled allows the DAM SRAM to support initialisation using word (32 bit) or smaller writes as well as 64 bit writes.

If memory integrity checking is enabled, a read access which fails the integrity check will be terminated with an SRI error condition. This behavior can be changed by setting the MEMCON.ERRDIS bit to 1<sub>B</sub>. If the bit is set then an SRI error will not occur.

An ECC error will also be reported to the SMU. The SMU will use this signal for error indication and triggering of an NMI trap (if enabled).

The DAM SRAM is internally organized as a 64 bit memory without the possibility of sub-word accesses. This means that any write access of less than 64 bits of data needs an internal Read-Modify-Write (iRMW) operation to correctly write the data and update the ECC data. This happens transparently to rest of the system unless an uncorrected ECC error is detected during the read phase of the iRMW. This ECC error will be flagged to the SMU in the same way as a data ECC error occurring during a normal read. In addition the DAM MEMCON.RMWERR flag will be set. The write operation will not take place as this would write incorrect ECC data to the memory (the ECC would match the written data but the data would potentially contain an uncorrected error).

## **Default Application Memory (DAM)**

If the access cannot be handled by the DAM SRAM (e.g. an attempt has been made to access RAM with the DAM clock disabled), an SRI bus error is reported by the DAM.

The ERRDIS bitfield of the MEMCON register is protected by MEMCON.PMIC bit. If the data written to the register has the bitfield set to  $0_B$ , no change will be made to ERRDIS (bit  $9_D$  of the register) regardless of the data written to the field.

### **8.2.2 Memory Protection**

The DAM allows for the definition of eight protected regions of SRAM memory. The protection applies only to accesses to SRAM included in the DAM, not registers.

The protection scheme is based on the use of Unique Master Tag IDs to identify the master attempting the access and allows for a six bit tag individually identifying up to 64 masters.

Each region is defined using six registers:

- RGNL<sub>A</sub>x (x=0-7) to define the lower address of the region, RGNU<sub>A</sub>x (x=0-7) to define the upper address of the region
- two registers RGNACCENWA<sub>x</sub> (x=0-7) and RGNACCENWB<sub>x</sub> (x=0-7), to individually select the master tags permitted write access to the defined address range
- two registers RGNACCENRA<sub>x</sub> (x=0-7) and RGNACCENRB<sub>x</sub> (x=0-7) to individually select the master tags permitted read access to the defined address range.

The scheme is compatible with the Tricore implementation so RGNL<sub>A</sub>x (x=0-7) defines the first address in the region.

After reset, the region address registers will be set to include the whole of the DAM SRAM address space and access by all masters will be enabled.

The registers implementing the memory protection scheme are protected by the “safety endinit” function.

If overlapping regions are defined, then an access only needs to be permitted by one of the overlapping regions for it to succeed.

When altering protection settings, it should be noted that, due to access pipelining in the DAM and resynchronization delays in the register block, an access to a memory address affected by the protection change occurring immediately after the register write initiating the change may, or may not, be affected by the changed settings.

For the Cerberus and HSM masters, if present in the product, access protection only applies to write accesses. Read accesses from these masters are always successful. Consequently the relevant bits in the RGNACCENRA<sub>x</sub> (x=0-7) or RGNACCENRB<sub>x</sub> (x=0-7) registers will always read as  $1_B$ .

### **8.2.3 DAM Register Protection**

The DAM implements the standard register protection scheme for peripheral registers using the ACCEN0 and ACCEN1 registers. This allows the DAM control registers to be protected from write accesses by untrusted masters. Masters are identified using the SRI tag of the access and, if the appropriate bit is not set in the access enable registers, write accesses will be disconnected with error acknowledge. See the On Chip Bus chapter for the product’s master Tag ID to master peripheral mapping. This protection scheme does not apply to the ACCEN0 and ACCEN1 themselves.

ACCEN0 and ACCEN1 are protected by Safe Endinit while all other registers are Endinit protected. The Endinit and Safe Endinit system status is defined by different Watchdog Units in the System Control Unit (SCU).

---

## Default Application Memory (DAM)

### 8.2.4 Error Detection and Signalling

The DAM will detect several different classes of error which cannot be signalled on the SRI during the associated transaction. These will cause a flag to be set in the MEMCON register and a trigger will be sent to either the SMU or the Interrupt system for processing. Unless explicitly stated below, the access will complete. The following list details the detected error conditions:

#### 8.2.4.1 SRI access address phase error

If an ECC error occurs on the address phase of an SRI access then the MEMCON.ADDERR bit will be set and an error will be signalled to the SMU. The SRI access will terminate with an error.

#### 8.2.4.2 SRI write access data phase error

If an ECC error occurs on the data phase of an SRI write access then the MEMCON.DATAERR bit will be set and an error will be signalled to the SMU

#### 8.2.4.3 Uncorrected ECC Error

If an uncorrected ECC error is signalled during an SRAM read then an error will be signalled to the SMU.

#### 8.2.4.4 Access Protection Violation

If either the memory protection or register protection detect a protection violation, then the violating access will

- be terminated with an error if a read
- be terminated with an error if a write

In both cases, the error signalled to the SMU.

### 8.2.5 Clock Control

The DAM contains a clock control register, CLC, which allows the DAM to be put into a power saving mode.

If CLC.DISR is set then the DAM will be disabled and all accesses will be errored unless they are addressed to a register. Accesses to DAM memory should not be attempted once the DAM has been disabled as accesses running when the register bit sets can either be cancelled or completed.

## Default Application Memory (DAM)

### 8.3 Registers

The DAM registers are mapped into a 32 kByte address space. Accesses to unused register space will cause an SRI bus error.

All registers are endinit or safe endinit protected and are accessible in Supervisor mode only.

SRI error will occur on SRAM ECC errors. Default after reset 1 <sub>B</sub> Test Mode. SRI errors will not be generated on an SRAM ECC error. This does not affect the generation of interrupts.

## Default Application Memory (DAM)

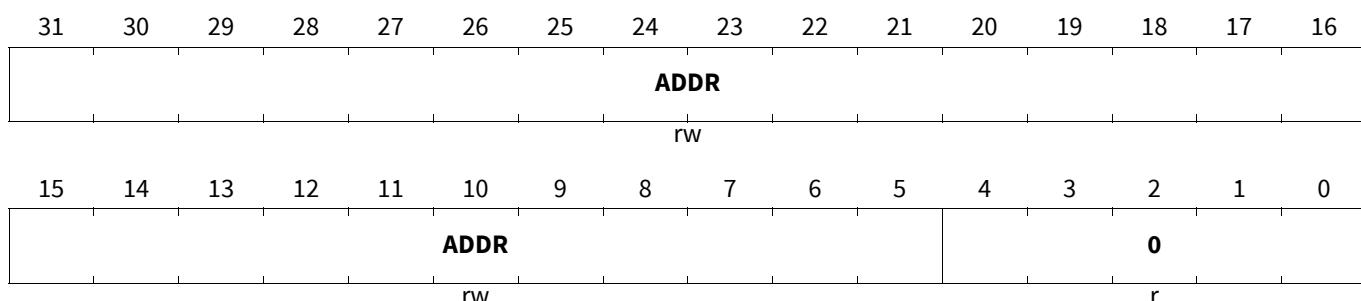

Field	Bits	Type	Description
0	1, 3, 5, 15:10, 31:16	r	<b>Reserved</b> Read as 0, must be written as 0

### DAM Region Lower Address Register

In conjunction with the associated RGNUA and RGNACCEN\*x registers, the RGNLA register provides control of a memory protection region. The register is cleared by a application (Class 3) reset. RGNLA defines the lower address of a region of memory, RGNUA defines the upper address and the RGNACCEN\*x registers define the Unique Master Tag IDs allowed to access the region. Address ranges can be set to be larger than the DAM address space but only accesses to the DAM are affected by these registers.

#### RGNLAX (x=0-7)

**DAM Region Lower Address Register** **(00050<sub>H</sub>+x\*10<sub>H</sub>)** **Application Reset Value: 0000 0000<sub>H</sub>**

Field	Bits	Type	Description
<b>ADDR</b>	31:5	rw	<b>Region Lower Address</b> Bits 31 to 5 of the SRI address which is the lower bound of the defined memory region
0	4:0	r	<b>Reserved</b> Read as 0 <sub>B</sub> , should be written with 0 <sub>B</sub> although written value will be ignored.

### DAM Region Upper Address Register

In conjunction with the associated RGNLA and RGNACCEN\*x registers, the RGNUA register provides control of a memory protection region. The register is cleared by an application (Class 3) reset. RGNUA defines the upper address of the memory region and will contain the first address outside the protected region.

0	4:0	r	<b>Reserved</b> Read as 0 <sub>B</sub> , should be written with 0 <sub>B</sub> although written value will be ignored.

### DAM Region Write Enable Register A

The Write Access Enable Register A controls write access for transactions to the protected memory region with the on chip bus master TAG ID 000000B to 011111B (see On Chip Bus chapter for the products TAG ID <-> master peripheral mapping). The DAM is prepared for an 6 bit TAG ID. The registers RGNACCENWAI / RGNACCENWBi are providing one enable bit for each possible 6 bit TAG ID encoding.

Mapping of TAG IDs to RGNACCENWAI.ENn: EN0 -> TAG ID 000000B, EN1 -> TAG ID 000001B, ... ,EN31 -> TAG ID 011111B.

## Default Application Memory (DAM)

### DAM Region Write Enable Register B

The Write Access Enable Register B controls write access for transactions to the protected memory region with the on chip bus master TAG ID 100000B to 111111B (see On Chip Bus chapter for the products TAG ID <-> master peripheral mapping). The DAM is prepared for an 6 bit TAG ID. The registers RGNACCENWB<sub>i</sub> / RGNACCENWB<sub>j</sub> are providing one enable bit for each possible 6 bit TAG ID encoding.

Mapping of TAG IDs to RGNACCENWB<sub>i</sub>.EN<sub>n</sub>: EN0 -> TAG ID 100000<sub>B</sub>, EN1 -> TAG ID 100001<sub>B</sub>, ... ,EN31 -> TAG ID 111111<sub>B</sub>.

## System Control Units (SCU)

### 9 System Control Units (SCU)

The System Control Unit (SCU) is a cluster of sub-modules which control various system functions, including:

- Reset Control (RCU)
- Trap generation (TR)
- System Registers for miscellaneous functions (SRU)
- Watchdog Timers (WDT)
- External Request handling (ERU)
- Emergency Stop (ES)
- Power Management Control (PMC)

These submodules share a common bus interface.

## System Control Units (SCU)

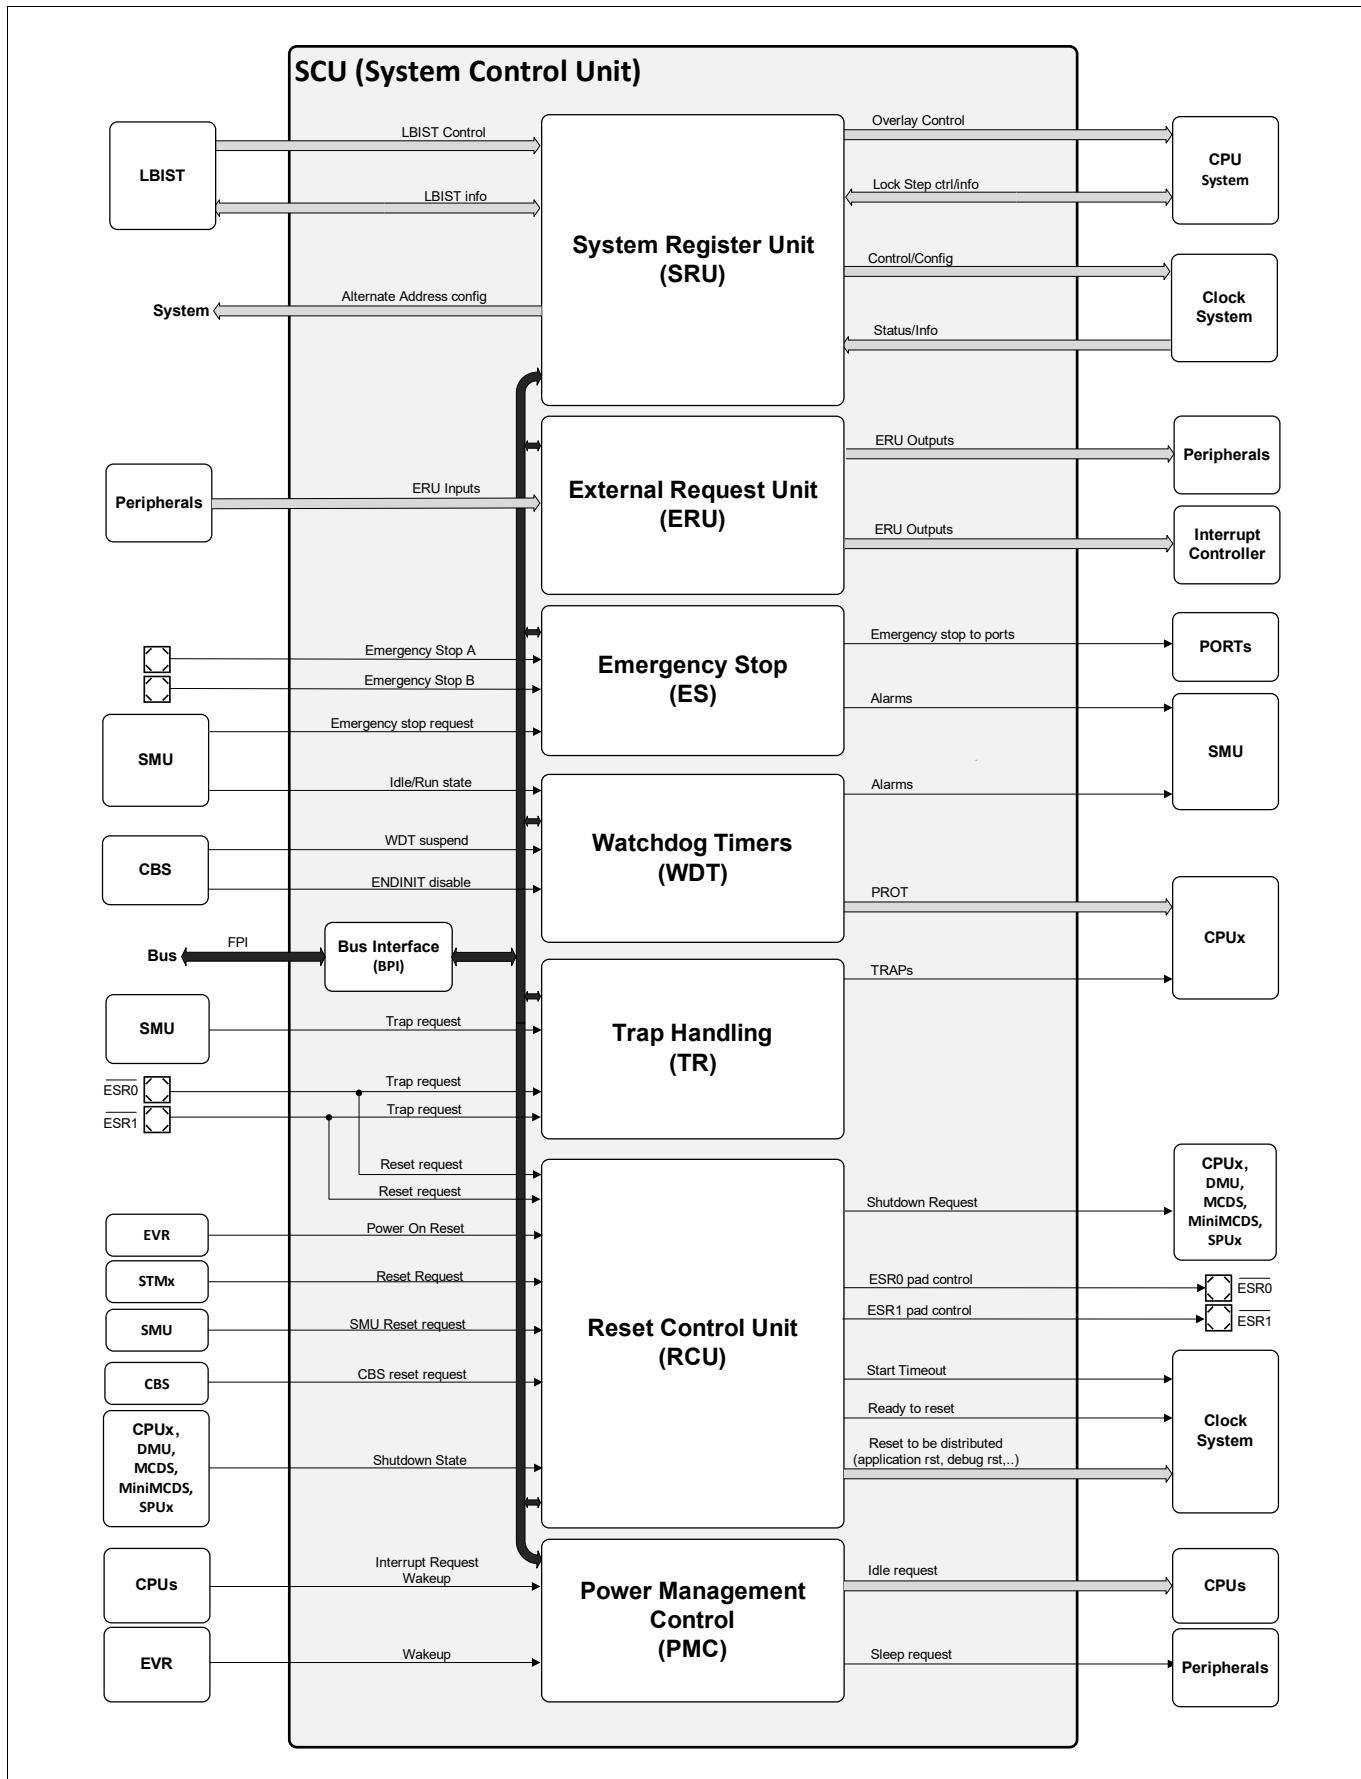

Figure 66 SCU Internal Structure Overview

## System Control Units (SCU)

### 9.1 Reset Control Unit (RCU)

This chapter contains the following sections:

- Basic Reset Operation (see [Section 9.1.2](#))
- External Reset sources and indications (see [Section 9.1.4](#))
- Boot Software Interface (see [Section 9.1.5](#))

#### 9.1.1 Feature List

- A complete device reset can be triggered by the primary voltage monitors
- Partial device resets can be triggered by assertion of the PORST, ESR0 or ESR1 pin(s)
- Partial device resets can be triggered in response to a Safety Alarm
- Partial device resets can be triggered by software
- Partial device resets can be triggered by test or JTAG
- Partial device resets can be triggered by any System Timer

Partial reset definition can be extracted from [Table 244](#) (reset sources to reset type) together with [Table 245](#) (reset type to which part of the device is affected).

This module has the same features and functionality in all TC3xx devices.

#### 9.1.1.1 Delta to AURIX

The TC3xx reset concept is based upon the reset concept of the TC2xx product range. The most significant changes are:

- Each CPU can be individually reset using CPUx\_KRSTy registers (See CPU chapter)
- Several registers formerly protected by SE are now only protected by E (to allow easier changes during Safety Applications)

#### 9.1.2 Overview

This section describes the conditions under which the AURIX™ TC3xx Platform will be reset and the reset operation configuration and control.

#### 9.1.2.1 Reset Triggers

The following reset request triggers are available:

- Supply monitor (SWD) triggers a power-on reset (cold reset)
- Core voltage EVR (EVRC) monitor triggers a power-on reset (cold reset)
- 3.3V EVR monitor triggers a power-on reset (cold reset) (If product has EVR33)
- Standby EVR (STBYR) monitor triggers a power-on reset (cold reset)
- External active low hardware “power-on” reset request trigger; PORST (can be either a warm reset or to extend a cold reset)
- External System Request reset trigger pins;  $\overline{\text{ESR0}}$  and  $\overline{\text{ESR1}}$  (warm reset)
- Safety Management Unit (SMU) alarm reset request trigger, (warm reset)
- Software reset (SW), (warm reset)
- System Timer (STMx) trigger (warm reset)
- Resets via the JTAG interface
- Resets initiated via On-Chip Debug System (OCDS)

## System Control Units (SCU)

- Software triggered module reset

*Note:* The JTAG resets are described in the OCDS chapter.

### 9.1.2.2 Reset Types

The following list describes the different reset types.

- Power-on Reset:

This reset results in initialization of the complete system into a defined state. A Power-on Reset also generates a Debug Reset and a System Reset and therefore also an Application Reset. (See also the section about Warm and Cold Resets)

- System Reset:

This reset leads to an initialization into a defined state of the complete system but without a reset of the power subsystem, debug subsystem or reset configuration registers.

A System Reset also generates an Application Reset.

- Debug Reset:

This reset leads to an initialization into a defined state of the complete debug system.

- Application Reset:

This reset leads to an initialization into a defined state of the complete application system with the following parts: all peripherals, the CPUs and parts of the SCU.

- Module Resets:

Module resets result in individual modules being initialized into a defined state without any impact on the rest of the system.

### 9.1.2.3 Reset Sources Overview

The connection of the reset sources and the activated reset signals/domains are shown in [Table 244](#).

**Table 244 Effect of Reset Triggers**

Reset Request Trigger	Application Reset	Debug Reset	System Reset
<b>PORST</b>	Activated	Activated	Activated
<b>STBYR</b>	Activated	Activated	Activated
<b>SWD</b>	Activated	Activated	Activated
<b>EVRC</b>	Activated	Activated	Activated
<b>EVR33</b>	Activated	Activated	Activated
<b>ESR0</b>	Configurable	Not Activated	Configurable
<b>ESR1</b>	Configurable	Not Activated	Configurable
<b>SMU</b>	Configurable	Not Activated	Configurable
<b>STMx</b>	Configurable	Not Activated	Configurable
<b>SW</b>	Configurable	Not Activated	Configurable

<b>Module Resets<sup>4)</sup></b>	Not Activated	Not Activated	Not Activated

1) Cerberus resets may be triggered by CBS\_OCNTRL or CBS\_OJCONF

## System Control Units (SCU)

- 2) Cerberus resets may be triggered by CBS\_OCNTRL or CBS\_OJCONF
- 3) Cerberus resets may be triggered by CBS\_OCNTRL or CBS\_OJCONF
- 4) Module Resets (via MOD\_KRSTx.RST register bits in some modules) have no effect on chip-level reset system. The scope of a module reset is limited to the module itself.

### 9.1.2.4 Warm and Cold Resets

A “Warm reset” is a reset which is triggered while the system is already operational and the supplies remain stable. It is used to return the system to the same known state. On a warm reset request, any reset of pin states will take place immediately, but the internal circuitry will only be reset after the system has been brought into a state where memory contents and debug trace data will not be corrupted and the current consumption has been ramped down. Note that PORST may be asserted as a warm reset. In this specification a register denoted as “Power-on Reset” shall also be reset on a warm PORST without a power-on event.

A “Cold Power-on Reset” is a reset which is triggered for the first time during a system power-up or in response to a temporary power failure. During the power-up the EVR primary undervoltage monitors will trigger a complete reset of the system, placing the system into a known state. The PORST pin can be used to extend this reset phase and control the timing of its release. The pins and internal states are placed immediately into their reset state when the trigger is asserted.

Some special registers in the EVR are associated with functionality which should not be re-initialized even in the case of a temporary violation of an undervoltage monitor but only on a real power-up event. These are reset only when the supply drops below a very low threshold. The reset for these registers is described as “EVR Power-On Reset”

### 9.1.2.5 EVR Resets and PORST

The PORST pin is a bidirectional reset in/output intended for external triggering of power-related resets. If this pin is left open then the default behavior shall be that the device remains in a reset state. If the PORST pin remains asserted after a power event then the reset will be extended until it is de-asserted. This does not replace the ESR pins functional reset.

### 9.1.2.6 Module Reset Behavior

**Table 245** lists how the various functions of the AURIX™ TC3xx Platform are affected by each reset type. An “X” means that this block has at least some register/bits that are affected by the corresponding reset.

**Table 245 Effect of Reset on Device Functions**

Module / Function	Application Reset	Debug Reset	System Reset	Warm “Power-on” Reset	Cold Power-on Reset
<b>CPUx<sup>1)</sup></b>	X	X	X	X	X

<b>Other</b>	Not affected, reliable	Not affected, reliable	Not affected, reliable	Not affected, reliable	Uninitialized

- 1) Lock-stepped checker cores are initialized to the same reset state as the main core to avoid comparator fails during start-up
- 2) Reliable here means that also the redundancy is not affected by the reset.
- 3) DSPR is partially used as a scratchpad by the startup firmware. Previous data stored can be overwritten on start-up. Please see firmware specification, chapter “RAM overwrite during start-up” for more detailed information. Initialization on reset can be optionally configured by DMU\_HF\_PROCONRAM.RAMIN and DMU\_HF\_PROCONRAM.RAMINSEL.
- 4) Depending upon DMU\_HF\_PROCONRAM.RAMIN and DMU\_HF\_RAMINSEL setting, these memories may be automatically erased on cold or warm resets.
- 5) Tag memories are invalidated by hardware at reset. Depending upon DMU\_HF\_PROCONRAM.RAMIN setting, cache content may also be automatically erased at reset (See MTU chapter for details).
- 6) Depending upon DMU\_HF\_PROCONRAM.RAMIN and LMUINSEL setting, these memories may be automatically erased on cold or warm resets. Initialization is disabled for DLMUs with standby capability if the standby is enabled.
- 7) HSM memories are accessible to the HSM module itself after application reset provided that access was already enabled prior to the reset. In this case the contents are reliable. In all other cases an automatic initialization will be triggered.

### 9.1.3 Reset Controller Functional Description

A reset is generated if an enabled reset request trigger is asserted. Most reset triggers can be configured to initiate different types of reset. No action (disabled) is a valid configuration which is selected by setting the corresponding bit field in the Reset Configuration Register to 00<sub>B</sub>.

## System Control Units (SCU)

A Debug Reset can only be requested by dedicated reset request triggers and can not be selected via a Reset Configuration Register . For more information see also register RSTCON.

### 9.1.3.1 Reset Generation

The figure below shows the RCU controlling the reset generation for the complete device, with the exception of the JTAG reset domain.

*Note:* The JTAG reset domain is controlled by the TRST pin.

The RCU detects the different reset requests, schedules a shutdown of the system, and then generates the appropriate internal reset pulse(s).

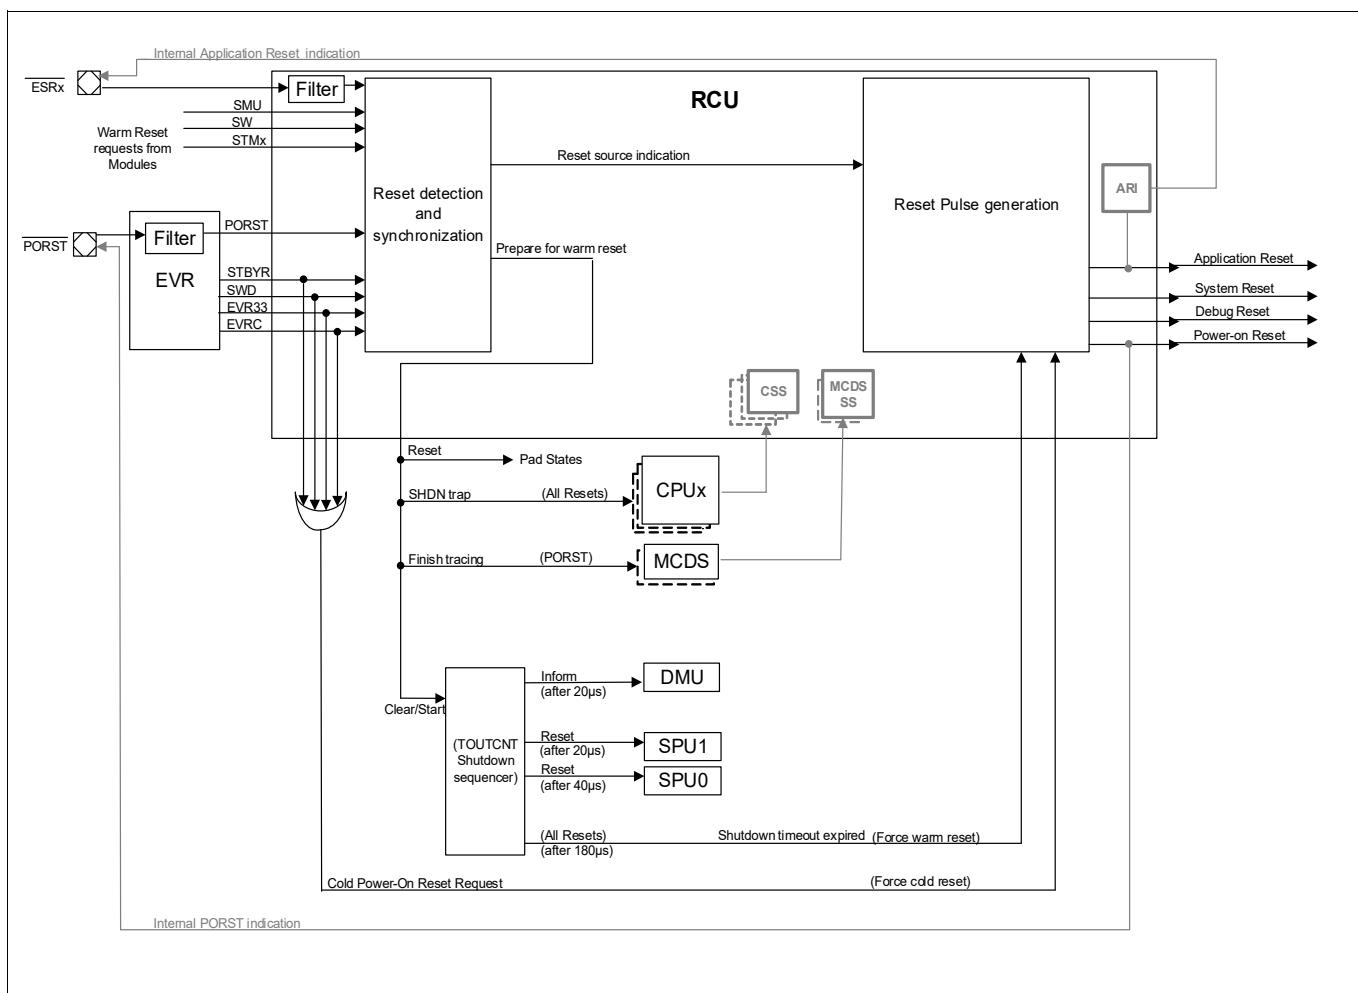

Figure 67 Reset Overview

### 9.1.3.2 Shutdown and Reset Delay Timeout Counter (TOUTCNT)

The system is automatically brought to a stable state before the internal reset(s) are applied so that the RAM content may be reliably reused after a warm reset and current jumps are controlled.

On detection of a warm Application Reset, System Reset or Power-On Reset trigger, the pads are put into their reset state and a Shutdown Trap request is sent by the RCU to the CPU(s). This request causes the CPU(s) which are not already in a halt or idle state to unconditionally execute an immediate ROM shutdown routine which executes a sequenced ramp-down of the device power consumption (to prevent current jumps which might trigger EVR reset). During this routine each CPU executes a WAIT instruction and stalls, to ensure that all ongoing

## System Control Units (SCU)

write transactions have been completed. Interrupts and NMI to the CPUs during the shutdown routine will not reawaken CPUs.

The internal reset starts when all relevant system modules are in the shutdown state. If timeout counter TOUTCNT exceeds a timeout period (180 microseconds) before the system become idle then the reset is started regardless. This timeout ensures that a reset would still occur in the case of an internal deadlock.

The RSTCON2.CSS bits indicate whether each CPU successfully flushed its write buffers and reached an idle state before the previous reset. These bits can therefore be used to determine whether RAM content integrity can be trusted after the previous reset cycle.

### 9.1.3.3 Reset Triggers

There are two types of reset triggers for the reset control logic:

- Triggers that lead to a specific reset
- Triggers that lead to a configurable reset

#### 9.1.3.3.1 Specific Reset Triggers

Assertion of these triggers leads to a predefined reset type. These triggers can not be enabled / disabled. All specific reset triggers are listed in [Table 246](#).

**Table 246 Specific Reset Triggers**

Reset Trigger	Reset Type Request
Cerberus 0 (CB0)	SystemReset
Cerberus 1 (CB1)	DebugReset
Cerberus 3 (CB3)	ApplicationReset
STBYR	Power-on Reset
SWD	Power-on Reset
EVRC	Power-on Reset
EVR33	Power-on Reset

#### 9.1.3.3.2 Configurable Reset Triggers

Assertion of these triggers leads to a configurable reset type. These triggers can be enabled / disabled. The result of the reset triggers is defined by the corresponding bit field in register RSTCON.

#### 9.1.3.3.3 Prevention of Double SMU Resets

The SMU can request a reset in response to an alarm. The type (Application or System Reset) is selected via register RSTCON.SMU. After boot firmware initialization, the default behaviour of the SMU/RCU is that a Watchdog timeout would result in an NMI followed by an Application Reset. If an SMU-induced Application Reset occurs twice, a severe system malfunction is assumed and the AURIX™ TC3xx Platform is held in permanent Application Reset until a Power-On or System Reset occurs. This prevents the device from being periodically reset if the application fails to service the watchdog correctly and the watchdog repeatedly times out.

An internal flag is set when the first SMU reset is requested. If a second reset is also requested by the SMU when the internal flag is already set, the double SMU reset event has occurred and a permanent reset request is automatically generated. This internal flag is only reset by a System Reset or when bit SMU\_WDTSCON1.CLRIRF is set and bit SMU\_WDTSCON0.ENDINIT has also been set. A correct service of the WDT does not automatically clear this flag.

## System Control Units (SCU)

If this behaviour is undesirable, then the CLRIRF bit should be written by the application during initialization (before the watchdog times out), to clear the flag and prevent any subsequent occurrence of a permanent reset.

**Note:** *If for any reason random code is executed bit field RSTCON.SMU can be updated unintentionally. This can result in an SMU alarm not leading to a reset. To avoid this after the SSW is finished this bit field should be checked and the Safety WDT ENDINIT protection enabled.*

### 9.1.3.4 Debug Reset Specific Behavior

For safety reasons it is required by the debugger that if the OCDS system is disabled a DebugReset is also asserted every time an Application Reset is asserted.

### 9.1.3.5 Module Resets

Many modules can be reset individually. The module reset has no effect outside the module itself. A module reset can only be triggered by writing ‘1’ into both of the module reset registers MOD\_KRST1.RST and register MOD\_KRST0.RST.

The Module Reset register bits may only be written by those masters which have been explicitly configured to have module access (See module ACCEN register). In addition, it is only possible to write to these reset bits during the short time window after a correct ENDINIT password unlock sequence (See Watchdog chapter for details). This prevents accidental module resets by rogue software.

The table below shows the modules which have Module Reset capability

**Table 247 Module Resets**

Module	Module Reset capability
CANx	Module reset implemented in CAN
ASCLINx	Module reset implemented in ASCLIN
GTM	Module reset implemented in GTM
ERAYx	Module reset implemented in ERAY
QSPIx	Module reset implemented in QSPI
HSSL	Module reset implemented in HSSL
ETHERMAC	Module reset implemented in ETHERMAC
MSCx	Module reset implemented in MSC
SENTx	Module reset implemented in SENT
VADC	Module reset implemented in VADC
EDSADC	Module reset implemented in EDSADC
SCR	Module reset implemented in PMS (PMSWCR1.SCRSTREQ)
CCU6	Module reset implemented in CCU6
GPT12	Module reset implemented in GPT12
STMx	Module reset implemented in STMx
PSI5	Module reset implemented in PSI5
PSI5-S	Module reset implemented in PSI5-S
DMA	Per channel reset implemented in DMA
SCU, RCU, PMS, CCU	No module reset capability
PMU, Flash	No module reset capability

## System Control Units (SCU)

**Table 247 Module Resets (cont'd)**

Module	Module Reset capability
LMU	No module reset capability
POTS	No module reset capability
IR	No module reset capability
IOM	Module reset implemented in IOM
HSM	No module reset capability
I2Cx	Module reset implemented in I2C
CPUx	Individual CPU reset capability
SPU	Module reset implemented in SPU
RIF	Module reset implemented in RIF
HSPDM	Module reset implemented in HSPDM
FCE	Module reset implemented in FCE
SDMMC	Module reset implemented in SDMMC

### 9.1.3.5.1 CPU Module Resets

A CPU Module reset has the same effect on an individual CPU as an Application Reset, but without a full reinitialization of other system elements outside the CPU

- CPU0 - Jumps to application start after a Module Reset
- Other CPUs - Wait in HALT mode after Module Reset

The CPUx\_KRST.STATUS registers can be used to determine whether the last CPUx reset was caused by a Module Reset or a chip-level reset. It is recommended that this register should be cleared by the application after reading. See CPU and Start-Up Chapters for more details.

### 9.1.3.6 Reset Controller Registers

#### 9.1.3.6.1 Status Registers

After a chip level reset has been executed, the Reset Status registers provide information on the trigger of the last reset(s). Warm reset status bits are updated upon each reset cycle. A reset cycle is finished when all resets are deasserted. Within a reset cycle the status flags are used as sticky flags. Module level resets have no effect on the Reset Status register. Bits which may indicate a cold reset trigger (STBYR, SWD,EVR33, PORST and EVRC and ) provide useful information to the application and are not cleared automatically. The application may clear these bits by writing to bit RSTCON2.CLRC.

*Note:* All bits of this register are implemented in the IP. The product specific names are purely defined by the product integration.

## Software Reset Configuration Register

This register controls the SW Reset operation.

As for other kernel registers, write access to the SWRSTCON register is configurable via SCU\_ACCENO and additionally is temporally restricted by ENDINIT. These restrictions can be used to provide protection against accidental reset by unauthorised CPUs or system bus masters.

### SWRSTCON

Software Reset Configuration Register (0060<sub>H</sub>) Reset Value: [Table 250](#)

## System Control Units (SCU)

### 9.1.4 External Reset Sources and Indications

ESR interface pins are provided to give an external indication of internal resets, and to provide a mechanism for external sources to trigger internal resets:

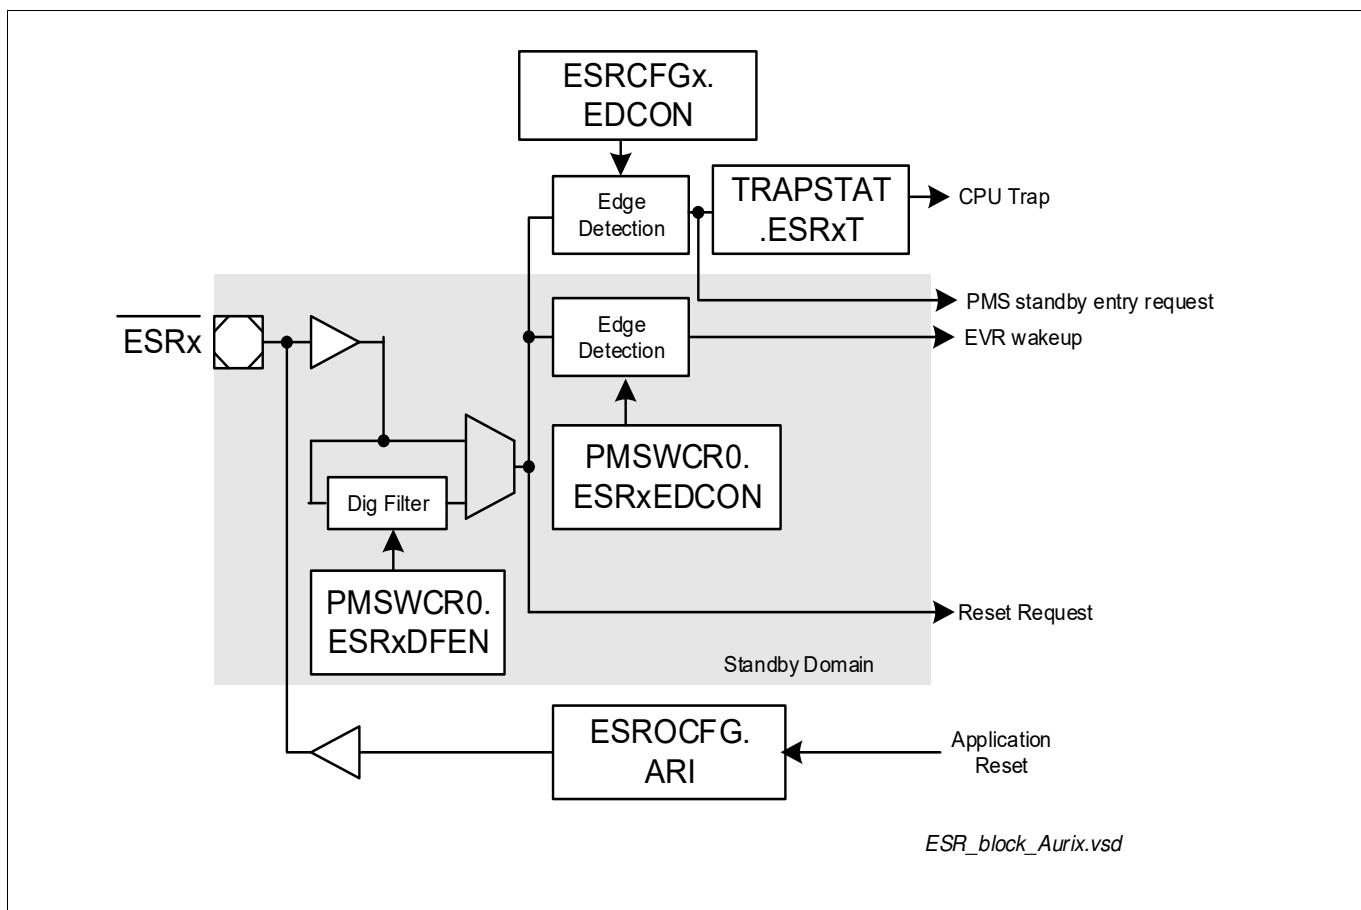

#### ESR pin functions

- Reset request trigger
- Wakeup trigger
- Reset indication output
- Trap request trigger

#### 9.1.4.1 External Service Requests (ESRx)

The ESR pins can be used in various ways:

- ESR inputs can trigger a reset
- ESR outputs can provide a reset indication
- ESR inputs can trigger a trap request
- ESR pins can be used as general data I/O pins
- ESR inputs can trigger a wake-up from standby mode

**Figure 68 ESR Operation**

## System Control Units (SCU)

### 9.1.4.1.1 ESRx as Reset Request Trigger

An ESR0/ESR1 pin reset request trigger can lead to a System or Application Reset. The type of the reset is configured via RSTCON.ESRx.

The input signals ESR0/ESR1 can be filtered. The filter can be disabled by register bit PMSWCR0.ESRxDFEN.

If the digital filter is enabled then pulses less than 30 ns cannot trigger a reset and pulses longer than 100ns will always result in a trigger..

The port pin behavior of ESR0/ESR1 pins can be configured by programming registers ESRCFG0/1.

The pad control functionality can be configured independently for each pin. The configuration comprises:

- Selection of driver type (open-drain or push-pull)
- Enable of the output driver (input and/or output capability)
- Enable of internal pull-up or pull-down resistance

By default at reset ESRx pads have pull-ups (but during LBIST the ESRx pin is changed to a weak pull-down)

### 9.1.4.1.2 ESRx as Reset Output

The external pins ESR0/ESR1 can provide a reset output indication (open drain) for Application Resets .

Register ESROCFG.ARI determines the output of the ESR pin(s) when one or more are configured as functional reset outputs. ARI is set automatically when any Application Reset starts and cleared by Boot or Application software (Note that an Application Reset also occurs on a System Reset or Power-On Reset). While the ARI bit is set, the configured ESR pin(s) drive active low. A subsequent write to ESROCFG.ARC clears the ARI bit, which deasserts the ESR output(s). The exact duration of the ESR pulse is determined by the value of the Flash Config Sector setting “ESR0CNT” which is copied by Boot Code into DMU\_HF\_PROCONDF.ESR0CNT on a cold power-on reset. The effect of this value is shown in **Table 253**. When the same ESR pin is configured as a PORT output, its state can instead be controlled directly by application software so that the application has the possibility to reset external devices.

**Table 253 ESRx Reset Indication Options**

ESR0CNT value	ESR Reset Indication Behaviour
0000 0000 <sub>H</sub>	ESR0 de-asserted as soon as possible after start of Boot Code execution
> 0000 0000 <sub>H</sub> and < FFF <sub>H</sub>	ESR0 de-asserted after programmed delay (by Boot Code). Boot Code may be extended and Application start may be delayed if programmed delay exceeds the normal Boot Code execution time. Programmed delay is ESR0CNT * 10 microseconds
FFF <sub>H</sub>	ESR0 not de-asserted by Boot Code. Application code must de-assert ESROCFG.ARI bit or PORT output to de-assert ESRx pin(s).

An external device may extend an existing reset condition by holding the ESR pin active.

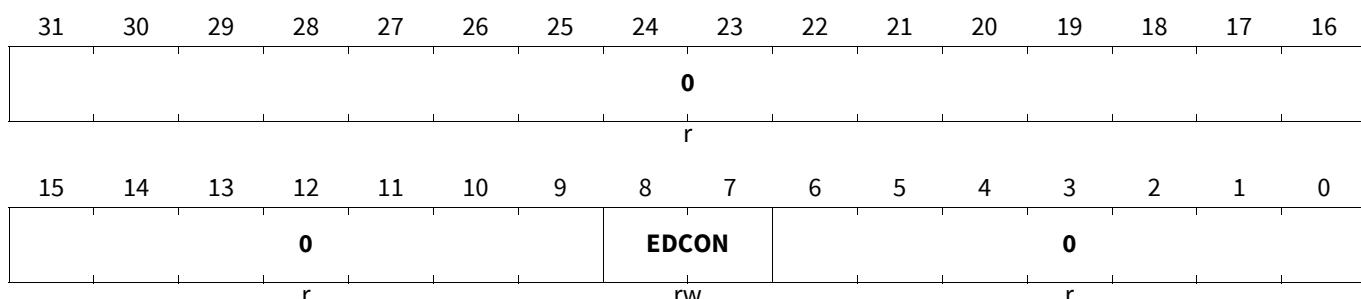

## System Control Units (SCU)

### 9.1.4.1.3 ESR Registers

#### ESRx Input Configuration Register

**ESRCFGx (x=0-1)**

**ESRx Input Configuration Register (0070<sub>H</sub>+x\*4)** **System Reset Value: 0000 0100<sub>H</sub>**

## System Control Units (SCU)

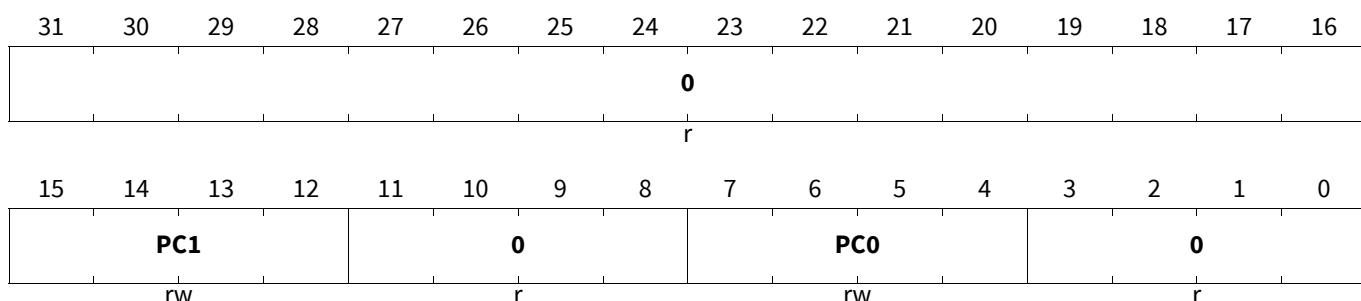

### Input/Output Control Register

The input/output control registers select the digital output and input driver functionality and characteristics of the pin. Direction (input or output), pull-up or pull-down devices for inputs, and push-pull or open-drain functionality for outputs can be selected by the corresponding bit fields PCx (x = 0-1).

### Input/Output Control Register

#### IOCR

**Input/Output Control Register (00A0<sub>H</sub>) System Reset Value: 0000 XOE0<sub>H</sub>**

Field	Bits	Type	Description
<b>PC0</b>	7:4	rw	<b>Control for ESR0 Pin</b> This bit field defines the ESR0 functionality according to the coding tables.
<b>PC1</b>	15:12	rw	<b>Control for ESR1 Pin</b> This bit field defines the ESR1 functionality according to the coding tables. The reset value of SCU_IOCR.PC1 is influenced by HWCFG6 and PMSWCR5.TRISTREQ. When a cold reset is activated and HWCFG6=1 then PC1 is reset to 2H and ESR1 will have input pull-up mode. If HWCFG6=0 then PC1 is reset to 0H and ESR1 will have tri-state mode. PC1 and the ESR1 reset state can also be configured by software with the PMSWCR5.TRISTREQ bit. PMSWCR5.TRISTREQ is not affected by warm reset or wake-up from standby so the IOCR.PC1 reset value is configured as per the state of the TRISTREQ bit prior to the warm reset
<b>0</b>	3:0, 11:8, 31:16	r	<b>Reserved</b> Read as 0; should be written with 0.

## System Control Units (SCU)

### Pad Control Coding

**Table 254** describes the coding of the PC0 bit field that determine the port line functionality.

**Table 254 PC0 Coding**

PC0[3:0]	I/O	Output Characteristics	Selected Pull-up/Pull-down/ Selected Output Function

## System Control Units (SCU)

### ESR Output Register

The output register determines the value of a GPIO pin when it is selected by IOCR as output. Writing a 0 to a OUT.Px (x = 0-1) bit position delivers a low level at the corresponding output pin. A high level is output when the corresponding bit is written with a 1. Note that each single bit or group of bits of OUT.Px can be set/cleared by writing appropriate values into the output modification register OMR.

### ESR Output Register

#### OUT

#### ESR Output Register

(00A4<sub>H</sub>)System Reset Value: 0000 0000<sub>H</sub>

Field	Bits	Type	Description
Px (x=0-1)	x	rwh	<b>Output Bit x</b> This bit determines the level at the output pin <u>ESRx</u> if the output is selected as GPIO output. Px can also be set/cleared by control bits of the OMR register. 0 <sub>B</sub> The output level of <u>ESRx</u> is 0 1 <sub>B</sub> The output level of <u>ESRx</u> is 1
0	31:2	r	<b>Reserved</b> Read as 0; should be written with 0.

## System Control Units (SCU)

### ESR Output Modification Register

The output modification register contains control bits that make it possible to individually set, clear, or toggle the logic state of a single pad by manipulating the output register.

### ESR Output Modification Register

#### OMR

#### ESR Output Modification Register

(00A8<sub>H</sub>)

System Reset Value: 0000 0000<sub>H</sub>

## System Control Units (SCU)

### 9.1.5 Boot Software Interface

In order to determine the correct starting point of operation for the software a minimum amount of hardware support is required. As much as possible is done via software. Some decisions have to be made in hardware because they must be known before any software is operational.

For a startup operation there are two general cases that have to be handled:

- Differentiation between Test Mode and Normal Mode for each Power-on Reset event (see [Section 9.1.5.1](#))
- Configuration of the boot option for each Application Reset event (see [Section 9.1.5.2](#))

#### 9.1.5.1 Configuration done with Start-up

At device power-on some basic operating mode selection has to be done. The first decision that has to be made is whether the device should operate in Test Mode or in Normal (Customer) Mode. The Test Mode is only for Infineon internal device testing, it is not intended for any customer and is not related to debug.

If the Normal Mode was selected the next decision is which debug interface type issued for debugging for this session (until the next power-on event).

**Table 257 Normal Mode / Test Mode Input Selection**

Field	Description
<b>TESTMODE</b>	<b>Latched TESTMODE Signal</b> 0 A Test Mode can be selected 1 Normal Mode is selected
<b>TRST</b>	<b>Latched TRST Signal</b> 0 The JTAG interface is active. 1 The DAP interface is active.

After these two decisions were made the detailed decision has to be made to define the real startup configuration. Most is made via the software and can be supported by some hardware selections depending on the startup configuration that should be selected.

#### 9.1.5.2 Start-up Configuration Options

The states of the HWCFG port pin inputs are latched on the rising edge of an Application Reset and stored in register STSTAT.HWCFG. The update of bit field STSTAT.HWCFG with the latched value is only done if bit STSTAT.LUDIS is cleared. If bit STSTAT.LUDIS is set then the value of STSTAT.HWCFG is not updated.

## System Control Units (SCU)

## System Control Units (SCU)

### 9.2 Trap Generation (TR)

The trap structure is shown in [Figure 69](#). A trap request trigger or the corresponding trap set bit (in register TRAPSET) can set flag bits in TRAPSTAT. Register bits in TRAPDIS[0:1] determine which CPUs shall receive traps from each TRAPSTAT trigger flag. By default after reset a trap is issued simultaneously to all CPUs. The TRAPSTAT trap flag can be cleared by software by writing to the corresponding bit in register TRAPCLR.

#### 9.2.1 Feature List

- CPU Traps may be triggered by transitions on ESRx pins or in response to a Safety Alarm
- CPU Trap trigger events are captured in a status register
- It is possible to generate or remove captured CPU Trap trigger events by software
- It is possible to disable or enable individual CPU Trap trigger events for individual CPUs

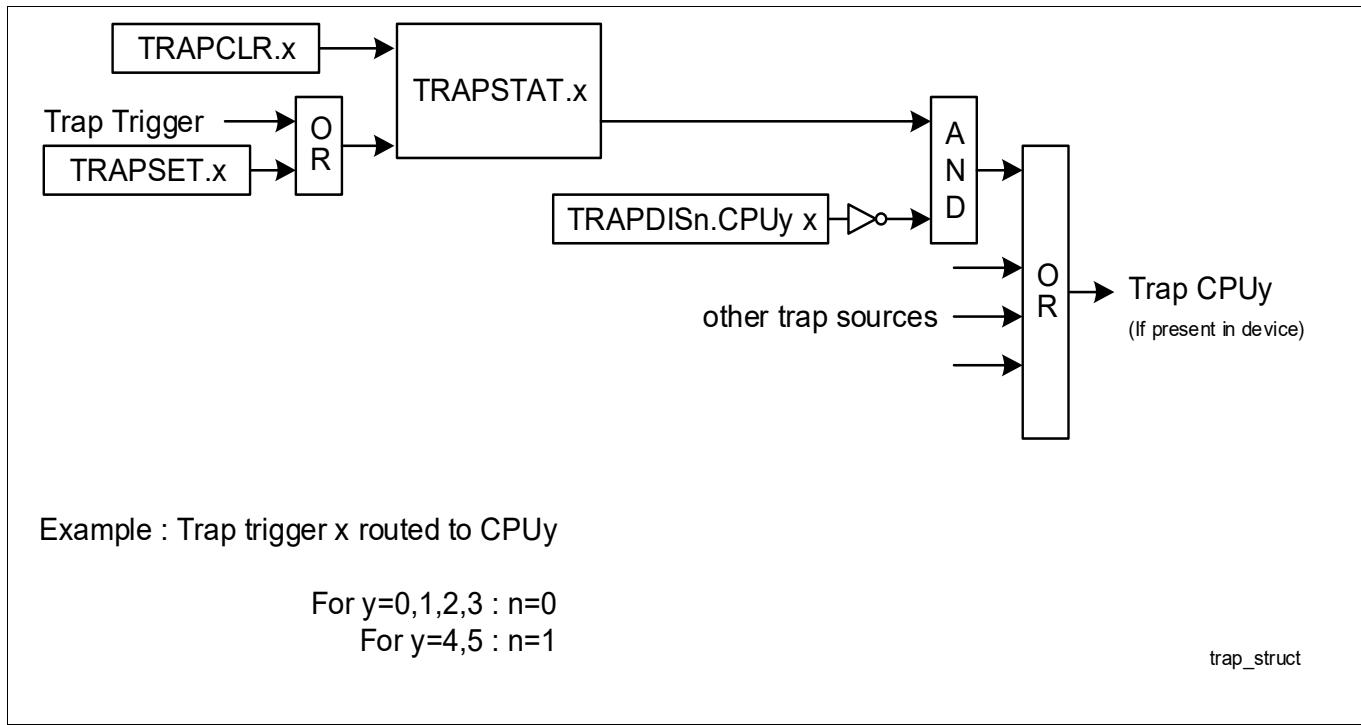

This module has the same basic features and functionality in all TC3xx devices although in some devices fewer CPUs may be available.

##### 9.2.1.1 Delta to AURIX

The TC3xx trap concept is based upon the trap concept of the TC2xx product range. The most significant change is:

- **TRAPDIS0** allows masking of trap types for individual CPUs (Similar **TRAPDIS1** added for additional CPUs)

#### 9.2.2 Trap Handling

**Figure 69 CPU Trap Generation**

As a trap is generated while the trap source is enabled AND the trap status flag is set, it is recommended to clear the trap status flag via TRAPCLR before a trap source is enabled in TRAPDISn. The trap status flag can be set

---

## System Control Units (SCU)

before the trap source is enabled and simply enabling the trap source can result in unintended CPU traps. At the end of a trap handling routine the trap status flag should be cleared.

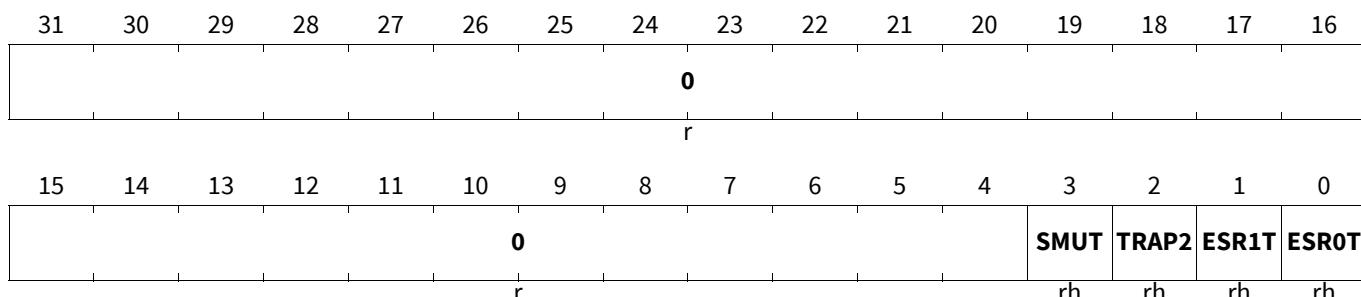

## System Control Units (SCU)

## System Control Units (SCU)

### 9.3 System Register Unit (SRU)

The System Register Unit (SRU) contains miscellaneous control registers associated with various system functions.

#### 9.3.1 Feature List

This module contains control/status registers associated with various other functions/blocks:

- Lockstep control/status (for LCLx)
- LBIST control (for TCU)
- Overlay control (for CPUx)
- Start-up storage registers (for Boot SSW)
- Clock System control (for the Clock System configuration)

This module contains the same registers in all TC3xx products.

Some of the registers may be “reserved” in some products due to missing functionality or modules.

The functional groups of registers are as follows:

- CPU Lockstep Comparator Logic registers (LCL) (see [Section 9.3.2](#))
- Logic Built-in-Self-Test registers (LBIST) (see [Section 9.3.3](#))
- Clock System Control registers (see [Section 9.3.4](#))
- Overlay Control registers (OVC) (see [Section 9.3.5](#))
- Other registers (see [Section 9.3.6](#))

#### 9.3.1.1 Delta to AURIX

The most significant changes between the TC2xx SCU and TC3xx SRU are:

- Name change for clarification: SRU is a sub-module of the SCU cluster
- Structural repartitioning of SCU module with no impact on SW
- Added the LBIST description
- Some registers are now SE protected

### 9.3.2 Lockstep Comparator Logic Configuration

This section contains the registers which are used to configure and enable CPU Lockstep Mode. These registers are only writeable by start-up firmware and are configured by the BMI . See the Firmware and Lockstep Comparator Logic chapters for further details.

#### 9.3.2.1 Lockstep Comparator Logic Control Registers

##### LCL CPU0 and CPU2 Control Register

Provides control for CPU0and CPU2 Lockstep Comparator Logic blocks.

## System Control Units (SCU)

### 9.3.3 LBIST Support

AURIX™ TC3xx Platform supports automatic and user-triggered Logic Built-In Self-Test (LBIST) execution. Sub-sections below provide LBIST functional description and control registers for LBIST execution control and status.

#### 9.3.3.1 Introduction

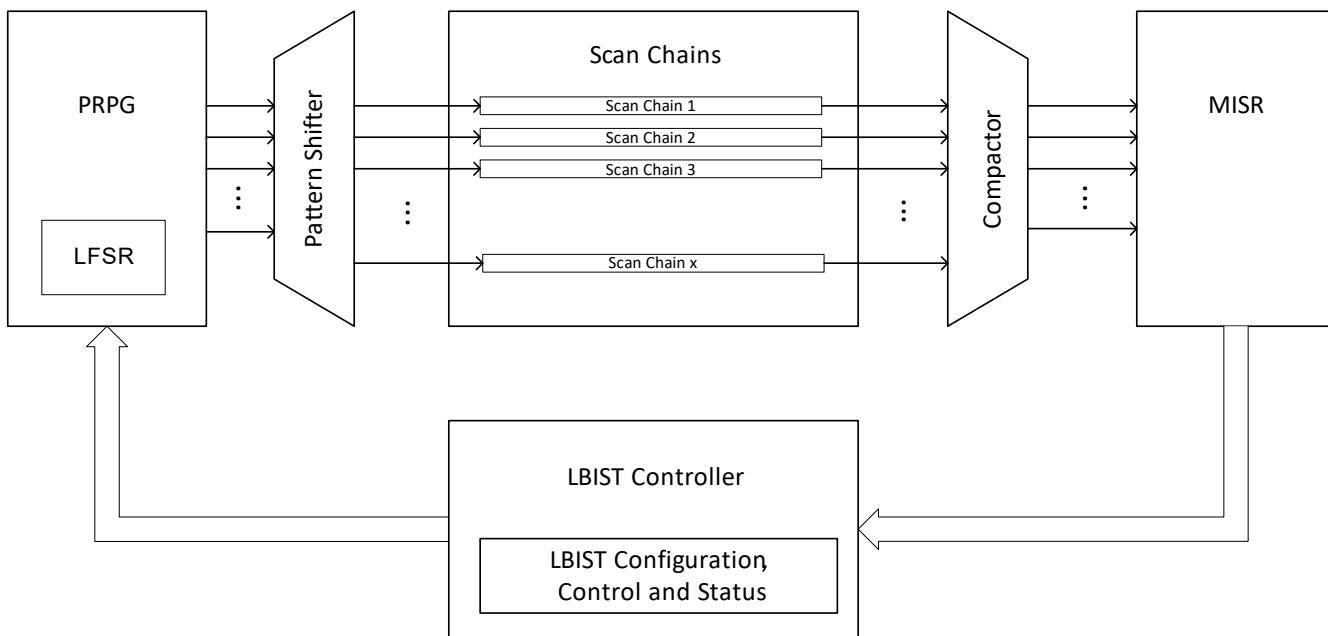

The LBIST is an on-chip hardware mechanism that can be used to detect MCU latent faults. The LBIST implementation in the AURIX TC3xx Platform allows to execute periodic self-tests for the MCU logic. The execution of the LBIST in MCU application mode is based on the DFT structures implemented for production testing and thus reusing scan chains, control and status mechanisms already available in MCU. There are two configurable ways to start LBIST execution: as a part of boot-up sequence or by application software in MCU functional mode. The results of LBIST execution are provided in LBIST result and status registers and can be used by application software to reach MCU safe state in case of detected latent faults.

#### 9.3.3.1.1 Functional Description

The Logic-BIST function is a structural test method for automatic in-system health-check of the digital design part. LBIST schemes use on-chip circuitry to generate test stimuli and analyze test responses, without any help from an chip-external test system. **Figure 70** depicts the TC3xx Platform LBIST architecture.

All the digital logic of the device with two exceptions is covered by LBIST. The two exceptions are:

- Logic in Power Management System, linked to the EVR and Standby Controller
- A part on the test control unit (including the LBIST controller)

**Figure 70 LBIST Architecture**

The LBIST structure applies pseudo-random patterns generated by a PRPG (Pseudo-Random Pattern Generator) to a full-scan circuit in parallel and compacts the test responses into a signature with a MISR (Multiple-Input Signature Register).

After LBIST execution has been successfully initiated from system-side (**LBISTCTRL0**, **LBISTCTRL1**, **LBISTCTRL2** registers), the whole design is switched into scan-mode. Afterwards the LBIST controller starts LBIST execution according to the configuration data (e.g. number of scan-loads, execution-speed or seed).

## System Control Units (SCU)

A Pseudo-Random Pattern Generator (PRPG) module is implemented to generate patterns to be shifted through scan-chains. The PRPG generates pseudo-random patterns using a Linear Feedback Shift Register (LFSR).

These patterns are loaded into the design through the scan-chains. In this case the core flip-flops are not operated in their functional mode but are organized in chains to allow a serial shift of these pseudo-random patterns into the complete MCU digital design. A specific shift counter keeps track of the number of shift-cycles to issue for each pattern.

The LBIST shift controller also uses the shift counter to separate the shift cycles from the capture cycles. Once a random pattern has been completely loaded into the digital logic scan-chains, the LBIST controller generates a single capture cycle.

In this case the flip-flops are switched back from serial scan-chain mode to their normal functional behavior, thus allowing to capture an actual state of the combinational logic.

The number of executed scan loads is selectable by software through the **LBISTCTRL0.PATTERNS** field. This field must be set before starting LBIST execution. The LBIST shift controller keeps track of how many patterns have been driven through the core and automatically stops the LBIST run when the programmed **LBISTCTRL0.PATTERNS** value has been reached.

During serial scan-chain shift cycles the outputs of the core flip-flop-chains are compressed through a XOR-gate network implemented in the Compactor module and permanently monitored through the MISR block, which generates a unique MISR signature. This signature allows application software to check if the MCU was tested by LBIST with or without errors.

The LBIST controller will automatically put the MISR into a static hold condition during loading of the first pseudo-random pattern into the scan-chains. This prevents the uninitialized values that are in the scan-chains prior to loading the first pattern from corrupting the MISR signature.

After LBIST execution is finished the MISR signature can be read out through the **LBISTCTRL3.SIGNATURE** field. Its value is only valid if **LBISTCTRL0.LBISTDONE** bit indicates a high value (i.e. LBIST run successfully terminated).

LBIST execution always terminates with an system warm reset, with an exception for the startup software that receives a cold reset (PMS/EVR settings of the startup software are not affected by this cold reset).

Therefore application software shall check if the LBIST execution was properly terminated and not interrupted by a PORST reset. The SCU.RSTSTAT register contains two status bits which capture LBIST termination status: RSTSTAT.LBPORST and RSTSTAT.LBTERM. The RSTSTAT.LBPORST status bit indicates if LBIST execution was terminated earlier due to a PORST assertion. If the status of this bit field is 0, the application must still check the RSTSTAT.LBTERM to check if the LBIST was terminated properly. The RSTSTAT.LBTERM stores the status if the LBIST execution was terminated properly.

A successfully finished LBIST procedure is indicated by the **LBISTCTRL0.LBISTDONE** bit. Value of **LBISTCTRL0.LBISTDONE** bit is not affected by the System or Application reset (it preserves its value). In case of warm or cold power-on reset, it resets LBISTDONE bit to 0, and soon after, if LBIST is configured to start, it will get its new result value.

The possible LBIST configuration options are located in the **LBISTCTRL0**, **LBISTCTRL1**, **LBISTCTRL2** registers.

The **LBISTCTRL0.PATTERNS** field defines the LBIST pattern count (i.e. number of scan-loads) which will be executed during LBIST procedure.

The value programmed to the **LBISTCTRL0.PATTERNS** field determines the number of scan-capture phases and not the number of scan-chain load/unload phases: a value of 0x00001 will result in two scan-chain loads with one capture in-between; a value of 0x00002 will result in 3 scan-chain loads with 2 captures, etc.). Consequently a value of 0x00000 is not valid, because no capture would be executed in this case.

## System Control Units (SCU)

The LBIST execution speed (i.e. shift-frequency) can be influenced through **LBISTCTRL1.LBISTFREQU** field.

In principle the LBIST Controller is operating on base of a 100MHz oscillator, whose output frequency can be scaled down by an integer value between 1 to 16 (determined through **LBISTCTRL1.LBISTFREQU** value).

A value of 3 or higher is recommended for a stable LBIST execution: 3=33MHz, 4=25MHz, 5=20MHz, ...,16=6,25MHz. Values 1 and 2 are not to be used for a stable LBIST: execution1=100MHz[not to be used], 2=50MHz[not to be used].

The generation of pseudo-random patterns by the PRPG can be influenced through the LBIST Seed option determined by **LBISTCTRL1.SEED** field.

This allows to vary the data-sequence, which is provided by the PRPG as input source for the core scan-chains.

In this way several LBIST runs with varying pattern sequences are possible. This allows to execute multiple time-sliced LBIST sequences with comparable test-coverage results as would be achieved in case of a single long running LBIST procedure.

The static GPIO behavior during LBIST-execution is selectable through the **LBISTCTRL1.BODY** bit.

Here the selection between tri-state (**LBISTCTRL1.BODY='1'**) and a weak pull-up (**LBISTCTRL1.BODY='0'**) behavior is possible.

As a rule all GPIO output drivers and input Schmitt-Triggers stay permanently disabled during LBIST-execution in order to isolate the device from the application-system.

The on-chip power consumption during LBIST-execution can be influenced through the **LBISTCTRL1.SPLITSH**-field. As a default all scan-chains are shifted concurrently during LBIST operation (**LBISTCTRL1.SPLITSH=0x0**), which can cause resulting power consumption exceeding the one of the maximum power pattern.

*Note:* Please check the LBIST power jump and execution time parameters with defined configurations in the device datasheet.

This might cause stability problems in certain application environments depending on the general supply strategy.

If power related stability problems should occur during LBIST execution it is possible to divide the core scan-chains either into two (**LBISTCTRL1.SPLITSH=0x5**) or four (**LBISTCTRL1.SPLITSH=0x4**) partitions, which are then shifted sequentially.

As a consequence the LBIST execution time will increase by a factor of 2 respectively a factor of 4.

To start a LBIST operation the **LBISTCTRL0.LBISTREQ** and **LBISTCTRL0.LBISTREQRED** bits must be written high. However a new LBIST sequence will only start if the **LBISTCTRL0.LBISTDONE** bit is reflecting a low value (i.e. no LBIST was executed since last power-on-reset).

The high value of **LBISTCTRL0.LBISTDONE** bit is an indication that the LBIST operation terminated normally and the SIGNATURE value is ready for readout.

Once this **LBISTCTRL0.LBISTDONE** bit is set to high, its value can be changed back to low by setting the **LBISTCTRL0.LBISTRES** bit to '1': this will reset **LBISTCTRL3.SIGNATURE** of the previous run and clear **LBISTCTRL0.LBISTDONE** status bit.

### LBIST Functional Safety Aspects

In order to fulfill ASIL-D safety standards the MCU must indicate any unintended states of LBIST-control block or of general test-mode enabling signals to the Application Software. For that purpose two alarm signals are implemented:

## System Control Units (SCU)

- LBIST-Alarm: This alarm signal shall be activated if the LBIST-FSM is NOT in the Reset/Idle state or if some global LBIST-enable signals are active. Consequently LBIST-alarm-signal is always active during LBIST execution.
- Test-Mode-Alarm: This alarm signal is activated if any of the TCU's general test-mode enabling signals are in unintended active state. Consequently Test-Mode-Alarm signal is always active if the MCU is operating in general test-mode.

Application software can trigger both listed above Alarms through error injection. For that purpose LBIST provides a single control bit in **LBISTCTRL0.LBISTERRINJ** to trigger LBIST-Alarm and Test-Mode-Alarm to SMU module.

To address unintended LBIST execution failure mode, the redundant LBIST request bit is implemented in the **LBISTCTRL0**. To start a LBIST operation the **LBISTCTRL0.LBISTREQ** and **LBISTCTRL0.LBISTREQRED** bits must be written high

### 9.3.3.2 LBIST Control Register

The LBISTCTRL Control Register provides the link between software and the LBIST-controller.

#### Logic BIST Control 0 Register

**LBISTCTRL0**

**Logic BIST Control 0 Register (0164<sub>H</sub>) Reset Value: Table 260**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
<b>LBIST REQR ED</b>	<b>LBIST ERRIN J</b>	0	<b>LBIST DONE</b>				0								<b>PATTERNS</b>
rw	rwh	r	rh				r								rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
														<b>LBIST RES</b>	<b>LBIST REQ</b>
														w	w

Field	Bits	Type	Description
<b>LBISTREQ</b>	0	w	<p><b>LBIST Request</b></p> <p>If written high this bit requests the execution of an automatic scan-test procedure. The request will only be approved if <b>LBISTCTRL0.LBISTDONE</b> bit reflects a '0'-value (i.e. no LBIST-procedure was triggered since the last power-on-reset or LBIST-controller has been restarted through the <b>LBISTCTRL0.LBISTRES</b>-bit). If read this bit always returns a '0'.</p> <p>This bit shall be implemented in a safety-relevant way to avoid unintended activation of LBIST during application.</p> <p><i>Note:</i> LBIST execution time depends on the number of scan-loads as defined in the PATTERNS field.</p>

## System Control Units (SCU)

Field	Bits	Type	Description
<b>LBISTRES</b>	1	w	<p><b>LBIST-Reset- LBISTRES</b> If written high this bit synchronously brings back the LBIST-controller to its initial Reset/Idle-state and also clears the stored MISR-signature to allow another execution from CPU-side. As a consequence the <b>LBISTCTRL0.LBISTDONE</b>- and SCU_LBISTCTRL3.SIGNATURE-bits will be set to '0'. If read this bit always returns a '0'.</p> <p><b>Note:</b> <i>It is strongly recommended to not change the LBISTFREQ parameter in LBISTCTRL1 after this bit has been set to '1', because there is no guarantee that the new frequency parameter value will be transferred to the LBIST-controller in-time before the next LBIST-run is started from user-side (i.e. LBISTCTRL0.LBISTREQ is set to '1').</i></p>
<b>PATTERNS</b>	19:2	rw	<p><b>LBIST Pattern Number</b> This field defines the number of scan-patterns (i.e. scan-loads), which will be executed during the LBIST-procedure. Please note that the value programmed to this field determines the number scan-capture phases not the number of scan-chain load/unload phases (i.e. a value of 0x00001 will result in two scan-chain loads with one capture in-between; a value of 0x00002 will result in 3 scan-chain loads with 2 captures, etc.). Consequently a value of 0x00000 is not valid, because no capture would be executed in this case.</p>
<b>LBISTDONE</b>	28	rh	<p><b>LBIST Execution Indicator</b> This bit indicates the actual LBIST-controller execution status:</p> <ul style="list-style-type: none"> <li>0<sub>B</sub> No LBIST executed since last power-on-reset or LBIST-controller has been restarted (via <b>LBISTCTRL0.LBISTRES</b> function). Values in SCU_LBISTCTRL3.SIGNATURE-field are all set to '0'.</li> <li>1<sub>B</sub> At least one LBIST-procedure successfully finished since last power-on-reset. Values in SCU_LBISTCTRL3.SIGNATURE-field reflect the resulting MISR-signature.</li> </ul>
<b>LBISTERRINJ</b>	30	rwh	<p><b>LBIST / Test-Mode Alarm Error Injection</b> If written high this bit triggers both, the LBIST- and the test-mode-alarm. This is required to allow self-testing of all LBIST-(and test-mode-)related safety mechanisms in the TCU. The bit will be reset automatically once the LBIST and test-mode alarm indicator signals from TCU are asserted. From these indicator signals SCU will also generate corresponding alarm trigger signals for SMU.</p>
<b>LBISTREQRED</b>	31	rw	<p><b>LBIST Request Redundancy</b> This bit represents the safety double of LBISTCTRL0.LBISTREQ. In order to generate a new LBIST request both, LBISTREQRED and LBISTREQ bits must be set to high due to safety reasons. The request will only be approved if LBISTCTRL0.LBISTDONE bit reflects a '0'-value. If read this bit always returns a '0'.</p>
<b>0</b>	27:20, 29	r	<p><b>Reserved</b> Read as 0; should be written with 0.</p>

### 9.3.4 Clock System Control registers

The Clock System Control registers are implemented in the SRU and the SCU SPB bridge is used to access all of these registers. Nevertheless the register description is present in the specific Clock System chapter.

Please address the Clock System Chapter for a complete description of these registers.

## System Control Units (SCU)

### 9.3.5 Global Overlay Controls

The following registers control the Global Overlay functionality.

Overlay functionality is described in more detail in the CPU Overlay Subchapter.

Two registers globally control the overlay operation for all CPUs:

- Overlay Enable Register OVCENABLE disables or enables data access overlay individually for each CPU.
- Overlay Control Register OVCCON can be used to perform the following actions on a selected set of CPUs:
  - concurrently enable / disable selected overlay blocks,
  - concurrently disable overlay blocks,
  - invalidate data cache.

All overlay control registers are reset to their default values with the Application Reset . A special debug reset is not considered.

The external overlay feature is not available in product variants offering ADAS functionality.

## System Control Units (SCU)

Field	Bits	Type	Description
<b>OVCONF</b>	24	rw	<p><b>Overlay Configured</b></p> <p>Overlay configured status bit</p> <p>This bit may be used as handshake bit between a debug device (via JTAG interface and Cerberus) and CPU(s).</p> <p>0<sub>B</sub> Overlay is not configured or it has been already started</p> <p>1<sub>B</sub> Overlay block control registers are configured and ready for overlay start</p>
<b>POVCONF</b>	25	w	<p><b>Write Protection for OVCONF</b></p> <p>This bit enables OVCONF write during OVCCON write. Return 0 if read.</p> <p>0<sub>B</sub> OVCONF remains unchanged.</p> <p>1<sub>B</sub> OVCONF can be changed with write access to register OVCCON</p>
<b>0</b>	15:6, 23:19, 31:26	r	<p><b>Reserved</b></p> <p>Read/write 0.</p>

- 1) Dirty (modified) cache lines are not effected by this operation. If data cache contains modified data, it is not invalidated, and has to be written-back and invalidated by the user. Therefore, it is highly recommended to either: access overlaid data in read-only mode, or use only non-cached access.

## System Control Units (SCU)

### 9.3.6 Miscellaneous System Control

This section collects different registers that serve various system purposes.

#### 9.3.6.1 System Control Register

##### System Control Register

###### SYSCON

<b>0</b>	1, 5, 6, 31:16	r	<b>Reserved</b> Read as 0

## System Control Units (SCU)

### 9.3.6.2 Identification Registers

#### Chip Identification Register

The CHIPID register can be used to determine the sales part number of the device (See Product Datasheet).

In general, the part number is of the form SAx-TC3yzab-ccFddd bc, where:

- CHIPID.CHID = Device Series Class (y)
- CHIPID.CHPK = Package Class (z)
- CHIPID.SEC = Feature Option (HSM enable, derived from b)
- CHIPID.EEA = Feature Option (Emulation part enable, derived from b)
- CHIPID.FSIZE = Flash size (derived from c)
- CHIPID.VART is used to differentiate any other marking options or special variants (e.g. Non-standard Temperature Range (x), Frequency (d) or Package Pitch (e) as defined in the Product Datasheet.

#### CHIPID

#### Start-up Memory Register 6

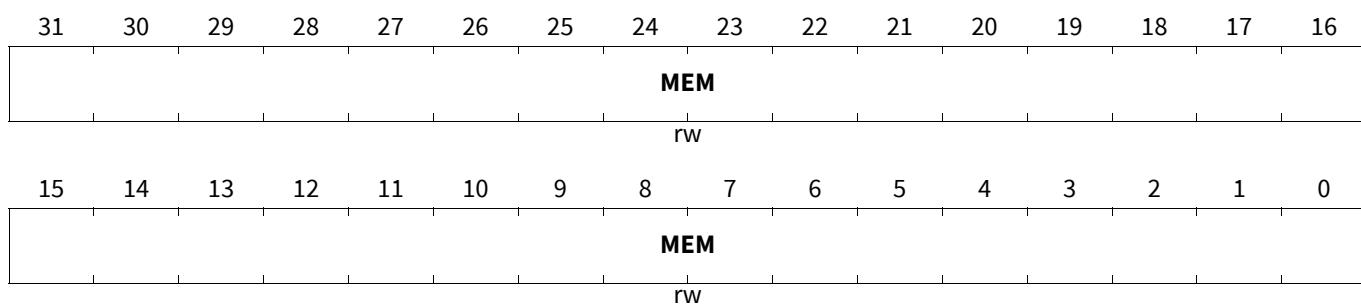

Please check this register description in the System Firmware chapter

### STMEM6

#### Start-up Memory Register 6

(01CC<sub>H</sub>)

System Reset Value: 0000 0000<sub>H</sub>

Field	Bits	Type	Description
MEM	31:0	rw	<b>Memory</b> This register is used by the start-up software as memory.

## System Control Units (SCU)

### 9.3.6.4 SCU Access Restriction Registers

#### Access Enable Register 00

The Access Enable Register 0 restricts write access to SCU, RCU, CCU and PMC registers marked “P0” so that they may only be written by specified bus masters (eg CPUs). See the Bus chapter for the mapping of TAG ID to specific system masters and CPUs).

#### ACCEN00

##### Access Enable Register 00 (03FC<sub>H</sub>) Application Reset Value: FFFF FFFF<sub>H</sub>

## 9.4 Watchdog Timers (WDT)

### 9.4.1 Feature List

The TC3xx contains the following Watchdog Timers:

- One Safety Watchdog Timer
- One Watchdog Timer per CPU

Each Watchdog Timer has the following basic functionality:

- Programmable timebase and reload value
- Programmable password protection with configurable automatic password sequencing
- Programmable timestamp checking with programmable window
- Invalid or missing timer refresh sequence leads to Safety Alarm

## System Control Units (SCU)

- Possible to suspend the Watchdog operation during debug
- Critical register write-protection which can be unlocked only for short time-out duration

### 9.4.1.1 Changes to AURIX TM Family

The most significant changes between the AURIX TC2xx SCU WDT and AURIX TM TC3xx SCU WDT are:

- Register address changed
- Additional Watchdog Timers for additional CPUs
- ENDINIT unlock possible via new ENDINIT Timeout Counter (EICON registers) without affecting any CPU Watchdog Timer
- Safety ENDINIT unlock possible via new Safety ENDINIT Timeout Counter (SEICON registers) without affecting Safety Watchdog Timer
- Separate ACCEN protection range for Safety Watchdog Timer
- External WDT “Alive Heartbeat” Indication feature removed

### 9.4.1.2 Changes from TC39x A-Step to AURIX TC3xx

The following differences exist between the TC39x A-Step device and later TC3xx devices:

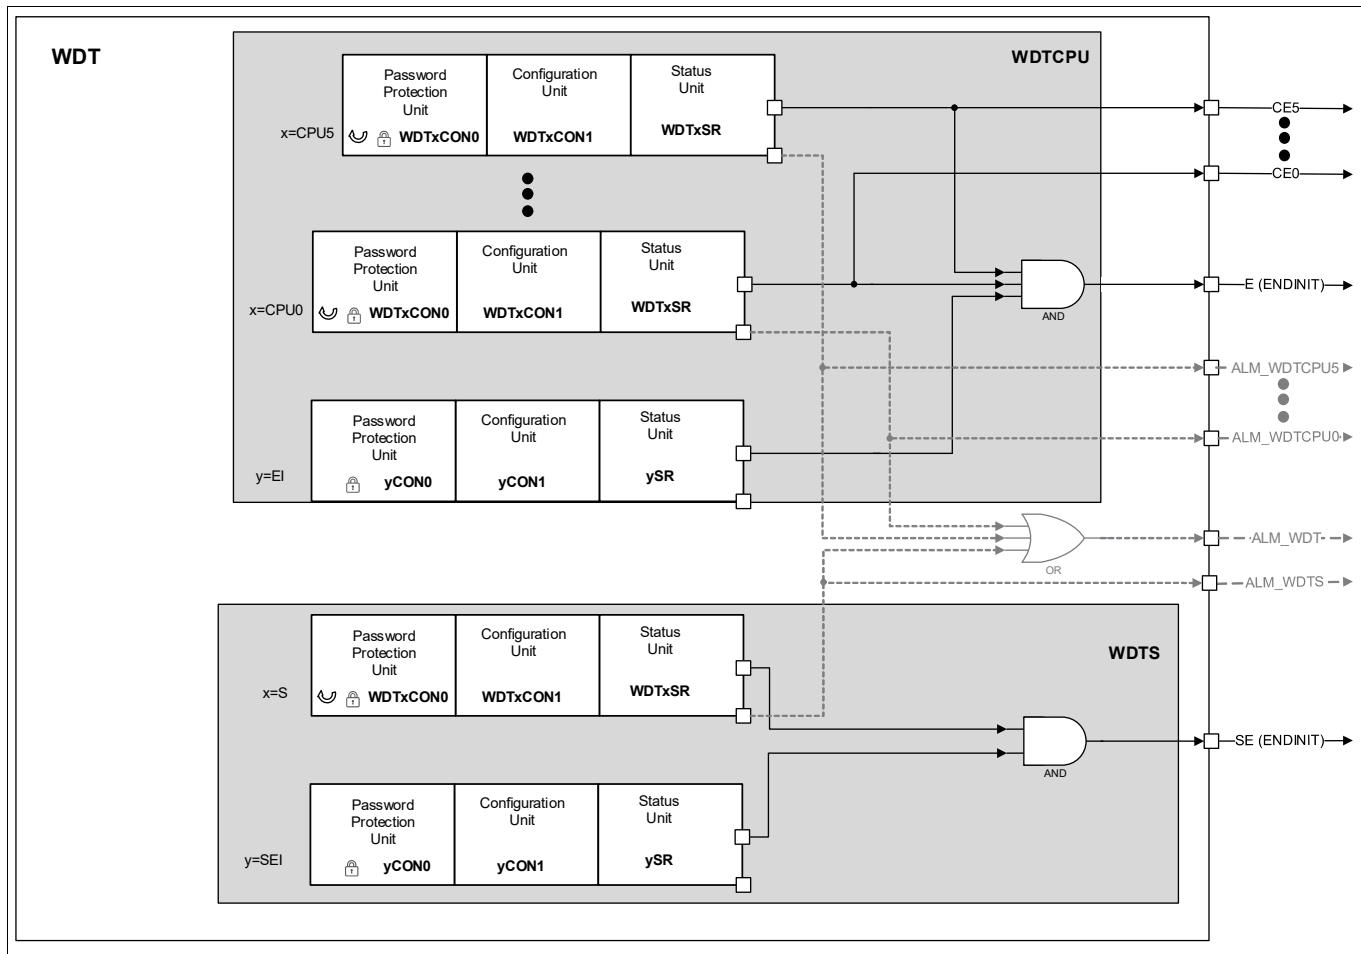

- In TC39X A-Step OCDS debug mode is not available for WDTS, EICON and SECICON.
- In later TC3xx devices the AURIX TC2XX solution is used for Suspend Mode Support. Dependency of WTDS/EICON/SEICON State is implemented according to [Table 270](#).

*Note: For WDTCPUy (y=CPU number), the Suspend Mode Support solution of AURIX TC2xx, TC39x A-Step and AURIX TM TC3xx SCU WDT are compatible ( see. [Table 269](#) ).*

### 9.4.2 Watchdog Timers Overview

The WDTs provide a highly reliable and secure way to detect and recover from software or hardware failure. The WDTs help to abort an accidental malfunction of a CPU or system within a user-specified time period.

## System Control Units (SCU)

**Figure 71 WDT Block Diagram**

In addition to this standard “Watchdog” function, each of the WDTs incorporates an End-of-Initialization (ENDINIT) feature which can protect critical registers from accidental writes.

Servicing the Watchdogs and modifying the ENDINIT bits are critical functions that must not be allowed in case of a system malfunction. To protect these functions a sophisticated scheme is implemented that requires a password and guard bits during accesses to the WDT control registers. Any write access that does not deliver the correct password or the correct value for the guard bits is regarded as a malfunction of the system, and results in a watchdog alarm. In addition, even after a valid access has been performed and an ENDINIT bit has been cleared to provide access to the critical registers, the Watchdog imposes a time limit for this access window. If the ENDINIT bit has not been properly set again before this limit expires, the system is assumed to have malfunctioned. These stringent requirements, although not guaranteed, nonetheless provide a high degree of assurance of the robustness of system operation.

Configuration options are available which enable a Watchdog service to additionally check code execution sequence and intermediate code execution time. If these checks are enabled then any incorrect sequence or out-of-limit execution time will also result in an SMU alarm request.

Expiry of any of the WDTs leads to an SMU alarm. It is possible to program the SMU to provide an interrupt or trap to provide some time for recovery or status recording before further action is taken (e.g. reset of the device or the CPU).

## System Control Units (SCU)

### 9.4.2.1 Safety Watchdog

The Safety Watchdog Timer provides an overall system level watchdog which is independent from the CPU Watchdog Timers and also provides another protection against unintended writes to safety critical system registers. When the Safety WDT is enabled, it can cause an SMU alarm request if it is not serviced within a user-programmable time period. A CPU must service the Safety WDT within this time interval to prevent this. The response to a Safety WDT timeout is configurable within the SMU. Hence, periodic servicing of the Safety WDT confirms that the system is functioning as expected.

Typically the SCU write protection (ACCEN) will be configured so that only restricted “Safety” CPU(s) can configure safety critical functionality. This includes the ability to service the Safety Watchdog. In addition, Safety Watchdog Timer disable/enable/configuration function requires a Safety ENDINIT password.

The registers marked “SE” in the SCU register overview table and other module Register Tables are considered to be static properties of a safety-critical system and are all write-protected after initialization. This write protection may be temporarily removed if the Safety ENDINIT bit is cleared.

### 9.4.2.2 CPU Watchdogs

The individual CPU Watchdog Timers provide the ability to monitor separate CPU execution threads without the need for software to co-ordinate the shared use of a common watchdog.

When a CPU WDT is enabled it can cause an SMU alarm request if it is not correctly serviced within a user-programmable time period. The CPU must service its CPU WDT within this time interval to prevent this. The response to each CPUy watchdog timeout is configurable within the SMU. Hence, periodic servicing of a CPU WDT confirms that the corresponding CPU is executing a software sequence as expected.

After a reset, CPU0 runs and CPU0 Watchdog Timer starts automatically.

Other CPUs are initially in a HALT state and therefore their corresponding Watchdog Timers are disabled. The other CPU Watchdog Timers are not configured to generate a time-out reset by default, but this can be enabled. A CPU Watchdog may only be configured, enabled or disabled by its corresponding CPU.

The registers marked “CEy” (y= CPU number) in SCU register overview table and CPU Register Tables are critical CPU-related registers considered unlikely to be changed during runtime. They are all write-protected after initialization. This write protection may be temporarily removed if the corresponding CPUy (y=CPU number) Watchdog ENDINIT bit is cleared.

The registers marked “E” in SCU register overview table and other Register Tables are critical system registers considered unlikely to be changed during runtime. They are all write-protected after initialization. This write protection may be temporarily removed if ANY of the CPU Watchdog ENDINIT bits is cleared.

## System Control Units (SCU)

### 9.4.3 Features of the Watchdog Timers

The main features of the WDTs are summarized here.

- 16-bit Watchdog Timer
- Selectable input frequency:  $f_{SPB}/64$ ,  $f_{SPB}/256$  or  $f_{SPB}/16384$
- 16-bit user-definable reload value for normal Watchdog Timer operation, fixed reload value for Time-Out Mode
- Incorporation of the corresponding ENDINIT bit and monitoring of its modifications
- Sophisticated Password Access mechanism with user-definable password fields
- Access Error Detection: Invalid password (during first access) or invalid guard bits (during second access) trigger an alarm request to the SMU
- Temporal and logical monitoring capabilities:
  - Optional Code Sequence checking. An incorrect code sequence signature identification will trigger an alarm request to the SMU
  - Optional Code Execution Time checking. Code execution times out of expected limits will trigger an alarm request to the SMU.
- Overflow Error Detection: An overflow of the WDT counter triggers an alarm request to the SMU
- Watchdog function can be disabled; access protection and ENDINIT bit monitor function remain enabled
- Configurable mechanism to prevent Watchdog reloads after an unserviced safety warning alarm to ensure that unserviced warnings lead to an SMU hardware response

### 9.4.4 The Endinit Functions

There are a number of registers that are usually programmed only once during the initialization sequence of the system or application. Modification of such registers during normal application run can have a severe impact on the overall operation of modules or the entire system.

While the Supervisor Mode and the Access Protection scheme provide a certain level of protection against unintentional modifications, they may not be sufficient to protect against all unintended accesses to system-critical registers.

Additional protection is provided for such registers, called Endinit (“End of initialization”). Endinit is a write-protection scheme that allows writes only during certain times and makes accidental modifications of registers protected by this feature nearly impossible.

The Endinit feature consists of an ENDINIT bit incorporated in each WDT control register. Registers protected via an Endinit determine whether or not writes are enabled. Writes are only enabled if a corresponding ENDINIT = 0 AND Supervisor Mode is active. Write attempts if this condition is not true will be discarded and the register contents will not be modified in this case.

To get the highest level of robustness, writes to the ENDINIT bits are protected by a highly secure access protection scheme implemented in the WDTs. This is a complex procedure, that makes it nearly impossible for ENDINIT bits to be modified unintentionally. In addition, each WDT monitors ENDINIT bit modifications by starting a time-out sequence each time software opens access to the critical registers through clearing the corresponding ENDINIT bit. If the time-out period ends before the corresponding ENDINIT bit is set again, a malfunction of the software is assumed and a Watchdog fault response is generated.

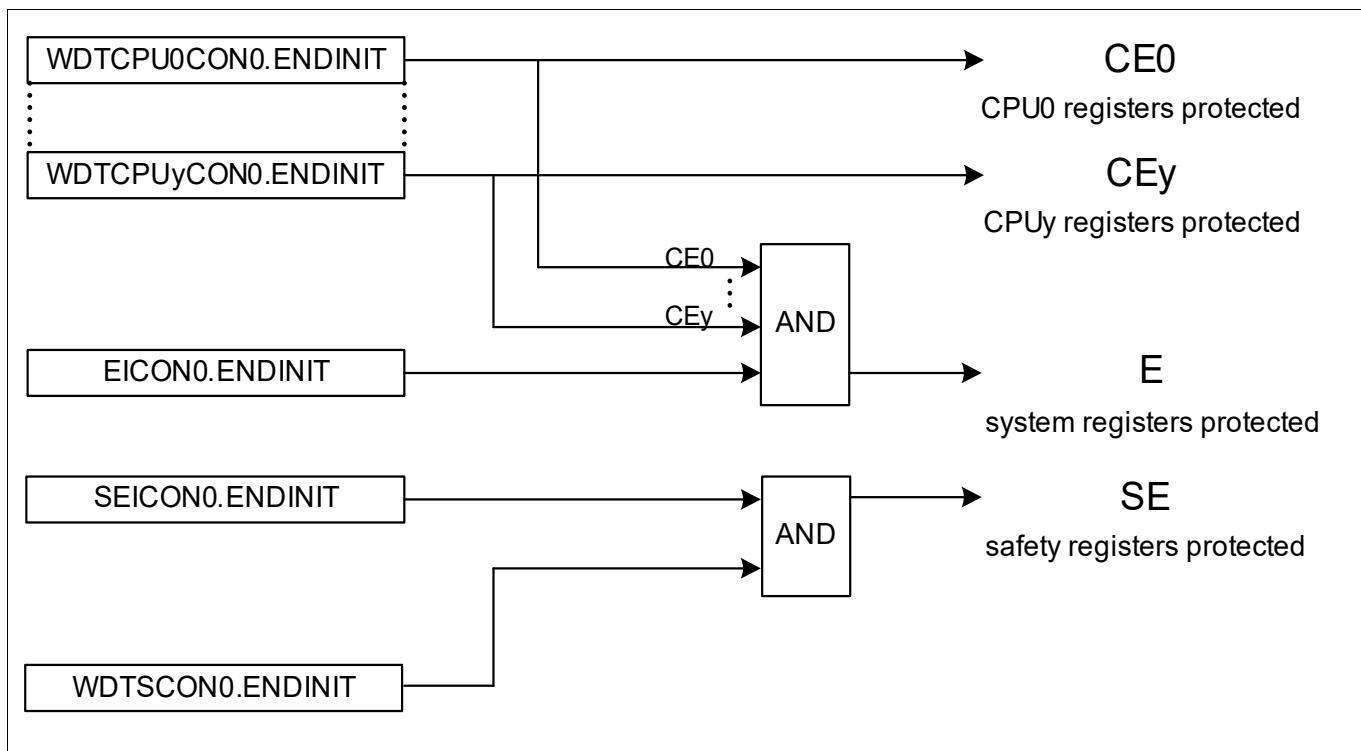

The access-protection scheme and the Endinit time-out operation of the WDTs is described in the following sections. In the register overview tables for each module (including the SCU itself) the registers which are protected via each Endinit type are identified in the column describing write accesses as follows:

- “CEy”- CPU critical registers. Writeable only when CPUy WDT ENDINIT=0 (y=CPU number)

## System Control Units (SCU)

- “E” - System critical registers - Writeable when any (one or more) CPUy Watchdog Timer ENDINIT=0 or EICON0.ENDINIT=0
- “SE” - Safety critical registers - Writeable only when Safety Watchdog Timer ENDINIT=0 or SEICON0.ENDINIT=0
- None of the above - accessible at any time

The options for unlocking the various ENDINIT write-protection modes are shown in [Figure 72](#).

**Figure 72 ENDINIT Control Registers**

Note: *The clearing of an ENDINIT bit takes some time. Accesses to Endinit-protected registers after the clearing of an ENDINIT bit must only be done when the ENDINIT bit is really cleared. As a solution the ENDINIT bit should be read back once before Endinit-protected registers are accessed the first time after bit ENDINIT has been cleared.*

### 9.4.4.1 Password Access to WDTxCON0

A correct password must be written to register WDTxCON0 ( $x = \text{CPUy}$  and  $y = \text{CPU number, or S}$ ) in order to unlock it for modifications. Software must either know the correct password in advance or compute it at runtime. The passwords for each of the Watchdogs Timers ( $x = \text{CPUy}$  and  $y = \text{CPU number, or S}$ ) can be different in order to provide independent watchdog functionality program flows to have independent watchdog functions.

The Safety Watchdog password register WDTSCON0 is protected by the generic SCU protection scheme which allows only configured master(s) to have write access (See [ACCEN10](#)).

CPU-specific Watchdog password registers WDTCPUyCON0 are individually protected such that they may only be written by the corresponding CPUy

A watchdog may be used within a safety application to provide a recovery time period during which software might attempt to recover from a safety alarm warning. To ensure that a CPU fault could not allow a fault to be ignored an option is provided to prevent watchdog unlocking if the Safety Management Unit (SMU) is in the FAULT state. This option may be enabled by bit WDTxCON1.UR .

## System Control Units (SCU)

If the password is valid and the SMU state meets the requirements of the WDTxSR.US bit then WDTxCON0 will be unlocked as soon as the Password Access is completed. The unlocked condition will be indicated by WDTxCON0.LCK = 0. To ensure the correct servicing sequence, a password access is only permitted when the WDTxCON0.LCK bit was set prior to the access.

If an improper password value is written to WDTxCON0 during the Password Access, a Watchdog Access Error condition exists. Bit WDTxSR.AE is set and an alarm request is sent to the Safety Management Unit (SMU).

The 14-bit user-definable password, WDTxCON0.PW, provides additional options for adjusting the password requirements to the application's needs. It can be used, for instance, to detect unexpected software loops, or to monitor the execution sequence of routines.

**Table 265** summarizes the requirements for the password. Various options exist, which are described in more detail below

**Table 265 Password Access Bit Pattern Requirements**

Bit Position	Required Value
[1:0]	Fixed; must be written to 01 <sub>B</sub>
[15:2]	If PAS=0: WDTxCON0.PW[7:2] must be written with inverted current value read from WDTxCON0.PW[7:2] WDTxCON0.PW[15:8] must be written with non-inverted current value read from WDTxCON0.PW[15:8]  If PAS=1: Must be written with Expected Next Sequence Password
[31:16]	If TCS=0: Must be written with current value of user-definable reload value, WDTxCON0.REL If TCS=1: Must be written with inverted estimate of the WDT count value, WDTxSR.TIM. This value must be within +/- WDTxSR.TCT of the actual value

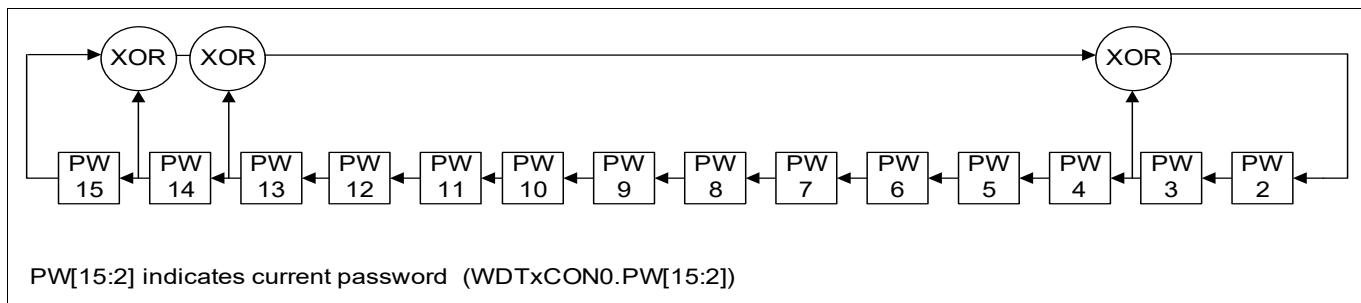

### 9.4.4.1.1 Static Password

In the static password mode (WDTxSR.PAS=0) the password can only be changed by a valid Modify Access. The Password Access has been designed such that it is not possible simply to read the register and re-write it. Some of the password read bits must be inverted (toggled) before being re-written. This prevents a simple malfunction from accidentally unlocking the WDT through a simple read/write sequence.

### 9.4.4.1.2 Automatic Password Sequencing

If automatic password sequencing is enabled (WDTxSR.PAS=1) then the password changes automatically after each password check (i.e. Password Access or Check Access). The Expected Next Password follows a pseudo-random sequence based upon a 14-bit Fibonacci LFSR (Linear Feedback Shift Register) with characteristic polynomial  $x^{14}+x^{13}+x^{12}+x^2+1$ . An initial password (or subsequent manual password updates) can also be provided by Modify Accesses.

## System Control Units (SCU)

**Figure 73 Password Sequencing LFSR**

### 9.4.4.1.3 Time-Independent Password

If time checking is not enabled (WDTxSR.TCS=0) then the REL field of the WDTxCON0 register must be simply re-written with the existing reload value during the Password Access.

### 9.4.4.1.4 Time Check Password

If time checking is enabled (WDTxSR.TCS=1) the REL field of the WDTxCON0 register must be written with an inverted (bit flipped) estimate of the current WDT count value. The acceptable margin of error of this estimate (in WDT clock periods) is specified by the value of WDTxSR.TCT. If the written estimate is outside the range WDTxSR.TIM +/- WDTxSR.TCT, then an SMU alarm condition is indicated. This mechanism can provide a check of the elapsed program execution time since the last WDT restart. Note that a Time Check comparison is still required for a Password or Check Access while the WDT is operating in Time-Out mode (e.g. After accessing ENDINIT-protected registers).

### 9.4.4.2 Check Access to WDTxCON0

A Check Access is identical to a Password Access except that the lock bit is not cleared and a subsequent Modify Access is therefore not allowed. A Check Access does not trigger an SMU Alarm Request provided that the write data requirements are satisfied. A Check Access may only be performed when the LCK bit is set.

This type of access is used for intermediate checkpoints between WDT services. This may be used (e.g. in conjunction with the timestamp count checking feature or sequence passwords) for task sequence or execution time monitoring.

**Table 266 Check Access Bit Pattern Requirements**

Bit Position	Required Value
[1:0]	Fixed; must be written to 11 <sub>B</sub>
[15:2]	If PAS=0: WDTxCON0.PW[7:2] must be written with inverted current value read from WDTxCON0.PW[7:2] WDTxCON0.PW[15:8] must be written with non-inverted current value read from WDTxCON0.PW[15:8]  If PAS=1: Must be written with Expected Next Sequence Password
[31:16]	If TCS=0: Must be written with current value of user-definable reload value, WDTxCON0.REL If TCS=1: Must be written with inverted estimate of the WDT counter WDTxSR.TIM. This value must be within +/- WDTxSR.TCT of the actual value

## System Control Units (SCU)

If an improper value is written to WDTxCON0 (x=CPUy and y=CPU number, or S) during the Check Access, a Watchdog Access Error condition exists. Bit WDTxSR.AE is set and an alarm request is sent to the Safety Management Unit (SMU).

### 9.4.4.3 Modify Access to WDTxCON0

If a WDTxCON0 (x=CPUy and y=CPU number, or S) is successfully unlocked by a Password Access, the following write access to WDTxCON0 can modify it. However, this access must also meet certain requirements in order to be accepted and regarded as valid. **Table 267** lists the required bit patterns. If the access does not follow these rules, a Watchdog Access Error condition is detected, bit WDTxSR.AE is set, and an alarm request is sent to the Safety Management Unit (SMU). After the Modify Access has completed, WDTxCON0.LCK is set again, automatically re-locking WDTxCON0. Before the register can be modified again, a valid Password Access must be executed again.

**Table 267 Modify Access Bit Pattern Requirements**

Bit Position	Value
0	User-definable; desired value for bit WDTxCON0.ENDINIT.
1	Fixed; must be written with $1_B$ .
[15:2]	User-definable; desired value of user-definable password field, WDTxCON0.PW.
[31:16]	User-definable; desired value of user-definable reload value, WDTxCON0.REL.

### 9.4.4.4 Access to Endinit-Protected Registers

If write access to Endinit-protected registers is required during run time, write access can be temporarily re-enabled for a limited time period. Two options are provided:

- Re-enable access to ENDINIT-protected registers with a WDT refresh
- Re-enable access to ENDINIT-protected registers without a WDT refresh

For debugging support the Cerberus module can override all the ENDINIT controls of all WDTs to ease the debug flow. If bit CBS\_OSTATE.ENIDIS is set all ENDINIT protection is disabled independent of the current status configured by the WDTs. If CBS\_OSTATE.ENIDIS is cleared the complete control is within the WDTs.

#### 9.4.4.4.1 Access to Endinit-Protected Registers using WDT

To re-enable access, WDTxCON0 must first be unlocked with a valid Password Access. In the subsequent valid Modify Access, ENDINIT can be cleared. Access to Endinit-protected registers is now open again. However, when WDTxCON0 is unlocked, the WDT is automatically switched to Time-Out Mode. The access window is therefore time-limited. Time-Out Mode is only terminated after ENDINIT has been set again, requiring another Valid Password and Valid Modify Access to WDTxCON0.

#### 9.4.4.4.2 Access to Endinit-Protected Registers without using WDT

In some applications the WDT may not be used and would be disabled (WDTxSR.DS = 1), although this is not recommended.

In other applications, the WDT Timestamp feature may be used and WDT accesses between refreshes would be undesirable.

In these circumstances it is still possible to enable temporary access to Endinit-Protected registers using the ENDINIT Global Control Registers (EICONx).

## System Control Units (SCU)

### 9.4.5 Timer Operation

The timers for Safety Watchdog and CPU0 are automatically active after an Application Reset.

Each 16-bit counter implementing the timer functionality is either triggered with  $f_{SPB} / 64$ ,  $f_{SPB} / 256$  or  $f_{SPB} / 16384$ . The three possible counting rates are controlled via bit WDTxCON1.IRx (x=CPUy and y=CPU number, or S) according to [Table 268](#):

**Table 268 WDT Rate Change via IRx bits (Request) and WDT Rate Indication via SRx bits (Status)**

xR1	xR0	Watchdog Timer Rate (Source Clock divider setting)
0	0	$f_{SPB} / 16384$
0	1	$f_{SPB} / 256$ .
1	0	$f_{SPB} / 64$ .
1	1	Reserved. Do not use.

#### Determining WDT Periods

All WDTs use the SPB clock  $f_{SPB}$ . A clock divider in front of each WDT provides three WDT counter frequencies,  $f_{SPB} / 64$ ,  $f_{SPB} / 256$  and  $f_{SPB} / 16384$ .

The general formula to calculate a Watchdog timeout period is:

$$\text{period} = ((2^{16} - \text{startvalue}) * \text{divider}) / f_{SPB}$$

The parameter startvalue represents the fixed value  $FFFC_H$  for the calculation of the Time-Out Period, and the user-programmable reload value WDTxCON0.REL for the calculation of the Normal Period.

The parameter divider represents the user-programmable source clock division selected by WDTxCON1.IRx, which can be 64, 256 or 16384.

#### 9.4.5.1 Timer Modes

Each Watchdog Timer can operate in one of three different operating modes:

- Time-Out Mode
- Normal Mode
- Disable Mode

The following overview describes these modes and how the WDT changes from one mode to the other.

##### Time-Out Mode

CPU0 WDT Time-Out Mode is entered after an Application Reset. Other CPUs are disabled after Application Reset. Time-Out Mode is also entered when a valid Password Access to register WDTxCON0 is performed. The Time-Out Mode is indicated by bit WDTxSR.TO = 1. The timer is set to  $FFFC_H$  and starts counting upwards. Time-Out Mode can only be exited properly by setting ENDINIT = 1 with a correct access sequence. If an improper access to the WDT is performed, or if the timer overflows before ENDINIT is set, and an alarm request is sent to the Safety Management Unit (SMU).

A proper exit from Time-Out Mode can either be to the Normal or the Disable Mode, depending on the state of the disable request bit WDTxCON1.DR.

## System Control Units (SCU)

### Normal Mode

In Normal Mode ( $DR = 0$ ), the WDT operates in a standard Watchdog fashion. The timer is set to  $WDTxCON0.REL$ , and begins counting up. It has to be serviced before the counter overflows. Servicing is performed through a proper access sequence to the control register  $WDTxCON0$ . This enters the Time-Out Mode.

If the WDT is not serviced before the timer overflows, a system malfunction is assumed. Normal Mode is terminated and an alarm request is sent to the Safety Management Unit (SMU).

### Disabled Mode

All CPU WDTs except CPU0 are in disabled mode after an Application Reset. Disabled Mode is provided for applications which do not require a WDT function. It can be requested from Time-Out Mode when the disable request bit  $WDTxCON1.DR$  is set. The Disabled Mode is entered when was requested AND bit  $WDTxCON0.ENDINIT$  is set. The timer is stopped in this mode. However, disabling the WDT only stops it from performing the standard Watchdog function, eliminating the need for timely service of the WDT. It does not disable Time-Out mode. If an access to register  $WDTxCON0$  is performed in Disabled Mode, Time-Out Mode is entered if the access was valid, and an alarm request is sent to the Safety Management Unit (SMU) if the access was invalid. Thus, the  $ENDINIT$  monitor function as well as (a part of) the system malfunction detection will still be active.

### 9.4.5.2 WDT Alarm Request

SMU alarm requests are generated for three cases:

- Invalid write data during access to register  $WDTxCON0$  ( $x=CPUy$  and  $y=CPU$  number, or S),  $SEICON0$  or  $EICON0$
- Not executing a password access before a timer overflow occurs in the Time-Out Mode of any WDT,  $ENDINIT$  Timeout Counter or Safety  $ENDINIT$  Timeout Counter
- Not serving any WDT before a timer overflow occurs in the Normal Mode

The resulting alarm response (e.g. Trap, Reset etc) is programmable within the Safety Management Unit (SMU).

*Note:* *The WDT itself is reset by any Application Reset.*

### Servicing the Watchdog Timer

If the WDT is used in an application and is enabled ( $WDTxSR.DS = 0$ ), it must be regularly serviced to prevent it from overflowing.

Service is performed in two steps, a valid Password Access followed by a valid Modify Access. The valid Password Access to  $WDTxCON0$  automatically switches the WDT to Time-Out Mode. Thus, the Modify Access must be performed before the time-out expires or an alarm request will be sent to the Safety Management Unit (SMU).

During the next Modify Access, the strict requirement is that  $WDTxCON0.ENDINIT$  is written with 1.

*Note:*  *$ENDINIT$  must be written with 1 to perform a proper service, even if it is already set to 1.*

Changes to the reload value  $WDTxCON0.REL$ , or the user-definable password  $WDTxCON0.PW$ , are not required. When a WDT service is properly executed, Time-Out Mode is terminated, and the WDT switches back to its former mode of operation, and the WDT service is complete.

Check Accesses are optional and may be performed at any time when the WDT is locked.

### 9.4.5.3 WDT Operation During Power-Saving Modes

If one or more of the CPU are in Idle Mode, they cannot service a WDT because no software is running. Excluding the case where the system is running normally, a strategy for managing WDTs is needed while a CPU is in Idle

## System Control Units (SCU)

Mode. There are two ways to manage a WDT in these cases. Firstly, the Watchdog can be disabled before idling the CPU. The disadvantage of this is that the system will no longer be monitored during the idle period.

A better approach to this problem relies upon the wake-up feature of the WDTs. Whenever CPUy is put in Idle or Sleep Mode and the WDT is not disabled, the CPUy is woken at regular intervals. When WDTx (x=CPUy and y= CPU number) changes its count value (WDTxSR.TIM) from  $7FFF_H$  to  $8000_H$ , CPUy is woken and continues execution at the instruction following the instruction that was executed before entering the Idle or Sleep Mode.

**Note:** *Before switching into a non-running power-management mode, software should perform a Watchdog service sequence. At the Modify Access, the Watchdog reload value, WDTxCON0.REL, should be programmed such that the wake-up occurs after a period which best meets application requirements. The maximum period between two CPU wake-ups is one-half of the maximum WDT period.*

### 9.4.5.4 Suspend Mode Support

During a debug session the Watchdog or SEI/EI Timeout Counter functionality might lead to unintended alarms.

By default, the WDTs and SEI/EI Timeout Counters are disabled when OCDS is enabled (and also during start-up). However, it is possible to enable WDTs and SEI/EI Timeout Counter even when OCDS is enabled if CBS\_OSTATE.WDTSUS=1.

CPUy WDTs may only be re-enabled if the corresponding CPUySUSOUT is inactive. In WDTS, SEICON and EICON CBS\_TLS.TL1 is used for this purpose.

For safety reasons it is essential that WDT ignores CPUySUSOUT when OCDS is disabled. WDTS, EICON/SEICON shall ignore CBS\_TLS.TL1 when OCDS is disabled.

**Table 269 CPUy WDT Suspend State**

STCON.STP	WDTxSR.DS (x=CPUy)	CBS_OSTATE.OEN	CBS_OSTATE.WDTSUS	CPUy SUSOUT	WDTCPUy State
0	X	X	X	X	Stopped
1	1	X	X	X	Stopped
1	0	0	X	X	Running
1	0	1	0	X	Stopped
1	0	1	1	0	Running
1	0	1	1	1	Stopped

**Table 270 Safety WDT, SEICON and EICON Endinit Counter Suspend State**

STCON.STP	WDTxSR.DS	CBS_OSTATE.OEN	CBS_OSTATE.WDTSUS	CBS_TLS. TL1	WDTS, SEICON, EICON State
0	X	X	X	X	Stopped
1	1	X	X	X	Stopped
1	0	0	X	X	Running
1	0	1	0	X	Stopped

## System Control Units (SCU)

### 9.4.6 Watchdog Timer Registers

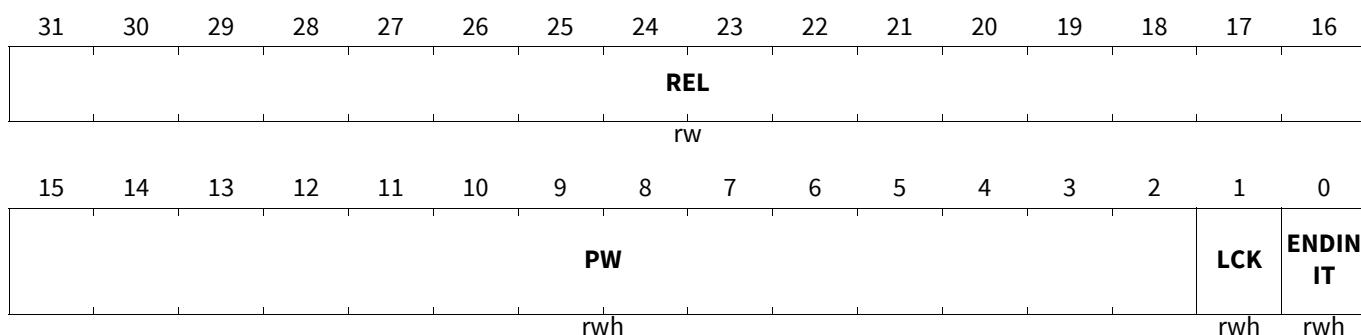

#### Safety WDT Control Register 0

This register is written with check data in Check Accesses and Password Accesses. It also stores the timer reload value, password update and the corresponding End-of-Initialization (ENDINIT) control bit during a Modify Access.

There is a WDT<sub>x</sub>CON0 register for each Watchdog x (x=CPUy with y= CPU number and x=S). For the Safety Watchdog Timer is x=S.

#### WDT<sub>S</sub>CON0

**Safety WDT Control Register 0** **(02A8<sub>H</sub>)** **Application Reset Value: FFFC 000E<sub>H</sub>**

Field	Bits	Type	Description
<b>ENDINIT</b>	0	rwh	<p><b>End-of-Initialization Control Bit</b></p> <p>This bit must be written with a ‘1’ during a Password Access or Check Access (although this write is only used for the password-protection mechanism and is not stored). This bit must be written with the required ENDINIT update value during a Modify Access.</p> <p>This bit may be used to access registers with “SE” protection, but the alternate register SEICON0.ENDINIT is recommended for this purpose so that the Watchdog Timer is not affected.</p> <p>0<sub>B</sub> Access to Endinit-protected registers is permitted (default after ApplicationReset)</p> <p>1<sub>B</sub> Access to Endinit-protected registers is not permitted.</p>
<b>LCK</b>	1	rwh	<p><b>Lock Bit to Control Access to WDT<sub>x</sub>CON0</b></p> <p>The current value of LCK is controlled by hardware. It is cleared after a valid Password Access to WDT<sub>x</sub>CON0 when WDT<sub>x</sub>SR.US is 0 (or when WDT<sub>x</sub>SR.US is 1 and the SMU is in RUN mode), and it is automatically set again after a valid Modify Access to WDT<sub>x</sub>CON0. During a write to WDT<sub>x</sub>CON0, the value written to this bit is only used for the password-protection mechanism and is not stored.</p> <p>This bit must be cleared during a Password Access to WDT<sub>x</sub>CON0, and set during a Modify Access to WDT<sub>x</sub>CON0.</p> <p>A Check Access does not clear LCK.</p> <p>0<sub>B</sub> Register WDT<sub>x</sub>CON0 is unlocked</p> <p>1<sub>B</sub> Register WDT<sub>x</sub>CON0 is locked (default after ApplicationReset)</p>

### CPUy WDT Control Register 0

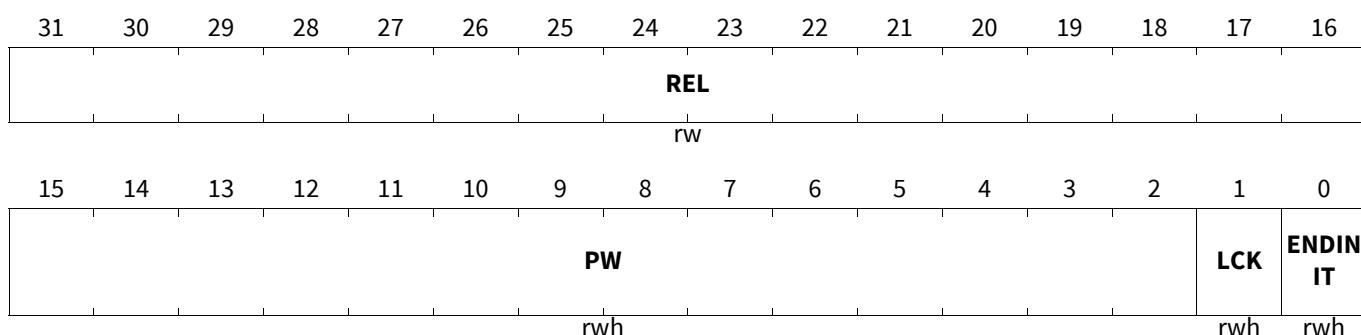

This register is written with check data in Check Accesses and Password Accesses. It also stores the timer reload value, password update and the corresponding End-of-Initialization (ENDINIT) control bit during a Modify Access. There is a WDTxCON0 register for each Watchdog x (x=CPUy with y= CPU number and x=S). For the CPU Watchdog Timers is x=CPUy with y=CPU number.

### Safety WDT Control Register 1

There is a WDTxCON1 register for each Watchdog Timer x (x=CPUy with y=CPU number and x=S). For the Safety Watchdog Timer is x=S. The register WDTxCON1 manages operation of the Safety WDT. It includes the disable request, password configuration and frequency selection bits. Each WDTxCON1 register is write-protected by the Safety ENDINIT (SE).

WDTSCON1 has an additional bit CLRIRF which can be used to clear the internal reset status used to detect double SMU (e.g. WDT) resets.

**Table 273 Reset Values of WDTCPUySR (y=0-5)**

Reset Type	Reset Value	Note
Application Reset	FFFC 0010 <sub>H</sub>	WDTCPU0SR
Application Reset	FFFC 0008 <sub>H</sub>	WDTCPUySR (y=1-5)

### ENDINIT Global Control Register 0

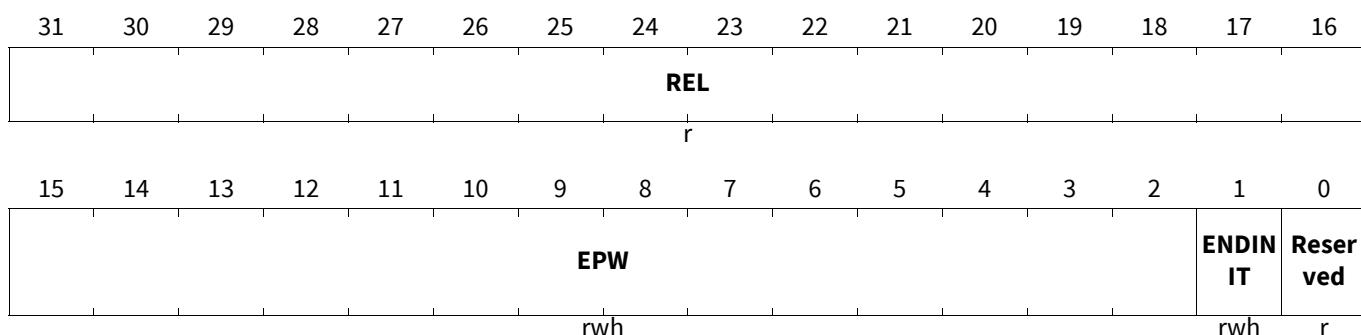

This register is part of the ENDINIT Timeout Counter. It is provided to allow an alternative way to access ENDINIT protected registers without affecting any CPU WDT counter values. The format of the EICON0 register is similar to that of a WDTxCON0 register, but the counter reload value is a fixed short timeout and the locking bit is the ENDINIT control. The password for ENDINIT access via EICON0 is static (i.e. No autosequencing is available) but may be updated on a Modify Access.

This allows an ENDINIT protected register to be accessed after a single Password Access write to EICON0, and to be re-locked with a single Modify Access write.

The System ENDINIT signal used to restrict register access is effectively the logical combination of EICON0.ENDINIT and all WDTxCON0.ENDINIT bits.

### EICON0

**ENDINIT Global Control Register 0** (029C<sub>H</sub>) **Application Reset Value: FFFC 000E<sub>H</sub>**

Field	Bits	Type	Description
<b>Reserved</b>	0	r	<b>Reserved Bit</b> Not writeable. Read as '0'.
<b>ENDINIT</b>	1	rwh	<b>End-of-Initialization Control Bit</b> The current value of ENDINIT is controlled by hardware. It is cleared after a valid EndInit Password Access to EICON0, and it is automatically set again after a valid EndInit Modify Access to EICON0. During a write to EICON0, the value written to this bit is only used for the password-protection mechanism and is not stored. This bit must be cleared during a Password Access to EICON0, and set during a Modify Access to EICON0. 0 <sub>B</sub> Access to Endinit-protected registers is permitted 1 <sub>B</sub> Access to Endinit-protected registers is not permitted unless one of WDTCPUyCON0.ENDINIT is 0.

## 9.5 External Request Unit (ERU)

The External Request Unit (ERU) is a versatile event and pattern detection unit. Its major task is the **generation of interrupts based on selectable trigger events** (e.g. to generate external interrupt requests if an edge occurs at an input pin).

The detected events can also be used by other target modules to trigger or to gate module-specific actions.

The available trigger sources and defined target modules are defined in the SCU Appendix for each device under the headline "Connectivity".

### 9.5.1 Feature List

- Supports generation of interrupts based on selectable trigger events at different inputs

## System Control Units (SCU)

- 8 independent Input Channels for input selection and conditioning of trigger or gating functions.
- Event distribution with a Connecting Matrix which defines the events of the Input Channel x that lead to a reaction of an Output Channel y.
- 8 independent Output Channels for combination of events, definition of their effects and distribution to the system (e.g. interrupt generation, timer triggering ...)

### 9.5.1.1 Delta to AURIX

The most significant changes between the TC2xx ERU and TC3xx ERU are:

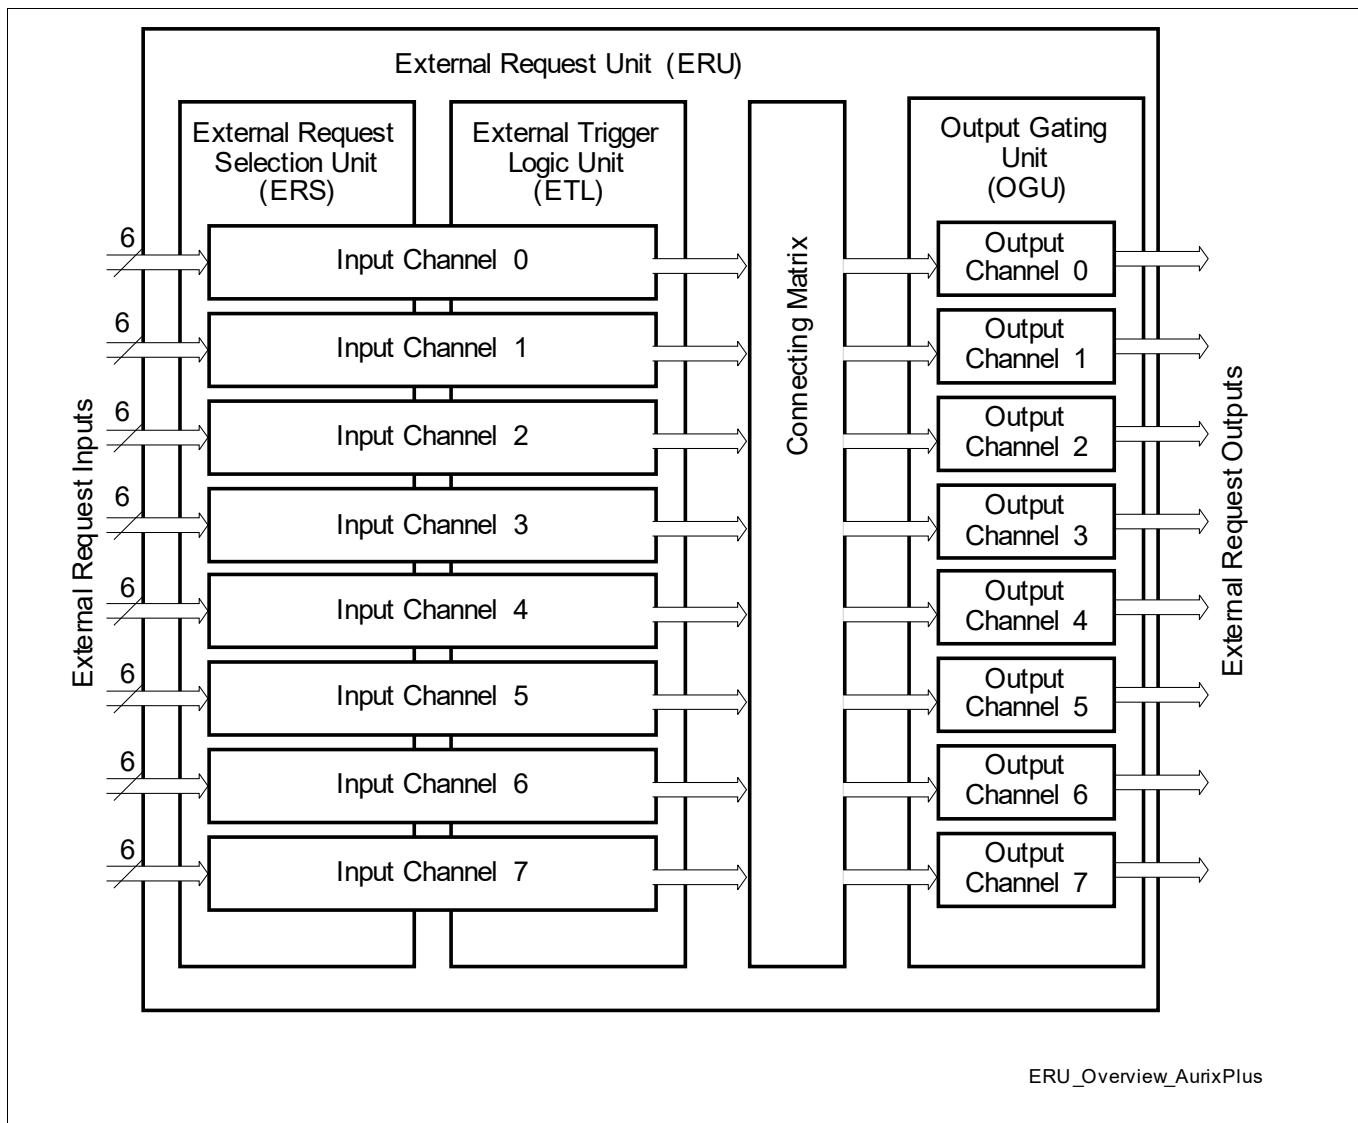

- Some register address changes
- ERU input mux widened from 4 to 6 inputs per channel to accommodate additional trigger sources
- Programmable digital glitch filtering available on ERU REQx inputs
- Ability to generate SMU alarms from ERU

### 9.5.2 Introduction

The ERU can be split in three main functional parts:

- **Input Channels x**
- **Connecting Matrix**
- **Output Channels y**

## System Control Units (SCU)

**Figure 74 External Request Unit Overview**

These tasks are handled by the following building blocks:

- An **External Request Select Unit (ERSx)** per Input Channel allows the selection of one input vector out of the 6 possible available inputs.
- An **Event Trigger Logic (ETLx)** per Input Channel allows the definition of the transition (edge selection, or by software) that lead to a trigger event and can also store this status. Here, the input levels of the selected signals are translated into events (event detected = event flag becomes set, independent of the polarity of the original input signals).
- The **Connecting Matrix** distributes the events and status flags generated by the Input Channels to the Output Channels.
- An Output Gating Unit (OGUy) per Output Channel that combines the available trigger events and status information from the Input Channels. An event of one Input Channel can lead to reactions of several Output Channels, or also events of several Input Channels can be combined to a reaction of one Output Channel (pattern detection).

Different types of reactions can be configured, e.g. generation of interrupts.

The inputs to the ERU can be selected from a large number of input signals. 16 of these inputs come directly from input ports, but other inputs come from various peripheral module status signals. Usually, such inputs would be

## System Control Units (SCU)

selected for an ERU function when the module input function is not used by the application, or when the module is not used at all. However, it is also possible to select an input which is also used by the other module, to also be used in the ERU as a trigger or to be combined with other signals (e.g. to generate an interrupt trigger when a start-of-frame is detected on a selected communication interface input) - to know the device specific input and output connections, please address the appendix file.

### 9.5.3 REQxy Digital PORT Input Glitch Filter (FILT)

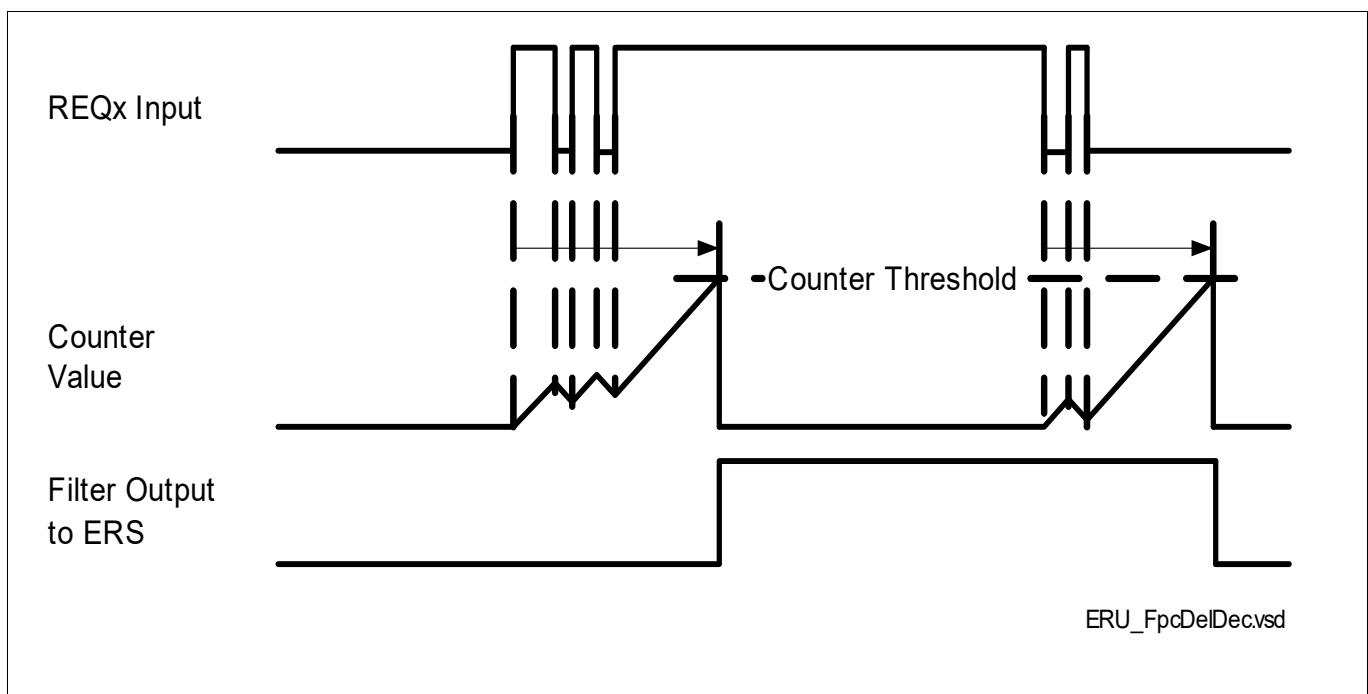

Signal noise can lead to unwanted fast transitions on input pins from PORTS. These unwanted transitions may be suppressed by digital glitch filters similar to Filter and Prescaler Cells (FPC) in Delayed Debounce Filter Mode with up and down (no reset).

The filter calculates the integral of the signal. If the integral reaches a programmable saturation point, the input change is passed on to the ERS.

The REQxy glitch filters are only available on the REQxy inputs coming directly from PORTS. They are enabled and configured using register **EIFILT**. The filters sample the input and are clocked with a clock of frequency  $f_{FILT}$ , where  $f_{FILT} = f_{SPB}/\text{EIFILT}.FILTDIV$ . On each sample period, if the state of the input sample differs from the current state of the filter output, then an internal counter is incremented by one. When the counter matches the compare threshold value stored in **EIFILT.DEPTH**, the state of the filter output is inverted and the counter is reset to zero. When the state of the input sample matches the current state of the filter output and the counter is not zero, the counter is decremented by one.

The filter predivider can be programmed to a value between 1 and 15, giving a range of possible glitch characteristics from 10ns to  $> 2\mu s$

The depth of the filter can be programmed to a value between 1 and 15. Typically a depth of 3 to 5  $T_{filt}$  is sufficient. By default it is cleared. If DEPTH is cleared all filters are inactive.

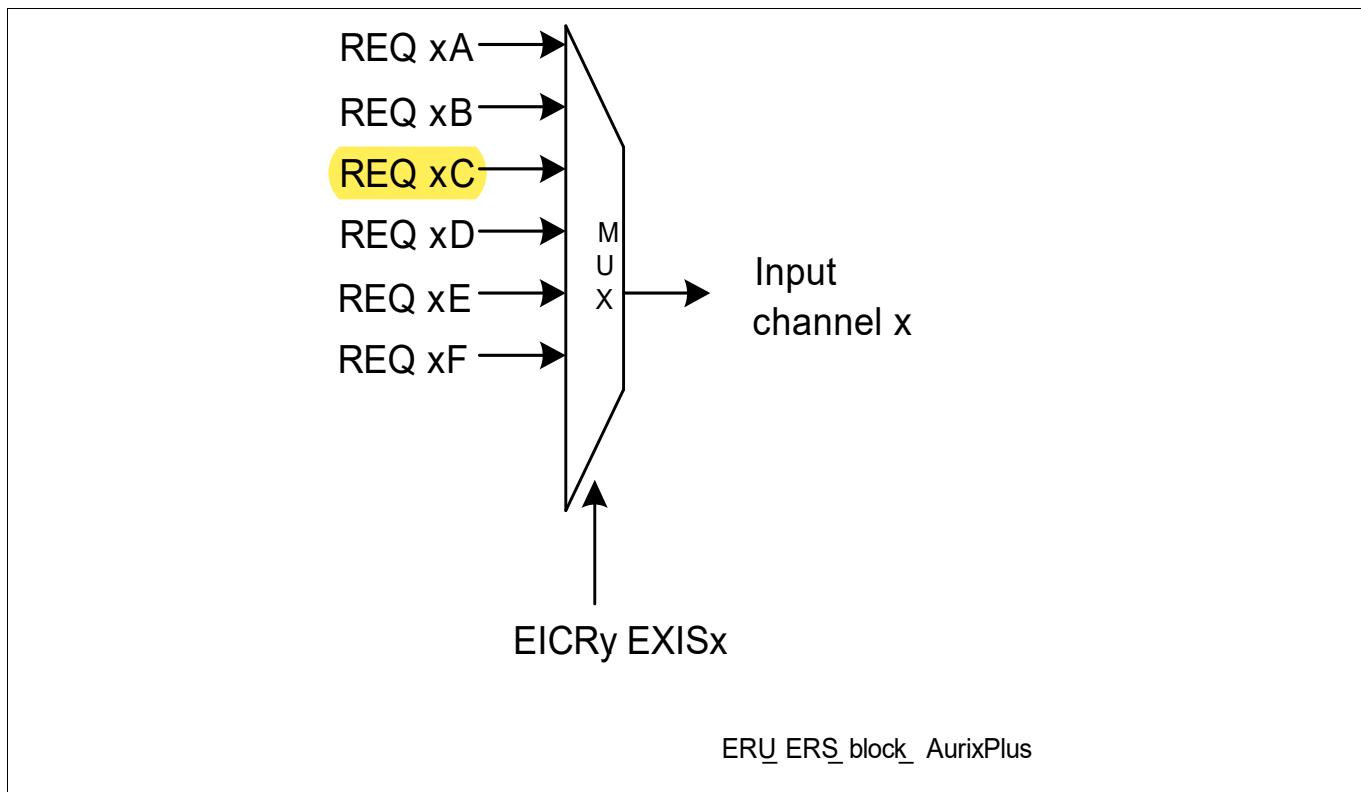

**Figure 75** REQxy Digital Filter

### 9.5.4 External Request Selector Unit (ERS)

Each ERS selects one of six inputs as the one input signal of the respective input channel. **Figure 76** shows the structure of this block.

## System Control Units (SCU)

**Figure 76 External Request Select Unit Overview**

The ERS unit for channel x is controlled via bit field EICRy.EXISx.

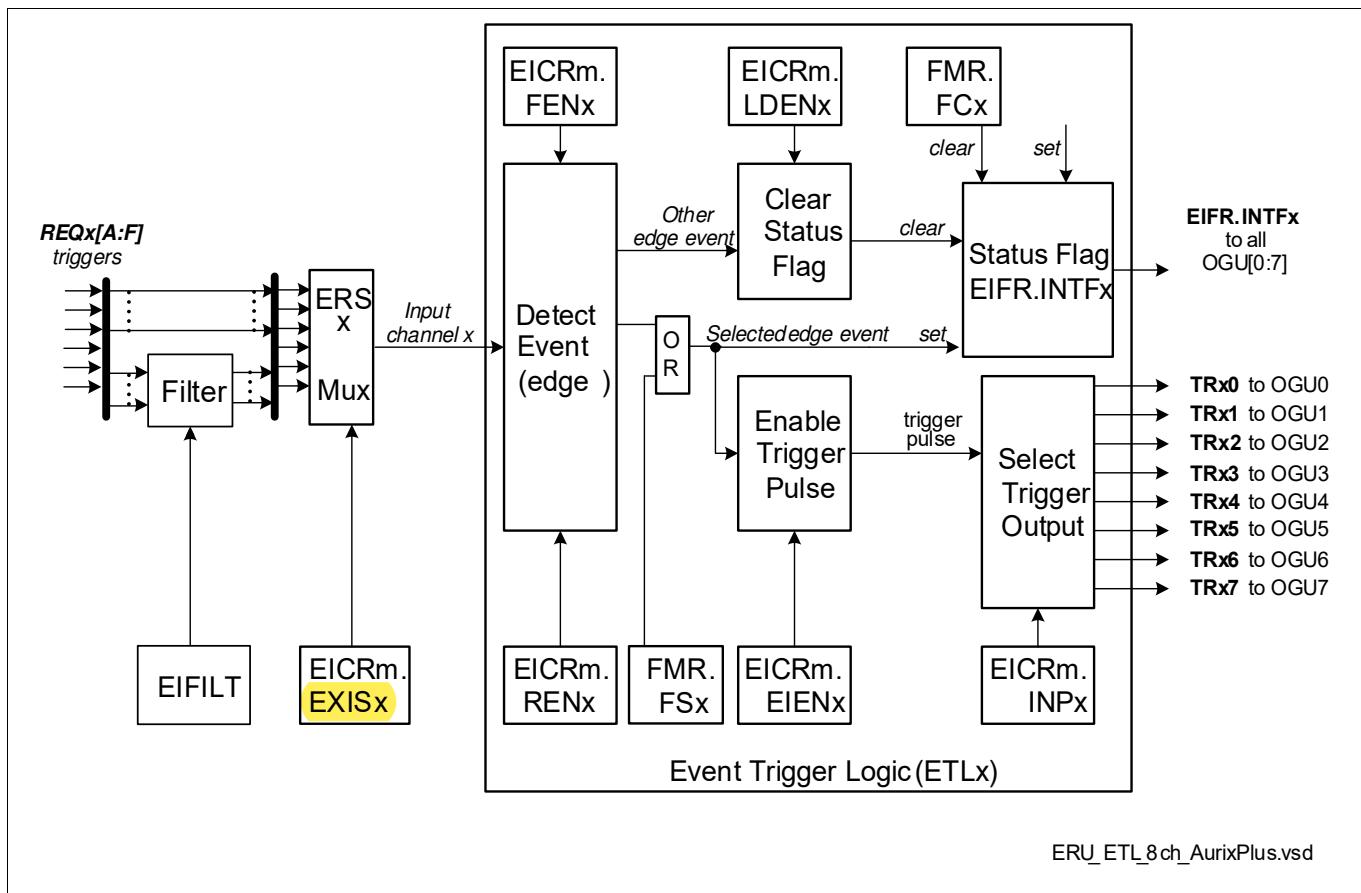

### 9.5.5 Event Trigger Logic (ETL)

For each Input Channel x, an event trigger logic ETLx derives a trigger event and a status from the input channel x delivered by the associated ERSx unit. Each ETLx is based on an edge detection block, where the detection of a rising or a falling edge can be individually enabled. Both edges lead to a trigger event if both enable bits are set (e.g. to handle a toggling input).

Each pair of the four ETL units has an associated EICRy register, that controls all options of an ETL (the register also holds control bits for the associated ERS unit pair).

An overview of the Event Trigger Logic block is shown below.

## System Control Units (SCU)

**Figure 77 Event Trigger Logic Overview**

When the selected event (edge) is detected, the status flag EIFR.INTFx becomes set.

The status flag is cleared automatically if the “opposite” event is detected, if so enabled via bit EICRy.LDENx = 1. For example, if only the falling edge detection is enabled to set the status flag, it is cleared when the rising edge is detected. In this mode, it can be used for pattern detection where the actual status of the input is important (enabling both edge detections is not useful in this mode).

The output of the status flag is connected to all following Output Gating Units (OGUz) in parallel (see **Figure 78**) to provide **pattern detection capability of all OGUz** units based on different or the same status flags.

In addition to the modification of the status flag, a trigger pulse output TRxz of ETLx can be enabled (by bit EICRy.EIENx) and selected to **trigger actions in one of the OGUz** units. The target OGUz for the trigger is selected by bit field EICRy.INPx.

The trigger becomes active when the selected edge event is detected, independently from the status flag EIFR.INTFx.

## System Control Units (SCU)

### 9.5.6 Connecting Matrix

The connecting matrix distributes the trigger signals (TRxy) and status signals (EIFR.INPFx) from the different ETLx units between the OGUs. **Figure 78** provides a complete overview of the connections between the ETLx and the OGUs.

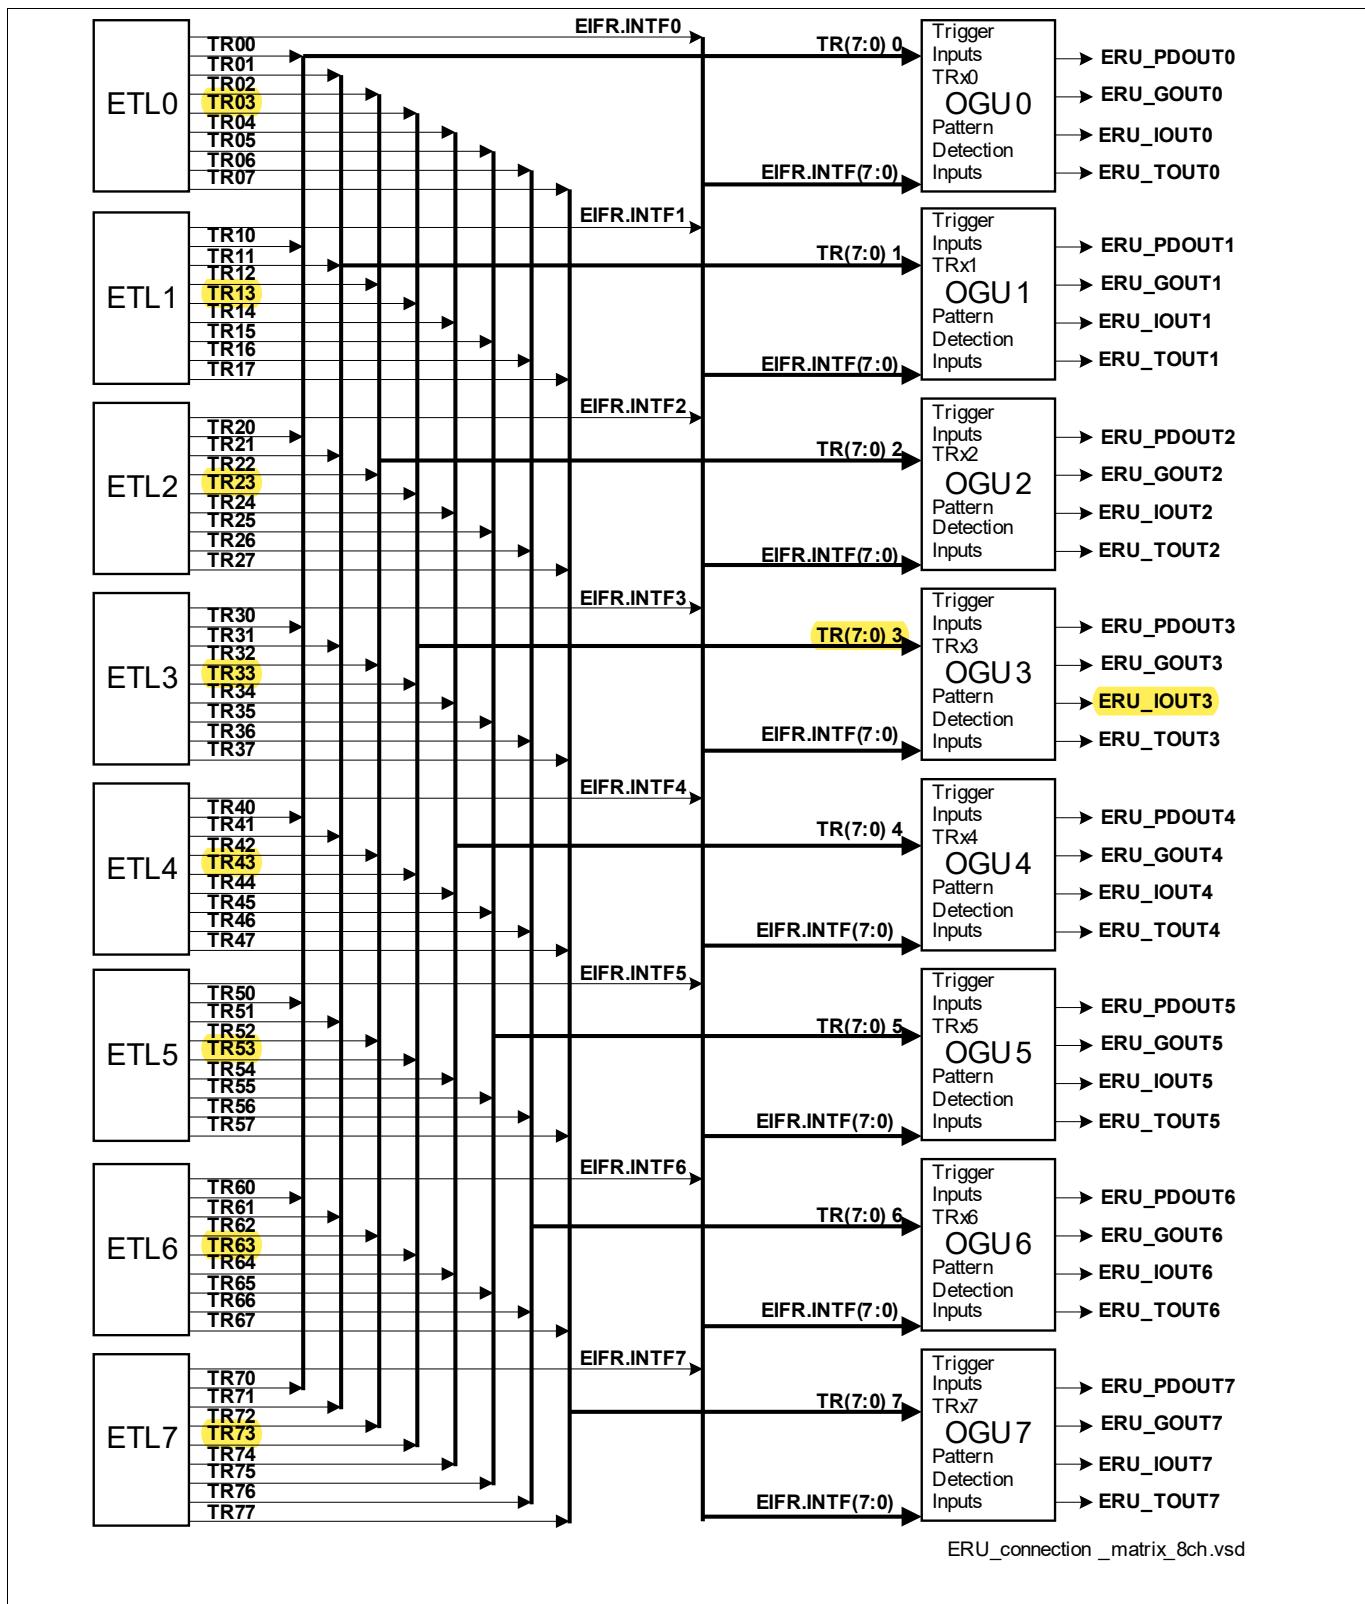

Figure 78 Connecting Matrix between ETLx and OGUs

## System Control Units (SCU)

### 9.5.7 Output Gating Unit (OGU)

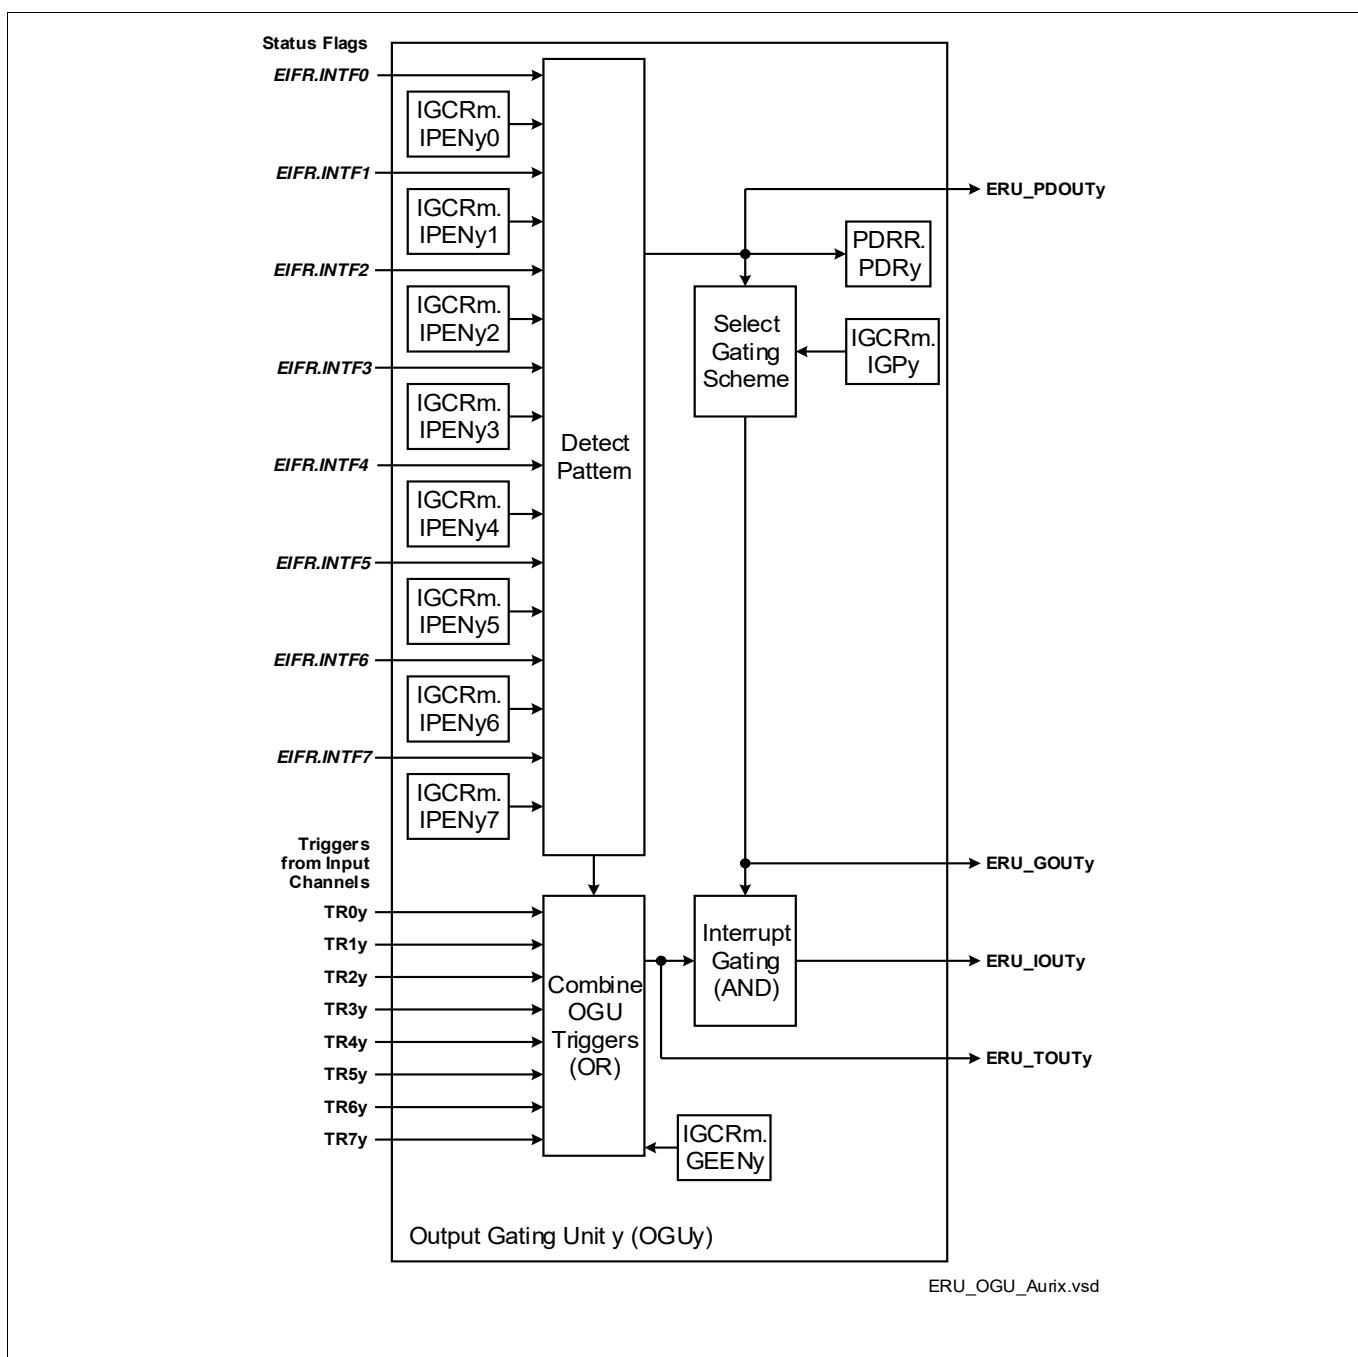

Each OGUy unit combines the available trigger events and status flags from the Input Channels and distributes the results to the system. **Figure 79** illustrates the logic blocks within an OGUy unit. All functions of an OGUy unit are controlled by the associated IGCRm registers, one for each pair of output channels e.g. IGCR1 for OGU2 and OGU3. The function of an OGUy unit can be split into two parts:

- Trigger combination:**

All trigger signals TRxy from the Input Channels that are enabled and directed to OGUy and a pattern change event (if enabled) are logically OR-combined.

- Pattern detection:**

The status flags EIFR.INTFx of the Input Channels can be enabled to take part in the pattern detection. A pattern match is detected while all enabled status flags are set.

**Figure 79 Output Gating Unit for Output Channel y**

## System Control Units (SCU)

Each OGUY units generates 4 output signals that are distributed to the system.

- **ERU\_PDOUTy** to directly output the pattern match information for gating purposes in defined target modules (pattern match = 1).
- **ERU\_GOUTy** to output the pattern match or pattern miss information (inverted pattern match), or a permanent 0 or 1 under software control for gating purposes in other modules.
- **ERU\_TOUTy** as combination of a peripheral trigger, a pattern detection result change event, or the ETLx trigger outputs TRxy to trigger actions in other modules.
- **ERU\_IOUTy** as gated trigger output (ERU\_GOUTy logical AND-combined with ERU\_TOUTy) to trigger interrupts (e.g. the interrupt generation can be gated to allow interrupt activation during a certain time window).

### 9.5.7.1 Trigger Combination

The “Combine OGU Triggers” block logically OR-combines different trigger inputs to form a common trigger ERU\_TOUTy. Possible trigger inputs are:

- In each ETLx unit of the **Input Channels**, the trigger output TRxy can be enabled and the trigger event can be directed to one of the OGUY units.
- In the case that at least one **pattern detection** input is enabled (IGCRm.IPENxy) and a change of the pattern detection result from pattern match to pattern miss (or vice-versa) is detected, a trigger event is generated to indicate a pattern detection result event (if enabled by IGCRm.GEENy).

The trigger combination offers the possibility to program different trigger criteria for several input signals (independently for each Input Channel) or peripheral signals, and to combine their effects to a single output, e.g. to generate an interrupt or to start an ADC conversion. This combination capability allows the generation of an interrupt per OGU that can be triggered by several inputs (multitude of request sources -> one reaction).

### 9.5.7.2 Pattern Detection

The “Detect Pattern” block allows the combination of the status flags of all ETLx units. Each status flag can be individually included or excluded from the pattern detection for each OGUY, via control bits IGCRm.IPENxy. The pattern detection block outputs the following pattern detection results:

- **Pattern match** (PDRR.PDRy = 1 and ERU\_PDOUTy = 1):  
A pattern match is indicated while all status flags that are included in the pattern detection are 1.
- **Pattern miss** (PDRR.PDRy = 0 and ERU\_PDOUTy = 0):  
A pattern miss is indicated while at least one of the status flags that are included in the pattern detection is 0.

In addition, the pattern detection can deliver a trigger event if the pattern detection result changes from match to miss or vice-versa (if enabled by IGCRm.GEENy = 1). The pattern result change event is logically OR-combined with the other enabled trigger events to support interrupt generation or to trigger other module functions (e.g. in an ADC). The event is indicated when the pattern detection result changes and PDRR.PDRy becomes updated.

The interrupt generation in the OGUY is based on the trigger ERU\_TOUTy that can be gated (masked) with the pattern detection result ERU\_PDOUTy. This allows an automatic and reproducible generation of interrupts during a certain time window, where the request event is elaborated by the trigger combination block and the time window information (gating) is given by the pattern detection. For example, interrupts can be issued on a regular time base while a combination of input signals occurs (pattern detection based on ETLx status bits).

Interrupt/service requests can be generated only by the ERU OGU[0-3] via its outputs ERU\_IOUT[0-3]. These outputs are connected to the IR Service Request registers SRC\_SCUERU[0-3] via the signals ERU\_INT[0-3] as described below.

**System Control Units (SCU)****Table 274 OGU to SRC connection**

<b>OGUy.ERU_IOUTy (OGU I-output signal)</b>	<b>SRC_SCUERUx (interrupt SRC register)</b>
OGU0.ERU_IOUT0	SRC_SCUERU0
OGU1.ERU_IOUT1	SRC_SCUERU1
OGU2.ERU_IOUT2	SRC_SCUERU2
<b>OGU3.ERU_IOUT3</b>	<b>SRC_SCUERU3</b>

The mapping of interrupt requests to OGUy blocks is shown in the ERU connection diagram.

A programmable gating scheme introduces flexibility to adapt to application requirements and allows the generation of interrupt requests ERU\_IOUTy under different conditions:

- **Pattern match** ( $IGCRm.IGPy = 10_B$ ):  
An interrupt request is issued when a trigger event occurs while the pattern detection shows a pattern match.
- **Pattern miss** ( $IGCRm.IGPy = 11_B$ ):  
An interrupt request is issued when the trigger event occurs while the pattern detection shows a pattern miss.
- **Independent** of pattern detection ( $IGCRm.IGPy = 01_B$ ):  
In this mode, each occurring trigger event leads to an interrupt request. The pattern detection output can be used independently from the trigger combination for gating purposes of other peripherals (independent use of ERU\_TOUTy and ERU\_PDOUTy with interrupt requests on trigger events).
- **No interrupts** ( $IGCRm.IGPy = 00_B$ , default setting)  
In this mode, an occurring trigger event does not lead to an interrupt request. The pattern detection output can be used independently from the trigger combination for gating purposes of other peripherals (independent use of ERU\_TOUTy and ERU\_PDOUTy without interrupt requests on trigger events).

### 9.5.7.3 Triggering SMU alarms

It is possible to trigger alarms to the SMU via the functional outputs of the ERU.

This is normally used to trigger a safety alarm from an external component, e.g. the component fail signal is connected to the ERU inputs and when it fails the ERU detects a transition on this input, it will trigger an alarm to the SMU.

The ERU outputs that are connected to the SMU are the IOUT signals - IOUT0 throughout IOUT7.

Please address the SMU chapter to know which alarm lines are being used for each signal.

To enable the triggers on the ERU, one shall do the following steps:

1. Identifiy which ERU input signal shall be used as alarm trigger source
2. Configure then , the specific ETL unit by:
  - configure the EXISx register field to select the input
  - configure the RENx and FENx register fields to select if the input signal is active on a rising edge or falling edge
  - if the trigger signal from the ETL shall be used instead of the status flag, as source for the Alarm, then configure the INPx field
3. Configure the specific OGU that shall be used to trigger the SMU Alarm - this is linked to which output shall be used, e.g. IOUT4, then the OGU4 shall be configured:
  - configure the IPENy0 to IPENy7 if one or more status flags are used to generate or gate the trigger signal
  - configure GENNy field to use the pattern detection path to trigger/generate the Alarm/IOUT
  - configure the IGPy field to select the gating scheme for the output Alarm/IOUT

---

**System Control Units (SCU)**

One shall address the SMU chapter, to understand if additional configuration is needed to enable a specific alarm line/trigger.

## System Control Units (SCU)

### 9.5.8 External Request Unit Registers

#### External Input Filter Register

The External Input Filter Register enables and configures optional digital Glitch Filters on the ERS inputs from PORTS.

#### EIFILT

## **System Control Units (SCU)**

## 9.6 Emergency Stop (ES)

The Emergency Stop unit (ES) provides a fast reaction to an emergency event without the intervention of software. In response to the emergency event, selected output ports can be immediately placed into a defined state (for more information see the PORT chapter).

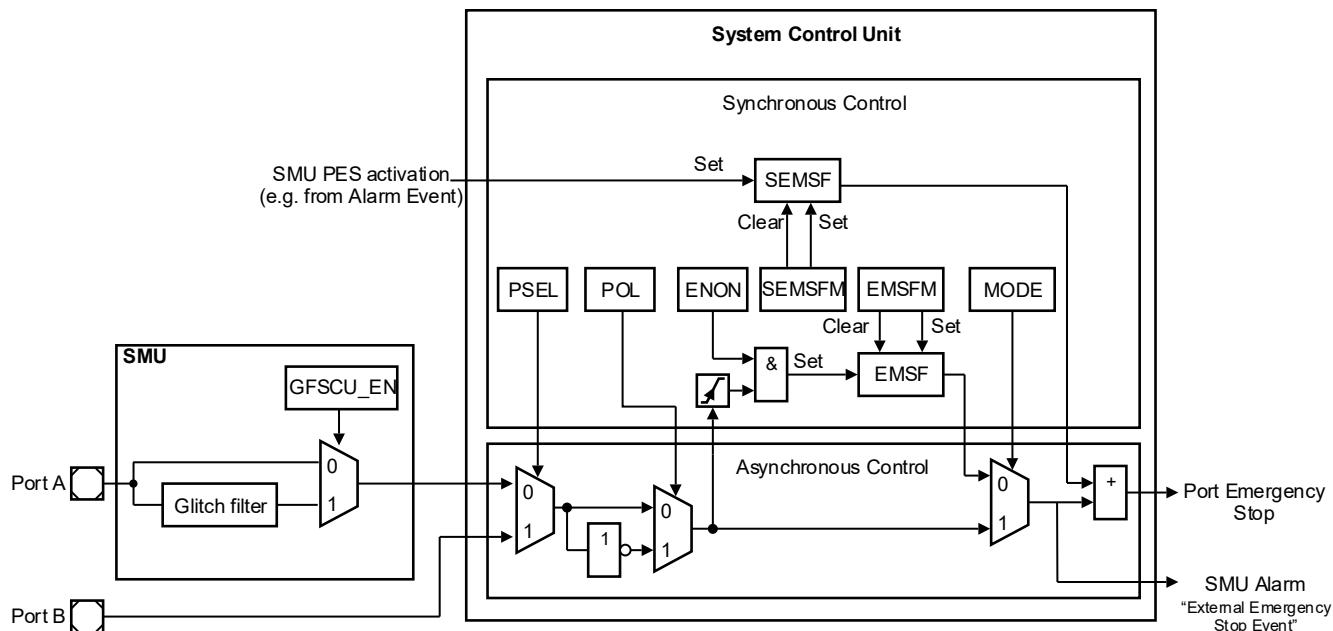

### **9.6.1 Feature List**

An Emergency Stop may be triggered by either of the following emergency events:

- A transition on the port which is configured as the Emergency Stop input
  - An SMU alarm event or SMU command which is enabled and configured to generate an Port Emergency Stop (PES). See SMU Chapter for details.

**Figure 80** shows a diagram of the emergency stop input logic. This logic is controlled by the Emergency Stop Register EMSR. There is also a possibility of using a Glitch filter, implemented in the SMU, for the Port A.

**Attention:** When a dynamic fault signaling protocol (FSP) is used, the Port A cannot be chosen as input trigger for the SCU

**Figure 80 Emergency Stop Control**

## 9.6.2 Delta to AURIX

The most significant changes between the TC2xx and TC3xx are:

- Glitch filter implemented in Port A Emergency Stop Input
  - EMSR register is now SE protected
  - The SW set and Clear fields are now in a separate register/address

### **9.6.3 Port Triggered Emergency Stop**

This can be configured to trigger on either transition edge of either one of two ports.

The two input port options are (A) P 33.8 and (B) P21.2.

## System Control Units (SCU)

The emergency stop control logic for the ports can basically operate in two modes:

- Synchronous Mode (default after reset):  
Emergency case is activated by hardware and released by software.
- Asynchronous Mode:  
Emergency case is activated and released by hardware.

In Synchronous Mode (selected by EMSR.MODE = 0), the port signal is sampled for a inactive-to-active level transition, and an emergency stop flag EMSR.EMSF is set if the transition is detected. The setting of EMSR.EMSF activates the emergency stop. A port triggered emergency state can only be terminated by clearing EMSR.EMSF via software (Write EMSSW.EMSFM with  $10_B$ ). The synchronous control logic is clocked by the system bus clock  $f_{SPB}$ . This results in a small delay between the port signal and emergency stop signal generation.

In Asynchronous Mode (selected by EMSR.MODE = 1), the occurrence of an active level at the port input immediately activates the emergency stop signal. Of course, a valid-to-invalid transition of the port input (emergency case is released) also immediately deactivates the emergency stop signal.

The EMSR.POL bit determines the active level of the input signal from the port. The EMSR.MODE bit selects Synchronous or Asynchronous Mode for emergency stop signal generation and the EMSR.PSEL bit selects which of the two ports is used as the emergency stop trigger.

### 9.6.4 SMU Event Triggered Emergency Stop

The Safety Alarm(s) which can trigger an Emergency Stop are configured and enabled within the Safety Management Unit (SMU). All SMU triggered Emergency Stop cases are in Synchronous Mode, regardless of the state of EMSR.MODE. The safety emergency stop flag EMSR.SEMSF is set when a configured and enabled SMU Safety Alarm occurs. The setting of EMSR.SEMSF activates the emergency stop. An SMU triggered emergency state can only be terminated by clearing the EMSR.SEMSF via software (Write EMSSW.SEMSF with  $10_B$ ). The synchronous control logic is clocked by the system bus clock  $f_{SPB}$ .

<b>POL</b>	0	rw	<b>Input Polarity</b> This bit determines the polarity of the configured Emergency Stop input. $0_B$ Input is active high $1_B$ Input is active low
<b>MODE</b>	1	rw	<b>Mode Selection</b> This bit determines the operating mode of the emergency stop signal. $0_B$ Synchronous Mode selected; emergency stop is derived from the state of flag EMSF $1_B$ Asynchronous Mode selected; emergency stop is directly derived from the state of the input signal
<b>ENON</b>	2	rw	<b>Enable ON</b> This bit enables the setting of flag EMSF by an inactive-to-active level transition of input signal. $0_B$ Setting of EMSF is disabled $1_B$ Setting of EMSF is enabled
<b>PSEL</b>	3	rw	<b>PORT Select</b> This bit selects which one of the two Emergency Stop port options is monitored. $0_B$ Port A is used as Emergency Stop input $1_B$ Port B is used as Emergency Stop input
<b>EMSF</b>	16	rh	<b>Emergency Stop Flag</b> This bit indicates that a synchronous mode port-triggered emergency stop condition has occurred. $0_B$ An emergency stop has not occurred $1_B$ An emergency stop has occurred and emergency stop state becomes active (if MODE = 0)

## System Control Units (SCU)

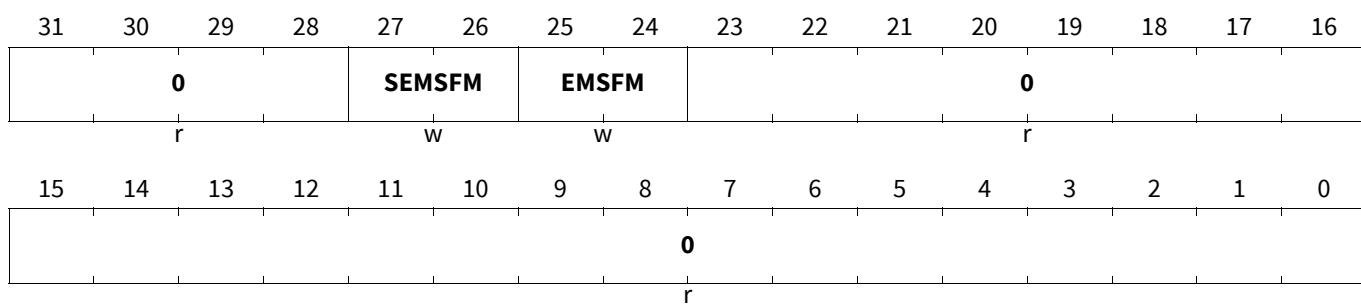

Field	Bits	Type	Description
<b>SEMSF</b>	17	rh	<b>SMU Emergency Stop Flag</b> This bit indicates that an SMU Safety Alarm triggered emergency stop condition has occurred. 0 <sub>B</sub> An emergency stop has not occurred 1 <sub>B</sub> An emergency stop has occurred and emergency stop state becomes active
<b>0</b>	15:4, 31:18	r	<b>Reserved</b> Read as 0; should be written with 0.

### Emergency Stop Software set and clear register

#### EMSSW

Emergency Stop Software set and clear register(0100<sub>H</sub>)

Application Reset Value: 0000 0000<sub>H</sub>

Field	Bits	Type	Description
<b>EMSF</b>	25:24	w	<b>Emergency Stop Flag Modification</b> This bit field sets or clears flag EMSF via software. EMSFM is always read as 00 <sub>B</sub> . 00 <sub>B</sub> EMSF remains unchanged 01 <sub>B</sub> EMSF becomes set 10 <sub>B</sub> EMSF becomes cleared 11 <sub>B</sub> EMSF remains unchanged
<b>SEMSFM</b>	27:26	w	<b>SMU Emergency Stop Flag Modification</b> This bit field sets or clears flag SEMSF via software. SEMSFM is always read as 00 <sub>B</sub> . 00 <sub>B</sub> SEMSF remains unchanged 01 <sub>B</sub> SEMSF becomes set 10 <sub>B</sub> SEMSF becomes cleared 11 <sub>B</sub> SEMSF remains unchanged
<b>0</b>	23:0, 31:28	r	<b>Reserved</b> Read as 0; should be written with 0.

---

**System Control Units (SCU)****9.7 Power Management Control Registers (PMC)**

Various control registers for Power Management are also part of the SCU.

For convenience these are described in the PMS subchapter “Power Management Control Registers (SCU)”.

**System Control Units (SCU)****9.8 Registers**

Note: Write access to LCLCONx registers are ignored without any further action when ST protection is active.

## System Control Units (SCU)

### 9.8.1 Safety Flip-Flops

Safety flip-flops are special flip-flops that implement a hardware mechanism capable to detect single event effects, that may lead to single event upsets (bit flip). The configuration and control registers that are implemented with safety flip-flops are:

- **EMSR[16]**
- **EMSR[17]**
- **EMSR[3:0]**
- **LBISTCTRL0**
- **LBISTCTRL1**
- **LBISTCTRL2**
- **LBISTCTRL3**
- **CHIPID**
- **TRAPSTAT**
- **TRAPPDIS0**
- **TRAPPDIS1**
- **ESRCFGx (x=0-1)[8:7]**
- **ESROCFG[0]**
- **IOCR**
- **WDTCPUyCON1 (y=0-5)**
- **WDTSCON1**
- **EICON1**
- **SEICON1**
- **WDTCPUyCON0 (y=0-5)[0]**
- **WDTSCON0[0]**
- **EICON0[1]**
- **SEICON0[1]**

### 9.9 IO Interfaces

The table below lists all the interfaces of the SCU to other modules in the device.

**Table 276 List of SCU Interface Signals**

Interface Signals	I/O	Description
ERU_INT(3:0)	out	<b>SCU ERU Service Request x</b>
E_REQ0(5:0)	in	<b>ERU Channel 0 input X; x=0-5, where 0 is input A and 5 is input F.</b>
E_REQ1(5:0)	in	<b>ERU Channel 1 input X; x=0-5, where 0 is input A and 5 is input F.</b>
E_REQ2(5:0)	in	<b>ERU Channel 2 input X; x=0-5, where 0 is input A and 5 is input F.</b>
E_REQ3(5:0)	in	<b>ERU Channel 3 input X; x=0-5, where 0 is input A and 5 is input F.</b>

## System Control Units (SCU)

**Table 276 List of SCU Interface Signals (cont'd)**

Interface Signals	I/O	Description
E_REQ4(5:0)	in	<b>ERU Channel 4 input X; x=0-5, where 0 is input A and 5 is input F.</b>
E_REQ5(5:0)	in	<b>ERU Channel 5 input X; x=0-5, where 0 is input A and 5 is input F.</b>
E_REQ6(5:0)	in	<b>ERU Channel 6 input X; x=0-5, where 0 is input A and 5 is input F.</b>
E_REQ7(5:0)	in	<b>ERU Channel 7 input X; x=0-5, where 0 is input A and 5 is input F.</b>
E_IOUT(7:0)	out	<b>ERU IOUTn output (MSB is IOUT7 and LSB is IOUT0)</b>
E_PDOT(7:0)	out	<b>ERU PDOUTn output (MSB is PDOUT7 and LSB is PDOUT0)</b>
EMGSTOP_PORT_A	in	<b>Emergency stop Port Pin A input request</b>
EMGSTOP_PORT_B	in	<b>Emergency stop Port Pin B input request</b>
ESR0_PORT_IN	in	<b>ESR0 Port Pin input - can be used to trigger a reset or an NMI</b>
ESR1_PORT_IN	in	<b>ESR1 Port Pin input - can be used to trigger a reset or an NMI</b>
SMU_EMGSTP_REQ	in	<b>Emergency stop request from SMU</b>
SMU_TRAP_REQ	in	<b>TRAP request from the SMU</b>
CBS_ENDINIT_DIS	in	<b>Watchdog ENDINIT disable from Cerberus</b>
CBS_WDT_SUSP	in	<b>Watchdog suspend from Cerberus</b>
RST_REQ_STM(5:0)	in	<b>Reset request from STMn (MSB is STM5 and LSB is STM0)</b>
TRAP_CPU(5:0)	out	<b>TRAP output to CPUn (MSB is CPU5 and LSB is CPU0)</b>

## 9.10 Revision History

### 9.10.1 SCU Complete Revision History

This is the complete revision history of the SCU. It contains all the relevant functional modifications for all devices. For a specific device revision history, one can address the Appendix revision history.

**Table 277 Revision History**

Reference	Change to Previous Version	Comment
V2.1.21	Revision History entries up to V2.1.20 removed.	
<a href="#">Page 126</a>	Added the Safety Flip-Flop Section	
<a href="#">Page 126</a>	LBIST reset termination textual description was updated (still missing the part of the register reset overview)	
<a href="#">Page 126</a>	Removed "Attention" note referring to TESTMODE pin.	
<a href="#">Page 18</a>	Added description "For products with no MCDS/miniMCDS/MCDSlight, the bit will always read '1'." to RSTCON2.MCDSS and RSTCON2.CSSx bitfields.	

## System Control Units (SCU)

**Table 277 Revision History (cont'd)**

Reference	Change to Previous Version	Comment
<a href="#">Page 31</a>	Note referring to TESTMODE pin has been removed from documentation.	
<b>V2.1.22</b>		
	Revision History entries up to V2.1.22 removed.	
<a href="#">Page 11</a>	Cold PORST reset value changed from 1xx10000 to 0xx10000 in RSTSTAT register.	
<a href="#">Page 11</a>	Additional cold_power_on_reset value “LVD Reset” added to RSTSTAT register.	
<a href="#">Page 61</a>	SCU_CHIPID register, CHID bitfield: Entered description of CHID constant value $E_H$ (14) for TC3Exx: “ $E_H$ SAx-TC3Exx”.	
<a href="#">Page 61</a>	SCU_CHIPID register, CHPK bitfield: Corrected description for constant value “2” to TQFP-80.	
<a href="#">Page 51</a>	LBISTCTRL0: System Reset value set to “Internal”. Added note to CFS Value in reset table: “Value installed after System and Power-On Reset.”	
<a href="#">Page 43</a>	LCLCON0 and LCLCON1: Cold PORST reset table values updated/corrected.	
<a href="#">Page 74</a>	Several typos of “ENDINIT” corrected.	
<a href="#">Page 43</a>	LCLCON0 and LCLCON1: Cold PORST reset table values updated/corrected.	
<b>V2.1.23</b>		
	Revision History entries up to V2.1.21 removed.	
	TC38EVOX product name changed to TC3Ex.	
	Typo “Value” corrected in Revision History V2.1.22.	
<a href="#">Page 70</a>	Corrected “ENDINIT Timeout Counter register (EICON0)” to “ENDINIT Global Control Registers (EICONx)” in section “Access to Endinit-Protected Registers without using WDT”.	
<a href="#">Page 129</a>	Improved the generic description of SCU_E_REQ x_request pins for all ERU channel X input descriptions, e.g.: ‘ERU channel 2 input ; x=0-5, where 0 is input A and 5 is input F.’.	
<a href="#">Page 43</a>	Typo “Mhz” corrected to “MHz” in SRU Functional Description.	
<a href="#">Page 43</a>	SCU_CHIPID register, CHID bitfield updated (clean-up, SAx-TC3Exx new) in section “Identification Registers”.	
<a href="#">Page 43</a>	Bitfield “LBISTREQRED” in register LBISTCTRL0 changed from “w” to “rw”.	
<a href="#">Page 43</a>	Masked LBISTCTRL0 reset value to display “000-----” instead of “0000-0000” in “Reset Values of LBISTCTRL0” table. Added note “The correct reset value of the LBISTCTRL0 register has to be looked up in the product-specific appendix document.”.	
<a href="#">Page 43</a>	Added information regarding stickyness of LBISTCTRL0.LBISTDONE bit to System and Application resets in section “LBIST Support”.	
<b>V2.1.24</b>		
<a href="#">Page 126</a>	Added note regarding register LCLCONx in Registers chapter.	

## System Control Units (SCU)

**Table 277 Revision History (cont'd)**

Reference	Change to Previous Version	Comment
<a href="#">Page 43</a>	Added note regarding STCON.STP bit field in chapter SRU.	
<a href="#">Page 43</a>	Updated reset values of LBISTCTRL0 register in chapter SRU.	
<a href="#">Page 35</a>	Added an inversion to CPU Trap Generation figure.	
<a href="#">Page 3</a>	Added overline to STSTAT.TRST bit field description instead of 'TRSTL'.	
<a href="#">Page 43</a>	Updated register EMDS to EMSSW twice in chapter SRU section "Emergency Stop".	

### V2.1.25

<a href="#">Page 3</a>	Updated figure "ESR Operation" in section "External Service Requests (ESRx)".	
<a href="#">Page 43</a>	Changed CHIPID.CHPK[11:8] value A to "BGA216" and CHIPID.CHID[15:12] value A to "SAx-TC3Axx".	
<a href="#">Page 102</a>	Updated description in chapter ERU section "Introduction" and added table to Chapter Pattern Detection.	

## Clocking System

# 10 Clocking System

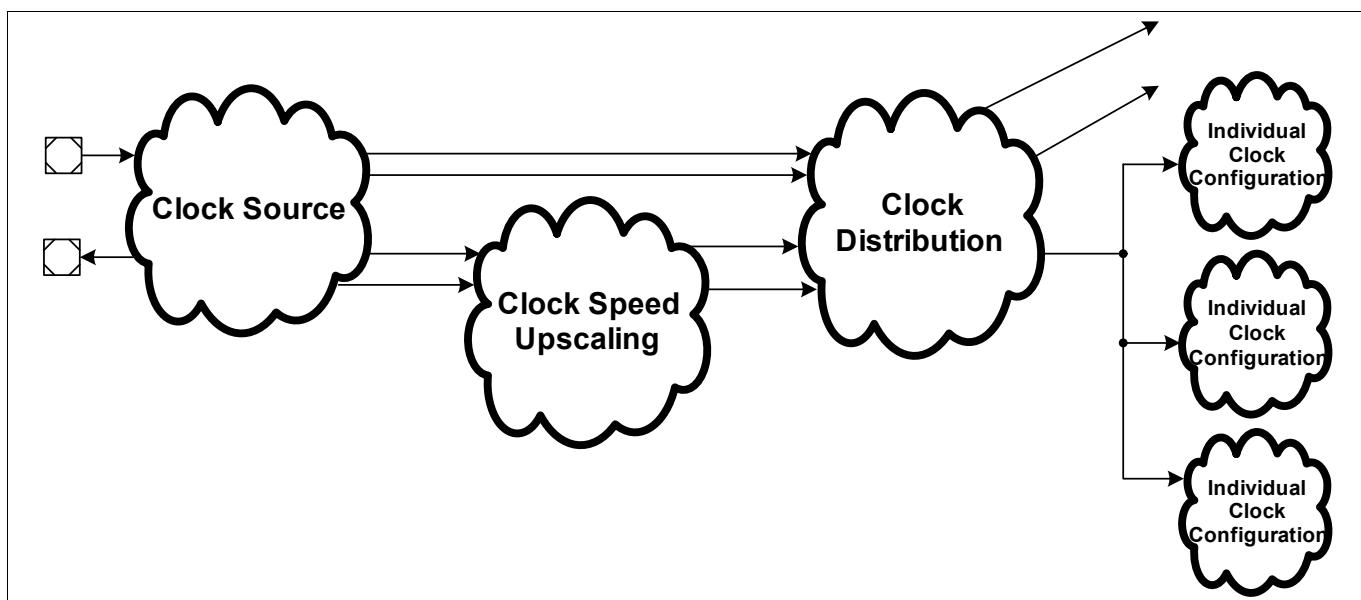

This section describes the clock system, its configuration, and the principles upon which it is based.

## 10.1 Overview

The clock system itself is built up as a chain composed from different building blocks which allow different certain function parts for this complete chain.

The building blocks are:

- Basic clock generation (Clock Source)
- Clock speed up-scaling (PLLs)
- Clock distribution (CCU)
- Individual clock configuration (Peripherals)

**Figure 81 Clock Tree**

Aside from the pure clock generation options, there are several support functions which have been integrated in order to support easy and convenient controls.

In the following subsections the clock tree is explained from left to right. Using this flow for the initial configuration is also recommended. Expert users can of course execute the configuration in an individual order.

**Note:** *If a running system needs to be re-configured not all parts of the clock tree need to be configured. Only these parts that are required can be updated.*

## Clocking System

### 10.2 Clocking System Registers Overview

The following table lists all SCU registers which are specific to the clocking system. They are prefixed with *SCU\_* in the register files.

**Table 278 Register Overview - CCU (ascending Offset Address)**

<b>Short Name</b>	<b>Long Name</b>	<b>Offset Address</b>	<b>Access Mode</b>		<b>Reset</b>	<b>Page Number</b>
			<b>Read</b>	<b>Write</b>		
OSCCON	OSC Control Register	0010 <sub>H</sub>	U,SV	SV,SE,P0	See page 6	6
SYSPLLSTAT	System PLL Status Register	0014 <sub>H</sub>	U,SV	BE	See page 14	14
SYSPLLCNO	System PLL Configuration 0 Register	0018 <sub>H</sub>	U,SV	SV,SE,P0	System Reset	15
SYSPLLCN1	System PLL Configuration 1 Register	001C <sub>H</sub>	U,SV	SV,SE,P0	System Reset	16
SYSPLLCN2	System PLL Configuration 2 Register	0020 <sub>H</sub>	U,SV	SV,SE,P0	System Reset	17
PERPLLSTAT	Peripheral PLL Status Register	0024 <sub>H</sub>	U,SV	BE	System Reset	20
PERPLLCNO	Peripheral PLL Configuration 0 Register	0028 <sub>H</sub>	U,SV	SV,SE,P0	System Reset	21
PERPLLCN1	Peripheral PLL Configuration 1 Register	002C <sub>H</sub>	U,SV	SV,SE,P0	System Reset	22
CCUCONO	CCU Clock Control Register 0	0030 <sub>H</sub>	U,SV	SV,SE,P0	See page 28	28
CCUCON1	CCU Clock Control Register 1	0034 <sub>H</sub>	U,SV	SV,SE,P0	System Reset	32
FDR	Fractional Divider Register	0038 <sub>H</sub>	U,SV	SV,SE,P0	System Reset	49
EXTCON	External Clock Control Register	003C <sub>H</sub>	U,SV	SV,SE,P0	System Reset	47
CCUCON2	CCU Clock Control Register 2	0040 <sub>H</sub>	U,SV	SV,SE,P0	System Reset	36
CCUCON3	CCU Clock Control Register 3	0044 <sub>H</sub>	U,SV	SV,SE,P0	System Reset	53
CCUCON4	CCU Clock Control Register 4	0048 <sub>H</sub>	U,SV	SV,SE,P0	System Reset	55
CCUCON5	CCU Clock Control Register 5	004C <sub>H</sub>	U,SV	SV,SE,P0	System Reset	39
CCUCON6	CCU Clock Control Register 6	0080 <sub>H</sub>	U,SV	SV,SE,P0	System Reset	41
CCUCON7	CCU Clock Control Register 7	0084 <sub>H</sub>	U,SV	SV,SE,P0	System Reset	42
CCUCON8	CCU Clock Control Register 8	0088 <sub>H</sub>	U,SV	SV,SE,P0	System Reset	42
CCUCON9	CCU Clock Control Register 9	008C <sub>H</sub>	U,SV	SV,SE,P0	System Reset	43

## Clocking System

**Table 278 Register Overview - CCU (ascending Offset Address) (cont'd)**

<b>Short Name</b>	<b>Long Name</b>	<b>Offset Address</b>	<b>Access Mode</b>		<b>Reset</b>	<b>Page Number</b>
			<b>Read</b>	<b>Write</b>		
CCUCON10	CCU Clock Control Register 10	0090 <sub>H</sub>	U,SV	SV,SE,P0	System Reset	<b>43</b>
CCUCON11	CCU Clock Control Register 11	0094 <sub>H</sub>	U,SV	SV,SE,P0	System Reset	<b>44</b>

### 10.2.1 Safety Flip-Flops

Safety flip-flops are special flip-flops that implement a hardware mechanism capable to detect single event effects that may lead to single event upsets (bit flip). The configuration and control registers that are implemented with safety flip-flops are:

- [OSCCON](#)
- [SYSPLLCON0](#)
- [SYSPLLCON1](#)
- [SYSPLLCON2](#)
- [PERPLLCON0](#)
- [PERPLLCON1](#)
- [CCUCON0](#)
- [CCUCON1](#)
- [CCUCON2](#)
- [CCUCON3](#)
- [CCUCON4](#)
- [CCUCON5](#)
- [CCUCON6](#)
- [CCUCON7](#)
- [CCUCON8](#)
- [CCUCON9](#)
- [CCUCON10](#)
- [CCUCON11](#)

### 10.3 Clock Sources

There are several clock sources available which either source the complete device, a major or minor part, or only dedicated modules. This depends on the sources and the configuration.

Please note that several clock sources can be used in parallel inside the system, but the main function of each peripheral is only related to one source at any time.

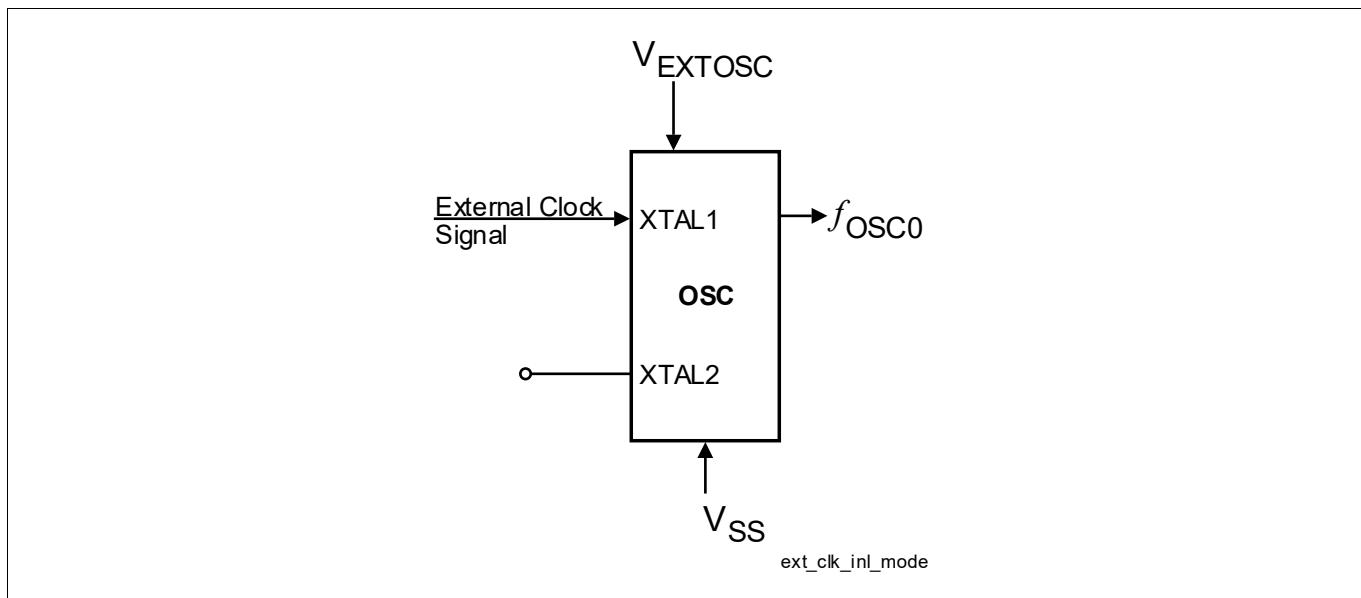

#### 10.3.1 Oscillator Circuit (OSC)

The oscillator circuit, a Pierce oscillator, is designed to work with both an external crystal / ceramic resonator or an external stable clock source. The circuit consists of an inverting amplifier with XTAL1 as input, and XTAL2 as output with an integrated feedback resistor.

## Clocking System

### 10.3.1.1 External Input Clock Mode

When using an external clock signal it must be connected to XTAL1. XTAL2 is left open (unconnected).

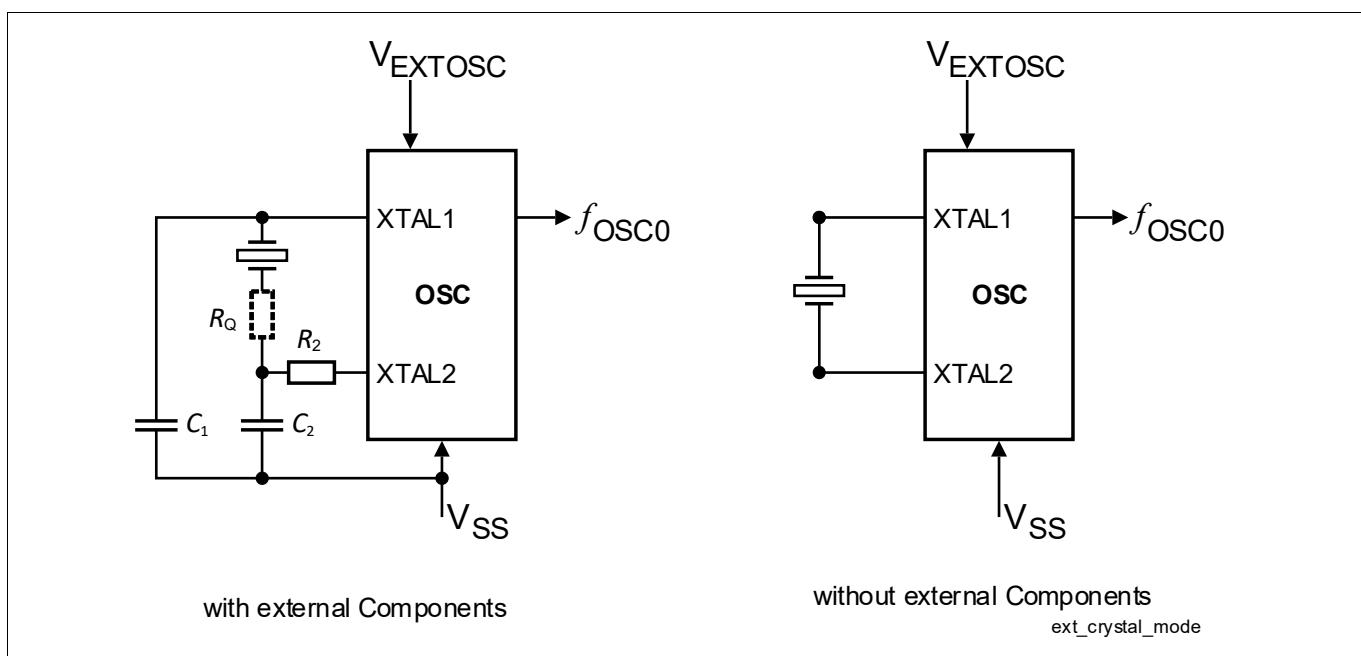

**Figure 82 AURIX™ TC3xx Platform Direct Clock Input**

When supplying the clock signal directly, not using an external crystal / ceramic resonator and bypassing the oscillator, the input frequency needs to be equal or greater than the PLL's DCO input frequency (the value is listed in the Data Sheet) if used in normal Mode.

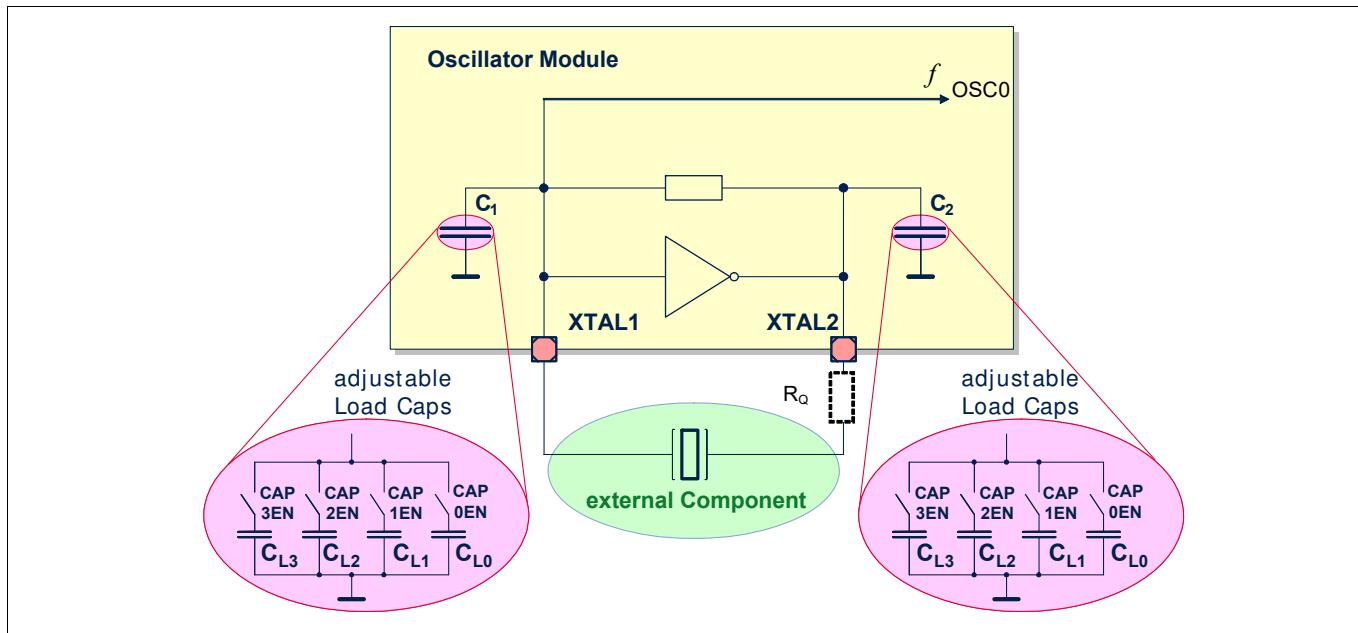

### 10.3.1.2 External Crystal / Ceramic Resonator Mode

**Figure 83** shows the recommended external circuits for both operating modes: External Crystal / Ceramic Resonator Mode with and without external components.

**Figure 83 External Circuitry for Crystal / Ceramic Resonator operation**

## Clocking System

**Figure 84 Circuitry for Crystal / Ceramic Resonator operation with internal caps**

When using an external crystal / ceramic resonator, its frequency can be within the allowed range (the values are listed in the Data Sheet). An external oscillator load circuitry can be used, connected to both pins, XTAL1 and XTAL2. Also needed are two load capacitors  $C_1$  and  $C_2$  (see [Figure 83](#)) or the internal loads can be used (see [Figure 84](#)). Also, depending on the crystal / ceramic resonator type, a series resistor  $R_2$  is needed to limit the current. A test resistor  $R_Q$  may be temporarily inserted to measure the oscillation allowance (negative resistance) of the oscillator circuitry.  $R_Q$  values are typically specified by the crystal / ceramic resonator vendor. The  $C_1$  and  $C_2$  values shown in the Data Sheet can be used as starting points for the negative resistance evaluation and for non-production systems. The exact values and related operating range are dependent on the crystal / ceramic resonator frequency, and have to be determined and optimized together with the crystal / ceramic resonator vendor using the negative resistance method. Oscillation measurement with the final target system is strongly recommended to verify the input amplitude at XTAL1 and to determine the actual oscillation allowance (margin negative resistance) for the oscillator-crystal / ceramic resonator system.

The oscillator can also be used in combination with a ceramic resonator. The final circuitry must be also verified by the resonator vendor.

## Clocking System

## Clocking System

**Table 279 Reset Values of OSCCON**

Reset Type	Reset Value	Note
System Reset	0000 0X1X <sub>H</sub>	

### 10.3.1.4 Configuration of the Oscillator

A configuration of the oscillator is always required before an external crystal / ceramic resonator can be used as clock source.

After any power-on reset the oscillator is disabled and needs to be configured as described in this section. During and after any other reset the oscillator is not affected and operates as previously configured, no re-configuration is required for this case.

For this start-up configuration, two options are supported:

- Configuration via the SSW
- Configuration after the execution of the SSW

#### Configuration via SSW

This option is enabled when bit FLASH0\_PROCOND.OSCCFG is set. In this mode the control information for the register OSCCON is loaded from FLASH0\_PROCOND by the SSW. Therefore the required information needs to be stored in UCB\_DFlash at offset 00<sub>H</sub>.

In this mode OSCCON.MODE, OSCCON.GAIN, OSCCON.HYSEN, OSCCON.HYSCTL, OSCCON.AMPCTL, and OSCCON.CAPxEN together with bit OSCCON.APREN are controllable.

If the oscillator was disabled it must be enabled by setting bit field OSCCON.MODE = 00<sub>B</sub>.

The gain setting should be adjusted to the needs of the connected external crystal / resonator in conjunction with the used capacitor configuration.

If the integrated capacitors should be used this can be enabled via the bits OSCCON.CAPxEN. If OSCCON[27:24] ≠ 0000<sub>B</sub> then bit OSCCON.APREN need to be set too. Please note that Amplitude Regulation must always be enabled when integrated caps are used. Enabling Amplitude Regulation does not require a change for OSCCON.GAINSEL, which should be left at 11<sub>B</sub>.

#### Configuration after SSW

After the optional configuration in the SSW there is always an option to configure the oscillator in the application software.

This is done via register OSCCON. The register itself is Safety ENDINIT protected.

In general the same rules apply for configuration as described in the previous section.

### 10.3.1.5 Oscillator Watchdog

The oscillator clock is selected as the source for the watchdog by configuring SYSPLLCON0.INSEL = 01<sub>B</sub>.

In combination with the System PLL, a monitoring function is implemented. This feature is defined to detect severe malfunctions of an external crystal / ceramic resonator. The system can detect a loss of clock input or a much too high input frequency (operation on a higher harmonic).

The oscillator watchdog monitors the incoming clock frequency  $f_{osc}$  from OSC. A stable and defined input frequency is a mandatory requirement for operation. Therefore this mode is selected automatically after each System Reset.

## Clocking System

The expected input frequency  $f_{\text{osc}}$  is selected via the bit field OSCCON.OSCVAL. The OSC\_WDT checks for frequencies which are too low or too high.

$$f_{\text{osc}} = \text{OSCCON.OSCVAL} - 1 + 16 \text{ MHz} \quad (10.1)$$

Before configuring the OSC\_WDT function, all the SMU Oscillator Watchdog alarm response options should be disabled, to avoid unintended SMU alarms. Thereafter the value of OSCCON.OSCVAL can be changed. Then the OSC\_WDT should be reset by setting OSCCON.OSCRES. This requests the start of OSC\_WDT monitoring with the new configuration. When the expected positive monitoring results of OSCCON.PLLLV and / or OSCCON.PLLHV are set, the input frequency is within the expected range. As setting OSCCON.OSCRES clears both bits OSCCON.PLLLV and OSCCON.PLLHV both status flags shall be set. Therefore both flags should be cleared before the SMU alarm responses are enabled again. The SMU alarm disabling-clearing-enabling sequence should also be used if only bit OSCCON.OSCRES is set without any modification of OSCCON.OSCVAL.

If the SMU detects an oscillator watchdog alarm, the same recovery procedure as from a PLL loss of lock event has to be executed.

**Note:** *The oscillator watchdog is intended to be used primarily when the PLL input clock  $f_{\text{osc}_i}$  is set to  $f_{\text{osc}_0}$  via register SYSPLLCON0.INSEL = 01<sub>B</sub>. If the SYCLK is used as source for  $f_{\text{osc}_i}$  via SYSPLLCON0.INSEL = 10<sub>B</sub>, the user shall either restrict the SYCLK frequency to be in the same range as when using a crystal or disable the watchdog alarms in the SMU. When using the backup clock as input for  $f_{\text{osc}_i}$  via SYSPLLCON0.INSEL = 00<sub>B</sub>, the watchdog alarms need to be disabled as well. The usable crystal frequency range and the allowed frequency range when driving the SYCLK via its assigned GPIO input pin is listed in the datasheet.*

### 10.3.2 Back-up Clock

A back-up clock source is available as an alternate clock source. This clock source provides a stable but reliable clock source that can be used as clock for the system. It provides less accuracy than an external crystal or ceramic resonator. The back-up clock can not be enabled or disabled, or otherwise be controlled that could prevent its general operation. Therefore, no control bits are available beside selecting the backup-clock as source (CCUCON0.CLKSEL = 00<sub>B</sub> as clock source for the clock distribution and SYSPLLCON0.INSEL = 00<sub>B</sub> as clock source for the two PLLs).

## 10.4 Clock Speed Up-Scaling (PLLs)

Typical CPU operating speeds are about 10 times faster (or even faster) than the speed of the used crystal as clock source. Therefore an up-scaling of the clock frequency is required.

For the up-scaling two Phase Lock Loop (PLLs) are provided.

### 10.4.1 System Phase-Locked Loop (System PLL) Module

The System PLL can convert a low-frequency external clock signal to a high-speed internal clock for maximum performance. It allows the use of a wide range of input and output frequencies by varying the different divider factors.

The System PLL also has fail-safe logic that detects degenerate external clock behavior, such as abnormal frequency deviations or a total loss of the external clock. It can execute emergency actions if it loses its lock on the external clock.

#### 10.4.1.1 Features

- DCO lock detection

---

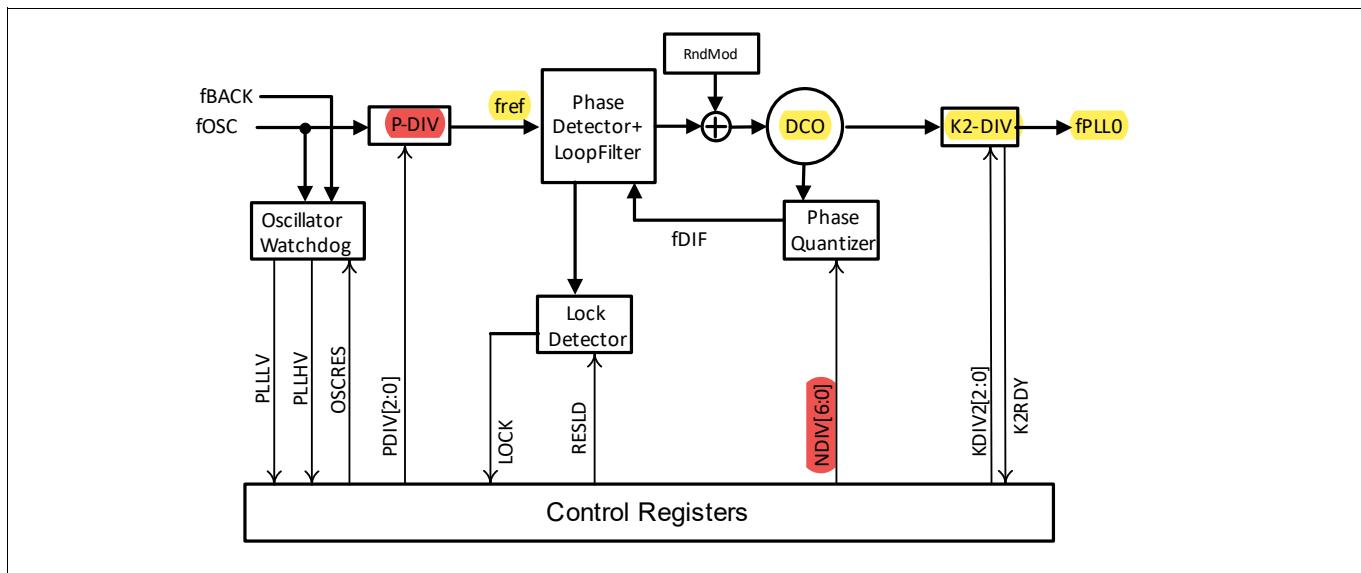

## Clocking System

- 3-bit input divider **P** (divide by PDIV+1)
- 7-bit feedback divider **N** (multiply by NDIV+1)
- 3-bit output divider **K2** (divide by K2DIV+1)
- Oscillator Watchdog
  - Detection of input frequencies that are too low
  - Detection of input frequencies that are too high
- Frequency Modulation with low jitter

## Clocking System

### 10.4.1.2 System PLL Functional Description

The following figure shows the System PLL block structure.

**Figure 85 System PLL Block Diagram**

#### Basic System PLL Operation

The input frequency  $f_{OSC}$  is divided down by a factor P, multiplied by a factor N, and then divided down by a factor K2.

The output frequency is given by

$$f_{PLL0} = (N * f_{OSC}) / (P * K2) \quad (10.2)$$

1)

Operation requires an input clock frequency of  $f_{OSC}$ . Therefore it is recommended to check and monitor if an input frequency  $f_{OSC}$  is available at all by checking OSCCON.PLLV. For better monitoring, the upper frequency can also be monitored via OSCCON.PLLHV.

The system operation frequency is controlled by the values of the three dividers: P, N, and K2. **A modification of the two dividers P and N has a direct influence to the DCO frequency and could lead to a loss of the Lock status.** A modification of the K2-divider has no impact on the lock status, but still changes the System PLL output frequency  $f_{PLL0}$ .

**Note:** *Changing the system operation frequency by changing the value of the K2-Divider has a direct coupling to the power consumption of the device. Therefore this has to be done carefully.*

When the frequency of the System PLL output frequency must be modified, the following sequence should be followed:

The SMU alarm generation for the Loss of Lock should be disabled.

While a different clock source is used for the CCU, the System PLL can be configured and checked for a positive DCO Lock status. The first target frequency should be selected in a way that it matches or is only slightly higher as the one used currently by the CCU. This avoids big changes in the system operation frequency (and therefore power consumption) when later switching to the System PLL. The P and N divider should be selected in the following way:

1) Please refer to the Data Sheet for valid PLL frequencies to determine the N,P and K2 settings

## Clocking System

- Select P and N in a way that  $f_{DCO}$  is in the lower area of its allowed values. This leads to slightly reduced power consumption but to slightly increased jitter.
- Select P and N in a way that  $f_{DCO}$  is in the upper area of its allowed values. This leads to slightly increased power consumption but to slightly reduced jitter.

After the P, N, and K2 dividers have been updated on the first configuration, the indication of the DCO Lock status should be checked (SYSPLLSTAT.LOCK = 1).

### Notes

1. It is recommended to reset the DCO Lock detection (SYSPLLCON0.RESLD = 1) after the new values of the dividers are configured to get a defined DCO lock check time.

After System PLL lock, the switch to the System PLL can be done.

The SMU status flag for the System PLL Loss-of-Lock event should be cleared and then enabled again. The intended System PLL output target frequency can now be configured by changing only the K2-Divider.

Depending on the selected value of the K2-Divider, the cycle time of the output clock is selected. This can have an impact for the operation with an external communication interface.

Change the K2-Divider in multiple steps, to avoid large changes in output frequency, and thus large changes in power consumption. Wait 6 cycles of  $f_{PLL0}$  between updates of the K2-Divider value.

### System PLL Lock Detection

The System PLL has a lock detection feature, that supervises the DCO part of the System PLL to differentiate between stable and unstable DCO circuit behavior. The lock detector marks the DCO circuit and therefore the output  $f_{DCO}$  of the DCO as unstable if the two inputs  $f_{REF}$  and  $f_{DIV}$  differ too much. Changes in one or both input frequencies below a certain level are not marked by a loss of lock, because the DCO can handle small changes without any problem for the system.

### System PLL Loss-of-Lock Event

The System PLL may become unlocked, due to a break of the crystal / ceramic resonator or the external clock line. In such a case, an SMU alarm event is generated.

### System PLL Power Down Mode

The System PLL offers a Power Down Mode. This mode can be entered to save power if the System PLL is not needed at all. The Power Down Mode is entered by setting bit SYSPLLCON0.PLLPWD. While the System PLL is in Power Down Mode, no System PLL output frequency is generated.

### Frequency Modulation

The System PLL output frequency  $f_{PLL0}$  can additionally be modified by a low-frequency modulation to reduce EMI. A random sequence is added to the DCO resulting in a randomly modulated  $f_{DCO}$ . The modulation frequency is defined by  $f_{REF}$ .

The modulation is enabled via bit SYSPLLCON0.MODEN. The modulation itself alters the DCO frequency randomly within the range of the configured modulation amplitude (MA). The modulation amplitude is selected via SYSPLLCON2.MODCFG[9:0].

$$\text{SYSPLLCON2.MODCFG[9:0]} = \text{HEX}[(64 * (\text{MA} / 100)) * (f_{osc} / P) * (N / f_{MV})] \quad (10.3)$$

Example: for MA = 1.25%;  $f_{osc}$  = 20 MHz; P = 2; N = 60;  $f_{MV}$  = 3.6 MHz the resulting bit field setting is 0x85.

The modulation is performed in a way that the resulting accumulated jitter added by the modulation stays below  $J_{MOD}$  (see the Data Sheet for the defined value). The modulation itself is monitored with  $f_{REF}$  and therefore the P-Divider should be configured with the smallest possible value.

**Clocking System****10.4.1.3 System PLL Registers**

The System PLL registers can be accessed by all CPUs in the system. However, it is suggested that only one CPU is used to control the clocks. As CPU0 is the active and available CPU immediately after a reset, this is the logical choice.

**System PLL Status Register**

These registers reflects the settings of the System PLL.

**SYSPLLSTAT****System PLL Status Register**(0014<sub>H</sub>)Reset Value: [Table 280](#)

### 10.4.2 Peripheral Phase-Locked Loop (Peripheral PLL) Module

The Peripheral PLL can convert a low-frequency external clock signal to a high-speed internal clock for maximum performance. It allows the use of input and output frequencies over a wide range by varying the different divider settings.

The Peripheral PLL also has fail-safe logic that detects degenerate external clock behavior such as abnormal frequency deviations or a total loss of the external clock. It can execute emergency actions if it loses its lock on the external clock.

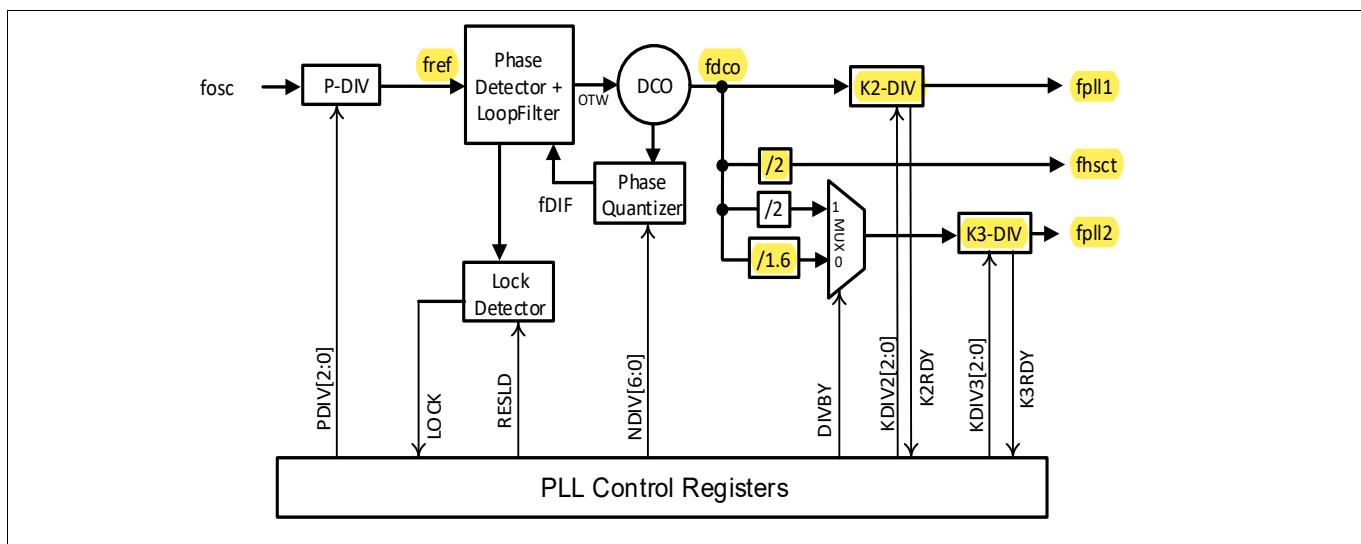

#### 10.4.2.1 Features

- DCO lock detection
- 3-bit input divider **P** (divide by PDIV+1)
- 7-bit feedback divider **N** (multiply by NDIV+1)
- 3-bit output divider **K2** (divide by K2DIV+1)
- 3-bit output divider **K3** (divide by K3DIV+1)

## Clocking System

### 10.4.2.2 Peripheral PLL Functional Description

The following figure shows the Peripheral PLL block structure.

**Figure 86 Peripheral PLL Block Diagram**

#### Basic Peripheral PLL Operation

The input frequency  $f_{osc}$  is divided down by a factor P, multiplied by a factor N, and then divided down by a factor K2 / K3.

The output frequency is given by:

$$f_{PLL1} = (N * f_{osc}) / (P * K2) \quad (10.4)$$

$$f_{PLL2} = (N * f_{osc}) / (P * K3 * 1,6) \text{ if } DIVBY = 0 \text{ or } f_{PLL2} = (N * f_{osc}) / (P * K3 * 2) \text{ if } DIVBY = 1 \quad (10.5)$$

1)

In addition the Peripheral PLL provides a special clock output  $f_{HSCT}$

$$f_{HSCT} = f_{Dco} / 2 \quad (10.6)$$

Operation does require an input clock frequency of  $f_{osc}$ . Therefore, it is recommended to check and monitor if an input frequency  $f_{osc}$  is available at all by checking OSCCON.PLLLV. For better monitoring, the upper frequency can also be monitored via OSCCON.PLLHV.

The system operation frequency is controlled by the values of the four dividers: P, N, and K2 / K3. A modification of the two dividers P and N has a direct influence to the DCO frequency and could lead to a loss of the Lock status. A modification of the K2 / K3-divider has no impact on the lock status, but still changes the Peripheral PLL output frequency  $f_{PLL1/2}$ .

**Note:** Changing the system operation frequency by changing the value of the K2 / K3-Divider has a direct coupling to the power consumption of the device. Therefore this has to be done carefully.

When the frequency of the Peripheral PLL output frequency must be modified, the following sequence should be followed:

The SMU alarm generation for Loss of Lock should be disabled.

1) Pls. refer to the Data Sheet for valid PLL frequencies to determine the N,P and K2/3 settings

## Clocking System

Configuration of the Peripheral PLL can be done independent of the System PLL. While configuring the Peripheral PLL the connected modules should either operate on the different clock source, or be configured for no operation. The P and N divider should be selected in the following way:

- Select P and N in a way that  $f_{DCO}$  is in the lower area of its allowed values. This leads to slightly reduced power consumption but to slightly increased jitter
- Select P and N in a way that  $f_{DCO}$  is in the upper area of its allowed values. This leads to slightly increased power consumption but to slightly reduced jitter

After the P, N, and K2 / K3 dividers have been updated on the first configuration, the indication of the Lock status should be checked (PERPLLSTAT.LOCK = 1).

### Notes

1. It is recommended to reset the Lock detection (PERPLLCON0.RESLD = 1) after the new values of the dividers are configured to get a defined lock check time.

After the Peripheral PLL is locked, the switch to the Peripheral PLL can be performed.

The SMU status flag for the Peripheral PLL Loss-of-Lock event should be cleared and then enabled again. The intended Peripheral PLL output target frequency can now be configured by changing only the K2 / K3-Divider.

Depending on the divider value of the K2 / K3-Divider the cycle time of the clock is selected. This can have an impact for the operation with an external communication interface.

Change the K2 / K3-Divider in multiple steps, to avoid large frequency changes, and thus large changes in power consumption. Wait 6 cycles of  $f_{PLL1}$  between updates of two K2 / K3-Divider.

### Peripheral PLL Lock Detection

The Peripheral PLL has a lock detection feature that supervises the DCO part of the Peripheral PLL in order to differentiate between stable and unstable DCO circuit behavior. The lock detector marks the DCO circuit and therefore the output  $f_{DCO}$  of the DCO as unstable if the two inputs  $f_{REF}$  and  $f_{DIV}$  differ too much. Changes in one or both input frequencies below a certain level are not marked by a loss of lock, because the DCO can handle small changes without any problem for the system.

### Peripheral PLL Loss-of-Lock Event

The Peripheral PLL may become unlocked, due to a break of the crystal / ceramic resonator or the external clock line. In such a case, an SMU alarm event is generated.

### Peripheral PLL Power Down Mode

The Peripheral PLL offers a Power Down Mode. This mode can be entered to save power if the Peripheral PLL is not needed at all. The Power Down Mode is entered by setting bit PERPLLCON0.PLLPWD. While the Peripheral PLL is in Power Down Mode, no Peripheral PLL output frequency is generated.

**Clocking System****10.4.2.3 Peripheral PLL Registers**

The Peripheral PLL registers can be accessed by all CPUs in the system. However, it is suggested that only one CPU is used to control the clocks. As CPU0 is the active and available CPU immediately after a reset, this is the logical choice.

**Peripheral PLL Status Register**

These registers displays the setting of the Peripheral PLL.

**PERPLLSTAT**

## Clocking System

### 10.5 Clock Distribution (CCU)

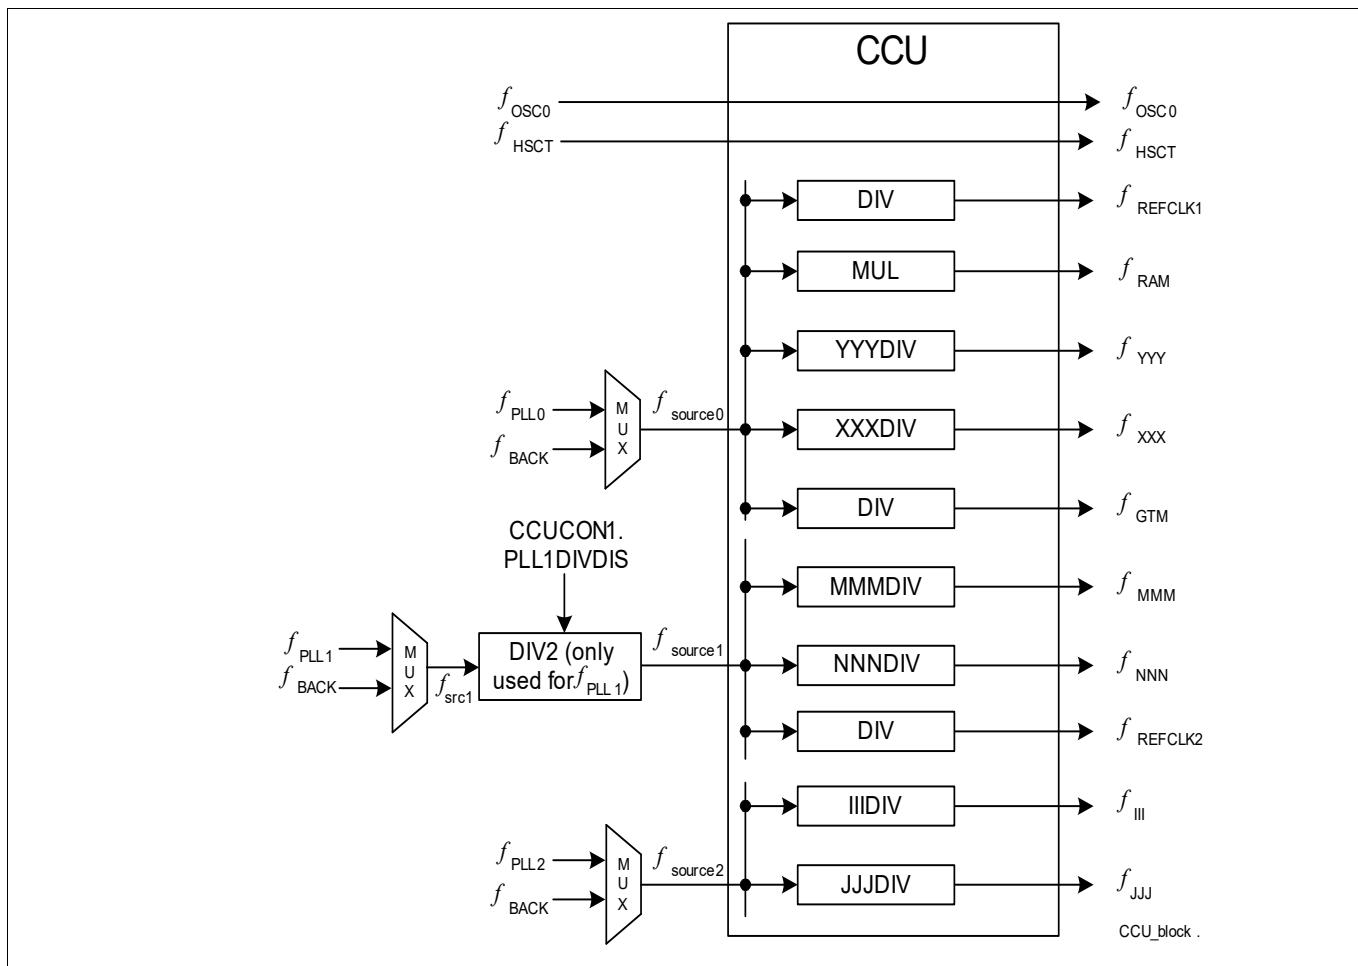

Using the first two parts of the Clock System, all root clocks the system relies on for operation are defined. In the following, these root clocks need to be individually adapted in frequency (divided) and distributed to all the MCU's modules, CPUs and blocks. This is done with focus on performance and power consumption optimization.

For clock distribution, the system is split into several sub-clock domains where the clock speed could be configured individually. There are also limitation for each sub-clock domain derived out of the internal interfaces. Each sub-clock domain defines a logical unit from a clocking perspective point of view.

The clock distribution is done via the Clock Control Unit (CCU). The CCU receives the clocks that are created by the two PLLs ( $f_{PLL0}$  and  $f_{PLL1/2}$ ), the back-up clock  $f_{Back}$ , and  $f_{Osc0}$ . These clocks are either forwarded directly or divided in order to supply the sub-clock domains.

#### 10.5.1 Clock Control Unit

The Clock Control Unit (CCU) receives the clocks that are created by the two PLLs ( $f_{PLL0}$  and  $f_{PLL1/2}$ ), the back-up clock  $f_{Back}$ , and  $f_{Osc0}$ .

**Figure 87 Clock Control Unit Overview**

For most clocks, a linear divider is provided to adapt the clock frequency to the application requirement. This divider is controlled by the bit field XXXDIV in the registers CCUCONy.

The clocking system is very flexible in its configuration. This allows the adaptation of the frequency change to a specific current limit defined by the application.

## Clocking System

For the GTM, there is a fixed divider and a programmable divider in the CCU, delivering a clock that is only dependent on the System PLL or the back-up clock.

$$f_{\text{GTM}} = f_{\text{SOURCEGTM}} / \text{GTMDIV} \quad (10.7)$$

$$f_{\text{SOURCEGTM}} = f_{\text{SPB}} * 2 \text{ if } \text{GTMDIV} = 0001_B \text{ else } f_{\text{SOURCEGTM}} = f_{\text{SOURCEO}} \quad (10.8)$$

For the Ethernet RAMs, there is a fixed divider in the CCU, delivering a constant clock from either the System PLL or the back-up clock.

$$f_{\text{RAM}} = f_{\text{SPB}} * 2 \quad (10.9)$$

For the ERAY, there is a fixed divider in the CCU, delivering a constant clock from either the Peripheral PLL  $f_{\text{PLL1}}$  or the back-up clock.

$$f_{\text{ERAY}} = f_{\text{source1}} / 2 \quad (10.10)$$

For the EBU, there is a fixed divider in the CCU, delivering a constant clock from either the Peripheral PLL  $f_{\text{PLL1}}$  or the back-up clock.

$$f_{\text{EBU}} = f_{\text{source1}} \quad (10.11)$$

For the ADCs, there is a fixed divider in the CCU, delivering a constant clock from either the Peripheral PLL  $f_{\text{PLL1}}$  or the back-up clock.

$$f_{\text{ADC}} = f_{\text{source1}} \quad (10.12)$$

For the HSPDM, there is a fixed divider in the CCU, delivering a constant clock from either the Peripheral PLL  $f_{\text{PLL1}}$  or the back-up clock.

$$f_{\text{HSPDM\_160}} = f_{\text{source1}} \quad (10.13)$$

$$f_{\text{HSPDM\_320}} = f_{\text{src1}} \quad (10.14)$$

For the HSCT there is a connection from Peripheral PLL  $f_{\text{PLL1}}$ .

$$f_{\text{HSCT}} = f_{\text{DCO}} / 2 \quad (10.15)$$

There is also a fixed reference clock REFCLK1/2 for the debug block, which divides the master clock  $f_{\text{SOURCEO/1}}$  by 24. This allows the OCDS to generate timestamps independent of the selected SRI and SPB clock speeds.

### 10.5.1.1 Basic Clock System Mechanisms

The clocking system offers many options and a high amount of flexibility. For different IPs (CPUs, modules or module clusters), options are included to influence the application execution / performance via the clock control.

The following is a brief overview of the different clocks:

- System buses
  - $f_{\text{SRI}}$  defines the operating performance of the SRI-Bus, and therefore the data exchange rate between all connected masters and slaves
  - $f_{\text{SPB}}$  defines the operating performance of the SPB-Bus, and therefore the data exchange rate between all connected masters and slaves and the interrupt system
- CPU controls
  - $f_{\text{CPUx}}$  defines the execution speed of CPUx
- PMU controls
  - $f_{\text{FSI2}}$  defines the execution speed of the PFlash for reading operations
  - $f_{\text{FSI}}$  defines the execution speed for all other flash operations

## Clocking System

- Peripheral options
  - $f_{STM}$  defines the basic frequency for the STMs independent of the rest of the system (beside the limitations listed in [Table 282](#)). This allows the STMs to operate on a constant frequency.
  - $f_{GTM}$  defines the basic frequency for the GTM independent of the rest of the system (beside the limitations listed in [Table 282](#)). This allows the GTM to operate on a constant frequency.
  - $f_{MCAN}$  defines the basic frequency for the MCAN independent of the rest of the system. This allows the MCAN to operate on a constant baud rate (frequency).
  - $f_{MCANH}$  defines the frequency for the internal clocking of the MCAN module. This frequency is independent to  $f_{SPB}$  and allows the MCAN to continue operation when  $f_{SPB}$  is reduced in frequency, thus enabling pretended networking.  $f_{MCANH}$  must always be greater than  $f_{MCAN}$ .
  - $f_{ADC}$  defines the basic frequency for the ADCs (valid for EVADC and EDSADC) independent of the rest of the system. This allows the ADCs to operate on a constant frequency.
  - $f_{MSC}$  defines the basic frequency for the MSCs independent of the rest of the system. This allows the MSCs to operate on a constant baud rate (frequency).
  - $f_{QSPI}$  defines the basic frequency for the QSPIs independent of the rest of the system. This allows the QSPIs to operate on a constant baud rate (frequency).
  - $f_{ASCLINF/S}$  defines the basic frequencies for the ASCLINs independent of the rest of the system. This allows the ASCLINs to operate on a constant baud rate (frequency).
  - $f_{EBU}$  defines the basic frequency for the EBU independent of the rest of the system. This allows the EBU to operate on a constant baud rate (frequency). Please note that this clock is not available in all products. Please refer to the Platform Feature Overview whether the module EBU is present at all for the variant you are using.
  - $f_{I2C}$  defines the basic frequency for the I2C independent of the rest of the system. This allows the I2C to operate on a constant baud rate (frequency).
  - $f_{ERAY}$  defines the basic frequency for the ERAY independent of the rest of the system. This allows the ERAY to operate on a constant baud rate (frequency).
  - $f_{HSCT}$  defines the basic frequency for the HSCT independent of the rest of the system. This allows the HSCT to operate on a constant baud rate (frequency).
  - $f_{GETH}$  defines the basic frequency for the Gigabit Ethernet Kernel. This frequency is independent of  $f_{SPB}$  and allows the Gigabit Ethernet to operate at a constant baud rate (frequency).
  - $f_{ADAS}$  defines the basic frequency for the SPU and RIF Kernels. This frequency is independent to  $f_{SRI}$  and allows the SPU and RIF to operate at a constant frequency when  $f_{SRI}$  is reduced in frequency. Please note that this clock is not available in all products. Please refer to the Platform Feature Overview whether the modules RIF and SPU are present at all for the variant you are using.
- Debug system
  - Because debugging should be non-intrusive to the application system, a separate clock  $f_{BBB}$  for dedicated debug resources is available. This allows debugging (trace generation) during changes of the other clock configurations. Please note that  $f_{BBB}$  needs to be faster than or equal to  $f_{SPB}$  for debug.

**Table 281 CCU Clock Options**

CCU Clock Output	Clock Source				
	System PLL ( $f_{PLL0}$ )	Peripheral PLL ( $f_{PLL1}$ )	Peripheral PLL ( $f_{PLL2}$ )	Back-up ( $f_{BACK}$ )	OSC_XTAL ( $f_{osco}$ )
$f_{SRI}$	✓	-	-	Default	-
$f_{CPUx}$	$f_{SRI}$	-	-	-	-

## Clocking System

**Table 281 CCU Clock Options (cont'd)**

CCU Clock Output	Clock Source				
	System PLL ( $f_{PLL0}$ )	Peripheral PLL ( $f_{PLL1}$ )	Peripheral PLL ( $f_{PLL2}$ )	Back-up ( $f_{BACK}$ )	OSC_XTAL ( $f_{osco}$ )
$f_{SPB}$	✓	-	-	Default	-
$f_{FSI}$	$f_{SRI}$	-	-	-	-
$f_{FSI2}$	$f_{SRI}$	-	-	-	-
$f_{REFCLK1}$	✓	-	-	Default	-
$f_{REFCLK2}$	-	✓	-	Default	-
$f_{BBB}$	✓	-	-	Default	-
$f_{ERAY}$	-	✓	-	-	-
$f_{GTM}$	✓	-	-	Default	-
$f_{STM}$	✓	-	-	Default	-
$f_{MSC}$	-	✓	✓	Default	-
$f_{GETH}$	✓	-	-	Default	✓
$f_{ADAS}$	✓	-	-	Default	✓
$f_{MCANH}$	✓	-	-	Default	✓
$f_{MCAN}$	-	✓	-	Default	✓
$f_{ASCLINF}$	-	-	✓	Default	-
$f_{ASCLINS}$	-	✓	-	Default	✓
$f_{QSPI}$	-	✓	✓	Default	-
$f_{ADC}$	-	✓	-	Default	-
$f_{I2C}$	-	-	✓	Default	-
$f_{EBU}$	-	✓	-	Default	-
$f_{HSPDM\_160}$	-	✓	-	Default	-
$f_{HSPDM\_320}$	-	✓	-	Default	-

The overall clock system is divided into two major parts, each operating on a clock derived from one of the two available PLLs. The two parts are:

- System and Compute block containing:
  - CPUs and DMAs with its associated memories
  - System infrastructure such as the busses, clocking, reset and power control, interrupt system
  - Timers
  - Dedicated communication interfaces (Ethernet, SENT, and PSI5(-S))
  - Debug system
- Application block containing
  - ADCs
  - Jitter-sensitive communication interfaces (ERAY, HSCT, QSPI, MSC, ASCLIN, MCAN, I2C, and EBU)

This separation allows an independent configuration of the desired baud rates and conversion rates, independent of the power-optimized configuration of the system.

## Clocking System

### 10.5.1.2 Clock Divider Limitations

For the clock dividers which control the different sub-clock domains / modules, the allowed values are limited and the following ratios have to be observed. The ratios are defined in the following way: clock A =  $f_{AAA}$ ; clock B =  $f_{BBB}$  the allowed ratio is 1 : n where n has a defined range of values. Clock A is always faster or equal to clock B in this definition with  $f_{AAA}$  [MHz] = n \*  $f_{BBB}$  [MHz]. For synchronous clocks, n must be an integer value.

In addition, the divider values are limited by the resulting minimum/maximum frequencies. These frequencies are defined in the Target Data Sheet / ACDC Target Specification.

**Table 282 CCU allowed Clock Ratios**

Clock A	Clock B	Allowed Ratios	Notes	Recommended Default
$f_{SRI}$	$f_{SPB}$	1 : n	n = 1, 2, 3, 4, 5, 6,...	n = 2 or 3
$f_{SRI}$	$f_{FSI}$	1 : n	n = 1, 2, 3	n = 2 or 3
$f_{FSI2}$	$f_{FSI}$	1 : n	n = 1, 2, 3	n = 2 or 3
$f_{FSI}$	$f_{SPB}/2^1)$	1 : n	n = 1, 2, 3, 4, 5, 6,...	n = 2
$f_{GTM}$	$f_{SPB}$	1 : n	n = 1, 2	n = 2
$f_{SPB}$	$f_{GTM}$	1 : n	n = 1, 2, 3, 4, 5, 6	n = 2
$f_{SPB}$	$f_{STM}$	1 : n <sup>2)</sup>	n = 1, 2, 3, 4, 5, 6	n = 1
$f_{STM}$	$f_{SPB}$	1 : n <sup>2)</sup>	n = 1, 2, 3, 4, 5, 6,...	n = 1
$f_{SRI}$	$f_{BBB}$ <sup>3)</sup>	1 : n	n = 1, 2	n = 2
$f_{SRI}$	$f_{GETH}$	1 : n	n = 1, 2, 3, 4, 5, 6,...	n = 2
$f_{SPB}$	$f_{MCANH}$	1 : n	n = 1 <sup>4)</sup>	n = 1
$f_{MCANH}$	$f_{MCAN}$	1 : n <sup>5)</sup>	n >= 1.0	n = 1.0
$f_{ADAS}$	$f_{SRI}$	1 : n	n = 1, 2	n = 1
$f_{ADAS}$	$f_{BBB}$	1 : n <sup>6)</sup>	n = 2	n = 2

1) for FSI module, SPB-half clock is internally used, hence relevant for clock ratios

2)  $f_{STM}$  can be faster, slower, or equal to  $f_{SPB}$

3)  $f_{BBB}$  has to be slower, or equal to  $f_{SRI}$

4) restriction only valid when not in pretended networking / LP mode

5) n is not an integer as the related clocks are asynchronous to each other

6)  $f_{BBB}$  has to be half the SPU frequency  $f_{ADAS}$

**Note:** The recommended values do not necessarily reflect the default configuration after a reset event. Instead they should give a hint about how to configure the system for the optimal performance. In addition, it may happen that applying an allowed ratio on two selected clocks violates the ratio of others. Due to the complexity, this cannot be shown here in all combinations. The user has to take care not to violate clock ratios depending on the use case, i.e. enabled clocks.

## Clocking System

### 10.5.1.3 CCU Registers

The CCU registers may be accessed by any CPU in the system. However, it is suggested that only one CPU is used to control the clocks. As CPU0 is the active and available CPU after a reset, this is the logical choice.

## 10.6 Clock Emergency Behavior

In case of a clock error, the CCU switches to the back-up clock  $f_{BACK}$  as the clock source.

A clock error is defined by the occurrence of at least one of the following conditions:

- loss of lock event of the System PLL while selected as clock source for the CCU (CLKSEL = 01<sub>B</sub>)
- loss of lock event of the Peripheral PLL while selected as clock source for the CCU (CLKSEL = 01<sub>B</sub>)

A clock error, as described above, is active until the next time when CCUCON0.UP is set to transfer a new CLKSEL value (even if it is the old one).

A clock error will also trigger an SMU alarm.

**Note:** After a clock emergency, the bit fields CLKSELx have to be re-written. After the root cause for the clock error disappears, the application can reconfigure the clock system, including CLKSELx.

## 10.7 External Clock Output

Two external clock outputs are provided via pins EXTCLK0 and EXTCLK1. These external clocks can be enabled/disabled via bits EXTCON.EN0 for EXTCLK0 and EXTCON.EN1 for EXTCLK1. Each of the clocks that defines a clock domain can individually be selected to be seen at pins EXTCLK0 or EXTCLK1; this is configured via bit field EXTCON.SEL0/1. Changing the content of bit field EXTCON.SEL0/1 can lead to spikes at pins EXTCLK0/1.

### 10.7.1 Programmable Frequency Output for EXTCLK0

This section describes external clock generation using the Fractional Divider.

#### Overview

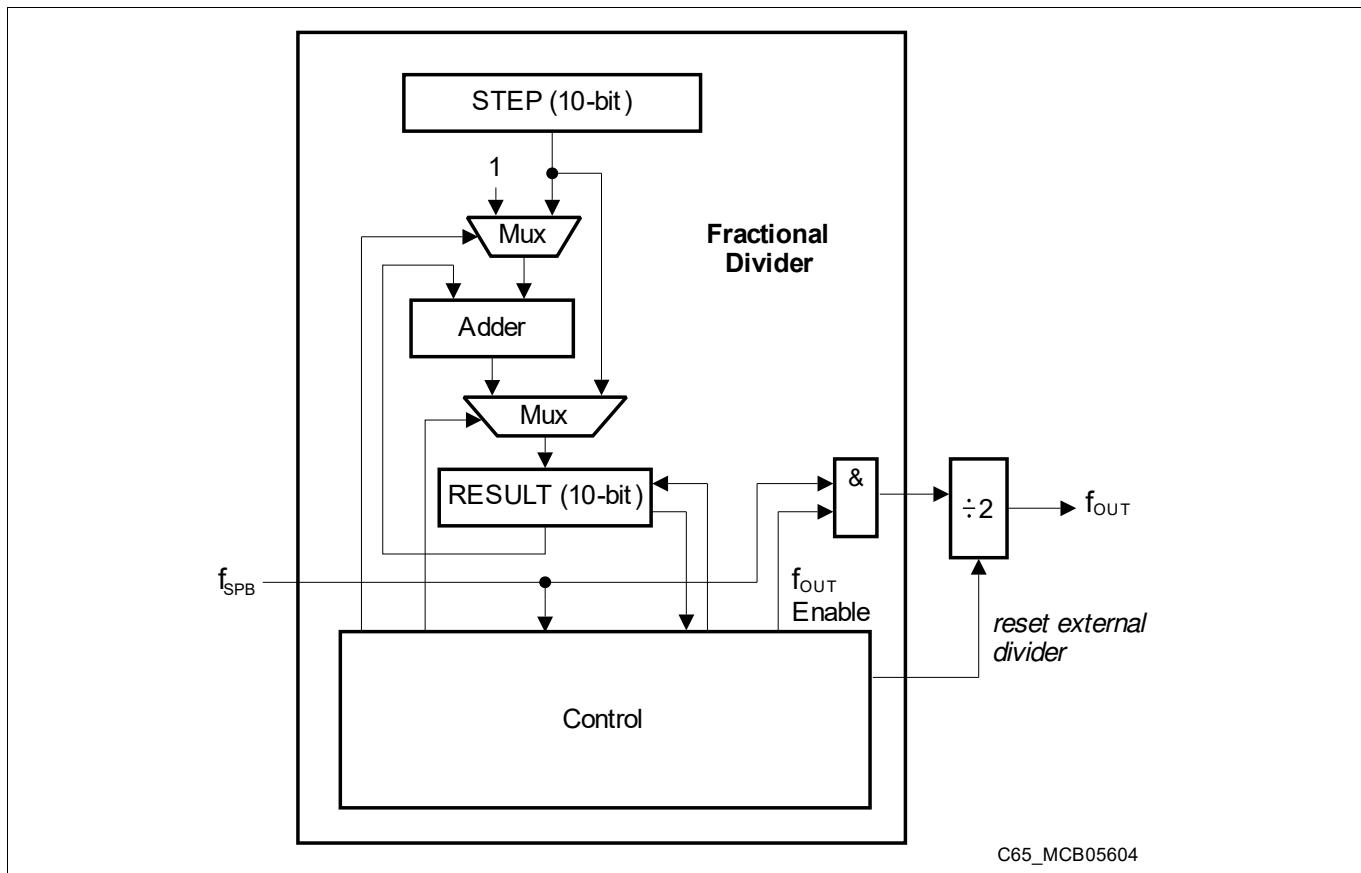

The fractional divider makes it possible to generate an external clock from the SPB clock using a programmable divider. The fractional divider divides the input clock  $f_{SPB}$  either by the factor 1/n or by a fraction of n/1024 for any

## Clocking System

value of n from 0 to 1023. This clock is thereafter divided additionally by a factor of two to guarantee a 50% duty cycle and outputs the clock  $f_{OUT}$ . The fractional divider is controlled by the FDR register. **Figure 88** shows the fractional divider block diagram.

The adder logic of the fractional divider can be configured for two operating modes:

- Reload counter (addition of +1), generating an output clock pulse on counter overflow
- Adder that adds a STEP value to the RESULT value and generates an output clock pulse on counter overflow

**Figure 88 Fractional Divider Block Diagram**

The adder logic of the fractional divider can be configured for two operating modes:

- **Normal Mode**: Reload counter ( $RESULT = RESULT + 1$ ), generating an output clock pulse on counter overflow
- **Fractional Divider Mode**: Adder that adds a STEP value to the RESULT value and generates an output clock pulse on counter overflow

### 10.7.1.1 Fractional Divider Operating Modes

The fractional divider has two operating modes:

- Normal Divider Mode
- Fractional Divider Mode

#### Normal Divider Mode

In Normal Divider Mode (FDR.DM = 01<sub>B</sub>), the fractional divider behaves as a reload counter (addition of +1) that generates an output clock pulse on the transition from 3FF<sub>H</sub> to 000<sub>H</sub>. FDR.RESULT represents the counter value and FDR.STEP determines the reload value.

## Clocking System

The output frequencies in Normal Divider Mode are defined according to the following formulas:

$$f_{\text{OUT}} = \frac{f_{\text{SPB}} \times \frac{1}{n}}{2}, \text{ with } n = 1024 - \text{STEP} \quad (10.16)$$

In order to get  $f_{\text{OUT}} = f_{\text{SPB}}/2$  STEP must be programmed with  $3FF_H$ .

### Fractional Divider Mode

When the Fractional Divider Mode is selected ( $\text{FDR.DM} = 10_B$ ), the output is derived from the input clock  $f_{\text{SPB}}$  by division of a fraction of  $n/1024$ , for any value of  $n$  from 0 to 1023, followed by the division of two. In general, the Fractional Divider Mode makes it possible to program the average output clock frequency with a higher accuracy than in Normal Divider Mode.

In Fractional Divider Mode, a pulse is generated depending on the result of the addition  $\text{FDR.RESULT} + \text{FDR.STEP}$ . If the addition leads to an overflow over  $3FF_H$ , a pulse is generated for the divider by two. Note that in Fractional Divider Mode, the clock  $f_{\text{OUT}}$  can have a maximum period jitter of one  $f_{\text{SPB}}$  clock period.

The output frequencies in Fractional Divider Mode are defined according to the following formulas:

$$f_{\text{OUT}} = \frac{f_{\text{SPB}} \times \frac{\text{STEP}}{1024}}{2} \quad (10.17)$$

### 10.7.2 Programmable Frequency Output for EXTCLK1

Clock  $f_{\text{OUT}}$  is generated via a counter, so the output frequency can be selected in small steps.

$f_{\text{OUT}}$  always provides complete output periods.

Register EXTCON provides control over the output generation (frequency and activation).

**Clocking System****10.7.3 Clock Output Control Register**

Clock Output Control registers can be accessed by all CPUs in the system. However, it is suggested that only one CPU is used to control the clocks. As CPU0 is the active and available CPU after each reset, this is the best choice.

**External Clock Control Register****EXTCON****External Clock Control Register****(003C<sub>H</sub>)****System Reset Value: 0000 0000<sub>H</sub>**

Field	Bits	Type	Description
<b>STEP</b>	9:0	rw	<b>Step Value</b> In Normal Divider Mode, STEP contains the reload value for RESULT. In Fractional Divider Mode, this bit field determines the 10-bit value that is added to RESULT with each input clock cycle.
<b>DM</b>	15:14	rw	<b>Divider Mode</b> These bit fields determine the functionality of the fractional divider block.  00 <sub>B</sub> Fractional divider is switched off; no output clock is generated. The Reset External Divider signal is 1. RESULT is not updated (default after System Reset). 01 <sub>B</sub> Normal Divider Mode selected. 10 <sub>B</sub> Fractional Divider Mode selected. 11 <sub>B</sub> Fractional divider is switched off; no output clock is generated. RESULT is not updated.
<b>RESULT</b>	25:16	rh	<b>Result Value</b> In Normal Divider Mode, RESULT acts as reload counter (addition +1). In Fractional Divider Mode, this bit field contains the result of the addition RESULT + STEP. If DM is written with 01 <sub>B</sub> or 10 <sub>B</sub> , RESULT is loaded with 3FF <sub>H</sub> .
<b>DISCLK</b>	31	rwh	<b>Disable Clock</b> 0 <sub>B</sub> Clock generation of f <sub>OUT</sub> is enabled according to the setting of bit field DM. 1 <sub>B</sub> Fractional divider is stopped. No change except when writing bit field DM.
<b>0</b>	13:10, 30:26	r	<b>Reserved</b> Read as 0; Should be written with 0.

## Clocking System

### 10.8 Clock Generation Unit

The Clock Generation Unit (CGU) allows a very flexible clock generation for the device. During user program execution, the frequency can be programmed for an optimal ratio between performance and power consumption.

**Figure 89 Clock Generation Unit Block Diagram**

The CGU includes clock source generation and clock up-scaling in addition to clock distribution.

For additional information, see the example sequence in [Chapter 10.10](#).

### 10.9 Safety Measures

#### 10.9.1 Clock Monitoring

For safety, clock alive monitors are available. For the following safety relevant clocks in the system, monitors are present:

- $f_{PLL0}$
- $f_{PLL1}$
- $f_{PLL2}$
- $f_{SPB}$

## Clocking System

- $f_{\text{BACK}}$

Each of these clocks is monitored by its own counter. For the PLL and SPB clocks, the back-up clock is used as a diverse clock source as a monitoring/checking clock. For monitoring the back-up clock,  $f_{\text{PLL0}}$  is used as the diverse clock.

The basic principle of alive monitoring is to detect that the monitored clock is toggling within a certain reference time slot generated by the diverse, observing/monitoring clock. If the monitored clock toggles, it is considered as alive.

The monitored clocks shall be divided down by a certain factor to deliver a lower frequency signal that can be properly sampled in the monitoring clock domain. I.e. division must be tailored in a way that the generated signal has lower frequency than the sampling/monitoring clock, but toggles at least once within the monitor reference time window. The division factor must also consider the allowed clock frequency ranges of both monitored and monitoring clocks and their effective combinations.

The monitoring clocks generate a trigger pulses every 512 clock cycles. With every trigger, the toggle check is performed again and if it fails, an SMU alarm is generated. Hence, the fault reaction time correlates with the duration of the reference timing window.

To ensure safe operation of the EVR33 and EVRC regulators, the backup clock is additionally monitored, as it is the operating clock of these blocks. To adapt to  $f_{\text{PLL0}}$  which is the diverse clock of that monitor, upper and lower monitoring thresholds need to be set accordingly.

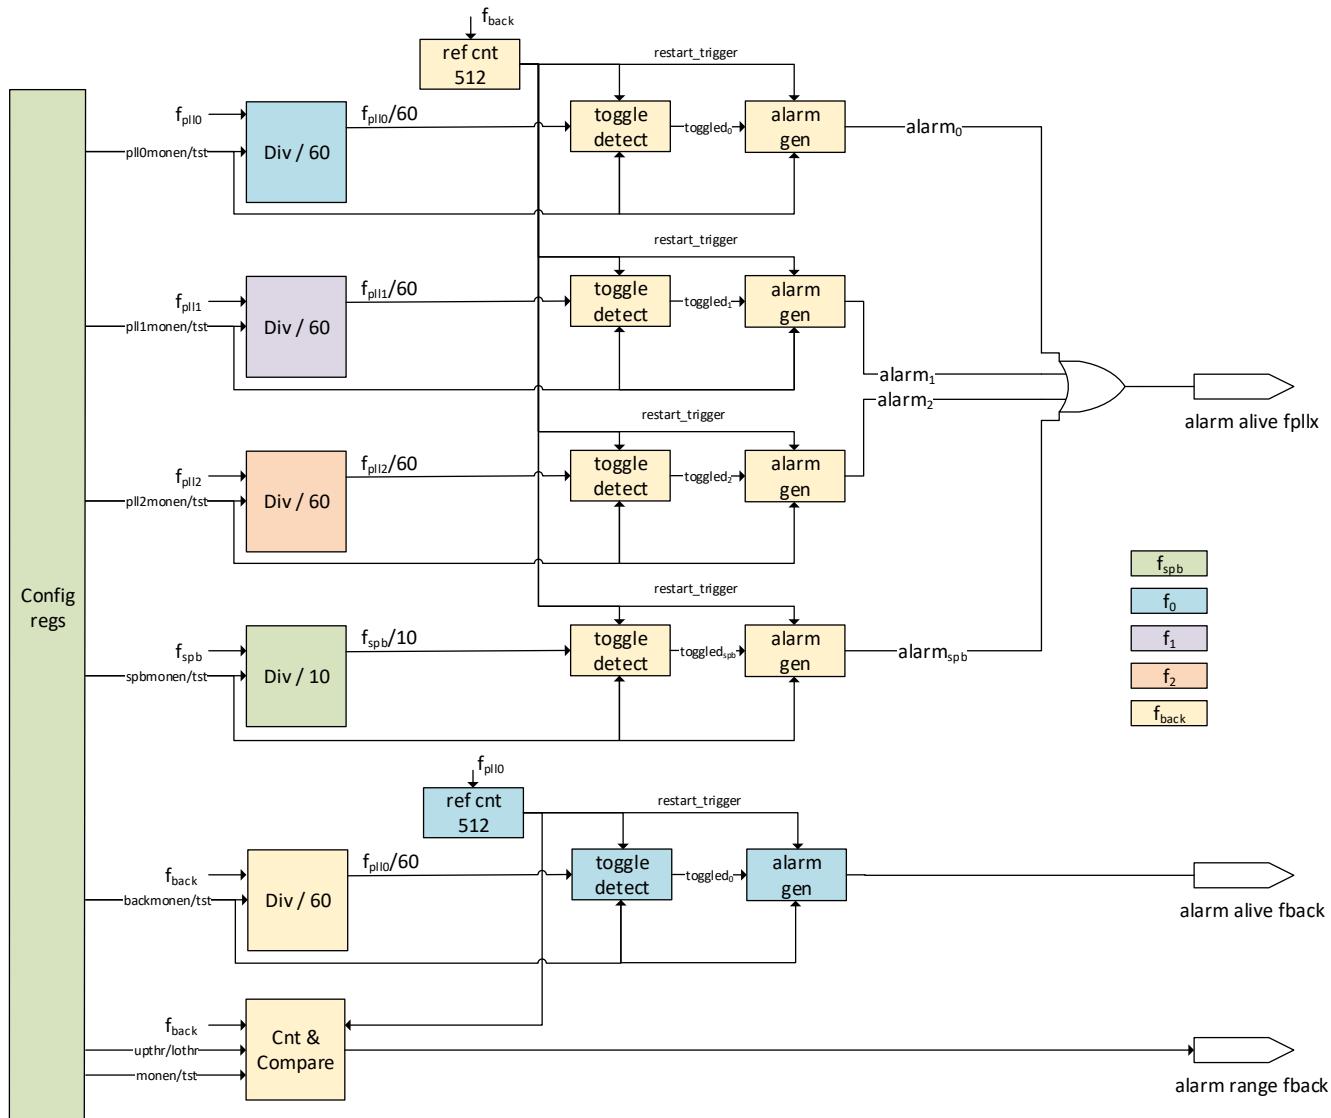

The backup clock monitor simply counts the number of backup clock cycles within a time window of 512  $f_{\text{PLL0}}$  clock cycles. If the number of counted cycles is either above the upper or below the lower threshold, an alarm is generated. This check is continuously repeated.

Clock monitor alarm generation is of level type; i.e., as long as the error condition persists (clock not alive or out of bounce), the alarm is asserted. If the error condition resolves until the next reference cycle restart (trigger), the alarm gets de-asserted again. This assures alarm generation to be long enough for the SMU to process it, i.e. at least one reference counter cycle.

In addition, all monitors can be enabled/disabled and tested via configuration registers. If the monitors get disabled, they will clear all internal status flags and counters to avoid false alerts when the monitor is enabled again.

Because configuration registers, monitored clock dividers, and monitoring logic are asynchronous to each other, synchronization logic has been inserted between the components.

## Clocking System

**Figure 90 Clock Monitor**

The clock alive counters generate two separate alarms; the back-up clock alive monitor generates an alarm signal inside the SPB clock domain, and the  $f_{PLL0}$ ,  $f_{PLL1}$ ,  $f_{PLL2}$  and  $f_{SPB}$  clock alive monitors generate a combined alarm signal inside the Back-up clock domain. The additional backup clock monitor generates an alarm within the SPB clock domain.

## Clocking System

### 10.9.1.1 Clock Monitor Registers

The Clock monitor registers can be accessed by all CPUs in the system. However, it is suggested that only one CPU is used to control the clocks. As CPU0 is the active and available CPU after each reset, this is the best choice.

## 10.10 Use Cases

### Clock Ramp-up Example

The following sequence gives an example for the clock ramp-up. The goal for normal target setting is that the system clock is based on the PLL with an external crystal.

- After power-on and system reset:
  - the system operates on the back-up clock
  - the oscillator (OSC) needs to be enabled via software or can be enabled by firmware via BMI settings
- Fast clocks (SRI-Bus and CPUs) run at the back-up clock frequency (trimmed to approximately 100 MHz)
- Peripherals and SPB-Bus run at 1/3 of the back-up clock frequency (trimmed to approximately 33 MHz)
- In the following steps, two settings AAA and BBB are described with the notation: AAA[BBB]  
 Setting AAA is defined for a 20MHz crystal / clock input and is configured for a 300MHz system.  
 Setting BBB is defined for a 25MHz crystal / clock input and is configured for a 300MHz system.
- Step 1: If  $f_{\text{OSC}0}$  is to be used but is not running, enable the oscillator and wait until it is providing a stable clock.
- Step 2: Initialize the PLLs to target  $f_{\text{DCO}}$  and  $f_{\text{PLLX}}$  frequency
  - Select PLL input clock via SYSPLLCON0.INSEL = 01<sub>B</sub>
  - Select P, K2, and N divider for final target DCO and PLL frequency  
 $\text{SYSPLLCON0} = 40013A00_H[40012E00_H]$   
 $\text{SYSPLLCON1} = 00000005_H[00000005_H]$   
 $\text{SYSPLL } f_{\text{DCO}} = 600\text{MHz}[600\text{MHz}]; f_{\text{PLL0}} = 100\text{MHz}[100\text{MHz}]$   
 $\text{PERPLLCON0} = 00013E00_H[00013E01_H]$

## Clocking System

`PERPLLCON1 = 00000101H[00000104H]`

$f_{DCO} = 640\text{MHz}[800\text{MHz}]$ ;  $f_{PLL1} = 320\text{MHz}[160\text{MHz}]$ ;  $f_{PLL2} = 200\text{MHz}[200\text{MHz}]$

- Step 3: Wait for PLL lock to be set
- Step 4: Configure CCUCON0, and CCUCON1 to first target setting  
 $\text{CCUCON0} = 07230113_{H}[07230113_{H}]$   
 $\text{CCUCON1} = 21210312_{H}[21210392_{H}]$

 $f_{\text{ADC}} = 160\text{MHz}[160\text{MHz}]$ ;  $f_{\text{HSCT}} = 320\text{MHz}[400\text{MHz}]$ ;  $f_{\text{RAM}} = 200\text{MHz}[200\text{MHz}]$ ;  
 $f_{\text{REFCLK1}} = 12.5\text{MHz}[12.5\text{MHz}]$ ;  $f_{\text{REFCLK2}} = 6.67\text{MHz}[6.67\text{MHz}]$ ;

Hint for step 4: CCUCON1.PLL1DIVDIS should be set to 0<sub>B</sub> if PERPLLCON1.K2DIV is configured to 0<sub>H</sub> or 1<sub>H</sub>. CCUCON1.PLL1DIVDIS should be set to 1<sub>B</sub> if PERPLLCON1.K2DIV is configured to 2<sub>H</sub> or a bigger value.

Important hint for steps 5 and 6:

- After every frequency programming step, a wait time is recommended until the supply ripple caused by the supply current transient has settled.

Note: *The wait time between frequency steps depends on the supply and block concept.*

### Clock Changing Example

If the setup of the clock system has to be changed, there are two different cases to distinguish between:

- Changing one or more frequencies, only requiring CCUCONx register changes
- Changing frequencies requiring a change in the SYSPLL and / or PERPLL

If only one or several CCUCON registers need to be updated for the new intended configuration, this can directly be done without further preparation.

If one or both PLLs have to be re-configured, some preparation should be done up front to the sequence described above for clock ramp-up. First, the clock system should be configured to operate again on the back-up clock as it does after any system reset. Changing the configuration setting of a PLL while the clock system operates on this clock source is not recommended. Before executing step 2 of the sequence, the PLL needs to be prepared.

If a change for P-divider setting is required, first a value different than the actual configuration should be written to clean the pipeline for the new value. Please note that this is only required for the P-divider, and not for the other PLL dividers or configuration bits.

If for any reason one PLL was set to Power Saving Mode, and thereafter configured to Normal Mode again, the same preparation as already described for the P-divider has to be done for the K- and N-dividers.

## Power Management System (PMS)

### 11.1 Overview

On-chip linear and switch mode voltage regulators are implemented in TC3xx thereby enabling a single source power supply concept. The external nominal system supply from external regulator may be either 5 V or 3.3 V. The Embedded Voltage Regulators (EVR33 & EVRC) in turn generate the VDDP3 and VDD supply voltages required internally for the core, flash and port domains. EVRC regulator is implemented as a SMPS regulator and generates core supply either from 5 V or 3.3 V external supply. EVR33 regulator is implemented always as a LDO regulator and is required only in case of 5 V external supply.

Depending on the chosen EVR mode, the actual power consumption, EMI requirements and thermal constraints of the system; additional external components like MOSFETs, inductors and capacitors may be required. It is also possible to supply all voltages (VEXT, VDDP3 and VDD) externally ensuring compliance to the legacy supply concept.

All supply and generated voltages are monitored for brownout conditions by primary monitors setting the device into cold power-on reset state in case of violation. All supply and generated voltages are monitored again redundantly by secondary monitors against programmable over-voltage and under-voltage levels. If these levels are violated, either an interrupt or an alarm to the SMU may be generated.

All internal supplies except analog supplies (VAREFx & VDDM) may be supplied by the EVR33 & EVRC. The analog supply domain is separated from the main EVR supply domain and can be supplied by separate external regulators or trackers. It is possible to have a mixed supply scheme with a 5 V ADC domain (VAREFx = VDDM = 5 V) and the remaining system running on 3.3 V supply (VEXT = VDDP3 = 3.3 V).

### 11.2 Functional Description

#### 11.2.1 Power Supply Infrastructure and Supply Start-up

##### 11.2.1.1 Supply Mode Selection

The choice of the supply scheme at startup is based on the latched status of HWCFG[2:1] pins before cold PORST release and is indicated by [PMSWSTAT](#).HWCFGEVR status flags. Following supply modes are supported and are further enumerated in [Table 285](#).

- Single source 5 V supply level ( $VEXT = 5\text{ V}$ ) is supported in following topologies.
  - EVRC in SMPS mode with external switches and EVR33 in LDO mode with internal pass devices.
- Single source 3.3 V supply level ( $VEXT = VDDP3 = 3.3\text{ V}$ ) is supported in following topologies.
  - EVRC in SMPS mode with external switches and EVR33 is inactive.
- Supplies are provided externally and the respective EVRs are in disabled state.
  - 5 V ( $VEXT$ ) and 1.25 V ( $VDD$ ) supplied externally. EVR33 in LDO mode with internal pass devices.
  - 5 V ( $VEXT$ ) and 3.3 V ( $VDDP3$ ) supplied externally. EVRC in SMPS mode with external switches.
  - 5 V ( $VEXT$ ), 3.3 V ( $VDDP3$ ) and 1.25 V ( $VDD$ ) are all supplied externally.

EVRC is enabled or disabled at startup via the HWCFG[2] configuration pin. In case EVRC is selected, VGATE1P and VGATE1N pins shall be connected to the gate of an external P-channel MOSFET and N-channel MOSFET respectively as shown in [Figure 103](#).

## Power Management System (PMS)

EVR33 is enabled or disabled at startup via the HWCFG[1] configuration pin. In case of single source 3.3 V supply, EVR33 is disabled and VDDx3 & VEXT pins are supplied externally by 3.3 V. EVR33 LDO uses internal pass devices distributed on the chip.

The allowed ranges of supplies among different supply rails during different power modes are documented in [Table 286](#) and [Table 287](#). The allowed combinations of nominal external supply voltages among different supply rails are documented in [Table 288](#). All externally provided supplies must be available and be stable before warm PORST reset release by external regulator(s).

HWCFG [2:1] are latched during supply ramp-up and the respective regulators are consequently started. The latched values are stored in PMSWSTAT.HWCFCGEVR register bits. The latched values are retained through a cold PORST and are only reset if EVR LVD (Low Voltage Detector) reset is asserted. HWCFG signals are filtered through a spike / glitch filter and are monitored for a constant level over a 28us - 115us nominal debouncing period before the value is considered as valid so as to ensure reliable operation in noisy environment. The current state of EVRs are reflected in EVRSTAT.EVRx3 flags. For small package variants, some of the HWCFG configuration pins may be absent and both EVRs are activated by default at startup.

HWCFG[6] pin is latched during early VEXT supply ramp-up ( $VEXT < VDDPPA$ ) to decide and set the default reset state of port pins as early as possible. During the intial ramp-up phase of VEXT and VEVRSB supply voltage from 0V up to VDDPPA limit, the voltage levels of pins are undefined till the transistor threshold voltages are reached. After VDDPPA limit, the pins behave as inputs with pull-up if HWCFG[6] = 1 or are in tristate if HWCFG[6] = 0. During the later stage of ramp-up, the latched HWCFG[6] value is stored in PMSWSTAT.TRIST register bit.

HWCFG [1,2,3,6] pins have weak internal pull-up active at start-up irrespective of HWCFG [6] pin level to ensure that the device boots with a defined configuration if HWCFG [1,2,3,6] pins are left unconnected. HWCFG [1,2,3,6] pins are only latched by the PMS on every initial supply ramp-up and are not re-latched during warm reset events (warm PORST, system or application resets) or on exit from Standby mode. All HWCFG pins are latched on internal reset release additionally (between 100us – 180us after warm reset assertion) and the status is stored redundantly in STSTAT register by SCU.

- HWCFG[6] and HWCFG[1,2] are recognized as high when the respective pin is open or pulled up to VEXT supply with pull device  $> 2\text{ k}\Omega$  and  $< 4.7\text{ k}\Omega$  on the external system.
- HWCFG[6] and HWCFG[1,2] are recognized as low when the respective pin is pulled down to GND with pull device  $> 2\text{ k}\Omega$  and  $< 4.7\text{ k}\Omega$  on the external system.

The lower limit of the pull resistance is derived from the overload and short specification (see data sheet) in case of a short event.

Regardless of the HWCFG[6] setting, the VEXT-buffered PU1 pads (see the PU1 buffer type in the data sheet) are set into tristate after standby mode entry.

HWCFG [1] P14.5	HWCFG [2] P14.2	HWCFG [3] P14.3	HWCFG [4] P10.5	HWCFG [5] P10.6	HWCFG [6] P14.4
0 - EVR33OFF 1 - EVR33ON	0 - EVRCOFF 1 - EVRCON	0 - Boot from pins HWCFG [5:4] 1 - Flash BMI boot	HWCFG [4:5] [0 0]- Generic Bootstrap (P14.0/1) [0 1]- ABM, Generic Bootstrap on fail (P14.0/1) [1 0]- ABM, ASC Bootstrap on fail (P15.2/3)	[1 1]- Internal start from Flash (weak pull-up active on reset)	Default Pad state 0 - Pins in tristate 1 - Pins with pull-up (weak pull-up active on reset)

1.) HWCFG [1:6] has weak internal pull-up active at start-up if the pin is left unconnected.

h.)	00 <sub>B</sub>	Overlapped P32.1 / P32.0 port pins may be used as standard GPIO.	VEXT & VEVRSB = 5 V external supply. VDDM = VAREFx = 5V or 3.3V external supply. VFLEX/VFLEX2 = 5 V or 3.3 V external supply. VDDP3 and VDDFL3 = 3.3V external supply. VDD = 1.25 V external supply.	5 V, 3.3 V and 1.25 V are supplied externally. EVRC and EVR33 inactive. 5 V or 3.3 V ADC domain. 5 V or 3.3 V Flexport domain. Standby Mode is supported and 3.3V and 1.25V supplies shall be switched off by external regulator after Standby state is entered.

1) if HWCFG[2,1] pins are left unconnected, it is ensured that EVR33 and EVRC are active owing to the internal weak pull-up active by default after start-up/cold PORST.

## Power Management System (PMS)

- 2) VGATE1P pin is connected to a P- ch. MOSFET in case of EVRC. In case EVRC is inactive via HWCFG2 = 0, VGATE1P pin behaves like a normal port pin (P32.1) and is by default configured as input with weak internal pull-up after start-up/cold PORST.
- 3) VGATE1N pin needs to be connected to the gate of the N- channel MOSFET in case EVRC regulator mode is selected. In case EVRC is inactive via HWCFG2 = 0, VGATE1N pin behaves like a normal port pin (P32.0) and is default configured as input with weak internal pull-up after start-up/cold PORST.
- 4) Only Nominal supply voltage values of respective rails are indicated in the table. The tolerances of the supply voltages are documented in datasheet.

$V_{DDM}^5)$	5 V				5 V <sup>6)</sup>	3.3 V		
$V_{DDP3}^7)$	3.3 V (external supply or generated by EVR33 )				3.3 V (external supply or generated by EVR33 )			
$V_{DD}$	1.25 V (external supply or generated by EVRC )				1.25 V (external supply or generated by EVRC )			
$V_{DDSB}^8)$	1.25 V (external supply or generated by EVRC )				1.25 V (external supply or generated by EVRC )			

- 1) All supply rails shall have ramped up to their minimum voltage operational limits as documented in the datasheet before warm PORST reset release. It is not allowed to leave any supply rail unsupplied after warm PORST reset release.
- 2) VEVRSB supply rail can be ramped down during VEVRSB Standby mode to 2.6 V minimum voltage.
- 3) VFLEX/VFLEX2 supply rails provide supply to specific ports and can be supplied with nominal 3.3V supply when remaining ports are supplied with nominal 5V. VFLEX /VFLEX2 may be supplied by the same external supply source connected also to VEXT supply rail. VFLEX/VFLEX2 supply level shall be less than or equal to VEXT supply level. VFLEX2 rail only available on TC37xEXT.
- 4) VEBU supply rail provides supply to ports P24, P25, P26, P30 and P31 and can be supplied with nominal 3.3V supply when remaining ports are supplied with nominal 5V. VEBU maybe supplied by the same external supply source connected also to VEXT supply rail. VEBU supply level shall be less than or equal to VEXT supply level.

## Power Management System (PMS)

- 5) VDDM analog supply and VAREFx analog reference supply shall have the same supply level. It is recommended to supply VDDM and VAREFx from the same external supply source with filters.
- 6) VDDM supplies only a part of analog pins. For shared analog pins supplied by VEXT (P00) and VEVRSB (P33), the voltage levels of the respective analog channels would be bounded by the respective supply voltages when they are lower than the VDDM / VAREF voltages.
- 7) EVR33 is designed to supply the current required only by VDDP3 rail and the associated modules requiring 3.3V supply. It is not intended to supply VFLEX/VFLEX2 and VEBU pad currents from 3.3V VDDP3 rail when EVR33 generates VDDP3 supply.
- 8) VDDSB shall be connected to VDD rail and supplied together in case of non emulation devices.

**Figure 94 TC39x Supply Pins and Module Connectivity**

## Power Management System (PMS)

### 11.2.1.2 Supply Ramp-up and Ramp-down Behavior

#### 11.2.1.2.1 Single Supply mode (a)

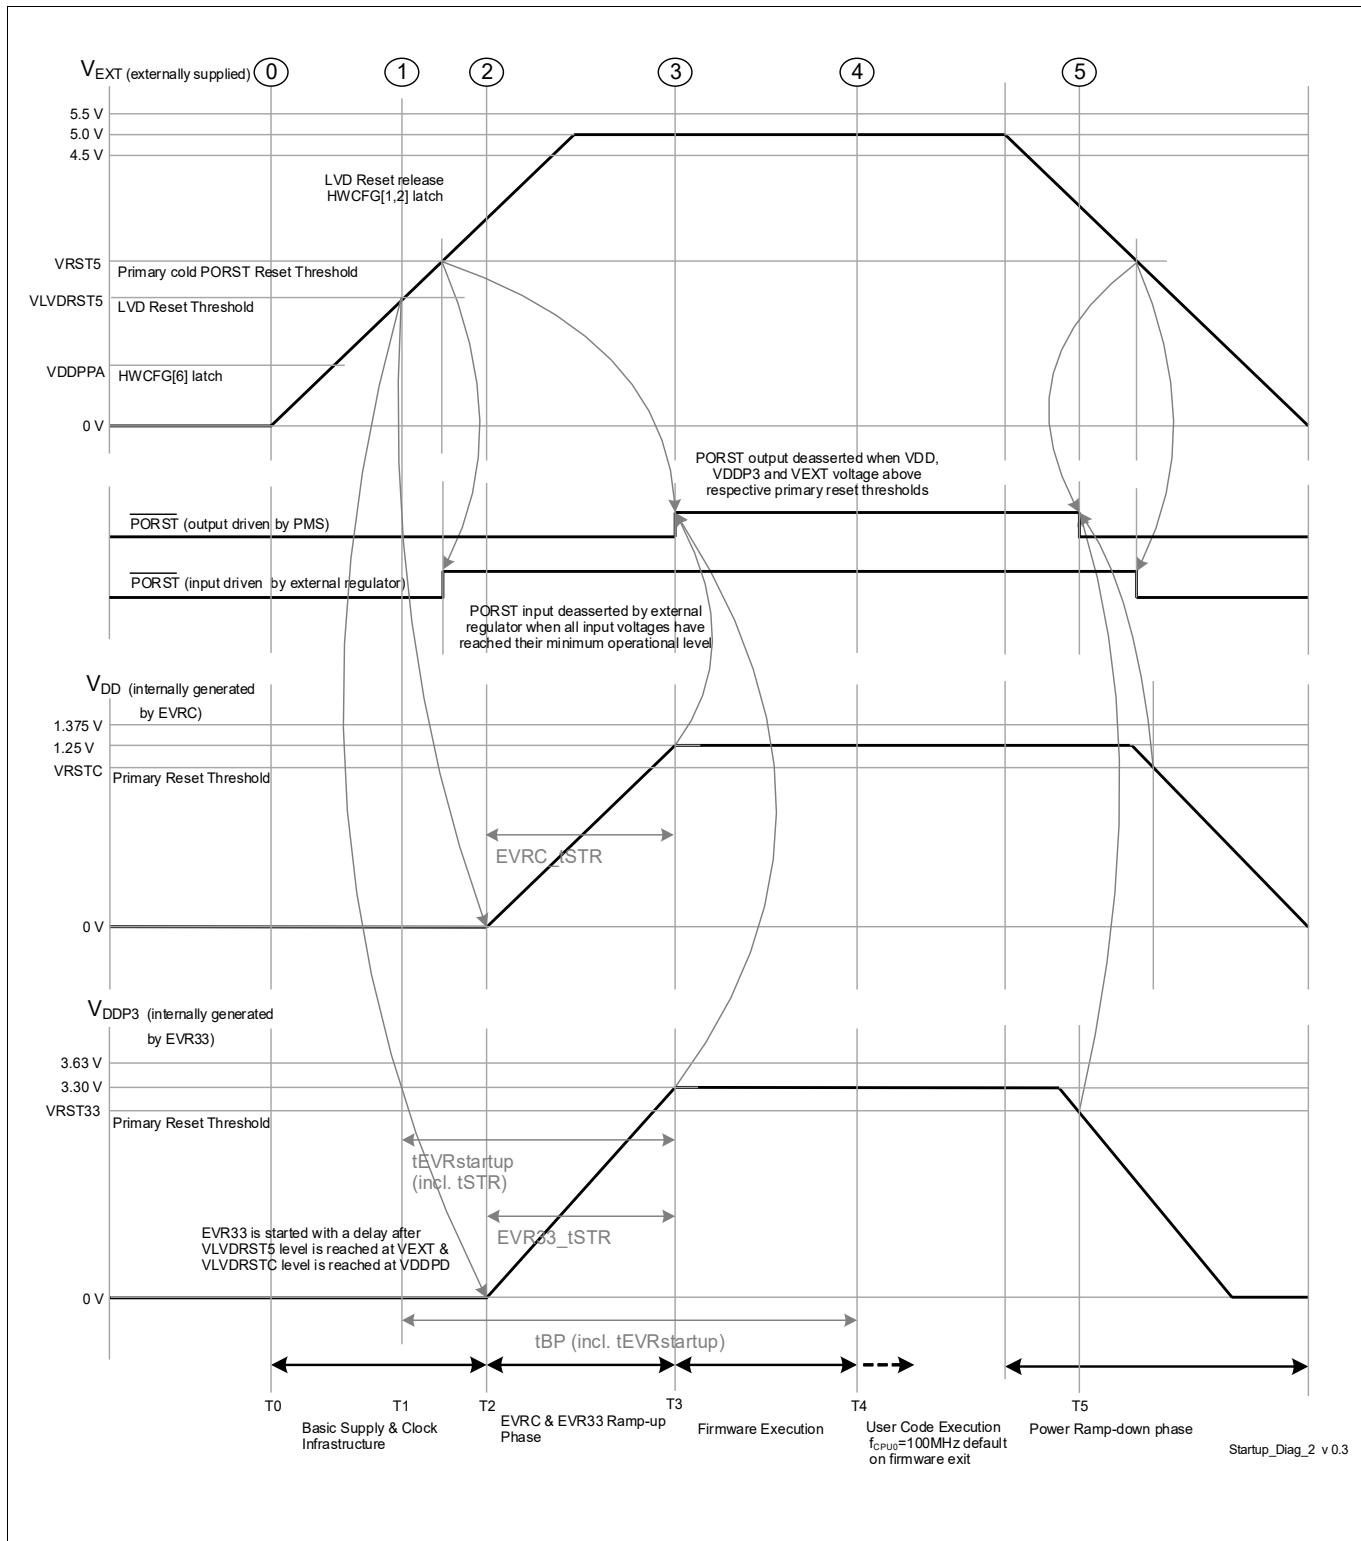

Figure 95 Single Supply mode (a) - VEXT (5 V) single supply

## Power Management System (PMS)

VEXT = 5 V single supply mode. VDD and VDDP3 are generated internally by the EVRC and EVR33 internal regulators.

- The rate at which current is drawn from the external regulator ( $dI_{EXT}/dt$ ) is limited during the basic infrastructure and EVRx regulator start-up phase (T0 up to T2) to a maximum of 100 mA with 100  $\mu$ s settling time. Start-up slew rates for supply rails shall comply to datasheet parameter SR. The slope is defined as the maximal tangential slope between 0% to 100% voltage level. Actual waveform may not represent the specification.
- Furthermore it is also ensured that the current drawn from the regulator ( $dI_{DD}/dt$ ) is limited during the Firmware start-up phase (T3 up to T4) to a maximum of 100 mA with 100  $\mu$ s settling time.
- PORST is active/asserted when either PORST (input) or PORST (output) is active/asserted.
- PORST (input) active means that the reset is held active by external agents by pulling the PORST pin low. It is recommended to keep the PORST (input) asserted until the external supply is above the respective primary reset threshold.
- PORST (output) active means that  $\mu$ C asserts the reset internally and drives the PORST pin low thus propagating the reset to external devices. The PORST (output) is asserted by the  $\mu$ C when atleast one among the three supply domains (VDD, VDDP3 or VEXT) violate their primary under-voltage reset thresholds. The PORST (output) is de-asserted by the  $\mu$ C when all supplies are above their primary reset thresholds and the basic supply and clock infrastructure is available. During reset release at T3, the load jump of upto 150 mA ( $dI_{DD}$ ) is expected.
- The power sequence as shown in [Figure 95](#) is enumerated below
  - T1 up to T2 refers to the period in time when basic supply and clock infrastructure components are available as the external supply ramps up. The bandgap and internal clock sources are started .The supply mode is evaluated based on the HWCFG[2:1,6] pins. These events are initiated after LVD reset release at T1. LVD reset is released when both input voltages VEXT and VEVRSB are above VLVRST5 and VLVRSTSB levels respectively. Internal pre-regulator VDDPD voltage is above VLVRSTC level.
  - T2 refers to the point in time where consequently a soft start of EVRC and EVR33 regulators are initiated. PORST (input) does not have any affect on EVR33 or EVRC output and regulators continue to generate the respective voltages though PORST is asserted and the device is in reset state. The generated voltage follows a soft ramp-up over the tSTR (datasheet parameter) time to avoid overshoots.
  - T3 refers to the point in time when all supplies are above their primary reset thresholds denoted by VRST5, VRST33 and VRSTC supply voltage levels. EVRC and EVR33 regulators have ramped up. PORST (output) is de-asserted and HWCFG[3:5] pins are latched on PORST rising edge by SCU. Firmware execution is initiated. The time between T1 and T3 is documented as tEVRstartup (datasheet parameter).
  - T4 refers to the point in time when Firmware execution is completed and User code execution starts with CPU0 at a default frequency of 100 MHz. The time between T0 and T4 is documented as tBP (datasheet parameter).
  - T5 refers to the point in time during the ramp-down phase when at least one of the externally provided or generated supplies (VDD, VDDP3 or VEXT) drop below their respective primary under-voltage reset thresholds.

## Power Management System (PMS)

### 11.2.1.2.2 Single Supply mode (e)

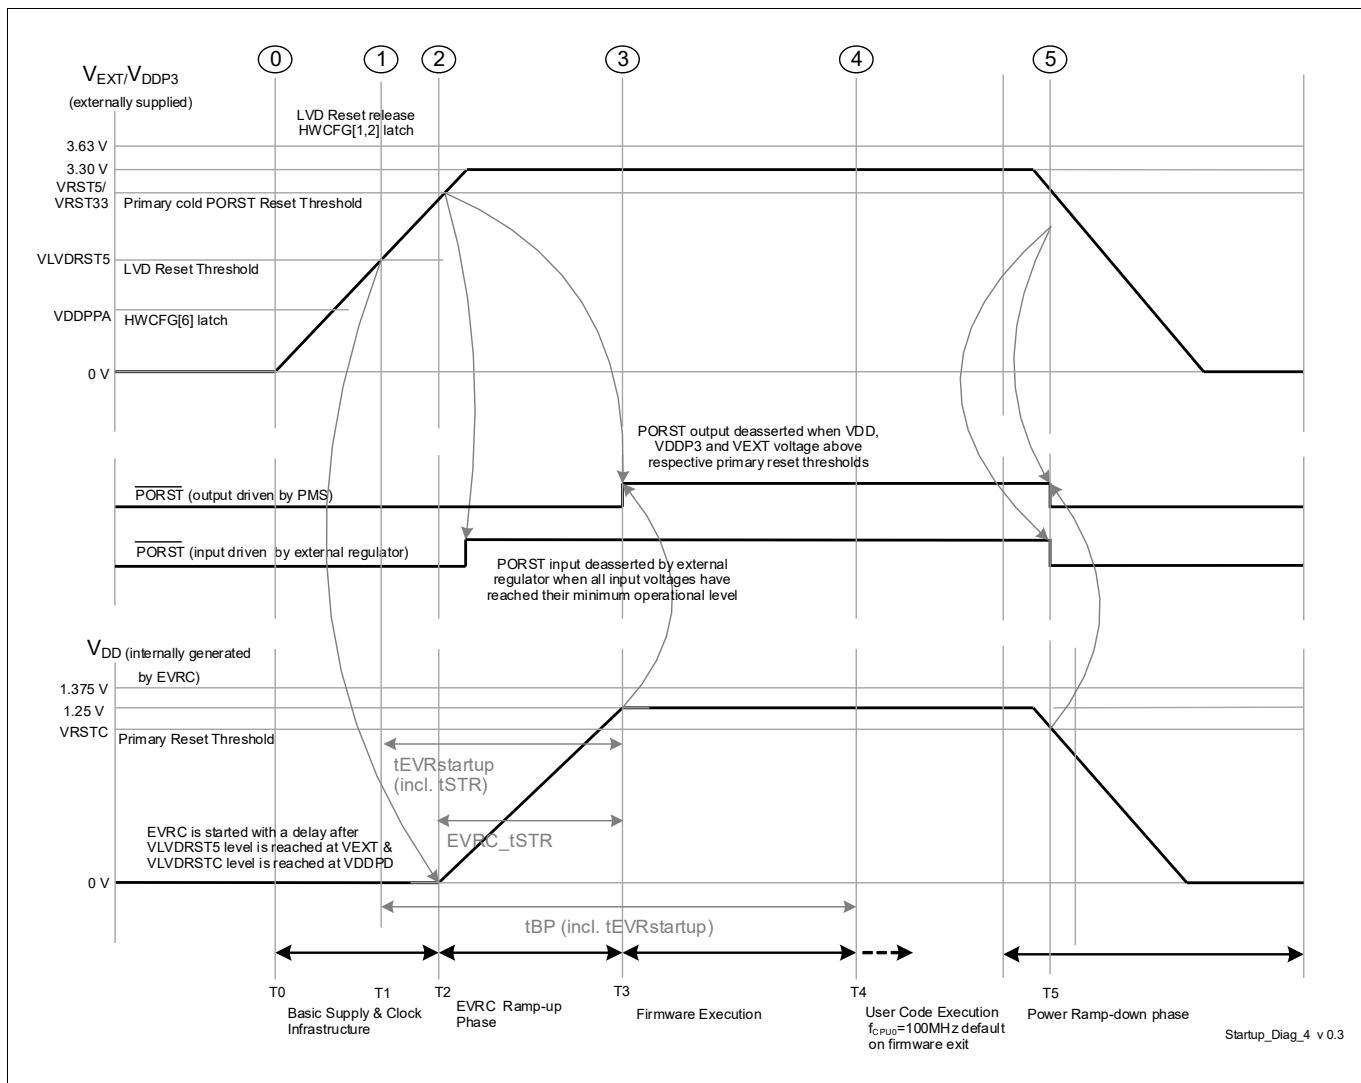

Figure 96 Single Supply mode (e) - (VEXT & VDDP3) 3.3 V single supply

V<sub>EXT</sub> = V<sub>DDP3</sub> = 3.3 V single supply mode. VDD is generated internally by the EVRC regulator.

- The rate at which current is drawn from the external regulator ( $dI_{EXT}/dt$ ) is limited in the Start-up phase to a maximum of 100 mA with 100  $\mu$ s settling time. Start-up slew rates for supply rails shall comply to datasheet parameter SR. The slope is defined as the maximal tangential slope between 0% to 100% voltage level. Actual waveform may not represent the specification.
- PORST is active/asserted when either PORST (input) or PORST (output) is active/asserted.
- PORST (input) active means that the reset is held active by external agents by pulling the PORST pin low. It is recommended to keep the PORST (input) asserted until the external supply is above the respective primary reset threshold.
- PORST (output) active means that  $\mu$ C asserts the reset internally and drives the PORST pin low thus propagating the reset to external devices. The PORST (output) is asserted by the  $\mu$ C when at least one among the three supply domains (VDD, VDDP3 or VEXT) violate their primary under-voltage reset thresholds. The PORST (output) is de-asserted by the  $\mu$ C when all supplies are above their primary reset thresholds and the

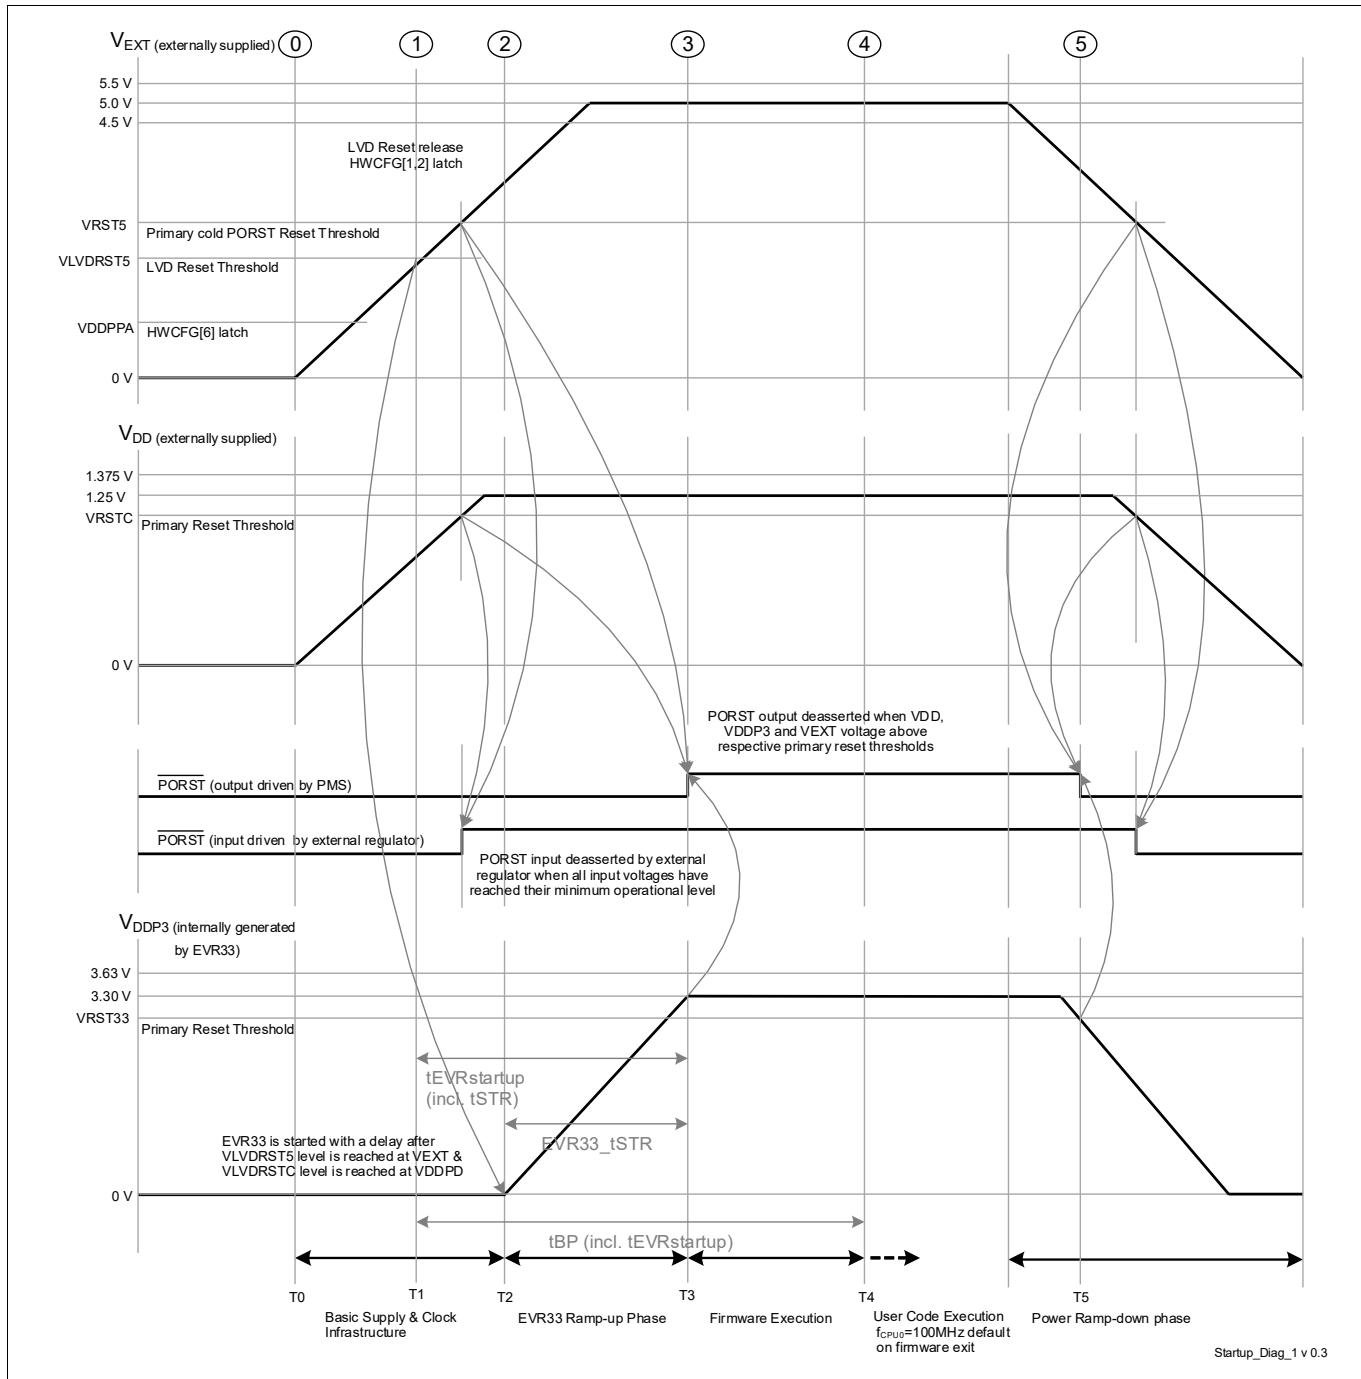

## Power Management System (PMS)

basic supply and clock infrastructure is available. During reset release at T3, the load jump of upto 150 mA (dIDD) is expected.

- The power sequence as shown in [Figure 96](#) is enumerated below
  - T1 up to T2 refers to the period in time when basic supply and clock infrastructure components are available as the external supply ramps up. The bandgap and internal clock sources are started .The supply mode is evaluated based on the HWCFG[2:1,6] pins. These events are initiated after LVD reset release at T1. LVD reset is released when both input voltages VEXT and VEVRSB are above VLVRST5 and VLVRSTSB levels respectively. Internal pre-regulator VDDPD voltage is above VLVRSTC level.
  - T2 refers to the point in time where consequently a soft start of EVRC regulator is initiated. PORST (input) does not have any affect on EVRC output and regulators continue to generate the respective voltages though PORST is asserted and the device is in reset state. The generated voltage follows a soft ramp-up over the tSTR (datasheet parameter) time to avoid overshoots.
  - T3 refers to the point in time when all supplies are above their primary reset thresholds denoted by VRST5, VRST33 and VRSTC supply voltage levels. EVRC regulator has ramped up. PORST (output) is de-asserted and HWCFG[3:5] pins are latched on PORST rising edge by SCU. Firmware execution is initiated. The time between T1 and T3 is documented as tEVStartup (datasheet parameter).
  - T4 refers to the point in time when Firmware execution is completed and User code execution starts with CPU0 at a default frequency of 100 MHz. The time between T0 and T4 is documented as tBP (datasheet parameter).
  - T5 refers to the point in time during the ramp-down phase when at least one of the externally provided or generated supplies (VDD, VDDP3 or VEXT) drop below their respective primary under-voltage reset thresholds.

## Power Management System (PMS)

### 11.2.1.2.3 External Supply mode (d)

**Figure 97 External Supply mode (d) - VEXT and VDD externally supplied**

V<sub>EXT</sub> = 5 V and V<sub>DD</sub> supplies are externally supplied. 3.3V is generated internally by the EVR33 regulator.

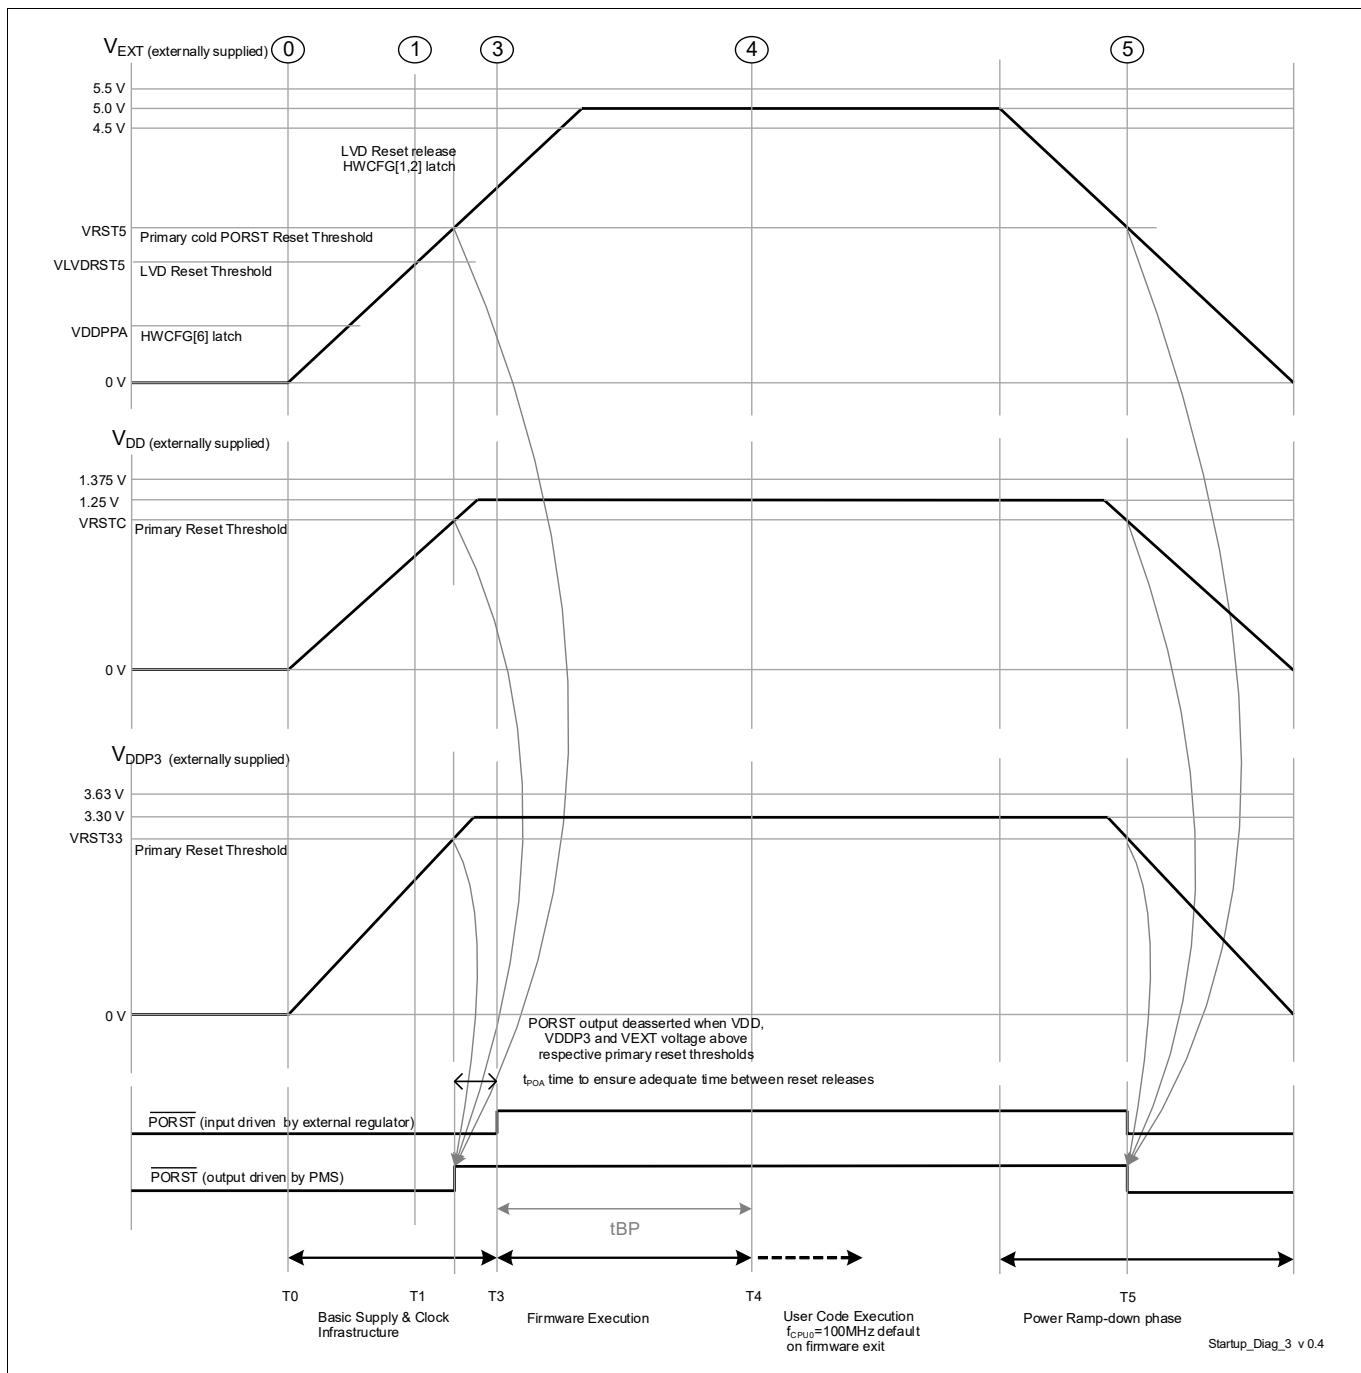

- External supplies V<sub>EXT</sub> and V<sub>DD</sub> may ramp-up or ramp-down independent of each other with regards to start, rise and fall time(s). Start-up slew rates for supply rails shall comply to datasheet parameter SR. The slope is defined as the maximal tangential slope between 0% to 100% voltage level. Actual waveform may not represent the specification. It is expected that during start-up, V<sub>EXT</sub> ramps up before V<sub>DD</sub> rail. If V<sub>DD</sub> voltage rail is ramped up before V<sub>EXT</sub>; V<sub>DD</sub> supply overshoots during start-up shall be limited within the operational voltage range.

## Power Management System (PMS)

- The rate at which current is drawn from the external regulator ( $dI_{EXT}/dt$  or  $dI_{DD}/dt$ ) is limited in the Start-up phase to a maximum of 100 mA with 100  $\mu$ s settling time.
- PORST is active/asserted when either PORST (input) or PORST (output) is active/asserted.
- PORST (input) active means that the reset is held active by external agents by pulling the PORST pin low. It is recommended to keep the PORST (input) asserted until all the external supplies are above their primary reset thresholds.
- PORST (output) active means that  $\mu$ C asserts the reset internally and drives the PORST pin low thus propagating the reset to external devices. The PORST (output) is asserted by the  $\mu$ C when at least one among the three supply domains (VDD, VDDP3 or VEXT) violate their primary under-voltage reset thresholds. The PORST (output) is de-asserted by the  $\mu$ C when all supplies are above their primary reset thresholds and the basic supply and clock infrastructure is available. During reset release at T3, the load jump of up to 150 mA ( $dI_{DD}$ ) is expected.
- The power sequence as shown in [Figure 97](#) is enumerated below
  - T1 up to T2 refers to the period in time when basic supply and clock infrastructure components are available as the external supply ramps up. The bandgap and internal clock sources are started. The supply mode is evaluated based on the HWCFG[2:1,6] pins. These events are initiated after LVD reset release at T1. LVD reset is released when both input voltages VEXT and VEVRSB are above VLVRST5 and VLVRSTSB levels respectively. Internal pre-regulator VDDPD voltage is above VLVRSTC level.
  - T2 refers to the point in time where consequently a soft start of EVR33 regulator is initiated. PORST (input) does not have any affect on EVR33 output and regulators continue to generate the respective voltages though PORST is asserted and the device is in reset state. The generated voltage follows a soft ramp-up over the tSTR (datasheet parameter) time to avoid overshoots.
  - T3 refers to the point in time when all supplies are above their primary reset thresholds denoted by VRST5, VRST33 and VRSTC supply voltage levels. EVR33 regulators has ramped up. PORST (output) is de-asserted and HWCFG[3:5] pins are latched on PORST rising edge by SCU. Firmware execution is initiated. The time between T1 and T3 is documented as tEVStartup (datasheet parameter).
  - T4 refers to the point in time when Firmware execution is completed and User code execution starts with CPU0 at a default frequency of 100 MHz. The time between T0 and T4 is documented as tBP (datasheet parameter).
  - T5 refers to the point in time during the ramp-down phase when at least one of the externally provided or generated supplies (VDD, VDDP3 or VEXT) drop below their respective primary under-voltage reset thresholds.

## Power Management System (PMS)

### 11.2.1.2.4 External Supply mode (h)

**Figure 98 External Supply mode (h) - VEXT, VDDP3 & VDD externally supplied**

All supplies, namely VEXT, VDDP3 & VDD are externally supplied.

- External supplies VEXT, VDDP3 & VDD may ramp-up or ramp-down independent of each other with regards to start, rise and fall time(s). Start-up slew rates for supply rails shall comply to datasheet parameter SR. The slope is defined as the maximal tangential slope between 0% to 100% voltage level. Actual waveform may not represent the specification. It is expected that during start-up, VEXT ramps up before VDDP3 and VDD rails. If smaller voltage rails are ramped up before VEXT; VDD and VDDP3 supply overshoots during start-up shall be limited within the operational voltage ranges of the respective rails.

## Power Management System (PMS)

- The rate at which current is drawn from the external regulator ( $dI_{EXT}/dt$ ,  $dI_{DD}/dt$  or  $dI_{DDP3}/dt$ ) is limited in the Start-up phase to a maximum of 100 mA with 100  $\mu$ s settling time.
- PORST is active/asserted when either PORST (input) or PORST (output) is active/asserted.
- PORST (input) active means that the reset is held active by external agents by pulling the PORST pin low. It is recommended to keep the PORST (input) asserted until all the external supplies are above their primary reset thresholds.
- PORST (output) active means that  $\mu$ C asserts the reset internally and drives the PORST pin low thus propagating the reset to external devices. The PORST (output) is asserted by the  $\mu$ C when at least one among the three supply domains (VDD, VDDP3 or VEXT) violate their primary under-voltage reset thresholds. The PORST (output) is de-asserted by the  $\mu$ C when all supplies are above their primary reset thresholds and the basic supply and clock infrastructure is available. During reset release at T3, the load jump of up to 150 mA ( $dI_{DD}$ ) is expected.
- The power sequence as shown in [Figure 98](#) is enumerated below
  - T1 up to T3 refers to the period in time when basic supply and clock infrastructure components are available as the external supply ramps up. The bandgap and internal clock sources are started. The supply mode is evaluated based on the HWCFG[2:1,6] pins. These events are initiated after LVD reset release at T1. LVD reset is released when both input voltages VEXT and VEVRSB are above VLVRST5 and VLVRSTSB levels respectively. Internal pre-regulator VDDPD voltage is above VLVRSTC level.
  - T3 refers to the point in time when all supplies are above their primary reset thresholds denoted by VRST5, VRST33 and VRSTC supply voltage levels. PORST (output) is de-asserted and HWCFG[3:5] pins are latched on PORST rising edge by SCU. Firmware execution is initiated.
  - T4 refers to the point in time when Firmware execution is completed and User code execution starts with CPU0 at a default frequency of 100 MHz. The time between T0 and T4 is documented as tBP (datasheet parameter).
  - T5 refers to the point in time during the ramp-down phase when at least one of the externally provided supplies (VDD, VDDP3 or VEXT) drop below their respective primary under-voltage reset thresholds.

## Power Management System (PMS)

### 11.2.1.2.5 HWCFG, P32.1 / VGATE1P, P32.0 / VGATE1N behavior during Start-up

EVRC SMPS regulator inactive (HWCFG [2] = 0)				
	P32.0 pad	VGATE1N pad	VGATE1P pad	P32.1 pad
VEXT Ramp-up	PU till HWCFG6 latch @ VDDPA. PU or Z based on HWCFG6 latch	Z	PU till HWCFG[2] latch	PU till HWCFG6 latch @ VDDPA. PU or Z based on HWCFG6 latch
RUN	Active		Z	Active

EVRC SMPS regulator active (HWCFG [2] = 1)				
	P32.0 pad	VGATE1N pad	VGATE1P pad	P32.1 pad
VEXT Ramp-up	PU till HWCFG6 latch @ VDDPA. PU or Z based on HWCFG6 latch	Z	PU	PU till HWCFG6 latch @ VDDPA. PU or Z based on HWCFG6 latch
EVRC Ramp-up	Z enps=0, trist=1	Active	Active	Z enps=0, trist=1
RUN		Active	Active	

**Figure 99 VGATE1P and VGATE1N pin connectivity**

VGATE1P / P32.1 pin and VGATE1N / P32.0 pins shall be connected to drive external Pch. and Nch. MOSFET if EVRC is active in SMPS mode. If VDD core supply is provided externally, P32.0 and P32.1 pins may be used as normal GPIOs. Each pin is double bonded or connected to two separate pads, namely VGATEEx pad dedicated for EVRC MOSFET drive function and P32.x pad supporting regular PORT / GPIO functions as shown in [Figure 99](#). The function for the respective pins are defined by HWCFG [2] pin as to whether internal EVRC regulator is used or not.

If EVRC regulator is inactive configured via HWCFG [2] = 0, then GPIO function is available and the pin control via PORT module is allowed. The default reset behavior of the P32.x is dependent on HWCFG[6] level as to whether pull-up or tristate request is active. If pin is used for GPIO function, it should be noted that these pads exhibit higher leakages as documented in the datasheet.

If EVRC regulator is activated via HWCFG [2] = 1, then GPIO function is no more available and the behavior of the pins during start-up is as portrayed in [Figure 100](#). During VEXT ramp-up, the VGATE1P / P32.1 pin is pulled high so that P-ch. MOSFET is completely switched off. Once the HWCFG[2:1] pins are latched, EVRC is ramped up and the regulator drives a PWM with increasing duty cycle via VGATE1P / P32.1 pin. The VGATE1N / P32.0 pin remains in tristate during VEXT and EVRC ramp-up phases respectively. Only after the EVRC VDD voltage output has crossed a minimum threshold does the regulator starts driving the N-ch. MOSFET via VGATE1N / P32.0 pin.

Furthermore in case of power-fail on VEXT or VEVRSB rails, the SMPS regulator is kept active for 4 clock cycles at 100MHz before the regulator goes into reset state . This ensures that the PMOS is turned-off properly so as to avoid overshoots on the VDD rail irrespective of the switching phase.

## Power Management System (PMS)

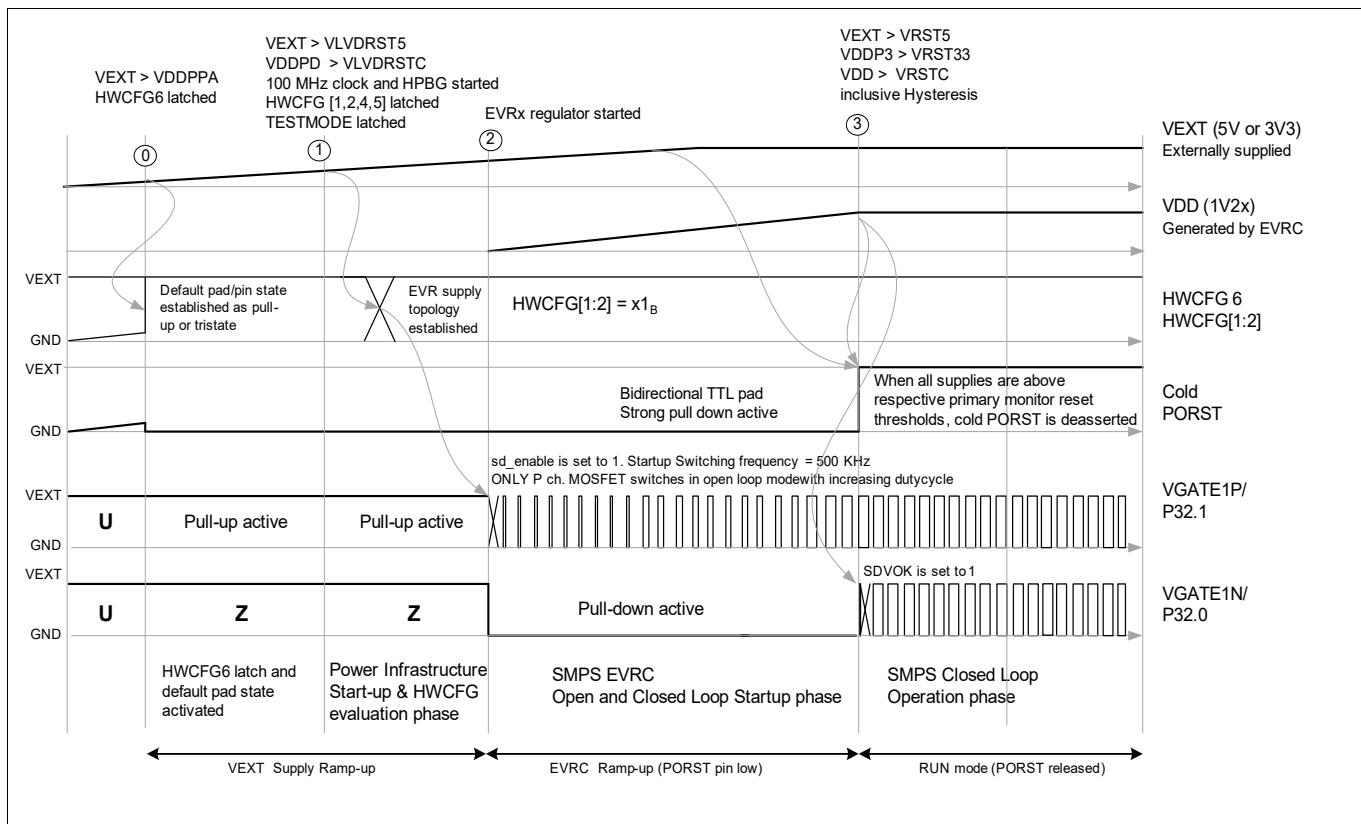

Figure 100 VGATE behavior during start-up when EVRC regulator is used

## Power Management System (PMS)

### 11.2.1.3 PMS Infrastructure Components

Power Management System constitutes infrastructure components which need to be started before ramping the EVR33 & EVRC Embedded Voltage Regulators.

- EVR Pre- Regulator (EVRPR)
- 100 MHz Back-up Clock Source (fBACK)
- Secondary High Precision Bandgap reference (SHPBG)
- 70 kHz Standby Clock Source (fSB)
- Primary Low Power Bandgap reference (PLPBG)

#### 11.2.1.3.1 Independent VEVRSB & VDDPD Supply domain and EVR Pre-Regulator (EVRPR)

The objective of the EVRPR is to supply the basic infrastructure components, the Standby domain and certain safety components with a dedicated low-noise independent supply. The EVRPR pre-regulator is supplied directly by the external 5 V or 3.3 V VEVRSB supply. It is implemented as a low drop-out regulator generating the 1.25 V VDDPD internal voltage which is buffered internally and is not routed to any external supply pin. Since EVRPR part is always powered on as long as the external supply is available and also in Standby mode, it is implemented to have low power consumption to meet IStandby current parameter limits in datasheet. The EVRPR supplies the high precision bandgap, the 100 MHz EVR clock source and EVRC / EVR33 regulators as the regulators have to be independent from their generated supplies. The EVRPR also supplies the Standby domain including the Standby RAMs, the Wake-Up Timer, the Standby Controller and a part of the Port domain (Port 33 / 34).

The minimum power detection logic ensures that a minimum voltage level is available on VEXT and VEVRSB external supplies and on the internally generated VDDPD supply via dedicated detectors. The VEXT supply is monitored for minimum VLDRST5 level to ensure that adequate voltage is available to latch HWCFG pins and start EVRC. Likewise, the internal VDDPD supply is monitored for minimum VLDRSTC voltage level by the VDDPD detector with in-built reference. When both conditions are fulfilled the start-up of the EVRPR has been successfully completed and the EVR Low Voltage Detector reset (LVD reset) is released. The 100 MHz clock and high precision bandgap are consequently started. The HWCFG pins are evaluated to establish the supply mode which needs to be activated. Consequently EVRC and EVR33 are started in parallel in a soft ramp-up to ensure a voltage ramp-up with minimal overshoots. In case both EVRC and EVR33 are activated, a normal start-up is completed when both the regulator outputs are stable and operational. Consequently cold PORST reset is released when VEXT, VDDP3 and VDD voltages ramp-ups are complete and the respective voltages are above their minimum operational limits (VRSTxx / VxxPRIUV).

#### 11.2.1.3.2 Reference Voltage Generation : Secondary Bandgap Reference (SHPBG)

The objective of the Secondary High Precision BandGap and Reference current circuitry is to provide an accurate voltage reference and reference currents to various modules. The reference is used by EVRC, EVR33, supply monitors, ADC modules, XTAL Oscillator, Flash, ADC and LVDS Pads.

The secondary high precision bandgap reference is checked against the primary low power bandgap reference or VDDPD voltage to detect bandgap drifts during start-up phase. This is part of the Power BIST ([Section 11.2.2.5.3](#)) which is carried out only during a supply ramp-up.

#### 11.2.1.3.3 100 MHz Back-up Clock Source (fBACK)

The 100 MHz clock source is a precise back-up on-chip clock used by EVRs, firmware and serves as the main system clock during the Start-up phase. It is further used as an independent clock reference for clock monitoring and can be used as a back-up clock in case of loss of lock or crystal failures. After start-up, the 100 MHz clock source has a higher variance in the order of  $\pm 40\%$  and the clock source is later trimmed by the start-up software.

---

## Power Management System (PMS)

as documented in datasheet. It shall be ensured that the PMS subsystem, boot software / Firmware and the start-up modules are tolerant and functionally robust to this clock variation.

The **EVROSCCTRL** register shall not be modified by the application software, as it is configured by the Start-Up Software in order to trim the back-up oscillator to the specified accuracy limits. Additional compensation for improved accuracy across the temperature range is possible by enabling the dynamic oscillator trimming in the register bits **EVROSCCTRL.OSCTEMPOFFS** and **EVROSCCTRL.OSCTRIMEN**.

---

**Power Management System (PMS)****11.2.1.4 Die Temperature Measurement**

The Die Temperature Sensor (DTS) generates a measurement result that indicates directly the current temperature. The DTS measures the temperature with an accuracy within ( $T_{NL} + T_{CALACC}$ ) parameter limits within the TSR temperature range documented in the datasheet. The result of the measurement is updated periodically in **DTSSTAT.RESULT** register bit field with a resolution less than 1/5th of a degree Kelvin. The Die Temperature Sensor is available after cold PORST reset release on a device start-up and temperature measurements are carried out continuously during normal RUN / SLEEP modes. The DTS and corresponding registers are not affected by a warm PORST, system or application reset; consequently DTSTAT temperature result from earlier conversion is available for immediate use after any warm reset.

After an ongoing temperature measurement is completed, **DTSSTAT.RESULT** bit field is updated coherently with the new value. An interrupt service request (SRC\_PMSDTS) can be generated after a measurement is completed. The DTS accuracy and measurement time is defined in the Data Sheet.

Die temperature upper and lower limits are configured in **DTSLIM.UPPER** and **LOWER** register bits. On violation of these limits, **DTSLIM.UOF** and **LLU** status bits are set and alarms are forwarded to SMU and HSM. After start-up, the DTS limits have to re-configured appropriately depending on the application before alarm reactions from SMU or HSM are activated. Only when a new DTS conversion result is available, the DTS comparators are consequently triggered to check the actual **DTSSTAT.RESULT** against the upper and lower limits.

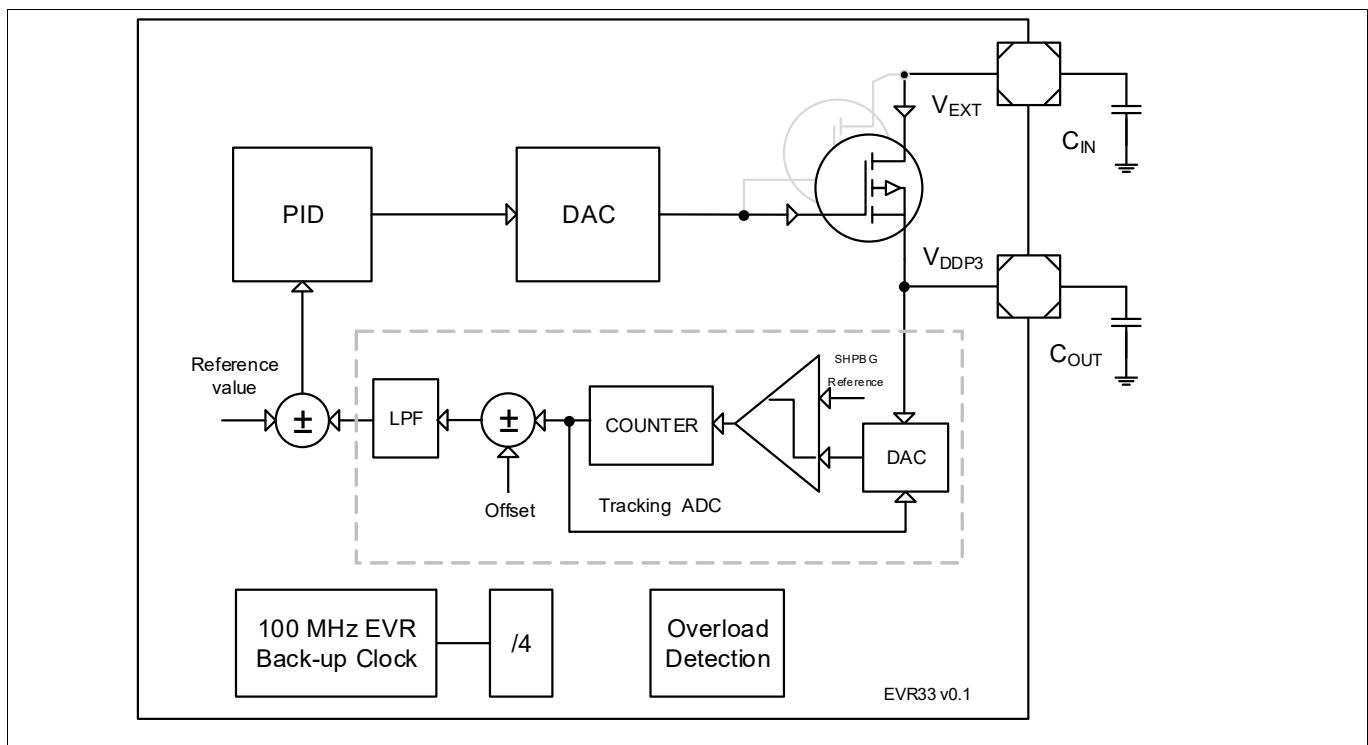

Note: LDMST or SWAPMSK.W should be used only with bit mask enabled for all 'rwh' bits in the **DTSLIM** register.

## Power Management System (PMS)

### 11.2.2 Power Supply Generation and Monitoring

#### 11.2.2.1 Linear Regulator Mode (EVR33)

The EVR33 regulator supplies the Flash module. EVR33 constitutes a digital regulator, a pass device control unit and a voltage feedback loop. In order to compensate technology and process variations, the ADC and the DAC are device individually trimmed. The EVR33 regulator output voltage ( $V_{DDP3}$ ) is measured by a dedicated ADC using SHPBG reference supply and the result is indicated also in register **EVRADCSTAT.ADC33V**. The closed loop regulation cycle is triggered at the end of the ADC conversion. The error difference is fed to a PID controller and the output of the controller is fed to the DAC to control the gate voltage of the pass devices. The pass device outputs are buffered by external capacitor to handle load transients so as not to violate the operating voltage limits. EVR33 can be individually disabled via HWCFG[1] pin as described in [Chapter 11.2.1.1](#). During the Start-up phase, the setpoint voltage is ramped up in steps over the start-up period to ensure a soft ramp-up of the  $V_{DDP3}$  voltage.

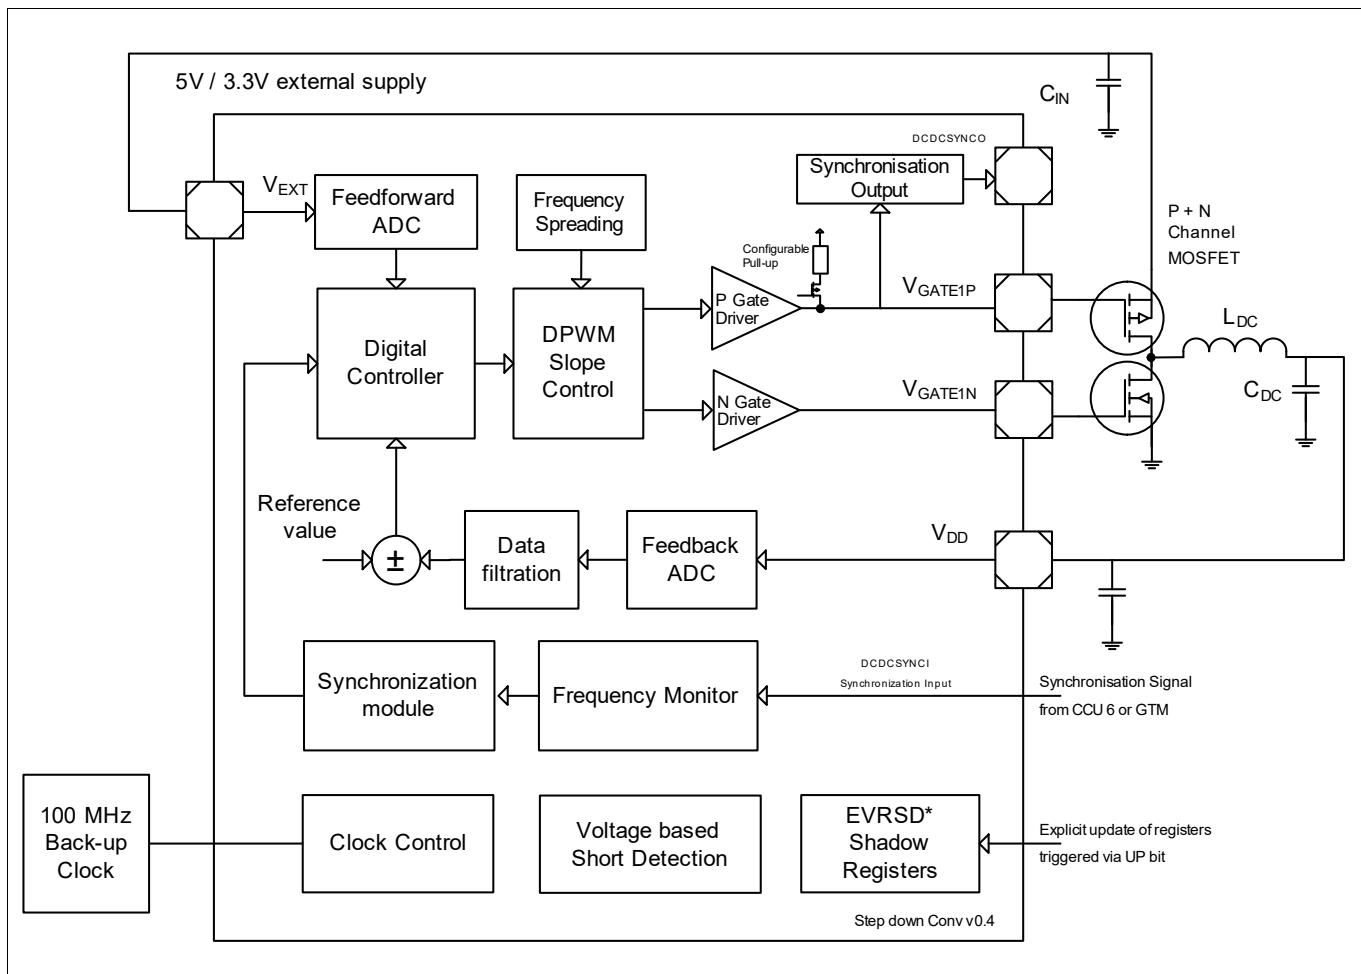

**Figure 101 EVR33 LDO regulator**

## Power Management System (PMS)

### 11.2.2.2 Step-down Regulator (EVRC)

The Step-down regulator provides a higher efficiency of power conversion compared to linear voltage regulator. However it requires additional external components and injects more switching noise into the system. The integrated EVRC regulator modulates an external charge device to buffer the energy in a LC filter in order to generate a regulated core supply. The 5 V or 3.3 V external VEXT supply shall be provided to the complementary MOSFET switches as shown in [Figure 103](#) and [Figure 105](#).

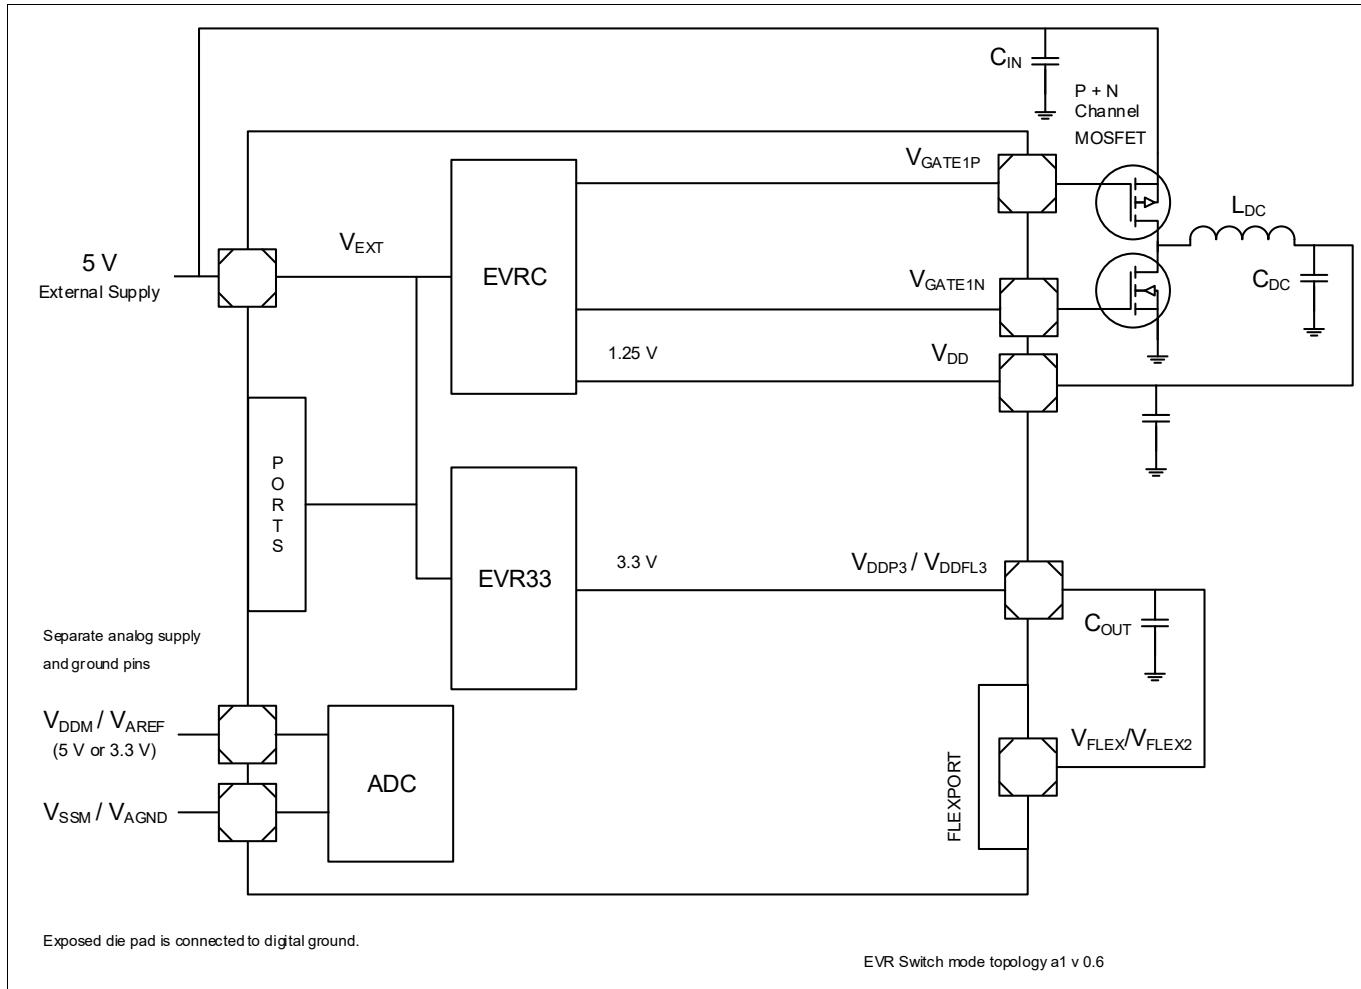

**Figure 102** EVRC Step down regulator

The control strategy involves synchronous switching of the complementary Pch. and Nch. MOSFETs at a defined switching frequency using pulse width modulation. The recommended nominal switching frequency is 1.8 MHz in PWM mode and is derived based on efficiency, performance and EMI/EMC trade-off. The duty cycle has a resolution of the base clock frequency of 100 MHz internal clock and is controlled using a programmable digital controller which reacts to the deviation of the input and output voltage against a reference voltage. The EVRC regulator operates in continuous conductance mode during normal PWM mode. The output voltage value is approximately equal to the input voltage multiplied by the duty cycle factor neglecting the parasitic components and losses.

The output voltage V<sub>DD</sub> is measured with a feedback ADC (FBADC) and sampled with an offset to the PWM switching event to mitigate switching noise influence. The measured output voltage is then fed into the digital filter and provided to the digital controller. The measured core voltage is indicated in [EVRSDSTAT0.ADCFBCV](#) status bits. The target of the digital controller is to compute the new duty cycle and the skip pulse information for the switching period based on the input information. The duty cycle is limited between maximum and minimum value in order to ensure proper commutation in the power switches. The duty cycle is realized by a Digital Pulse

## Power Management System (PMS)

Width Modulator which drives the respective Gate drivers. The duty cycle of the previous period is indicated in **EVRSDSTAT0.DPWMOUT** status bits. In case the controller output is above certain threshold during the start of a switching period and based on internal controller states, a pulse skipping mechanism is employed and the power switch will remain for a whole switching period in OFF state. The parameters for the digital controller are programmable. The external VEXT supply is also measured by the Primary SWD / VEXT Monitor ADC to facilitate a parameter switch if the voltage crosses a threshold and to differentiate between 5 V or 3.3 V external supply case.

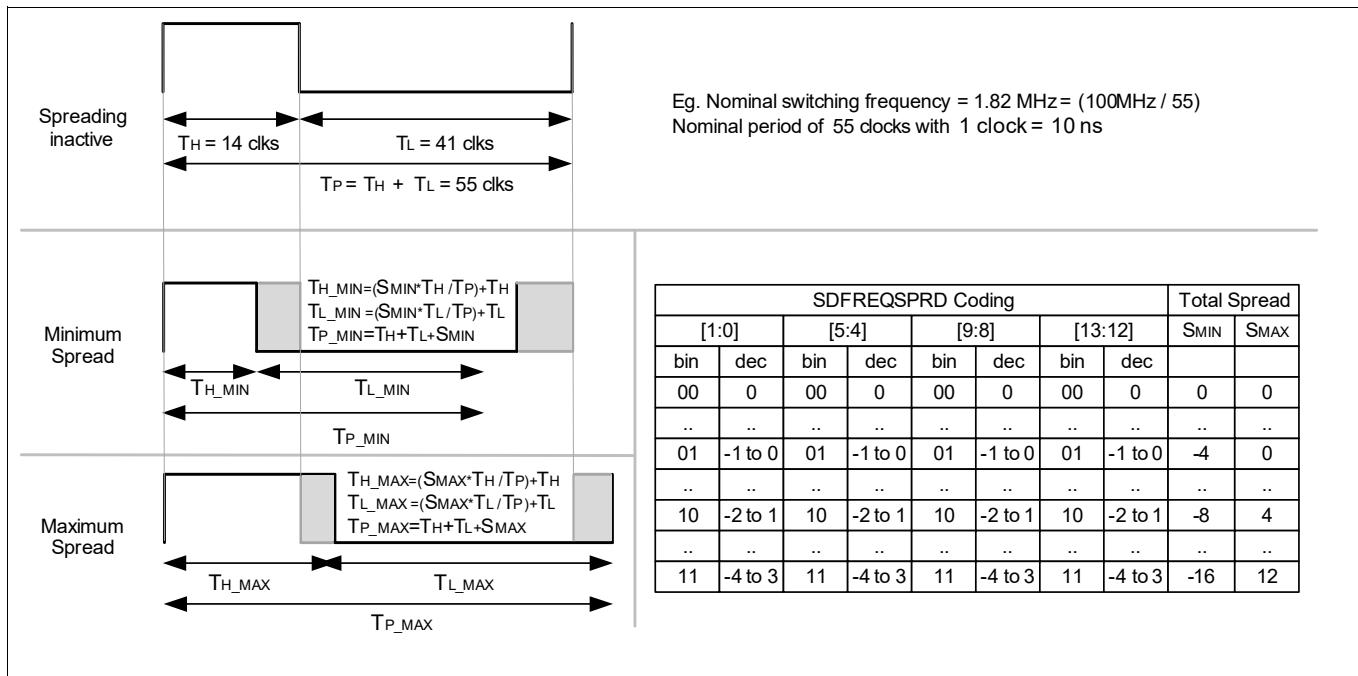

**Figure 103 EVR Switch mode topology (a) - 5 V single supply**

The nominal switching frequency is configured via **EVRSDCTRL0.SDFREQ** register bits with a nominal 10 ns switching period resolution at a base frequency of 100 MHz.

Frequency spreading may be activated via **EVRSDCTRL0.SDFREQSPRD** register bits in case of SMPS mode to comply with EMI / EMC requirements. The actual switching period is varied in a random manner between a minimum and maximum period spread as depicted in **Figure 104**. The maximum spread is bounded by the programmed value in SDFREQSPRD register field. It is ensured that duty cycle changes are compensated during frequency spreading over consecutive periods to ensure that the induced voltage ripple owing to frequency spreading is kept to a minimum. Furthermore, programmable slope control of the external MOSFETs is implemented by controlling the driver strength and slew rate and shall be adapted to the external components. A scaled switching (DCDCSYNCO) output derived from the actual EVRC switching output is routed to an external pin. The frequency of the scaled output is in the range between 50 kHz and the actual EVRC switching frequency. The scaling factor is configured in **EVRSDCTRL7.SYNCDIVFAC** bitfield and the output is enabled via **PMSWCR5.DCDCSYNCO** bitfield. The EVRC switching output with the current dutycycle is routed directly to the pin if SYNCDIVFAC = 0. For other configured SYNCDIVFAC values, the DCDCSYNCO output has 50% dutycycle.

## Power Management System (PMS)

The behavior of VGATE1N and VGATE1P during start-up and normal operation is described in section [Section 11.2.1.2.5](#).

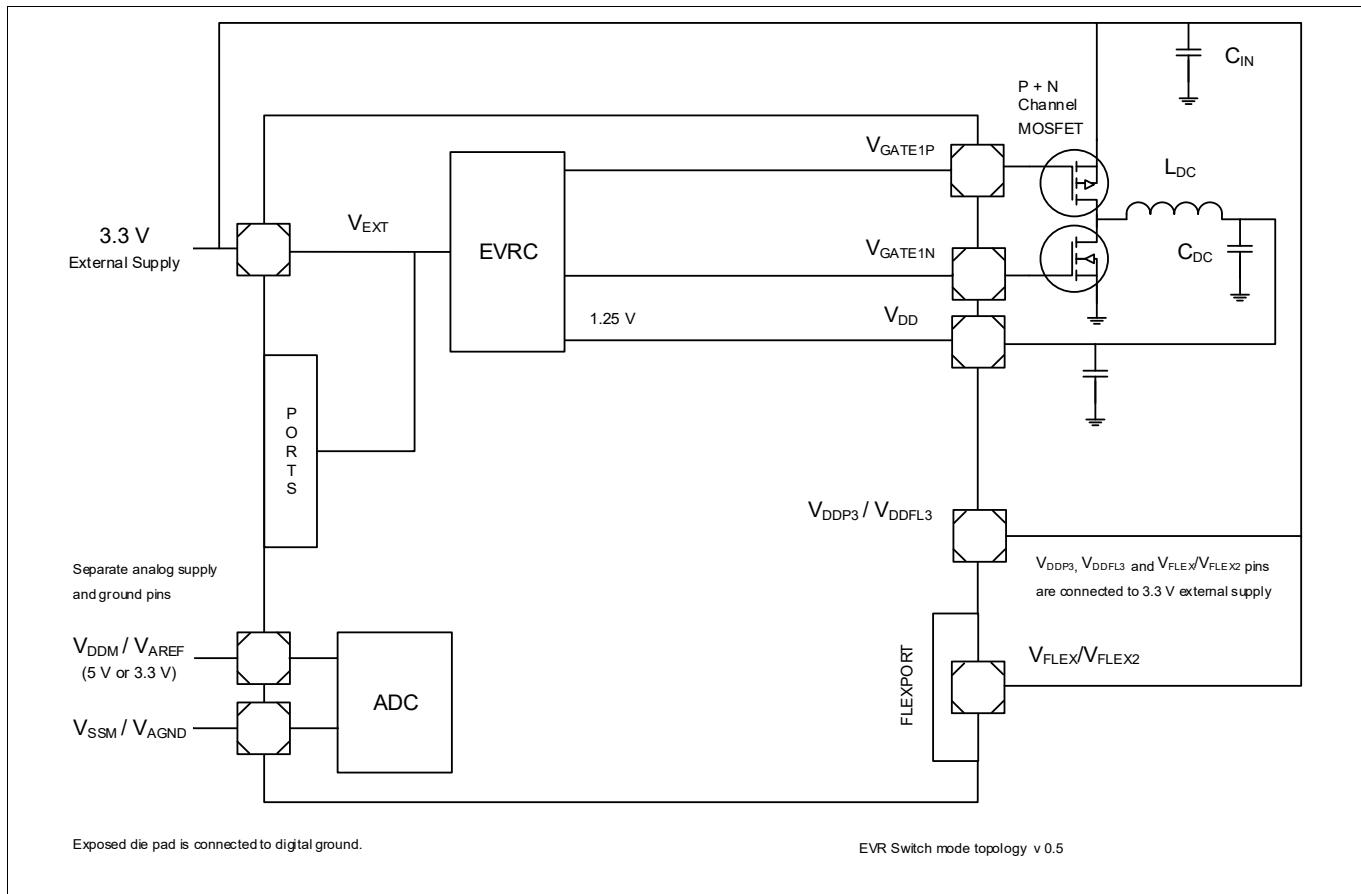

**Figure 104 EVRC Regulator Switching Frequency Spreading**

During the Start-up phase, a different control strategy is used in order to avoid current overload in the coil, overshoot of the output voltage and to charge the output capacitor in the shortest possible time. In this phase, only the P-channel MOSFET is switched ON / OFF gradually increasing the duty cycle starting at a preset value while the N-Channel MOSFET remains always OFF and behaves like a diode. This facilitates fast ramp-up to the target voltage without discharges during transients during the initial switching periods. The default switching frequency is 0.5 MHz during open loop start-up phase. The open loop operation ends when the FBADC output voltage reaches the threshold value configured in [EVRSDCTRL6.SVOTH](#) bitfield slightly below the setpoint target value. At this point the digital controller is configured and the normal closed loop operation begins and switch to 1.7 MHz switching frequency takes place. After a voltage transient (typically an overshoot), EVRC is ready and regulator output voltage is ok as indicated via [EVRSTAT.SDVOKE](#). [EVRSTAT.SDVOKE](#) remains set during RUN mode and is reset only if VDD set point was changed or VDD droop request was made during RUN mode. The start-up phase and VGATE1P and VGATE1N behavior is portrayed in [Figure 100](#). The parameters of the step down regulator is consequently updated by the Firmware after reset release to achieve a more accurate EVRC output voltage and improved performance. The step-down regulator is also later programmed with the values enumerated in [Table 290](#) so as to match the application needs and the components used. A complete parameter update is triggered explicitly by writing to [EVRSDCTRL0.UP](#) bit and it need to be ensured that all the registers are consistent before triggering the update. It need to be ensured that the EVRC registers are programmed with the right values to avoid cold PORST or overvoltage events and it cannot be always guaranteed that the EVRC recovers from wrong programming. The parameter update execution results typically in a VDD voltage transient (typically an overshoot). The parameter update is not allowed during Start-up and Low Power Mode. The droop compensation request, droop level and LPM request are taken immediately without waiting for a parameter update.

During consequent supply ramp-down phase or standby mode entry phase, the step down regulator uses the earlier programmed parameter set to ensure a graceful shut-down devoid of output voltage overshoots and coil overload. The state of both gate control outputs VGATE1P and VGATE1N during a consequent supply ramp-down phase is configured by the [EVRSDCTRL0.PGOFF](#) and [EVRSDCTRL0.NGOFF](#) register bits respectively.

## Power Management System (PMS)

The step-down regulator may be informed on anticipated load jumps so that adequate preparation can be made. The controller could lower or raise the output voltage to compensate and thus minimise voltage over-/undershoots owing to a sudden load jump. The management of voltage droop is described in Power Management [Section 11.2.3.5](#). The step down regulator issues the droop request only if the current VDD voltage level as measured by VDD FBADC is within the limits defined in [EVRSDCTRL11.DROOPVL](#) and [DROOVH](#) so as to avoid unintended resets and alarms owing to a voltage droop.

**Figure 105 EVR Switch mode topology (e) - 3.3 V single supply**

The step-down EVRC regulator also supports a Low Power Mode (LPM) which is activated on a Sleep Mode request. The activation of Low Power Mode is controlled via low power mode management and enabled via SCU\_PMTRCRS0.LPSLPEN register bit. The mode is limited to small load currents below 100 mA and has a minimum transition time of a single switching period to enter Low Power Mode. In this mode the output voltage is regulated according to a pulse frequency modulation scheme switching only the Pch. MOSFET and Nch. MOSFET acting like a diode. This mode reduces the switching losses thereby reducing the total Sleep Mode power consumption. The current mode of the step-down EVRC regulator is reflected in [EVRSTAT.EVRCMOD](#). On wake-up, the LPM mode is de-asserted and it has to be ensured that the immediate load jumps from application side are limited for the transition period as documented in the datasheet. The step-down EVRC regulator parameters are not updated during LPM mode.

During Low Power Mode, the synchronisation output (DCDCSYNCO) does not have a fixed frequency and it should be ensured that the synchronisation is not active between external regulator and TC3xx device during low power mode.

During fast ramp-down of VEXT input voltage followed by consecutive fast ramp-up bounded by datasheet parameter  $dVEXT/dT$  and during regulator start-up and standby transitions with large load jumps, voltage overshoots beyond operating conditions may occur for a short duration bounded by absolute maximum voltage

## Power Management System (PMS)

limits. During power fail of VEXT or VEVRSB input supply voltage triggering immediate LVD reset, EVRC VDD output voltage may consequently ramp down with damped oscillations leading to negative voltages on VDD rail for short duration of time (<100 us). During Standby entry , the EVRC is ramped down in a controlled manner to avoid such damped oscillations on VDD supply rail.

### 11.2.2.2.1 EVRC Frequency and Phase Synchronization to CCU6/GTM Input

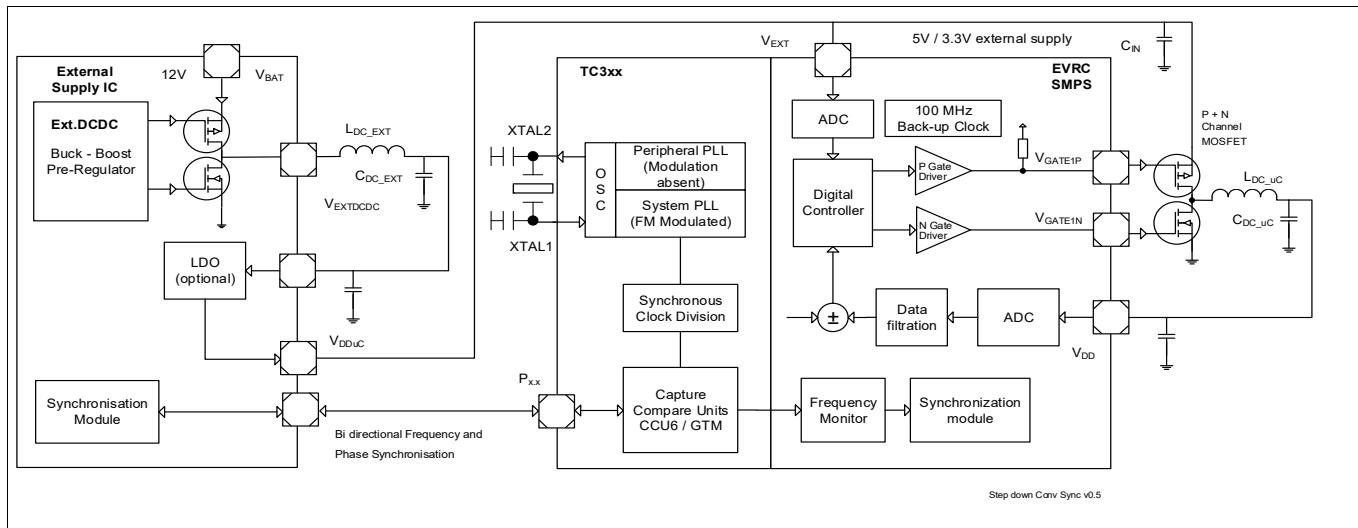

A synchronization input (DCDCSYNCI) can be provided to the EVRC SMPS regulator from CCU6 or GTM module to synchronize the frequency and the phase of the internal EVRC regulator to the external DC DC regulator. The CCU6 / GTM module provides / captures two phase synchronised PWM signals; one PWM output to the internal EVRC regulator and the other as either input from or output to an external DC DC regulator using a Port pin as shown in [Figure 106](#).

Salient aspects of the Synchronization feature are enumerated below:

- The nominal frequency of the synchronization input is 1.8 MHz. Bi-directional signal to/from external regulator is provided by the CCU6 or GTM unit.
- Frequency monitoring is carried out in the region between 1.6 MHz and 2 MHz.
- Loss of Synchronization Lock event is triggered if switching frequency range is violated. Loss of Synchronization Lock event is indicated via status bits and interrupt.
- Lock Hysteresis is provided for the Synchronization Lock signal to avoid limit cycling behavior.
- CCU60 COUT63, ATOM [0-4]\_1 and TOM [0-4]\_1 can be connected internally to LCDCDC synchronisation input.

The synchronization is supported only in the Normal PWM Mode via **EVRSCTRL11.SYNCEN** register bit and shall not be activated during Start-up or in Low Power Mode. The frequency monitor allows a maximum tolerable deviation of the synchronization input as configured in **EVRSCTRL11.SYNCMAXDEV** register bit fields. The duty cycle is not monitored, but it must be wide enough to allow proper sampling of the rising edges (minimum 2 clock cycles @100 MHz). The synchronization signal may be subjected to delays and jitter when it crosses over from the System PLL domain to the Back-up clock domain which would have an impact on the static accuracy of the EVRC regulator. The status of the synchronization lock is indicated via **EVRSTAT.SYNCLCK** bit. The loss of synchronization lock interrupt is enabled via **PMSIEN.SYNCLCK** register bit. A hysteresis is applied for the locking and unlocking, such that toggling lock behavior is avoided around the frequency monitoring limits as configured in **EVRSCTRL11.SYNCHYS** hysteresis width register bit field. Frequency spreading may be additionally activated and consequently the synchronized rising edge of the PWM signal is delayed in a random manner. Frequency step changes are limited to  $\pm 100$  kHz from CCU6 / GTM module and the dynamic frequency change in case of loss of synchronization is limited to  $\pm 200$  kHz. The component tolerances shall support the frequency range between 1.6 MHz to 2 MHz and the loss of lock dynamics. The parameters for Synchronization are documented in the datasheet.

## Power Management System (PMS)

**Figure 106 EVRC Synchronization Input**

### Synchronization Lock Procedure

- After the completion of the start-up phase or LPM mode, controller operation in EVRC PWM mode is ensured via **EVRSTAT.EVRCMOD**. The EVRC is configured for a nominal frequency of 1.8 MHz which also the reference frequency for the frequency monitor. All EVRC parameters are configured as per the intended configuration. The **EVRSDCTRL11.SYNCMAXDEV** and **SYNCHYS** bit fields are configured. Frequency spreading shall be deactivated in **EVRSDCTRL0.SDFREQSPRD** register field. Synchronization inherently provides additional jitter on switching signals which may be adequate for the EMI/EMC performance. Activating frequency spreading and synchronization jitter may increase the VDD voltage ripple.
- A synchronization input signal is provided and configured in GTM / CCU6 module and is selected via **EVRSDCTRL11.SYNCMUXSEL** bit field. GTM LCDCDCOUT signal is selected via the LCDCDCOUTSEL register in GTM module. In case of CCU60, only COUT63 is routed. A phase shifted signal may be provided to the external DCDC regulator. For High-End configurations, the register bitfield **EVRSDCOEFF0.M0SRMPCOEFF** is set to 0x09. For Low-End configurations, synchronization lock and synchronization unlock procedures shall not touch the bitfield **EVRSDCOEFF0.M0SRMPCOEFF** at all.
- When no load / line transients are ongoing, **EVRSDCTRL1.SYNCEN** bit is set to initiate the Synchronization Lock procedure.
- The frequency of the incoming synchronization signal is monitored for a single period consequently after **EVRSDCTRL1.SYNCEN** bit is set. At least one input period is required to evaluate whether the input frequency is valid. A parameter update is required to transfer the synchronization enable information.
- When the frequency of the synchronization signal is within the specified limits, immediate synchronization is started on the consecutive PWM rising edge. The synchronization is completed within 4 switching periods. The DCDC switching frequency and phase is altered and locked to the incoming signal.
- When the DCDC switching frequency is locked to the synchronization input, the **EVRSTAT.SYNCLCK** status bit is set into locked state indicating the completion of the lock procedure. The Synchronization Lock procedure takes less than 4 switching periods. After EVRC is locked to the synchronization input, the maximum delay between the rising edge of the synchronization input signal to EVRC and the consequent synchronized falling edge of the VGATE1P signal is less than 180ns.
- Depending on whether the input PWM rising edge coincides with a high or low phase of the DCDC switching period, the current switching period maybe extended or shortened.

## Power Management System (PMS)

### Synchronization Un-Lock Procedure

- Before entering LPM (Sleep) mode or Standby mode, the **EVRSDCTRL1**.SYNCEN bit shall be reset to initiate the Synchronization unlock procedure. Consequently register bitfield **EVRSDCOEFF0**.M0SRMPCOEFF, for High-End configurations, is set to 0x08. For Low-End configurations, synchronization lock and synchronization unlock procedures shall not touch the bitfield **EVRSDCOEFF0**.M0SRMPCOEFF at all.
- The **EVRSTAT**.SYNCLCK bit is set into unlocked state. The Synchronization unlock interrupt is generated if enabled. The Synchronization un-lock procedure takes less than 4 switching periods. The synchronization logic is consequently disabled.
- The synchronization input signal is consequently deactivated from GTM / CCU6 module via **EVRSDCTRL11**.SYNCMUXSEL bit field. The phase shifted signal to the external DCDC regulator from GTM / CCU6 is also deactivated.
- When the DCDC switching frequency is unlocked from the synchronization input, the **EVRSTAT**.SYNCLCK status bit is set into un-locked state indicating completion of the unlock procedure.

### Synchronization Unlock Event

- If the period of the incoming synchronization signal is respectively more than (normal period + maximum deviation) or is less than (normal period - maximum deviation); a Synchronization Unlock event is triggered.
- The **EVRSTAT**.SYNCLCK status bit is set into unlocked state. The Sync unlock interrupt is generated if enabled.
- The SMPS regulator switches to operate purely based on the internal back-up clock at default 1.8 MHz with an arbitrary phase. The Dynamic voltage deviation maybe higher during loss of synchronization (2 MHz / 1.6 MHz to 1.8 MHz jump) with consequent load jump.
- A re-lock is triggered respectively with hysteresis only if the incoming signal period is less than (normal period + maximum deviation - sync hysteresis) or more than (normal period - maximum deviation + sync hysteresis)

### 11.2.2.3 Components and Layout

The efficiency of the step-down regulator is influenced by the characteristics of the selected components and also the placement and routing of the components on the PCB. The additional external components constitute a coil, a capacitor and a complementary P-channel and N-channel MOSFET.

The coil need to have a low ESR and a relatively constant characteristic against temperature and current variations. Likewise the capacitor need to have a low ESR, a constant frequency characteristic and minimum DC voltage dependence. The capacitors may be a parallel combination of smaller and larger capacitors or capacitors of equal size for better efficiency or owing to safety considerations. The P-channel MOSFET is preferred with lower RDSON and gate capacitance values. The P-channel MOSFET gate need to be connected to VGATE1P pin. The N-channel MOSFET gate needs to be connected to VGATE1N pin for synchronous switching of the step-down regulator. In case of usage of Emulation devices, it should be taken care that the component choice also considers the current additionally drawn by Emulation RAM and additional modules.

Component characteristics would be recommended in the datasheet and is also documented in [Table 290](#).

After start-up, it need to be taken care that the register settings of EVRC are updated depending on the external components and switching frequency to ensure optimal efficiency and performance. Driver parameters are updated first followed by changing the driver slope control from hard to soft switching mode. Finally, controller parameters are updated.

It should be taken care that each supply pin in QFP packages or a pair of supply pins in BGA packages has a decoupling capacitor close to the pins. Supply pins belonging to a common supply rail shall be connected together after the respective decoupling capacitors and shall be buffered by an additional larger capacitor based on the requirements of the regulator which supplies the rail. In case of EVR33 and EVRC regulator, recommended buffer capacitors are enumerated in [Table 290](#). It should be taken care to have a low trace resistance to the

## Power Management System (PMS)

decoupling capacitors and buffer capacitors for better performance and EMI / EMC behavior. The dimensioning of the buffer capacitors is based predominantly on the load jumps triggered during reset events and stability criteria of the regulator.

### 11.2.2.4 External Supply Modes

The external supply modes involve deactivating any or both of the EVRC and EVR33 regulators. In this mode, EVR33 is disabled via the HWCFG[1] configuration pin and the EVRC is disabled via the HWCFG[2] configuration pin respectively.

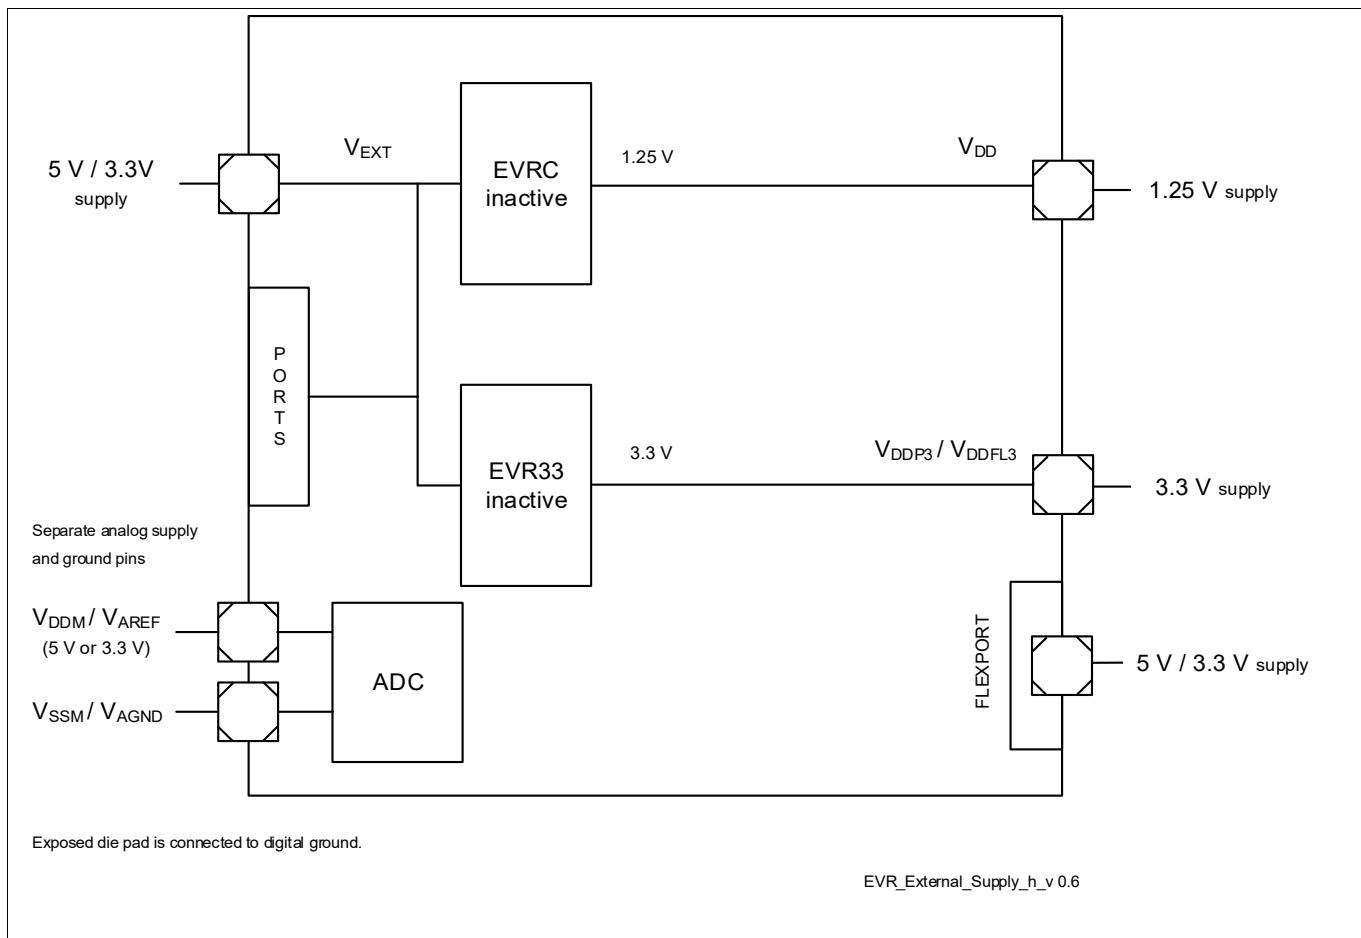

Following external supply modes are supported.

- VEXT = 5 V and VDD supplied externally. VDDP3 is generated using the EVR33 regulator as shown in [Figure 107](#).
- VEXT = 5 V or 3.3 V and VDDP3 is supplied externally. VDD is generated using the EVRC regulator.
- VEXT, VDDP3 and VDD are all supplied externally as shown in [Figure 108](#).

**Figure 107 External Supply mode (d) - VEXT and VDD externally supplied**

## Power Management System (PMS)

### 11.2.2.5 Supply Voltage Monitoring

The PMS module implements a staggered voltage monitoring build upon a primary and a secondary monitor providing adequate redundancy to meet safety requirements. The primary monitor ensures that the micro controller is put into a cold PORST reset state when the lowest operational voltage thresholds are violated. The secondary monitor serves as an additional safety monitor providing over- and under-voltage alarms for multiple supply rails. Monitors are realized using dedicated 8 bit ADC converters and result comparators.

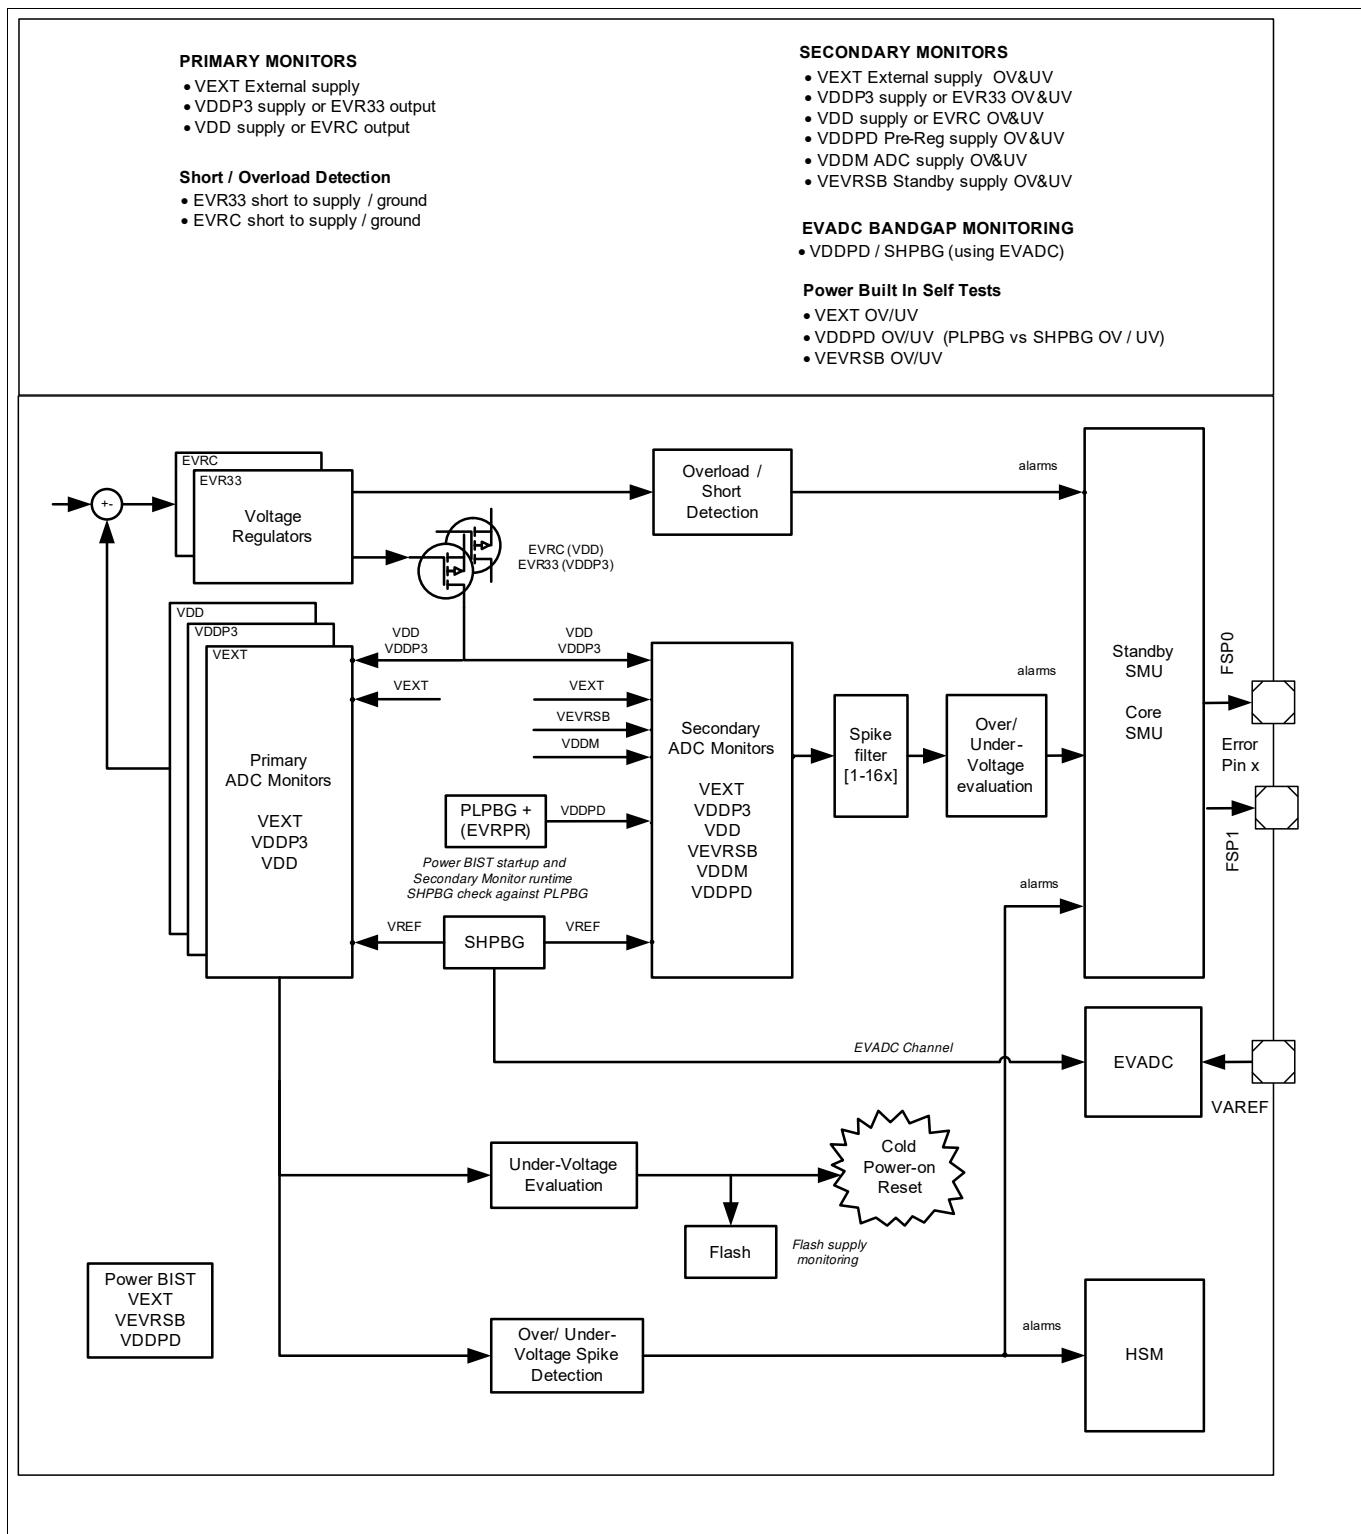

Figure 109 Supply Monitor Overview

## Power Management System (PMS)

### 11.2.2.5.1 Primary under-voltage monitors and Cold PORST

Primary under-voltage monitoring of the external VEXT supply, VDDP3 / EVR33 supply and VDD / EVRC supply are inherently carried out to ensure proper functioning of the system. The thresholds for the primary monitors represent the lowest possible thresholds for the correct functioning of the system. The threshold and tolerance is documented in datasheet as VxxPRIUV parameter. In case of violation of these thresholds, cold PORST is activated and PORST pin is pulled low (strong current sink) thus setting the device into reset state. Following the reset release and firmware boot, it can be inferred from STBYR, EVRC, EVR33 or SWD bits in RSTSTAT register as to whether the violation of these thresholds led to the previous reset. The primary under-voltage monitoring is kept active even if the respective EVRs have been disabled and the supply is provided externally as shown in [Table 292](#). The thresholds are trimmed and the monitoring is activated or deactivated via the [EVRRSTCON](#) register. The user shall not modify the default values of the [EVRRSTCON](#) register, as any alteration of the primary reset monitoring violates the operational conditions of the microcontroller and may lead to unexpected behavior during the dynamic undershoot regulation or during the power down sequence.

The cold PORST is asserted when the supply voltage drops below [EVRRSTCON.RSTxTRIM](#) value. During cold PORST reset release, to avoid consecutive toggling PORST during slow supply ramp-ups, a voltage hysteresis is supported. The cold PORST is de-asserted or released when the supply rises above ([EVRRSTCON.RSTxTRIM](#) + Hysteresis) value. The PORST pin is driven low for a minimum nominal time of 10 us on recognition of cold PORST irrespective whether the voltages have been immediately restored so that there is adequate time to recognise it externally.

Further more, additional power-on detectors are available for VEVRSB supply (supplied by VEXT), VEXT supply (supplied by VEVRSB) and VDDPD internal supply (via VDDPD POR monitor) to ensure a proper minimum-power detection, robust start-up and standby operation. Undervoltage of VDDPD internal supply and external VEXT supply will lead to the assertion of the LVD (Low Voltage Detector) reset. Undervoltage of external VEVRSB supply will lead to the assertion of the LVD reset indirectly via the VDDPD POR monitor as VDDPD is generated from VEVRSB. Assertion of LVD reset is reflected in RSTSTAT.STBYR bit and can be evaluated in the next start-up. After a normal supply start-up, only STBYR and PORST bits in RSTSTAT register are set.

The primary Supply WatchDog (SWD monitor) monitors the ramp-up of external VEXT supply voltage and keeps the micro controller in cold Power On Reset state as long as the supply has not reached the operational region. Likewise, it also allows detecting ramp-down or brown out conditions of external supply so that the device can be brought into a cold Power On Reset state when the voltage has dropped below the lowest operational threshold. Nevertheless, It is recommended to monitor externally all supplies generated external to the micro controller and to assert PORST reset pin in case of violation of the lowest operational limits. The pass device dropout voltage should be taken into consideration when setting these limits. In case of 5 V nominal external supply and 3.3 V in turn being generated by the internal EVR33 LDO regulator, the external supply shall maximum drop during normal RUN mode considering adequate pass device dropout as documented in datasheet.

The external VEXT supply, VDD / EVRC and VDDP3 / EVR33 supplies are measured by Primary Monitor ADCs and the measured value is updated in [EVRADCSTAT](#) register after conversion completion at every PMS clock cycle.

In case of primary monitor violation, respective status bits are set to indicate the event as shown in [Table 292](#). These bits maybe evaluated during consequent start-up after cold power-fail reset to recognize which among the supply rails had the power-fail.

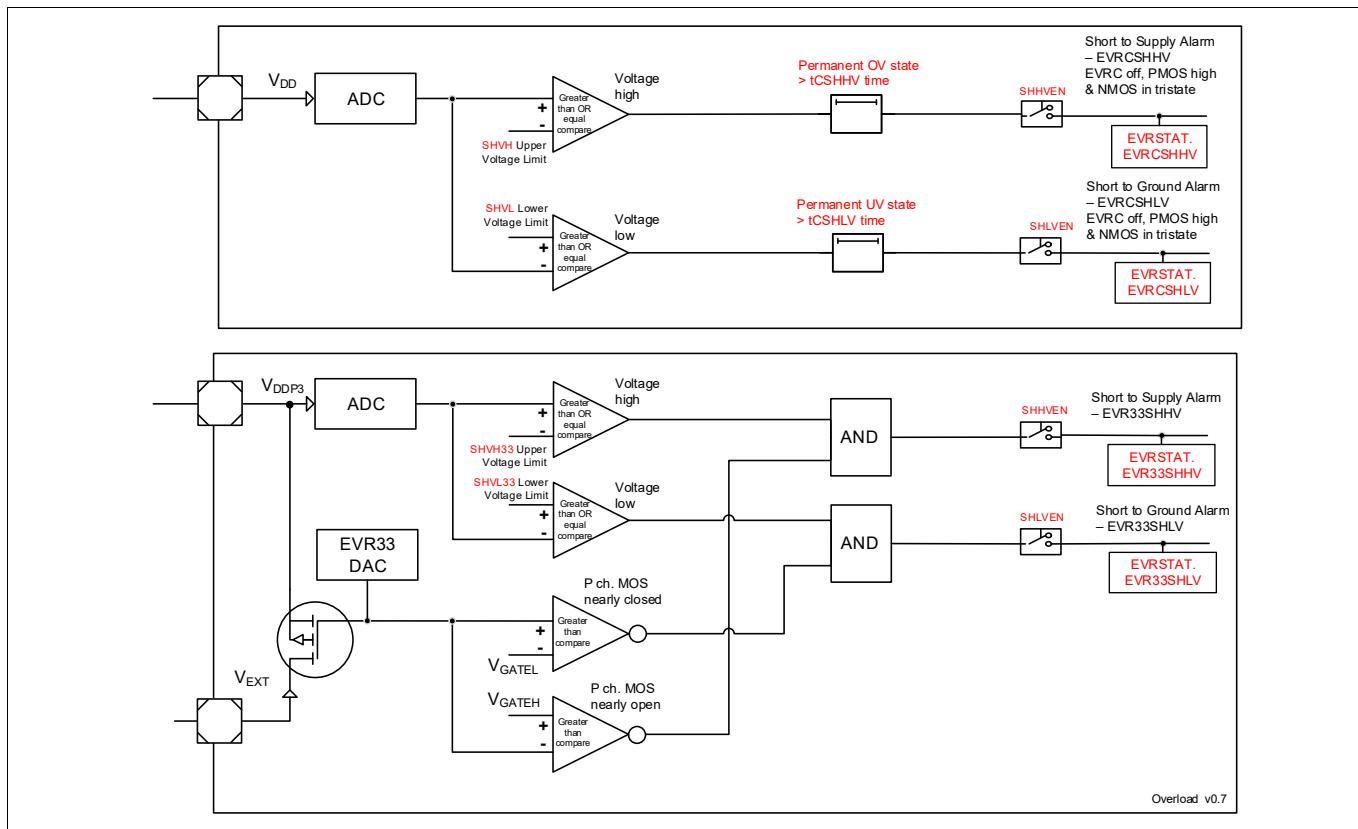

The violation of the primary under-voltage and over-voltage operational limits of VEXT, VDDP3 and VDD supply rails is communicated to the HSM module and to the SMU. HSM module may lock access to EVR registers via SLCK bit so that supply generation cannot be influenced by other masters. This is to ensure that trojan programs do not manipulate the supplies to gain access to the system. VEXT, VDDP3 and VDD rail primary monitor measurements are compared with [HSMOVMON](#) and [HSMUVMON](#) thresholds and alarms are routed to the HSM module and to the SMU (as shown in [Figure 109](#)). The violations are indicated in [EVRADCSTAT](#) status flags. The unfiltered primary monitor ADC measurements are used to detect power spikes on the main supply rails and consequently alarms are provided to HSM and SMU. Each primary monitor ADC tracking speed is bounded by the

## Power Management System (PMS)

maximum supply slope of a single LSB step every nominal 25 MHz ADC clock cycle. This results in a maximum tracking speed of 500V/ms (20mV LSB/40ns) for VEXT SWD primary monitor, 375V/ms (15mV LSB/40ns) for VDDP3 primary monitor

A voltage based short detection scheme is enabled for EVRC via **EVRSDCTRL10.SHLVEN / SHHVEN** register bit fields. The short detection scheme for EVRC output is as portrayed in [Figure 110](#). VDD FBADC result is compared against SHVL and SHHV thresholds. If the low voltage or high voltage condition occurs continuously for more than tCSHLV or tCSHHV duration, the respective voltage alarms are activated and are indicated by **EVRSTAT.EVRxSHHV** and **EVRSTAT.EVRxSHLV** register status bits. If the low voltage or high voltage condition disappears before tCSHLV or tCSHHV expiry, then tCSHLV or tCSHHV timers are reset. The recovery from EVRC short switch-off state is possible only with a renewed ramp-up of VEVRSB and VEXT supply rails. EVRC Short signal is filtered for 6 consecutive values using a spike filter and the filtered signal leads to EVRC switch off.

A short detection scheme may be activated for EVR33 via .SHLVEN / SHHVEN bits. The short detection scheme for EVR33 is portrayed in [Figure 110](#). Short to higher voltage is deduced when the voltage regulator control output or pass device gate voltage has saturated at the lower limit and at the same time the regulator voltage output has crossed the absolute maximum limit. Short to lower voltage is deduced when the voltage regulator control output or pass device gate voltage has saturated at the upper limit and at the same time the regulator voltage output has stayed at the minimum limit. In both cases the respective alarms are activated and indicated by **EVRSTAT.EVR33SHHV** and **EVRSTAT.EVR33SHLV** register bits.

**Figure 110 Short to Supply and Ground Detection**

## Power Management System (PMS)

### 11.2.2.5.2 Secondary over- and under-voltage monitors and alarm generation

Additional secondary over-voltage and under-voltage monitoring against programmable thresholds is provided for all supplied and generated voltages. The secondary monitors are based on a secondary bandgap reference independent from the primary band-gap reference. The monitored voltages include the external VEXT supply voltage, VDDP3 / EVR33 supply, VDD / EVRC supply, external VEVRSB supply voltage, external VDDM ADC supply voltage and the internally generated VDDPD Pre- Regulator output voltage as shown in [Figure 112](#) and [Figure 113](#). The secondary voltage monitors are kept active even if the respective EVRs have been disabled and the supply is provided externally as shown in [Table 292](#). In case of a threshold violation, an SMU alarm event is generated. The threshold and tolerance is documented in datasheet as VxxMON parameter.

The secondary monitor violation is notified depending on the direction of voltage transition as programmed in [EVROMONCTRL](#) register. The appropriate thresholds for voltage monitoring can be programmed in the [EVROVMON](#), [EVROVMON2](#), [EVRUVMON](#) and [EVRUVMON2](#) registers. These can be calculated by linear interpolation based on multiple voltage levels and corresponding thresholds provided in VxxMON datasheet parameters. In case of an active monitoring violation, respective status flags are set in the [EVRSTAT](#) register. It can be inferred from OVC, OV33, OVSWD, OVPRE, OVS and OVDDM bits in [EVRSTAT](#) register as to whether over-voltage thresholds for the respective voltage domains were violated. Likewise, it can be inferred from UVC, UV33, UVSWD, UVPRE, UVS and UVDDM bits in [EVRSTAT](#) register as to whether under-voltage thresholds were violated. The respective status bits may be evaluated to differentiate between an over-voltage or an under-voltage event and to recognize which supply rail had triggered the alarm event to SMU as shown in [Table 292](#). The secondary monitor measurement latency to measure all 6 supply rails is documented in datasheet as tMON parameter. The supply rails are converted one after another in a continuous scan mode. It is also possible to deactivate individually the secondary monitors in [EVROMONCTRL](#) register. If the respective OVMOD and UVMOD bits are set to 00, then the ADC conversion for the particular supply rail is skipped by the Secondary Monitor and (tMON/6) time is respectively reduced from the total conversion time.

The [EVRUVMON2.VDDMLVLSEL](#) bit-field shall not be modified by the application software (as it is not related to the secondary monitoring thresholds). The application SW shall always read out the default value of [EVRUVMON2.VDDMLVLSEL](#) and write it back unmodified together with any new undervoltage monitoring threshold information in the [EVRUVMON2](#) register.

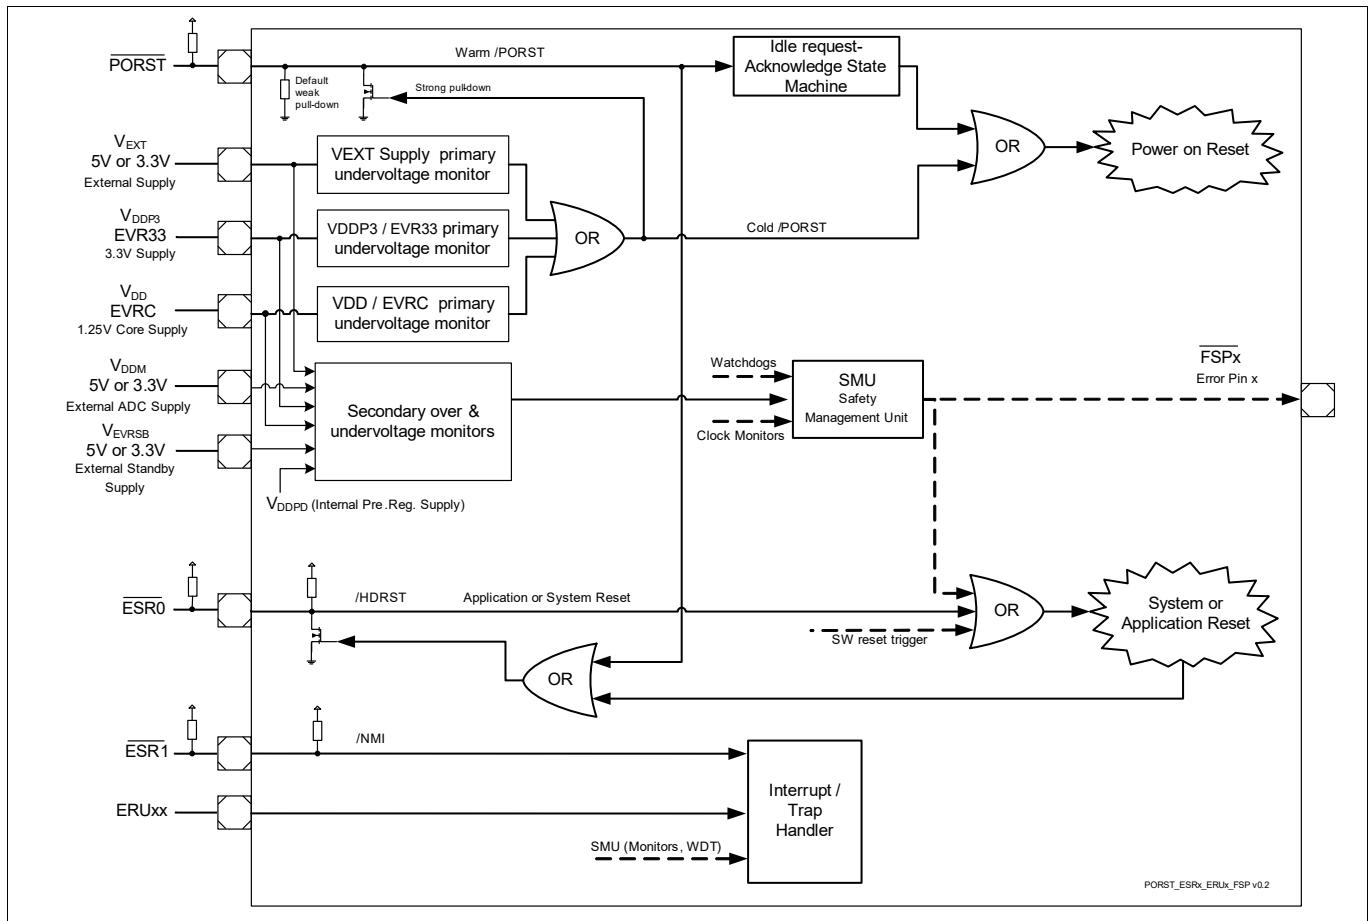

The monitored voltages, namely the VEXT, VDDP3, VDD, VDDPD, VEVRSB, and VDDM supplies are measured by Secondary Monitor ADCs and the actual measured value is updated in [EVROMONSTAT1](#) and [EVROMONSTAT2](#) register after conversion completion at regular intervals. Spike filtering of consecutive ADC results are used to generate alarm to SMU and also used for the filtered values indicated in [EVROMONSTAT1 / EVROMONSTAT2](#) registers as configured via adjustable filter coefficients in [EVROMONFILT.xx FIL](#) bit fields. In case VDDM supply voltage drops below 500 mV outside the operational limits, then Secondary monitor stops converting and the activity counter [EVROMONSTAT1.ACTVCNT](#) freezes at the last value.

In case of over-voltage supply alarms, it may be ensured that the supply to the device is switched off to avoid damage. The Error Pin Fail Safe Protocol ensures that the over-voltage condition is communicated to the external regulator even when TC3xx is in warm reset state.

After start-up, it may happen that supply over- or under-voltage alarms may already have been triggered depending on residual start-up voltages or supply dynamics. Likewise during [EVROMONCTRL](#) or [EVROMONFILT](#) reconfigurations, spurious alarms may be raised depending on filter state and changed configuration. Therefore before activating SMU alarm generation or triggering latent fault supply alarm tests, the secondary monitors and filters need to be completely reset. It needs to be ensured that SMU alarms and associated interrupts are foremost deactivated in [EVROMONCTRL / EVROMONFILT / PMSIEN](#) registers, then filters are cleared via [EVROMONFILT.CLRFIL = 1](#), alarms and interrupts are then consequently re-configured to the intended voltage level and filter settings in [EVROMONCTRL / EVROMONFILT](#) registers followed by activation of filters via [EVROMONFILT.CLRFIL = 0](#). A delay time of 4 us has to be awaited before alarm activation after configuration is changed in [EVROMONCTRL / EVROMONFILT](#) registers.

## Power Management System (PMS)

In case of application and system resets, PMS alarms happening during the respective reset shutdown and release will be reflected in SMU\_stdby AGX alarm status registers and consequently SMU\_stdby FSP reaction may be triggered if so configured in SMU\_stdby AGFSP.FEx registers. On the contrary, PMS alarms occurring during warm reset phase will be not be latched in SMU\_core AGX alarm status registers as they are in reset state. Furthermore, alarms which have occurred during the reset phase would not be consequently forwarded to the SMU\_core on reset release.

Monitoring tolerances and levels are specified in datasheet section EVR : Supply monitoring

**Figure 113 Voltage Monitoring - VEVRSB, VDDM & VDDPD**

## Power Management System (PMS)

### 11.2.2.5.3 Power Built In Self Test at Start-up (PBIST)

A Power Built-In-Self-Test (PBIST) at start-up allows the testing of supply levels, power functions and voltage monitors before cold PORST reset release.

The internal EVRPR Pre-regulator VDDPD voltage based on the primary low power bandgap (PLPBG) is tested using secondary monitor ADC against the secondary bandgap (SHPBG) at supply ramp-up. This allows to monitor the bandgap voltages against each other during start-up and the device continue to remain in reset state till the test has passed. During runtime, bandgap monitoring is realised by VDDPD monitoring using secondary monitor ADC and alarm is raised to SMU in case of VDDPD over and under-voltage event.

VEVRSB and VEXT voltage levels are checked using secondary monitor ADC before starting the regulators in PBIST state. In case the voltages are not within the limits, the device reset state is not deasserted. Furthermore, the PBIST test is passed and reset state is deasserted when VDDM supply voltage is above 500 mV.

After EVRC and EVR33 regulators are ramped up, additional overvoltage and undervoltage checks are carried out for VEVRSB ( $5,84V / 2,75V \pm 5\%$ ), VEXT ( $5,84V / 2,75V \pm 5\%$ ), VDDP3 ( $3,81V / 2,0V \pm 5\%$ ), VDD ( $1,46V / 1,0V \pm 5\%$ ) and VDDPD ( $1,46V / 1,0V \pm 5\%$ ) rails before cold PORST reset release in PBIST2 state. The limits are the default reset values of **EVROVMON**, **EVROVMON2**, **EVRUVMON** and **EVRUVMON2** registers.

### 11.2.2.5.4 Secondary Monitor and Standby SMU Built in Self Test (MONBIST)

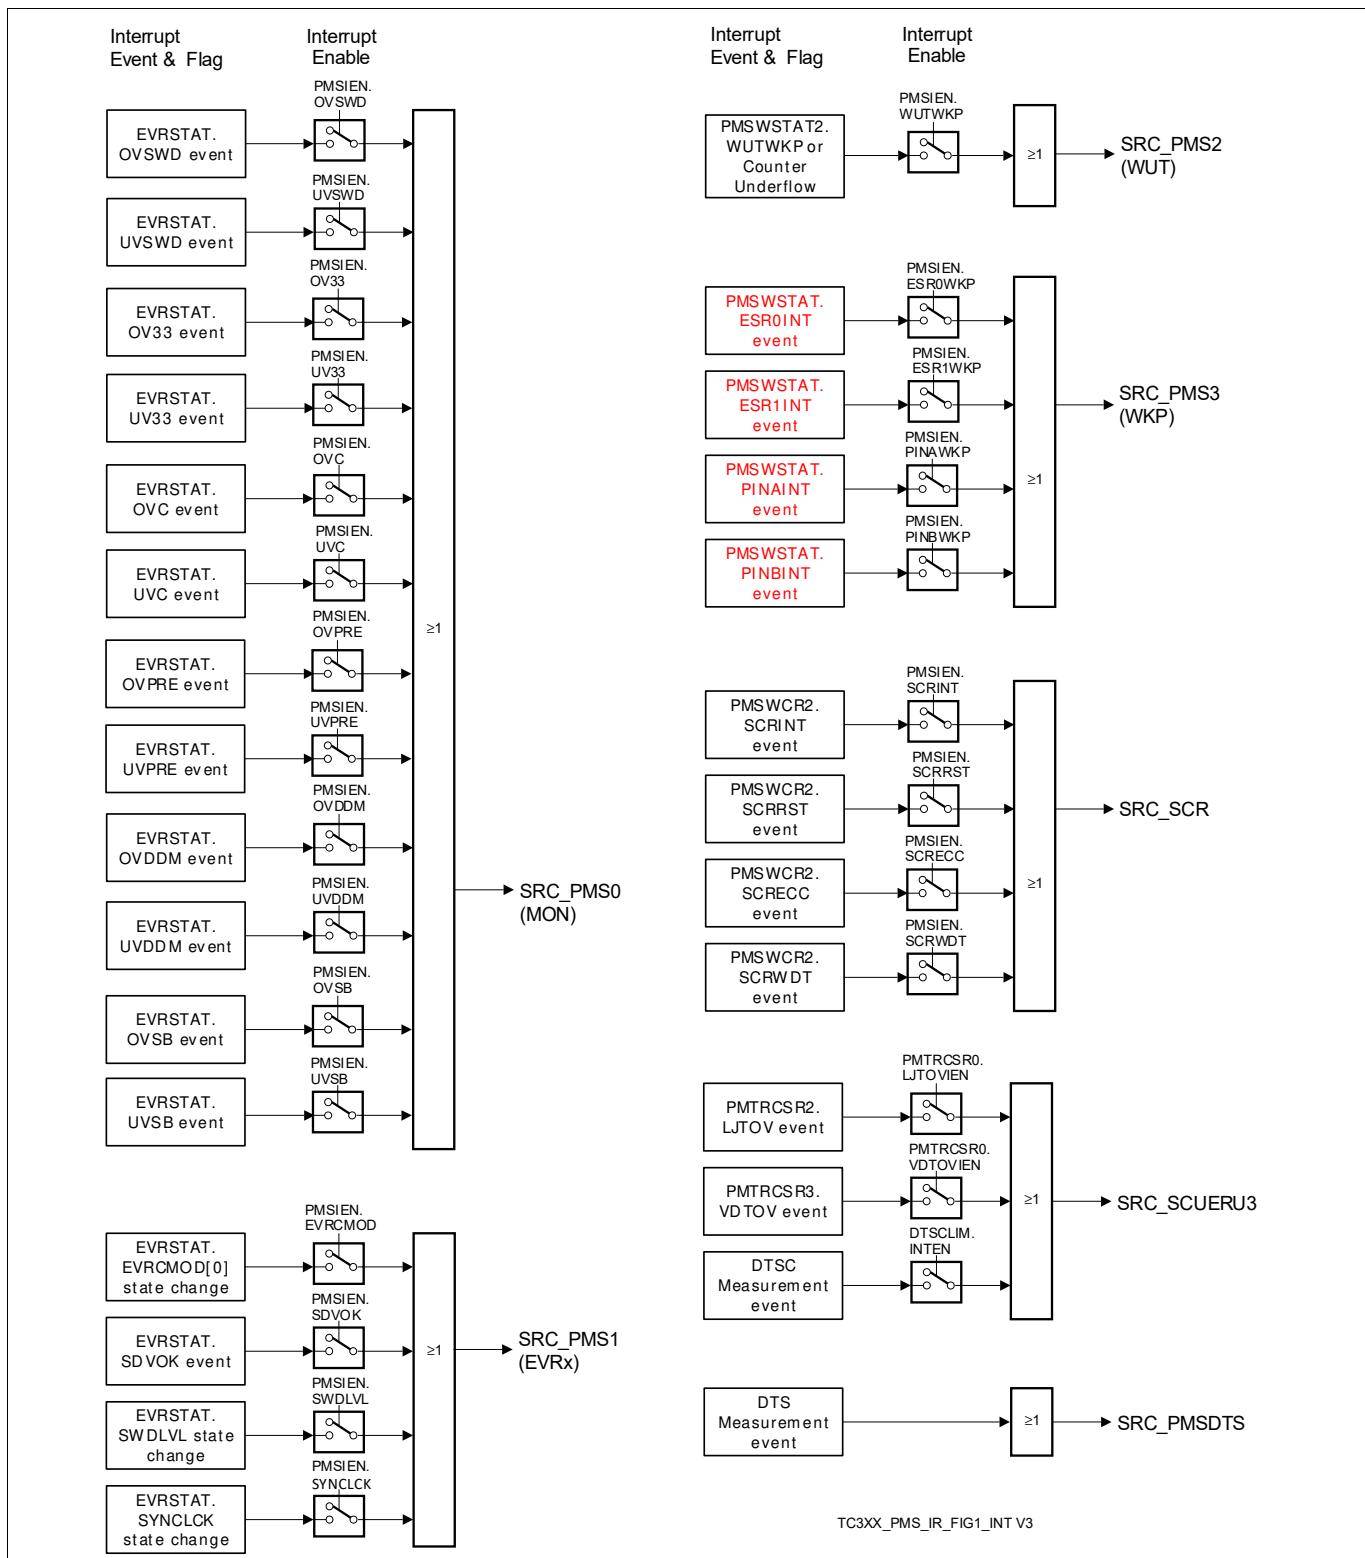

After reset release, MONBIST for the secondary monitors and alarm generation path may be carried out by user software. Secondary Monitor BIST ensures a higher latent fault coverage for the secondary monitors and the associated alarm and error pin fault logic routed to the Standby SMU. The MONBIST can be triggered during start-up via MONBISTCTRL.TSTEN register bit in Standby SMU module. During ongoing MONBIST, PMS SFF test shall not be triggered. MONBIST test takes less than 25 us execution time. The procedure is as follows :

- The Standby SMU shall be enabled via SMUEN register bitfield for MONBIST functionality.
- The MONBISTCTRL.TSTCLR bit shall be set foremost to clear all the flags and reset the test logic. This clears TSTEN, TSTRUN, TSTDONE, TSTOK, SMUERR and PMSERR bits.
- **EVRMONFILT** is set to 0x20000000 to clear the filter and to activate 1 x spike filter.
- **EVRMONCTRL** is set to 0xa5a5a5 to activate Over-voltage and Under-voltage alarms.
- The corresponding Over-voltage and Under-voltage interrupts are disabled by clearing **PMSIEN**.OVx/UVx register bit fields.
- FSP reaction on alarms are disabled by setting AGFSP.FEx to 0.
- CMD.FSP0EN and CMD.FSP1EN configuration bits are cleared to avoid spurious Error pin activation during MONBIST.
- CMD.ASCE is set to ensure that all pending alarms are cleared in AGx registers.
- **EVRMONFILT** is set back to 0x00000000 before enabling MONBIST to ensure alarm propagation.
- Consequently the MONBIST is enabled via MONBISTCTRL.TSTEN register bit.
- The MONBISTSTAT.TSTRUN register bit is set to indicate an ongoing test by MONBIST logic.
- Once the test is completed, MONBISTSTAT.TSTDONE bit is set and MONBISTSTAT.TSTRUN bit is cleared.
- The MONBISTSTAT.TSTOK bit indicates that the test was successfully completed.
- The MONBISTSTAT.SMUERR and MONBISTSTAT.PMSERR bits indicate that errors were detected during the MONBIST.
- FSPERR bit shall be cleared after MONBIST before enabling FSP reaction. If alarms happened during MONBIST, status registers may be updated and shall be cleared before Standby SMU initialization.TSTEN bit is cleared at the end of MONBIST.

## Power Management System (PMS)

### 11.2.2.6 Interrupts

Following events may be configured to lead to interrupts routed to Interrupt Router in Normal Run and Sleep System modes. If enabled by the related interrupt enable bit in register **PMSIEN**, an interrupt pulse can be generated on one of the service request outputs (SRC\_PMS0, SRC\_PMS1, SRC\_PMS2, SRC\_PMS3, SRC\_SCR, SRC\_SCUERU3). Interrupts are forwarded from PMS to IR module within 4 fspb clock cycles after the occurrence of the event.

**Figure 114 Interrupt Sources and Events**

## Power Management System (PMS)

### 11.2.2.7 OCDS Trigger Bus (OTGB) Interface

#### PMS OTGB Features

- Voltage signals and ADC outputs
  - Primary VDD, VDDP3 and VEXT voltage monitor outputs
  - Primary EVRC (SMPS) core voltage feedback ADC output
  - Secondary VDD, VDDP3 and VEXT voltage monitor outputs
  - EVRPR / VDDPD voltage monitor output
  - VEVRSB Standby supply voltage monitor output
  - VDDM ADC supply voltage monitor output
  - DTS temperature output
- EVR control outputs
  - EVR33 regulator DAC control output
  - EVRC switching control output routed to external MOSFETs
  - EVRC Regulator output and internal signals
  - Wake-up timer count
  - PMS and SCR register interface signals

The PMS module has two 16 bit ([Table 293](#)) trigger sets which are selected with the **OTSS** register. The trigger sets can be arbitrarily mapped to OTGB0/1 busses. Refer OCDS chapter for more details.

**Table 293 PMS Trigger Sets**

Trigger Set	Details
<a href="#">TS16_ADCMON Monitor Trigger Set</a>	<a href="#">Table 294</a>
<a href="#">TS16_EVRCON Control Trigger Set</a>	<a href="#">Table 295</a>

The PMS trigger signals relate to the 100 MHz internal back-up clock, which can be different to the OTGB/OTGM clock. It should be taken care that the triggers and associated signals are synchronised to SPB clock domain.

#### 11.2.2.7.1 ADC Monitor and Voltage Trigger Sets

ADC Monitor Trigger Sets consist of the important voltage signals measured by various PMS ADC monitors. The multiplexer allows to map arbitrary and different signal groups to the high and the low byte of a 16 bit Trigger Set. In addition it is possible to use one or two 16 bit Trigger Sets with this flexibility. All this is controlled with **OTSCO**.

## Power Management System (PMS)

**Table 294 TS16\_ADCMON Monitor Trigger Set**

Bits	Name	Description
[7:0]	SG0	8 bit Analog output from selected Analog monitors
		PRADCCV Primary Core / VDD voltage monitor output
		PRADC33V Primary VDDP3 voltage monitor output
		PRADCSWDV Primary VEXT voltage monitor output
		PRADCFBCV Primary EVRC SMPS core voltage feedback output
		SECADCCV Secondary Core / VDD voltage monitor output
		SECADC33V Secondary VDDP3 voltage monitor output
		SECADCSWDV Secondary VEXT voltage monitor output
		SECADCPRE EVRPR / VDDPD voltage monitor output
		SECADCSB VEVRSB standby voltage monitor output
		SECADCVDDM VDDM ADC voltage monitor output
		DTSRESULTL DTS Temperature output [7:0]
		DTSRESULTH DTS Temperature output [11:8]
[15:8]	SG1	Independent selection with same options as for Bits [7:0]

### 11.2.2.7.2 EVR Control output Trigger Sets

EVRCON Control Trigger Sets consist of the important control outputs of various regulators in PMS subsystem. All this is controlled with **OTSC1**.

**Table 295 TS16\_EVRCON Control Trigger Set**

Bits	Name	Description
[15:0]	EVR33OUT	EVR33 regulator DAC control output
	EVRCDPWM	EVRC digital PWM switching output to the external MOSFET
	EVRCOUT	Array of EVRC regulator signals from the SMPS module selected via DMOND multiplexer.
	WUTCNT	Wake-up timer count ([23:15] reduced to 15th bit)
	TCINT [7:0] SCRINT [15:8]	PMS and SCR output and input bus interface

## Power Management System (PMS)

### 11.2.3 Power Management

#### 11.2.3.1 Power Management Overview

The Power Management scheme allows activation of power down modes so that the system operates with the minimum required power for the corresponding application state. A progressive reduction in power consumption is achieved by invoking Idle, Sleep or Standby modes respectively. The Idle mode is specific to each individual CPU where as Sleep and Standby modes influence the complete system.

As shown in [Table 296](#), there are two power modes available for each CPU:

- CPU Run Mode
- CPU Idle Mode

**Table 296 CPU Power Management**

Mode	Description
<b>Run Mode</b>	The CPU clock is active and code is being executed.
<b>Idle Mode</b>	<p>CPU may enter Idle Mode on following events:</p> <ul style="list-style-type: none"> <li>• On a SW Idle request issued by setting register bits PMCSR<sub>x</sub>.REQSLP = 01<sub>B</sub> when CPU has no active tasks to perform.</li> <li>• On a SW Idle request (PMCSR<sub>y</sub>.REQSLP = 01<sub>B</sub>) issued by another CPU.</li> </ul> <p>The CPU code execution is halted and CPU clock is disabled in Idle state. The peripherals continue to remain active. CPU RAM memories (PSPR / DSPr / DLMU) are accessible to other bus masters and peripherals.</p> <p>CPU may exit Idle mode on following events:</p> <ul style="list-style-type: none"> <li>• When an interrupt occurs on a CPU returning the CPU to Run Mode.</li> <li>• When a trap occurs like an NMI trap event.</li> <li>• When the CPU watchdog or Safety watchdog timer overflow events trigger an SMU alarm in turn leading to a CPU interrupt.</li> <li>• When a MSB bit wrap of the CPU Watchdog counter takes place.</li> <li>• When a Application reset, System reset or any higher reset occurs.</li> <li>• On a SW Run request (PMCSR<sub>x</sub>.REQSLP = 00<sub>B</sub>) issued by another CPU.</li> </ul>

As shown in [Table 297](#), there are three main power modes available for the system:

- System Run Mode
- System Sleep Mode
- System Standby Mode

Furthermore, flexible reduction of power consumption is possible through following measures:

- Reduction of individual CPU power consumption by means of CPU clock scaling.
- Disabling the module clock by setting bit DISR in module CLC register if the module need not be active at the current point of time.
- Reducing the system frequency without changing individual peripheral clocks.
- Reducing individual peripheral clock frequency without changing system clock frequency. Main peripherals are provided with independent clocks separate from main system SRI and SPB clocks.

## Power Management System (PMS)

**Table 297 System Power Management**

Mode	Description
<b>Run Mode</b>	At least one master CPU has not requested Sleep Mode or Standby mode and is in Run mode. All peripheral modules are active.
<b>Sleep Mode</b>	<p>System may enter Sleep Mode on following events:</p> <ul style="list-style-type: none"> <li>• On a SW Sleep request issued by setting PMCSR<sub>x</sub>.REQSLP = 10<sub>B</sub> by the master CPU. CPU code execution is halted and CPU Idle state is entered. Peripherals are set into sleep state if so configured in the respective CLCx.EDIS bit. Ports retain their earlier programmed state.</li> </ul> <p>System may exit Sleep mode on following events:</p> <ul style="list-style-type: none"> <li>• When an interrupt or trap occurs on the master CPU.</li> <li>• When an NMI trap event takes place.</li> <li>• When the CPU watchdog or Safety watchdog timer overflow events trigger an SMU alarm leading in turn to a master CPU interrupt.</li> <li>• When a MSB bit wrap of master CPU Watchdog counter takes place.</li> <li>• When an Application reset, System reset or any higher reset occurs.</li> </ul>

## Power Management System (PMS)

**Table 297 System Power Management (cont'd)**

Mode	Description
Standby Mode (VEVRSB and VEXT supplied)	<p>System may enter Standby Mode on following events if so configured:</p> <ul style="list-style-type: none"> <li>• Standby entry on a SW Standby request issued by setting PMCSR<sub>x</sub>.REQSLP= 11<sub>B</sub> by the master CPU.</li> <li>• Standby entry on an ESR1 (NMI) assertion event. ESR1 (NMI) function doesn't require involvement of interrupt subsystem if configured as the standby entry trigger.</li> </ul> <p>The Standby domain constituting the Standby RAM, the 8 bit Standby Controller, shared ports and the wake-up unit remain actively supplied. The power to the rest of the chip is completely switched off. VEXT and VEVRSB rails remain supplied during Standby mode. ## Power Management System (PMS)

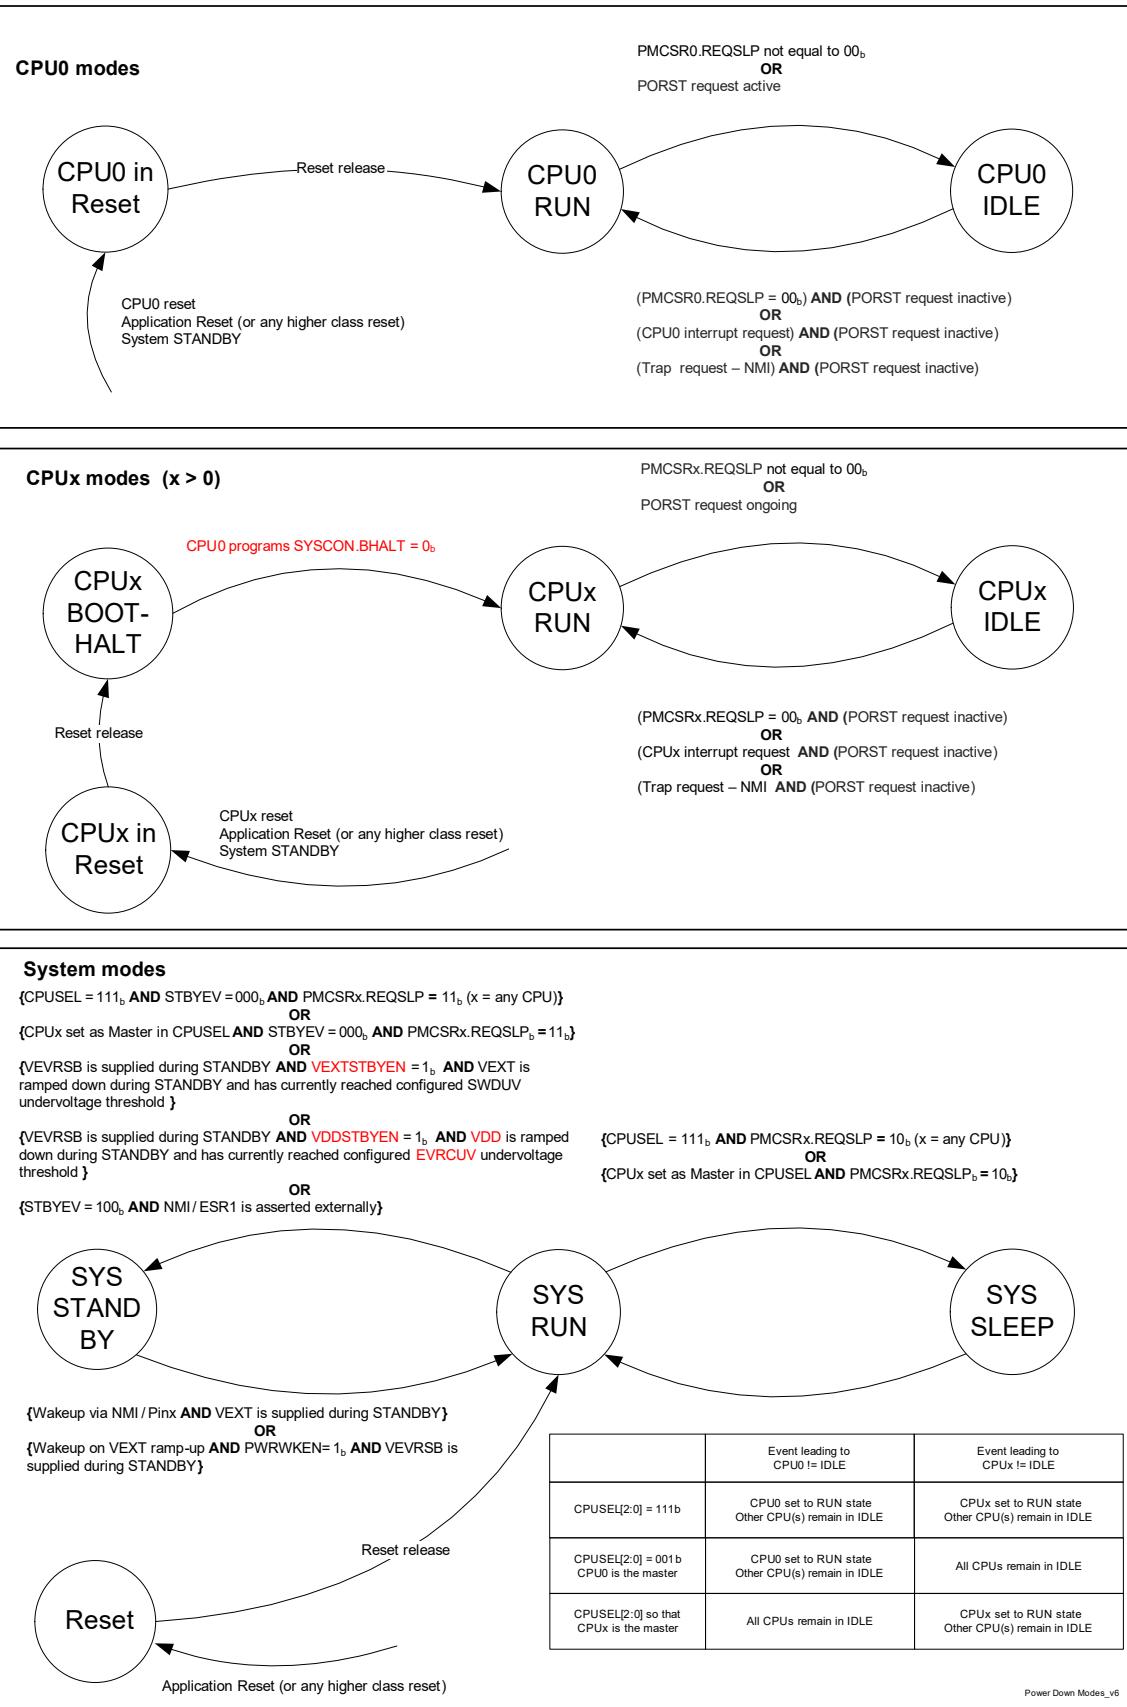

Figure 115 Power down modes and transitions

## Power Management System (PMS)

### 11.2.3.2 Idle Mode

In case there are no active tasks to perform, a CPU may be requested to enter Idle mode during runtime by writing to the respective PMCSR<sub>x</sub> register and setting the bit field REQSLP = 01<sub>B</sub>.

#### 11.2.3.2.1 Entering Idle Mode :

Following events can invoke a CPU<sub>x</sub> Idle request

- CPU<sub>x</sub> setting itself in Idle by writing its own PMCSR<sub>x</sub> register: The respective PMCSR<sub>x</sub> register shall be accessed by setting CPU<sub>x</sub> ENDINIT = 0<sub>B</sub> and consequently writing the bit field REQSLP = 01<sub>B</sub>. The Idle transition takes place only when CPU<sub>x</sub> ENDINIT = 1<sub>B</sub> is set back again. This ensures that a CPU<sub>x</sub> does not enter Idle mode when it's WDTx is in Time-Out mode and ENDINIT<sub>x</sub> = 0<sub>B</sub> to avoid wake-up on a consequent WDT time-out. Safety ENDINIT mechanism shall not be used by a CPU to set itself into Idle to avoid wake-up on a Safety WDT time-out. Idle mode may also be simultaneously triggered for additional CPUs based on SCU\_PMSWCR1.CPUIDLSEL configuration.
- Masters except CPU<sub>x</sub> setting CPU<sub>x</sub> into Idle (e.g.- CPU[y]): The PMCSR<sub>x</sub> register shall be accessed by such masters by setting Safety ENDINIT = 0<sub>B</sub>. The Idle request is issued immediately on setting PMCSR<sub>x</sub>.REQSLP = 01<sub>B</sub>. The device no longer waits for Safety ENDINIT = 1<sub>B</sub> to be set back to trigger Idle transition. It need to be taken care to grant access via ACCEN register as required by application.

The CPU watchdog may be disabled or slowed down by reprogramming the timers before triggering Idle request via Software. On an Idle request, the CPU finishes its current operations and sends an acknowledge signal back to the Power Management unit. It then enters an inactive state in which the CPU clocks and the respective DMI and PMI memory units are shut off. It is recommended to reduce respective CPU clocks via CPU<sub>x</sub>DIV register bit field before issuing Idle request.

#### 11.2.3.2.2 State during Idle mode

During Idle Mode, memory accesses to the DMI, PMI and DLMU from other bus masters cause these units to wake-up automatically to handle these transactions. When memory transactions are complete, the DMI, PMI and DLMU return to Idle state again. Once Idle Mode is entered, the state is reflected in PMCSR<sub>x</sub>.PMST status bits.

**Table 298 CPU[x] Idle Mode Entry Sequence, Behavior and Status Indication**

Condition	CPU[x] writes PMCSR[x].REQSLP = 01 <sub>B</sub>	Masters except CPU <sub>x</sub> (e.g.- CPU[y]) writes PMCSR[x].REQSLP = 01 <sub>B</sub>	CPU[y] writes PMCSR[y].REQSLP = 01 <sub>B</sub>
CPU[x] enters Idle Mode	A CPU[x] should be able to set itself into Idle.  CE[x] = 0 <sub>B</sub> SE = 0 <sub>B</sub> or 1 <sub>B</sub> PMCSR[x].REQSLP= 01 <sub>B</sub> CPU[x] Idle Entry happens when CE[x] = 1 <sub>B</sub> is set. If CE[x] = 1 <sub>B</sub> during PMCSR[x] write; FPI error issued and request is not taken.	A CPU[y] or (other masters except CPU[x]) should be able to set another CPU[x] into Idle if it has SE rights.  SE = 0 <sub>B</sub> CE[x] = 0 <sub>B</sub> or 1 <sub>B</sub> PMCSR[x].REQSLP= 01 <sub>B</sub> CPU[x] Idle Entry happens immediately. If SE = 1 <sub>B</sub> during PMCSR[x] write; FPI error issued and request is not taken.	CPUIDLSEL = y+1 is already set by a CPU having SE rights before.  CE[y] = 0 <sub>B</sub> SE = 0 <sub>B</sub> or 1 <sub>B</sub> PMCSR[y].REQSLP= 01 <sub>B</sub> All CPUs go into IDLE. when CE[y] = 1 <sub>B</sub> is set. If CE[y] = 1 <sub>B</sub> during PMCSR[y] write; FPI error issued and request is not taken.

CPU[x] exits Idle mode	PMCSR[x].REQSLP= 00 <sub>B</sub> PMCSR[x].PMST= 001 <sub>B</sub> PMSTAT0.CPU[x] & LS= 0 <sub>B</sub>	PMCSR[x].REQSLP= 00 <sub>B</sub> PMCSR[x].PMST= 001 <sub>B</sub> PMSTAT0.CPU[x] & LS= 0 <sub>B</sub>	PMCSR[x].REQSLP= 00 <sub>B</sub> PMCSR[x].PMST= 001 <sub>B</sub> PMSTAT0.CPU[x] & LS= 0 <sub>B</sub>

### 11.2.3.2.3 Exiting Idle mode

In Idle mode, the CPU will return to Run mode in response to the following wake-up events:

- An interrupt / trap received from an interrupt / trap source mapped to the CPU.
- An NMI trap request is received to wake-up the corresponding CPUs.
- A MSB bit wrap of the corresponding CPU Watchdog counter occurs.
- Setting the register bits PMCSR<sub>x</sub>.REQSLP = 00<sub>B</sub> to set the CPU<sub>x</sub> into Run mode.

The system enters reset state on an Application, System reset or any higher reset. If it is woken by a watchdog timer overflow event routed via the SMU to the CPU or by an NMI or by an interrupt, the CPU will immediately vector to the appropriate interrupt / trap handler.

CPU module reset will not result in exit from Idle mode if it was already in Idle state before. An explicit wake-up event has to happen before CPU is in run state again.

### 11.2.3.3 Sleep Mode

Sleep mode allows a progressive reduction of power consumption by gating the clocks of selected peripherals and keeping bare minimum modules active at their minimum clock frequencies during the Sleep state. Sleep mode maybe used to cater to Pretended Networking or ECU Degradation requirements. The clocks to a module maybe disabled individually using the respective CLCx.DISR register bits. Alternatively the clocks to selected peripherals may be simultaneously gated on a common sleep request if respective CLCx.EDIS register bits are cleared. The power consumption during Sleep state is predominantly dominated by the device leakage as power to the modules in core domain are not switched off. The dynamic core current component is reduced to the minimum as most of the module clocks are gated.

#### 11.2.3.3.1 Entering Sleep Mode

System may be requested to enter Sleep mode via software by master CPU by writing to the CPU's PMCSR<sub>x</sub> register and setting the bit field PMCSR<sub>x</sub>.REQSLP = 10<sub>B</sub>.

An example sequence for Sleep mode is enumerated below :

- The CLCx.EDIS register bit shall be cleared for all peripherals intended to be inactive in Sleep mode.
- All CPUs except the master CPU may be put into IDLE state. The respective watchdogs may be disabled or re-configured for slower modes. This allows to sequence the CPU load jumps before going into sleep mode
- Master CPU code execution maybe switched from Flash to PSPR RAM if required. Flash module may be explicitly set into Sleep state.
- The analog modules EVADC and EDSADC maybe switched off if not required to be active in Sleep state.
- It should be ensured to select the individual clocks from Clock Control Unit for peripherals which need to remain active during Sleep mode as shown in **Table 299**. Certain communication and timer peripherals have

## Power Management System (PMS)

clocks independent from the system frequencies, namely SRI and SPB clocks, to allow the possibility to bypass the system PLL. In such cases, the System PLL is switched into bypass mode and consequently the DCO would be switched off. Peripheral clock will continue to run clocking the modules active during sleep mode. The system clock frequencies, namely SRI and SPB clocks, maybe then reduced to the minimum possible values via the low power divider and / or Kx divider to reduce the current consumption. In some cases the respective peripherals may be clocked directly from external crystal / resonator depending on application.

- The interrupt control unit provides the infrastructure for wake-up from sleep state and therefore need to be kept active with a minimum SPB bus frequency. The respective module wakeup interrupts are routed to master CPU to wake-up on an interrupt event.
- Sleep Mode may be entered as a unanimous decision of all the CPUs when ALL of the PMCSR<sub>x</sub> registers in the system request it AND SCU\_PMSWCR1.CPUSEL = 111<sub>B</sub>. Sleep Mode may also be entered based on a singular decision of a master CPU based on the configuration of the CPUSEL register. The PMCSR<sub>x</sub> register shall be accessed by setting CPU<sub>x</sub> ENDINIT = 0<sub>B</sub>. The Sleep request is issued only after CPU<sub>x</sub> ENDINIT bit is set back again. Safety ENDINIT mechanism shall not be used by a CPU<sub>x</sub> to issue Sleep request. The master CPU watchdog may also be disabled or slowed down before issuing a Sleep request.

### 11.2.3.3.2 State during Sleep Mode

Sleep Mode is disabled for a unit if CLCx.EDIS bit is set. The sleep request is ignored in this case and the corresponding unit continues normal operation as intended. If CLCx.EDIS is cleared, the clock of the module is gated. CPU Idle state is entered for all the CPUs as described in the previous section. All ports retain their earlier programmed state. The current consumption during Sleep mode is documented in datasheet.

**Table 299 Module activity and configuration during Sleep mode**

Module active during Sleep mode	Module and Clock State during Sleep Mode
MCAN	<p>Peripheral System PLL active providing module clock (e.g. - f MOD = 20MHz - 40MHz).      Module may alternatively run on f OSC0 allowing also complete switch off of the Peripheral PLL.      Module FIFO and DMA allows autonomous handling of messages without involvement of CPU for a minimal amount of CAN messages.      System PLL may be switched into low power mode.      f SRI and f SPB clocks are reduced to (e.g. - ~1-2 MHz) via LPDIV and / or Kx dividers (available only in B step).      System PLL may also be switched off and switched to Back-up clock depending on application (available only in B step).      Wake-up on CAN wake-up message identifier via CAN interrupt.</p>
ASCLIN	<p>Peripheral PLL active providing module clock (e.g. - f MOD = 20MHz).      Module may alternatively run on f OSC0 allowing also switch off of the Peripheral PLL.      System PLL may be switched into low power mode.      f SRI and f SPB clocks are reduced to (e.g. - ~1-2 MHz) via LPDIV and / or Kx dividers.      Module FIFO and DMA allows autonomous handling of messages without involvement of CPU for a minimal amount of LIN frames.      System PLL may also be switched off and switched to Back-up clock depending on application.      Wake-up on LIN wake-up frame via ASCLIN interrupt.</p>

## Power Management System (PMS)

A timer module maybe used to trigger DMA or fill the FIFO allowing autonomous handling of messages without involvement of CPU.</p> <p>Wake-up in case of fault diagnosis of external device via a QSPI interrupt.</p>
Ethernet MAC	<p>Ethernet PHY active and provides module clock (e.g - f MOD = 25MHz) to the asynchronous part to decode the magic packet. Wake-up on magic packet via ETH interrupt.</p> <p>Alternatively PHY may trigger a wakeup directly via GPIO edge capture.</p> <p>Peripheral PLL may be disabled.</p> <p>System PLL may be switched into low power mode.</p> <p>f SRI, f SPB &amp; f ETH clocks are reduced to (e.g. - ~1-2 MHz) via LPDIV and / or Kx dividers.</p> <p>System PLL may also be switched off and switched to Back-up clock depending on application.</p>
I2C	<p>Peripheral PLL active providing module clock (e.g - f MOD = 20MHz).</p> <p>System PLL may be switched into low power mode.</p> <p>f SRI and f SPB clocks are reduced to (e.g. - 5 MHz) via LPDIV and / or Kx dividers.</p> <p>External communication remains active.</p>
GTM	<p>Peripheral PLL is disabled.</p> <p>System PLL is active and provides the module clock (e.g - f MOD ~f SPB ~ 1-2 MHz).</p> <p>f SRI and f SPB clocks are reduced to (e.g. - ~1-2 MHz) via LPDIV and / or Kx dividers.</p> <p>It is recommended to switch off the GTM module completely and use smaller timer modules like CCU6 / GPT12, STM or WUT during Sleep state to reduce power consumption.</p> <p>Wake-up on timer overflow or capture event via GTM interrupt.</p>
STM	<p>Peripheral PLL is disabled.</p> <p>System PLL is active and provides the module clock (e.g - f MOD ~f SPB ~ 1-2 MHz).</p> <p>f SRI and f SPB clocks are reduced to (e.g. - ~1-2 MHz) via LPDIV and / or Kx dividers.</p> <p>Wake-up on timer overflow via STM interrupt.</p>

## Power Management System (PMS)

**Table 299 Module activity and configuration during Sleep mode (cont'd)**

Module active during Sleep mode	Module and Clock State during Sleep Mode
Pin Wake-up ESR1 (NMI)	Peripheral PLL is disabled. System PLL bypassed. f SRI, f SRI clocks reduced to (e.g. - ~1-2 MHz) via LPDIV / Kx dividers. System PLL may also be switched off and switched to Back-up clock depending on application. Wake-up on Edge / Level detection on pin routed to ERUx, ESR1 (NMI) or PORT module via SCU interrupts or polling Port registers on an active timer interrupt.
WUT	Peripheral PLL is disabled. System PLL bypassed. f SRI, f SRI clocks reduced to (e.g. - ~1-2 MHz) via LPDIV / Kx dividers. System PLL may also be switched off as module clock is derived from Back-up clock Wake-up on timer overflow via WUT interrupt.

### 11.2.3.3.3 Exiting Sleep Mode

The system will exit Sleep mode on any wake-up event that causes any master CPU to exit Idle Mode depending on CPUSEL configuration. Only the master CPU associated with the interrupt wake-up event would be set into Run mode (REQSLP = RUN, PMST = RUN). Other CPUs will remain in Idle (REQSLP = SLEEP, PMST = IDLE). An NMI trap event will wake-up the respective CPU as configured in TRAPDIS0 and TRAPDIS1 registers. A MSB bit wrap of the corresponding master CPU Watchdog counter would also wake-up the master CPU. The response of the CPU to being woken up from Sleep Mode is also the same as for Idle Mode. Peripheral units that have entered Sleep Mode will switch back to their selected Run Mode operation. Wake-up latency from Sleep mode depends mainly on the extent of clock ramp-up required after wake-up keeping the load jump constraints. If DCO or PLL is switched off, the wake-up latency would include the time to power and lock the PLL. The sequence after wake-up is dependent on the entry sequence and mainly constitutes ramping back the clock system, activating analog and Flash modules, switching from RAM to Flash execution and activating additional CPUs. The time taken between interrupt trigger availability until CPU has woken up and is executing next instruction is less than 3 SPB + 20 SRI clock cycles.

## Power Management System (PMS)

**Table 300 System Sleep Mode Entry Sequence, Behavior and Status Indication**

Condition	Master CPU[x] writes PMCSR[x].REQSLP = 10 <sub>B</sub>	CPU[y] writes PMCSR[x].REQSLP = 10 <sub>B</sub>	All CPU[y] writes respective PMCSR[y].REQSLP = 10 <sub>B</sub>

## Power Management System (PMS)

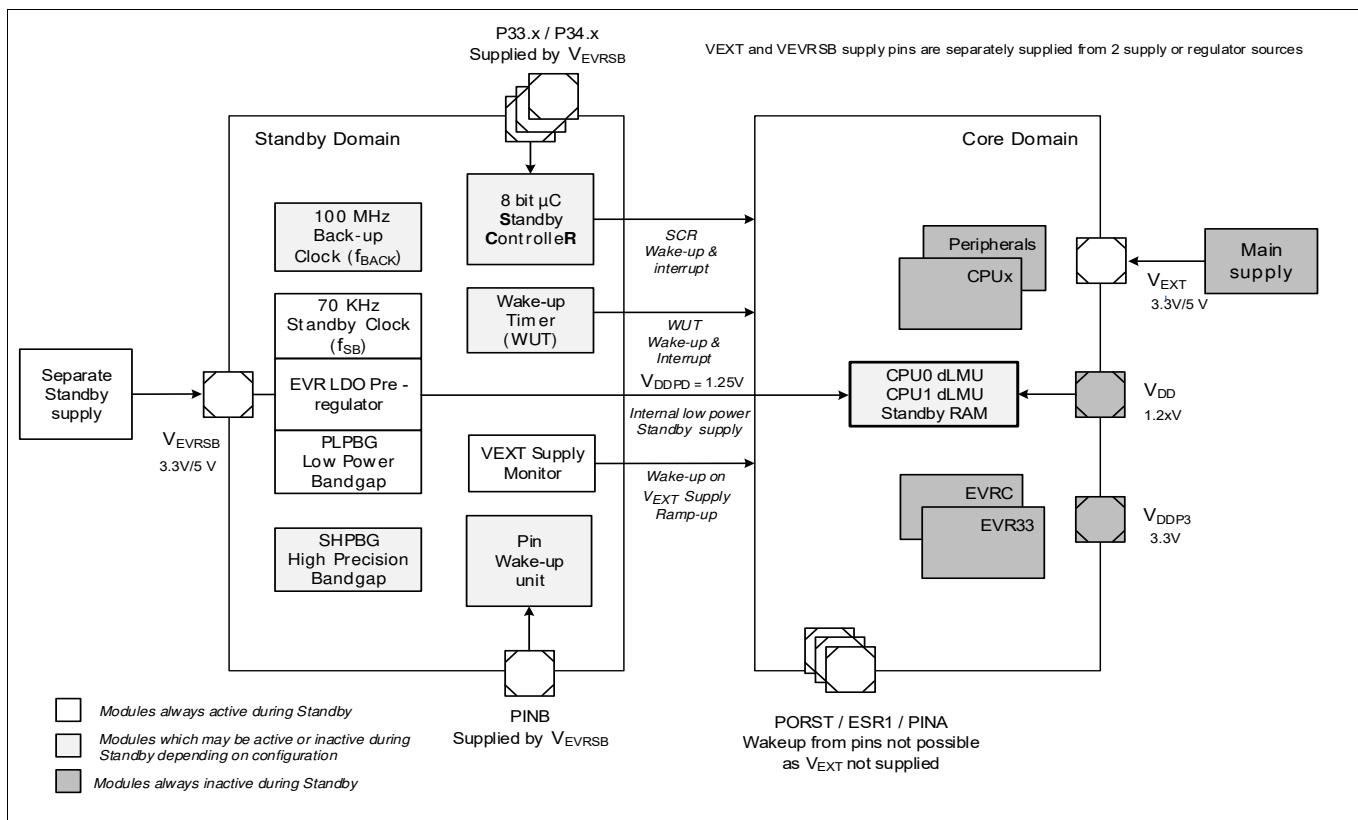

### 11.2.3.4 Standby Mode

The Standby domain constitutes the Standby RAM, the 8 bit Standby Controller, the Power Management unit, the Pin Wake-up unit, the Wake-up timer, the VEXT supply monitor and basic infrastructure components. The Standby domain is supplied by the EVRPR pre-regulator and is by default clocked by the 70 kHz internal low power clock source in Standby Mode. The 3.3V / 5V dedicated external Standby supply pin VEVRSB supplies the EVRPR pre-regulator and the Port domain P33.x / P34.x during the Standby mode when VEXT supply is switched off.

Following Standby topologies are supported with respective events which may trigger Standby mode entry and exit based on SCU\_PMSWCR1.STBYEV and **PMSWCR0.xWKEN** bits.

#### 11.2.3.4.1 Standby Mode with only VEVRSB domain supplied and VEXT domain switched off

As shown in **Figure 116**, only the Standby domain and Port domain P33.x/P34.x continue to be supplied by the separate VEVRSB supply pin during Standby mode. The main VEXT supply is switched off in Standby state. Consequently the rest of the PORT domain except P33.x/P34.x is devoid of supply.

**Figure 116 Standby domain supplied via a separate dedicated supply pin VEVRSB**

Standby Entry is triggered by following events :

- Standby entry on a secondary under-voltage event during VEXT supply ramp-down if configured in **PMSWCR0.VEXTSTBYEN** bits.
- Standby entry on SW request (PMCSR<sub>x</sub>.REQSLP = 11<sub>B</sub>) if configured via SCU\_PMSWCR1.STBYEV register bit field. The Standby request is issued only after CPU<sub>x</sub> ENDINIT bit is set back again. Safety ENDINIT mechanism shall not be used by a CPU<sub>x</sub> to issue Standby request. Standby entry on ESR1 (NMI) edge event if configured via SCU\_PMSWCR1.STBYEV register bit field.

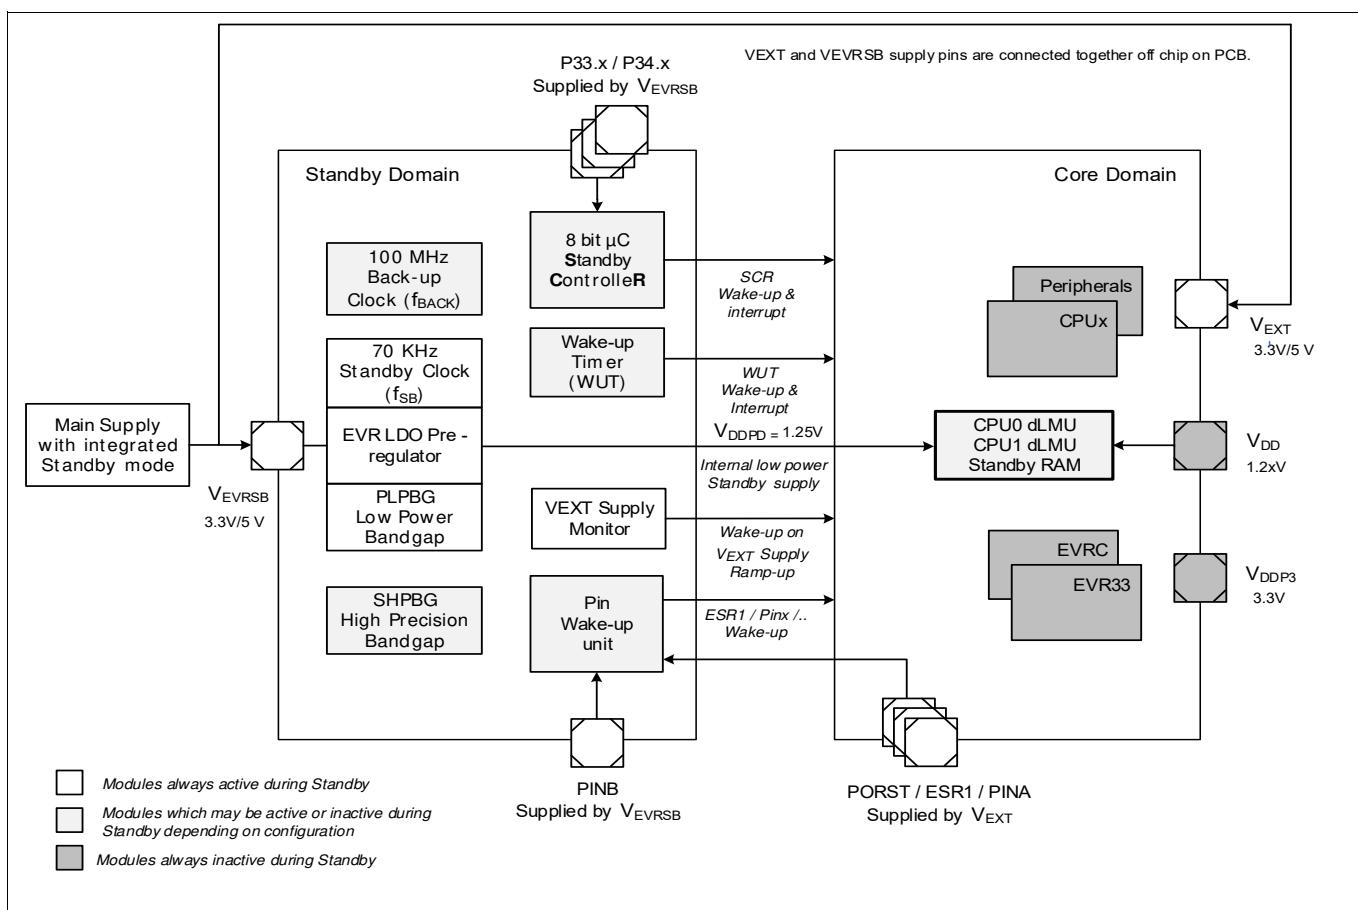

Standby Wake-up is triggered by following events after blanking filter time expiry :

## Power Management System (PMS)

- Wake-up is triggered when main VEXT supply ramps-up again if configured via **PMSWCRO.PWRWKEN** enable bit.
- Wake-up is triggered by Standby Controller if configured via **PMSWCRO.SCRWKEN** enable bit provided VEXT supply has already ramped-up before. Standby controller can also request for VEXT ramp-up to external regulator.
- Wake-up via Wake-up Timer if configured via **PMSWCRO.WUTWKEN** enable bit provided VEXT has already ramped-up before.
- Wake-up via Pin B if configured via **PMSWCRO.PINBWKEN** enable bit provided VEXT has already ramped-up before.
- It is to be noted that wake-up via PORST, Pin A, ESR0 & ESR1 pins which are in turn supplied by VEXT is not supported during STANDBY as VEXT is not supplied. Therefore it is required to disable the respective **PMSWCRO.xWKEN** bits.

### 11.2.3.4.2 Standby Mode with both VEXT and VEVRSB supplied via common supply rail.

As shown in **Figure 117**, the Standby domain and the complete Pad domain including P33.x/P34.x, PORST, ESRx and PINx continue to be supplied by (VEVRSB + VEXT) supply rail during Standby mode. This allows additional wake-up possibility via PORST, ESRx and PINx pins but at the cost of higher power consumption during Standby mode.

**Figure 117 Standby domain supplied via a common supply rail connected to both VEXT and VEVRSB**

Standby Wake-up is triggered by following events after blanking filter time expiry :

- Wake-up via NMI / Pinx: Wake-up on rising, falling or any edge of ESR1, Pin A or Pin B pins if configured via **PMSWCRO.ESRxWKEN** / **PINxWKEN** register bit fields.

## Power Management System (PMS)

- Wake-up is triggered by Standby ContolleR if configured via **PMSWCR0**.SCRWKEN enable bit.
- Wake-up via Wake-up Timer if configured via **PMSWCR0**.WUTWKEN enable bit.
- Wake-up via PORST pin if configured via **PMSWCR0**.PORSTWKEN enable bit.

Standby Entry is triggered by following events

- Standby entry on a secondary under-voltage event during VEXT supply ramp-down if configured in **PMSWCR0**.VEXTSTBYEN bits.
- Standby entry on SW request (PMCSR<sub>x</sub>.REQSLP = 11<sub>B</sub>) if configured via SCU\_PMSWCR1.STBYEV register bit field. The Standby request is issued only after CPU<sub>x</sub> ENDINIT bit is set back again. Safety ENDINIT mechanism shall not be used by a CPU<sub>x</sub> to issue Standby request.
- Standby entry on ESR1 (NMI) edge event if configured via SCU\_PMSWCR1.STBYEV register bit field.

### 11.2.3.4.3 Standby RAM

The Standby RAM constitutes ECC protected DLMU RAM of CPU0 (Block 0 and Block 1) and DLMU RAM of CPU1 (Block 0 and Block 1). The 32Kb Block 0 (lower half) is located at address \*0000H and 32Kb Block 1 (upper half) is located at address \*8000H of the respective address range of the corresponding CPUn DLMU RAM. The RAMs remain supplied during Standby mode if configured in **PMSWCR0**. STBYRAMSEL bits. On wake-up, the status which Standby RAMs remain supplied is reflected in **PMSWSTAT2**.STBYRAM bits. The initial 16 words from the start address of DLMU0/DLMU1 are not retained during standby mode as this memory region is used by start-up software.

The Standby RAM cell array is supplied by a separate supply pin (VEVRSB) during Standby state via the internal EVRPR Pre-Regulator. It shall be ensured that the external standby supply source continues to supply VEVRSB supply pin during Standby state with a supply between 2.6 V up to 5.5 V. Standby supply status is also monitored and indicated via RSTSTAT.STBYR bit which indicates EVRPR or VDDPD supply under-voltage LVD reset. It is to be taken care by the Start-up software after wake-up that Standby RAMs are not initialized if **PMSWSTAT2**.STBYRAM bits are set. Furthermore, if **PMSWCR0**.STBYRAMSEL bit is set to enable Standby RAM function and there was a VDD primary under-voltage (cold PORST) event, it is ensured that the Standby RAM supply is switched back to VDDPD supply rail. This ensures that RAM contents are not corrupted also during main VDD core supply loss.

### 11.2.3.4.4 VEXT Supply Monitor

If Standby mode is entered on a VEXT supply ramp down, the consequent wake-up on VEXT supply ramp up is triggered by the VEXT supply monitor activated by configuring **PMSWCR0**.PWRWKEN bit. The Standby request is issued by the secondary under-voltage monitor on crossing a voltage threshold as configured in **EVRUVMON** and **EVRMONCTRL** registers. Idle request acknowledge sequence issued to modules shall be deactivated on Standby entry by setting SCU\_PMSWCR1.IRADIS bit if VEXT supply is available. The EVR33 and EVRC regulators are switched off and Standby state is entered. Consequently VEXT and VDDM supplies may be ramped down, thus port and analog domains are also devoid of power. Wake-up is triggered when VEXT supply ramps up again and is detected by the VEXT supply monitor in the Standby domain. The detection time of the detector itself on reaching VLVDRST5 level is within 50 us. Nevertheless the complete time for start-up from Standby mode is quite the same as that for normal start-up and is documented tBP parameter in datasheet. VEXT wake-up is recognized as valid only after a minimum delay time has elapsed in Standby state as configured in **PMSWCR0**.BLNKFL register bits. This is to avoid spurious wake-up events owing to residual voltage on VEXT supply due to external buffer capacitors. After a successful wake-up, the register bit **PMSWSTAT**.PWRWKWP is set to indicate wake-up owing to a VEXT supply ramp-up and shall be cleared via **PMSWSTATCLR**.PWRWKPCCLR register bit.

### 11.2.3.4.5 Pin Wake-up Unit

External events may be mapped to ESRx / PINx pins in turn acting as wake-up signals for the system. In Run Mode, ESR1 pin may be used as fault or functional interface for external devices. In Standby Mode, an edge event on the

## Power Management System (PMS)

ESR1 pin may be configured to trigger wake-up of the main core domain via **PMSWCRO**.ESR1WKEN bit and is reflected in **PMSWSTAT**.ESR1WKEN status flag. It can be configured to trigger a wake-up on rising, falling or both edges via **PMSWCRO**.ESR1EDCON bit. The minimum pulse width of the external wakeup input signal without the digital filter activated shall be atleast 2 clock cycles. Glitches on ESR1 input are filtered out by activating the filter via **PMSWCRO**.ESR1DFEN bit. The reset behavior is documented in External Service Requests chapter in RCU chapter. Additional pins (PINA - P14.1 and PINB - P33.12) may likewise be configured to trigger wake-up via **PMSWCRO**.xEDCON, xDFEN & xWKEN bits. On wake-up, **PMSWSTAT**.ESR1WKP or PINxWKP event flags provide information as to the wake-up source. It should be taken care after wake-up to clear the event flags via **PMSWSTATCLR** register. In case new wake-up events are captured while **PMSWSTAT**.xWKP flags are still set, then **PMSWSTAT**.xOVRRUN flags are set to indicate an overrun state owing to consecutive un-serviced wake-up events.

### 11.2.3.4.6 Standby ContolleR (SCR) Interface

The 8 bit Standby controller (SCR) subsystem constitutes an XC800 core, 8KB XRAM memory, various timer modules, ADC comparator, various communication peripherals and up to 16 shared pins executing autonomous activity during Idle, Sleep and Standby modes. Various Standby functions and periodic monitoring tasks may be encapsulated in the SCR with minimal power consumption overheads.

The SCR is enabled via **PMSWCR4**.SCREN bit and the status is reflected in **PMSWSTAT**.SCR bit. If SCR is disabled via **PMSWCR4**.SCREN bit, it is ensured that SCR 100MHz clock request, pending requests from SCR wake-up sources and other SCR interfaces do not have any effect on the main system. After start-up, CPU0 programs the SCR via FPI interface and copies the code into the internal XRAM.

A reset may be issued to the SCR via **PMSWCR4**.SCRSTREQ register bit. Consequently **PMSWSTAT**.SCRST status register bit is flagged to indicate SCR reset. SCRRST register bit is cleared via **PMSWSTATCLR**.SCRSTCLR bit. **PMSWCR4**.SCRSTREQ register bit is cleared after reset has been issued. The SCR is reset in case of warm PORST assertion based on **PMSWCR4**.PORSTREQ register configuration reflected in PORST register bit during normal RUN and SLEEP modes. The SCR is not affected by an Application or System reset. After reset release, the firmware initializes the SCR subsystem based on the hardware configuration programmed in **PMSWCR4**.SCRCFG bits. In case of LVD reset, a complete power-on reset of SCR is carried out.

The 20 MHz stand-by clock source is the default SCR clock active in System Standby Mode enabling higher-performance of the SCR subsystem. The SCR clock source may be switched to the internal 20 MHz (derived from the 100 MHz back-up clock) clock source via SCRCLKSEL register bit thus enabling higher performance on the SCR subsystem. Fundamentally SCR is in control of its clock needs and may request a clock switch via CMCON.OSCPD register overruling the behavior configured in SCRCLKSEL register. A watchdog ensures that the clock received after the request is adequate for reliable operation.

SCR PORT module shares a part of the PORT (P33.0 - P33.7, P33.9 - P33.15 and P34.1) domain with the main port system which may be kept active during Standby mode. The SCR ports are supplied by VDDPD and VEVRSB standby supply. The control to these pins need to be allocated explicitly to the SCR via port configuration Pxx\_PCSR register. Unused wake-up pins may be configured as tristate in Standby Mode. Furthermore dedicated wake-up pins, namely ESR0, ESR1, PINA - P14.1 and PINB - P33.12 are also routed to the SCR subsystem to recognise wake-up edges on these pins. When SCREN = 0 is programmed, PINB wakeup is configured as explained in section [Section 11.2.3.4.5](#). Alternatively if SCREN=1 is programmed, PINB ownership is to be foremost transferred to SCR and SCR PINB Port configuration need to be set to input.

The SCR XRAM is accessible from the main domain via the FPI interface. Simultaneous access to XRAM via FPI interface and the SCR is arbitrated with SCR having default priority for XRAM access. In case of wake-up from Standby, it is ensured that SCR XRAM is not re-initialised.

An additional register interface with interrupt support using **PMSWCR2** register bit fields for exchange and facilitate status handshake between the two domains. The SCR can make a direct interrupt request to any CPUx by writing to register NMICON.SCRINTTC SCR register bit. An additional 8 bit information maybe written to

## Power Management System (PMS)

SCRINTEXCHG SCR register which is also transferred to **PMSWCR2**.SCRINT register bit field to decode the interrupt reason. The routing of the interrupt to the service request node need to be enabled via **PMSIEN**.SCRINT register bit.

Likewise any CPU may also trigger a direct interrupt request to the SCR by writing to **PMSWCR2**.TCINTREQ register bit. An additional 8 bit information maybe written to **PMSWCR2**.TCINT register which is likewise transferred to TCINTEXCHG SCR register bit field to decode the interrupt reason on SCR side.

Critical SCR errors / events like XRAM ECC errors, SCR watchdog overflow event and SCR internal reset need to be communicated back to the main core domain via **PMSWCR2**.SCRECC, SCRWD and SCRRST register bits. These events may additionally trigger internal SCR reset if configured in RSTST SCR register. The occurrence of SCRECC, SCRWD and SCRRST events may be routed to interrupt based on **PMSIEN**.SCRECC, SCRWD and SCRRST register bits.

Like-wise resets of the main system, namely application, system and power-on resets, are reflected in **PMSWCR2**.RST register bit and communicated to SCR register MRSTST.RST bit. Furthermore, SMURST is differentiated via **PMSWCR2**.SMURST and communicated to SCR register MRSTST.SMURST bit. Interrupt maybe generated in SCR subsystem when MRSTST register bits are set. The bits are cleared when SCR has latched the information.

During standby mode, the SAR secondary monitor ADC maybe used to carry out analog conversions of up to 4 analog inputs (P33.4, P33.5, P33.6 & P33.7) if requested by SCR. Refer SCR ADCOMP chapter for more details.

During a standby to run mode transition on a wake-up event, the P33 and P34 PCSR.SELx shadow register value retains the programmed value of PCSR.SELx value before standby entry. This is to ensure that SCR continues to have control over the respective P33 and P34 port pins during and after exit from Standby, though the Port register PCSR.SELx value is reset. Only on a consequent explicit write to the register after reset release will a new PCSR.SELx value be taken to switch the Port 33 and P34 control.

The SCR may wake-up the main core domain from Standby state if configured in SCRWKEN register bit. The enabling of SCR wake-up via SCRWKEN should be programmed when SCR is running at 20 MHz. A wake-up request is issued by the SCR SW via SCRWP bit in STDBYWKP register as documented in the SCR SCU chapter. On wake-up of the main core domain, SCRWP event flag is set which shall be cleared via SCRWPCLR register bit.

### 11.2.3.4.7 Wake-up Timer (WUT)

The Wake-up Timer is a basic low power counter which may be used to wake-up the system periodically from Standby mode. The timer may also be used during RUN, IDLE or SLEEP modes. The following list enumerates the salient features.

- 24 bit counter running on 70 kHz clock source with programmable reload value.
- 24 bit counter status register providing the current count value.
- Timer resolution of 70 kHz or (70 kHz / 2<sup>10</sup>) configured via a clock divider.
  - 14.3 us resolution : 14.3 us - 240 s range ± 60% default tolerance
  - 14.3 ms resolution : 14.3 ms - 2.7 days range ± 60% default tolerance
- 2 operating modes :
  - Auto Reload mode - WUT is started and stopped via Software. Automatic reload on counter underflow and triggers a system wake-up.
  - Standby Auto Stop mode - Counter starts counting down from reload value on Standby entry. Counter stops on underflow and triggers a system wake-up.
- Events on WUT counter underflow
  - Interrupt request on SRC\_PMSx (WUT) interrupt node on counter underflow during RUN, IDLE or SLEEP mode.
  - Wake-up trigger on counter underflow during STANDBY mode.

## Power Management System (PMS)

- Capture trigger on counter underflow to CCU60\_CC60IND, CCU61\_CC60IND and GTM (TIM 0.7) for trimming purpose.
- Over-run indication of consecutive un-serviced wake-up triggers

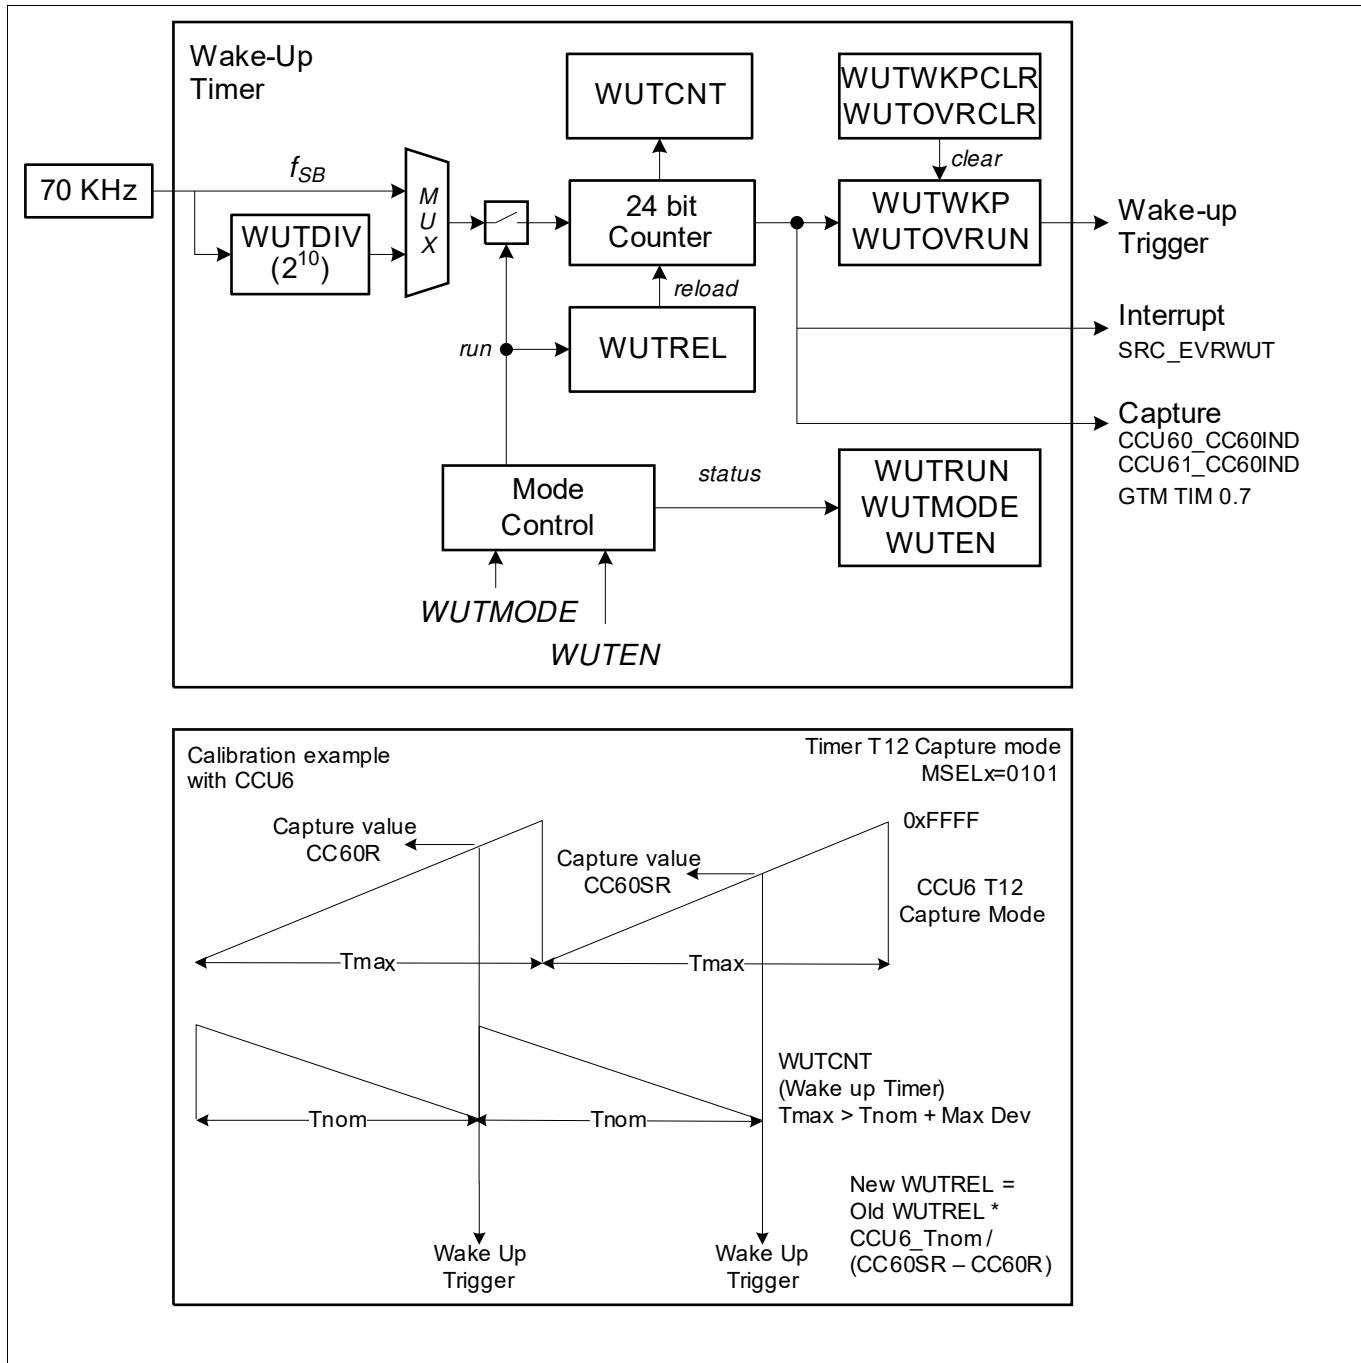

Figure 118 Wake-up Timer (WUT)

## Power Management System (PMS)

**Table 301 Wake-up Timer Operation and Modes**

WUTEN	WUTMODE	Mode Description
0B	XB	<p>WUT is disabled and counter is stopped.</p> <p><b>PMSWCR3.WUTREL</b> reload value may be updated.</p> <p><b>PMSWSTAT2.WUTCNT,WUTRUN,WUTWKP &amp; WUTOVR</b> flags read 0.</p>
1B	0B	<p>Software Auto Reload mode :</p> <p>WUT starts running when <b>PMSWCR3.WUTEN</b> = 1 and <b>WUTMODE</b> = 0 is set. <b>PMSWCR0.WUTWKEN</b> = 1 is set to activate system wake-up from standby state. <b>PMSWSTAT.WUTRUN</b> bit is set indicating that WUT timer is currently running.</p> <p><b>PMSWUTCNT.WUTCNT</b> bit field indicates the actual counter value. On counter underflow, WUT is automatically reloaded with WUTREL value. During Standby, WUT underflow triggers system wake-up if <b>PMSWSTAT2.WUTWKEN</b> is set and <b>PMSWSTAT2.WUTWKP</b> flag is set. During Run, Idle or Sleep modes, WUT underflow triggers an interrupt request and <b>PMSWSTAT2.WUTWKP</b> flag is set. WUTREL reload value shall not be updated in this state.</p> <p>On wake-up, the <b>PMSWSTAT2.WUTWKP</b> flag shall be cleared by <b>PMSWSTATCLR.WUTWKPCLR</b> bit. In case of un-serviced consecutive counter underflow events, <b>PMSWSTAT2.WUTOVRUN</b> flag is set to indicate an over-run wake-up event.</p> <p>Interrupt over-run event can be detected via SRC.IOV bit during RUN mode.</p>
1B	1B	<p>Standby Auto Stop mode:</p> <p>The mode is selected by setting <b>PMSWCR3.WUTEN</b> = 1, <b>WUTMODE</b> = 1 is set. <b>PMSWCR0.WUTWKEN</b> = 1 is set to activate system wake-up from standby state.</p> <p>WUT starts running only when Standby mode is entered. On counter underflow, WUT stops running and the wake-up of system is triggered and <b>PMSWSTAT2.WUTWKP</b> flag is set.</p> <p>WUT starts running again on the next Standby mode entry. The intention is to have the timer running only during the Standby state.</p> <p><b>PMSWUTCNT.WUTCNT</b> reloads <b>PMSWCR3.WUTREL</b> value on a wake-up.</p> <p><b>PMSWSTAT.WUTRUN</b> reads 0 after a wake-up.</p> <p><b>PMSWCR3.WUTREL</b> reload value shall not be updated in this state.</p> <p>On wake-up, the <b>PMSWSTAT2.WUTWKP</b> flag shall be cleared by <b>PMSWSTATCLR.WUTWKPCLR</b> bit. In case system was woken up by other wake-up triggers while WUT was still running, an interrupt request is generated on WUT underflow. In case of un-serviced consecutive counter underflow events, <b>PMSWSTAT2.WUTOVRUN</b> flag is set to indicate an over-run wake-up event.</p> <p>Interrupt over-run event can be detected via SRC.IOV bit during RUN mode.</p>

In case of timer overflow, an interrupt is issued on the interrupt node SRC\_PMSx (WUT). Wake-up Timer reload value maybe trimmed during Run mode by comparing the time stamp on a WUT underflow captured by a GTM-TIM or CCU6x based on a more precise clock as shown in [Figure 1.18](#). This allows to compensate on short term the 70 kHz (fSB) clock source variations owing to technology, voltage and temperature.

## Power Management System (PMS)

### 11.2.3.4.8 Entering Standby Mode (only VEVRSB domain supplied)

The Standby Mode entry may be requested via VEXT supply ramp-down triggered by a secondary SWDUV under-voltage event if configured in **PMSWCR0.VEXTSTBYEN** bits.

The Standby Mode entry may be requested by writing to PMCSR<sub>x</sub> register to set bit field REQSLP = 11<sub>B</sub> or via ESR1 (NMI) assertion as configured in SCU\_PMSWCR1.STBYEV bits.

Standby mode via SW may be entered based on a singular decision from a master CPU based on the configuration in the CPUSEL register. It may also be entered as a unanimous decision of all the CPUs when ALL of the PMCSR<sub>x</sub> registers in the system request it and PMSWCR1.CPUSEL = 111<sub>B</sub>. Each PMCSR<sub>x</sub> register is written by the corresponding CPU<sub>x</sub>.

Before entering Standby mode, modules may be sequentially shut off to avoid large load jumps.

- All peripherals and interrupts associated with CPUs except master CPU are switched off. This is to avoid wake-up of the CPUs once they are put into IDLE state.
- All CPUs except the master CPU are sequentially put into IDLE state. All watchdogs may be disabled or re-configured for slower modes. Peripherals module clocks are switched off in the respective CLC.DISR registers.
- Master CPU frequency reduction in steps compliant to load jump constraints. Master CPU code execution switched from Flash to PSPR RAM. Flash modules may be deactivated.
- System Clock is switched to internal 100 MHz clock source. System PLL & Peripheral PLL are switched off. Clock dividers are programmed to lower values.
- Standby SMU module shall be disabled via CMD\_STDBY.SMUEEN before going into Standby mode.
- SCU\_PMSWCR1.IRADIS bit set to disable Idle Request Acknowledge sequence activation for fast Standby Mode entry. System and Application reset generation possibilities are disabled. Only remaining reset possibility in this phase is via PORST or power-fail
- Standby RAM block selected via **PMSWCR0**.STBYRAMSEL bits. Dcache write back to be executed before Standby entry.
- Select the 70 kHz Standby clock source ( fSB ) via **PMSWCR4**.SCRCLKSEL bits. Configure the blanking filter appropriately via **PMSWCR0**.BLNKFIL bits.
- Configure pad state via **PMSWCR5**.TRISTREQ bit. All pads may be set into tristate or have pull-up device active. Regardless of the **PMSWCR5**.TRISTREQ setting, the VEXT-buffered PU1 pads (see the PU1 buffer type in the data sheet) are set into tristate after standby mode entry. Configure **PMSWCR5**.ESR0TRIST bit to set ESR0 behavior as reset output active or tristate. In case of HWCFG [2:1,6] pins it is recommended to tie them to external pull devices.
- SCR may be kept running before entering the Standby state. The shared ports supplied by VEVRSB are configured either to be in tristate during standby or left to the control of SCR. The enabling of wake-up from SCR via **PMSWCR0**.SCRWKEN should be programmed when SCR is running at 20 MHz.
- Wake-up Timer may also be kept running before entering the Standby state. The wake-up from WUT may be activated via **PMSWCR0**.WUTWKEN bit.
- Wake-up via PORST, Pin A, ESR0 & ESR1 pins is not supported during Standby mode as VEXT will be ramped down on Standby entry. Therefore the respective **PMSWCR0**.PORSTWKEN, PINAWKEN, ESR0WKEN and ESR1WKEN wake-up configuration bits shall be disabled to avoid spurious wake-up triggers. It should be taken care that SCR is not reset on a standby entry by clearing **PMSWCR4**.PORSTREQ bit field.
- Enable wake-up on VEXT supply ramp-up via **PMSWCR0**.PWRWKEN bit. It need to be ensured that both PWRWKEN and VEXTSTBYEN register bits are both set before entering Standby mode. VEXTSTBYEN register bitfield shall be set to ensure that when VEXT supply is removed during Standby state, no LVD reset is generated consequently exiting from Standby mode.
- In case standby entry is triggered by VEXT supply ramp down, the threshold is configured in **EVRUVMON**.SWDUVVAL and transition condition in **EVRMONCTRL** register respectively. In case of nominal

## Power Management System (PMS)

VEXT supply voltage of 5 V, it is recommended to configure SWDUVVAL register bitfield at 4 V for standby entry to have adequate distance to primary reset levels as well as operational region limits. In case of nominal VEXT supply voltage of 3.3V, it is recommended to configure SWDUVVAL register bitfield at 3.1 V for standby entry above primary reset levels. Nevertheless since there is only a minimal margin to reset levels in this case, Standby entry is additionally triggered by the crossing of primary undervoltage limits if VEXTSTBYEN register bit is set to ensure Standby entry in case of fast VEXT slopes. The parasitic diode path from VDDP3 to VEXT will keep the VEXT voltage at (VDDP3 - diode drop), so it should be ensured that SWDUVVAL is configured above (VDDP3 - diode drop) for standby entry if VDDP3 and VEXT supply rails are separately supplied. The selection of only VEXT supply voltage monitoring in **EVRMONCTRL** would reduce the secondary monitor standby entry latency time to (tMON/3). Configure Standby entry event in **PMSWCRO.VEXTSTBYEN** register bit.

- It shall be ensured that the primary under-voltage reset monitors are active before Standby entry is triggered and shall not be disabled in **EVRRSTCON** register.
- The external regulator is communicated to switch off VEXT supply. A controlled ramp-down of VEXT slope during Standby entry is recommended from external regulator (E.g - 0.5V/ms to 1.5V/ms). It need to be ensured that the VEXT supply is ramped below VEXT LVD reset level after standby entry before blanking filter time has expired. This is to avoid an immediate wake-up triggered by the residual VEXT voltage if it is above VEXT LVD reset level after blanking time has expired. It need to be also ensured that VDD and VDDP3 supply rails are consequently switched off after VEXT ramp down to reduce standby current within blanking filter time.
- All xWKP / xOVRUN flags activated by respective xWKEN bits shall be cleared before renewed Standby entry request, otherwise System will remain in Operation state and not enter Standby state. Standby request is issued via VEXT supply undervoltage event or via SW or NMI event. Once Standby entry event is recognised, the primary under-voltage reset generation is disabled and Standby RAM supply is switched from VDD to VDDP3 within a single 25 MHz clock cycle. During Standby state entry, the wake-up logic is unable to detect wake-up events for a minimal time period less than 300 ns, therefore it need to be ensured that the wake-up pulse is asserted long enough that wake-up is detected. On entry into Standby mode, blanking filter is activated. The external standby regulator continues to supply the Standby domain via VEVRSB supply pin. Blanking filter is always activated on entry to Enter Standby state.
- When entering standby with external pass devices or external MOSFET complementary switch in case of EVRC regulator, it should be taken care that when VEXT supply is ramped down also the supply to the pass devices/MOSFET is also ramped down along with VEXT supply. Otherwise it may happen, that the VEXT supply is still held high via the diode path through the VGATE pins to VEXT supply rail. This would lead to immediate wake-up after blanking time has expired as VEXT supply is above the wake-up voltage threshold between 2,6 - 2,97 V. Adequate blanking filter time shall be configured before entering standby to ensure that VEXT has ramped down completely within this time to avoid immediate wake-up.
- Standby request issued via REQSLP bit field or ESR1/NMI event.
- Select required edge configuration in SCU\_ESRCFG1.EDCON if ESR1 is used as a trigger for standby entry.

## Power Management System (PMS)

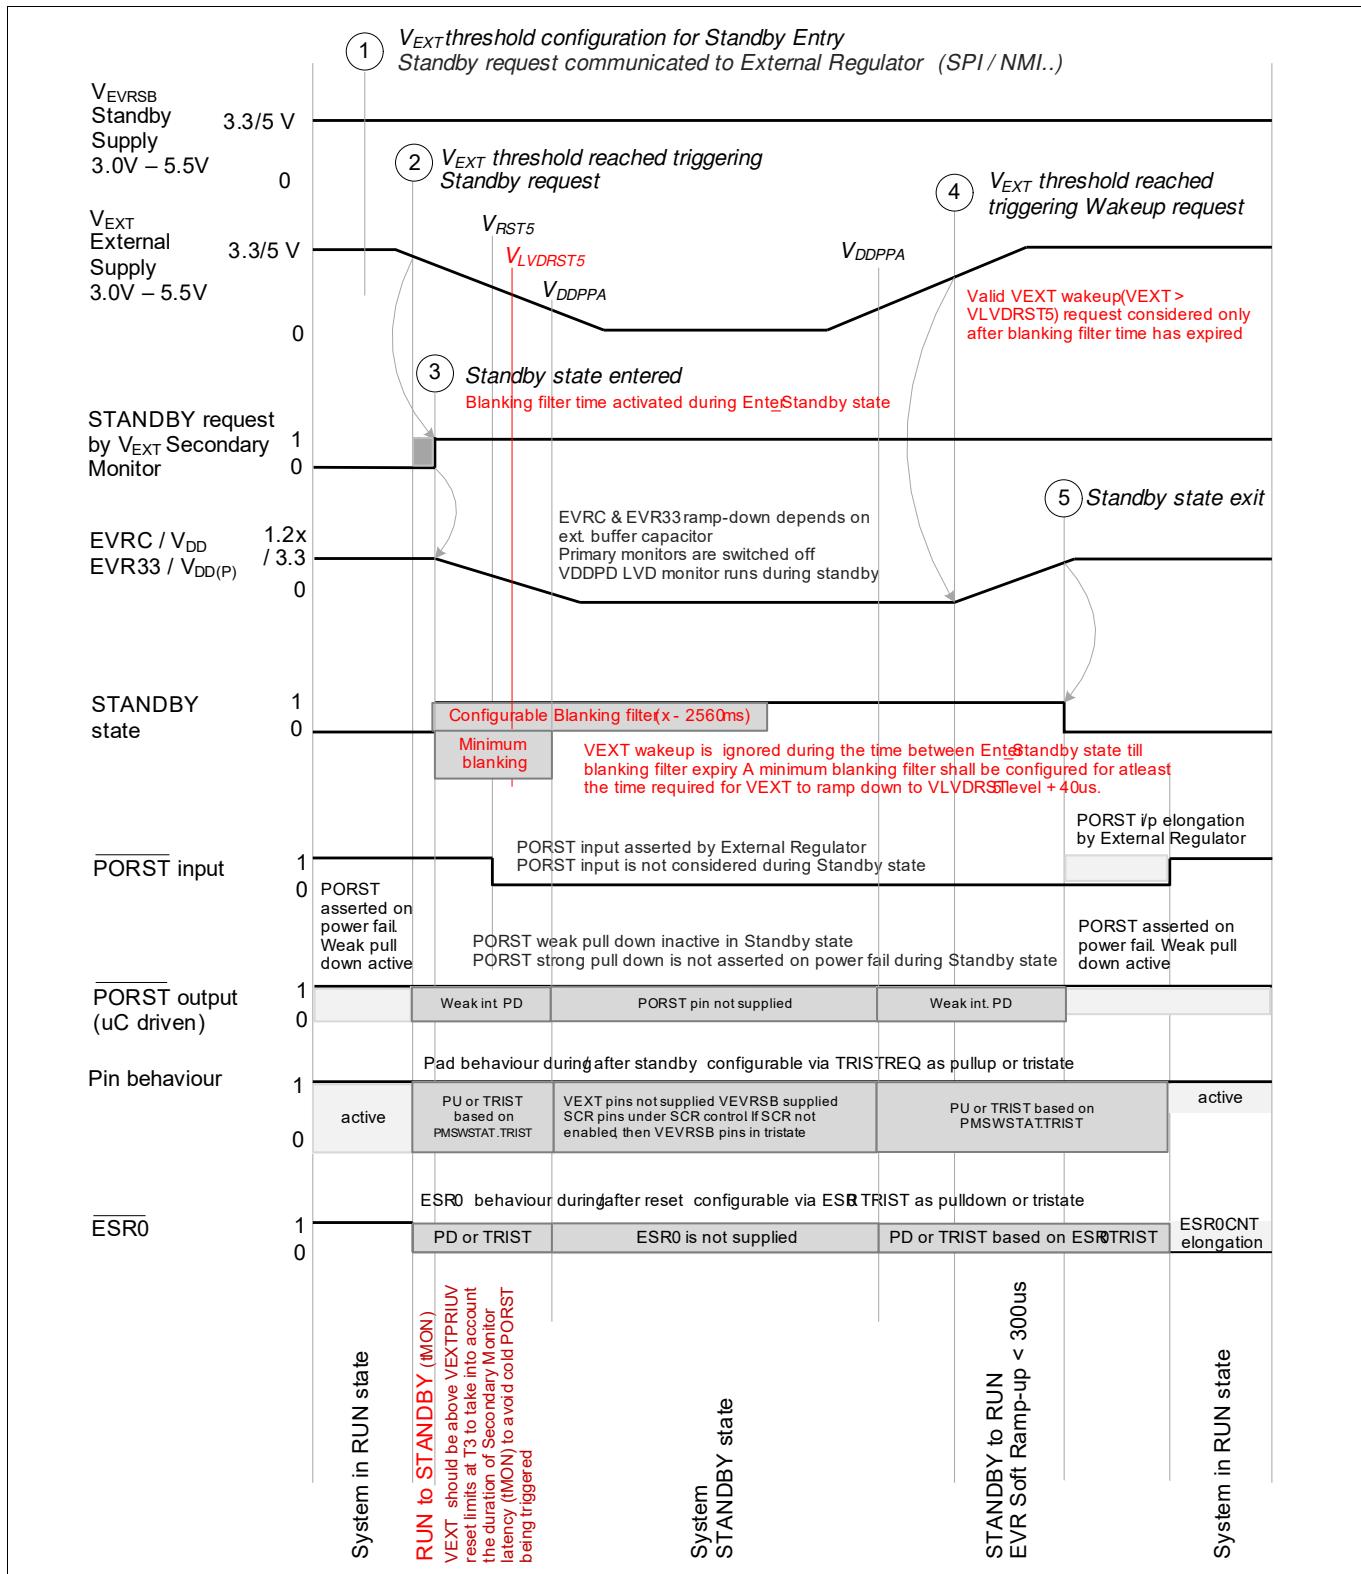

Figure 119 Standby entry on VEXT ramp-down and wake-up on VEXT ramp-up

## Power Management System (PMS)

### 11.2.3.4.9 Entering Standby Mode (both VEVRSB and VEXT domain supplied)

The Standby Mode entry may be requested by writing to PMCSR<sub>x</sub> register to set bit field REQSLP = 11<sub>B</sub> or via ESR1 (NMI) assertion as configured in SCU\_PMSWCR1.STBYEV bits.

Standby mode via SW may be entered based on a singular decision from a master CPU based on the configuration in the CPUSEL register. It may also be entered as a unanimous decision of all the CPUs when ALL of the PMCSR<sub>x</sub> registers in the system request it and PMSWCR1.CPUSEL = 111<sub>B</sub>. Each PMCSR<sub>x</sub> register is written by the corresponding CPUx.

Before entering standby mode, various modules should be sequentially shut off in a sequence mainly to avoid large current jump on standby entry.

- All peripherals and interrupts associated with CPUs except master CPU are switched off. This is to avoid wake-up of the CPUs once they are put into IDLE state.
- All CPUs except the master CPU are sequentially put into IDLE state. CPU watchdogs may be disabled or re-configured for slower modes. Peripheral module clocks are switched off in respective CLC.DISR registers.
- Master CPU frequency reduction in steps compliant to load jump constraints. Master CPU code execution is switched from Flash to PSPR RAM. Flash modules are deactivated.
- System Clock is switched to the internal 100 MHz clock source. System PLL & Peripheral PLL are switched off. Clock dividers are programmed to lower values.
- Standby SMU module shall be disabled via CMD\_STDBY.SMUEN before going into Standby mode.
- Set SCU\_PMSWCR1.IRADIS bit to disable Idle Request Acknowledge sequence activation for fast Standby Mode entry. This ensures that standby request is not blocked by a pending reset request / sequence.
- Select the Standby RAM block via **PMSWCR0**.STBYRAMSEL bits. Dcache write back to be executed before Standby entry.
- Select the 70 kHz Standby clock source ( fSB ) via **PMSWCR4**.SCRCLKSEL bits. Configure the blanking filter appropriately via **PMSWCR0**.BLNKFIL bits.
- Select the clock source which need to be active on entry into Standby Mode via **PMSWCR4**.SCRCLKSEL bits. Wake-up trigger edge configuration and filter activation is configured via **PMSWCR0**.xxxEDCON and **PMSWCR0**.xxxDFEN bits.
- Configure pad state via **PMSWCR5**.TRISTREQ bit. All pads may either be in tristate or have pull-up devices active. Regardless of the **PMSWCR5**.TRISTREQ setting, the VEXT-buffered PU1 pads (see the PU1 buffer type in the data sheet) are set into tristate after standby mode entry. Configure **PMSWCR5**.ESR0TRIST bit to configure ESR0 behavior as reset output or tristate during Standby and on wake-up. In case of HWCFG [2:1,6] pins it is recommended to tie them to external pull devices.
- Wake-up Timer may also be kept running before entering the Standby state. The wake-up from WUT may be activated via **PMSWCR0**.WUTWKEN bit.
- Enable ESR1 or PINx pins for wake-up via **PMSWCR0**.xxxWKEN bits.
- SCR may be kept running before entering the Standby state. The shared ports supplied by VEVRSB are configured either to be in tristate during standby or left to the control of SCR. The enabling of wake-up from SCR via **PMSWCR0**.SCRWKEN should be programmed when SCR is running at 20 MHz.
- All xWKP / xOVRUN flags activated by respective xWKEN bits shall be cleared before renewed Standby entry request, otherwise System will remain in Operation state and not enter Standby state. Configure Standby Entry event in SCU\_PMSWCR1.STBYEV register bits.
- It shall be ensured that the primary under-voltage reset monitors are active before Standby entry is triggered and shall not be disabled in **EVRRSTCON** register.
- Standby request issued via REQSLP bit field or ESR1/NMI event. An orderly shut down of various sub-systems is triggered to enter Standby mode. Once Standby entry request is recognised, the primary under-voltage

## Power Management System (PMS)

reset generation is disabled and Standby RAM supply is switched from VDD to VDDPD within a single 25 MHz clock cycle. During Standby state entry, the wake-up logic is unable to detect wake-up events for a minimal time period less than 300 ns, therefore it need to be ensured that the wake-up pulse is asserted long enough that wake-up is detected. Blanking filter is always activated on entry to Enter\_Standby state. It need to be ensured that VDD and VDDP3 supply rails are consequently switched off after entry to standby to reduce standby current.

- Select required edge configuration in SCU\_ESRCFG1.EDCON if ESR1 is used as a trigger for standby entry.

### 11.2.3.4.10 State during Standby Mode

The Standby RAM (DLMU RAM of CPU0 and CPU1), the 8 bit Standby controller, the shared ports and the wake-up logic are kept alive in Standby mode. PORST pin, ESRx pins and PIN A provides wake-up function if VEXT is supplied. In case of wake-up on VEXT supply ramp-up and only VEVRSB is supplied, cold PORST function is resumed only after all supplies have ramped up.

All other pins are set in their default reset state. The default pin behavior during standby and after wake-up may be configured as pull-up or tristate accordingly by TRISTREQ register bit. Regardless of the [PMSWCR5.TRISTREQ](#) setting, the VEXT-buffered PU1 pads (see the PU1 buffer type in the data sheet) are set into tristate after standby mode entry. All pins can be set into tristate except the TESTMODE pin where the internal pull-up is active also during Standby mode. The ESR0 pin may be configured as reset output or tristate during Standby mode by configuring ESR0TRIST bit. The shared port supplied by VEVRSB may retain their state. It need to be ensured by the external regulator that the VEVRSB voltage is within the operational region during Standby state.

The SCR continues to operate as a stand-alone 8 bit controller executing the intended operations. It should be ensured that the shared ports are configured in the corresponding port registers and the ownership of the pins are assigned either to the SCR or the main domain. In case the SCR needs to drive outputs during Standby mode, the default clock may need to be switched from 70 kHz to 20 MHz clock source. The SCR may request the EVR to activate or deactivate the 20 MHz clock. Analog conversions maybe carried out using SCR ADCOMP unit. SCR may be programmed to issue wake-up based on inputs from internal modules or shared pins. When the wake-up of the main core domain is required, the SCR issues a wake-up request via SCRWK bit in STDBYWKP register as documented in the SCR SCU.

### 11.2.3.4.11 Exiting Standby Mode - Wake-up event

The wake-up trigger in case of Standby mode where VEVRSB domain is only supplied may happen

- On a VEXT Supply ramp up after the blanking filter time has expired. SCR may be active. Wake-up can indirectly be triggered via SCR by communicating to external regulator to request the ramp-up of VEXT voltage. The wake-up reason could be any SCR event, Pin B edge transition or WUT Wake-up. Pin B edge transition or WUT Wake-up is also communicated to SCR as shown in [Figure 120](#).

After VEXT wakeup is recognised, it is expected that the VEXT supply is stable afterwards. In case of immediate VEXT powerfail consequent to VEXT wake-up, LVD reset or cold PORST may be triggered.

It is expected that the VEXT Supply has ramped down within the configured blanking filter time. Blanking filter shall be configured for atleast the time required for VEXT to ramp down to VLDRST5 level + 40 us. VEXT wakeup is ignored during the time between Enter Standby state till blanking filter expiry. A wake-up is triggered when the VEXT Supply is above the wake-up threshold of VLDRST5 for a time duration greater than 20 us indicated by event 4 in [Figure 119](#). Wake-up triggered on a VEXT Supply ramp-up is indicated in [PMSWSTAT2.PWRWKP](#) register bit and shall be cleared by [PMSWSTATCLR.PWRWKP](#) clear register bit.

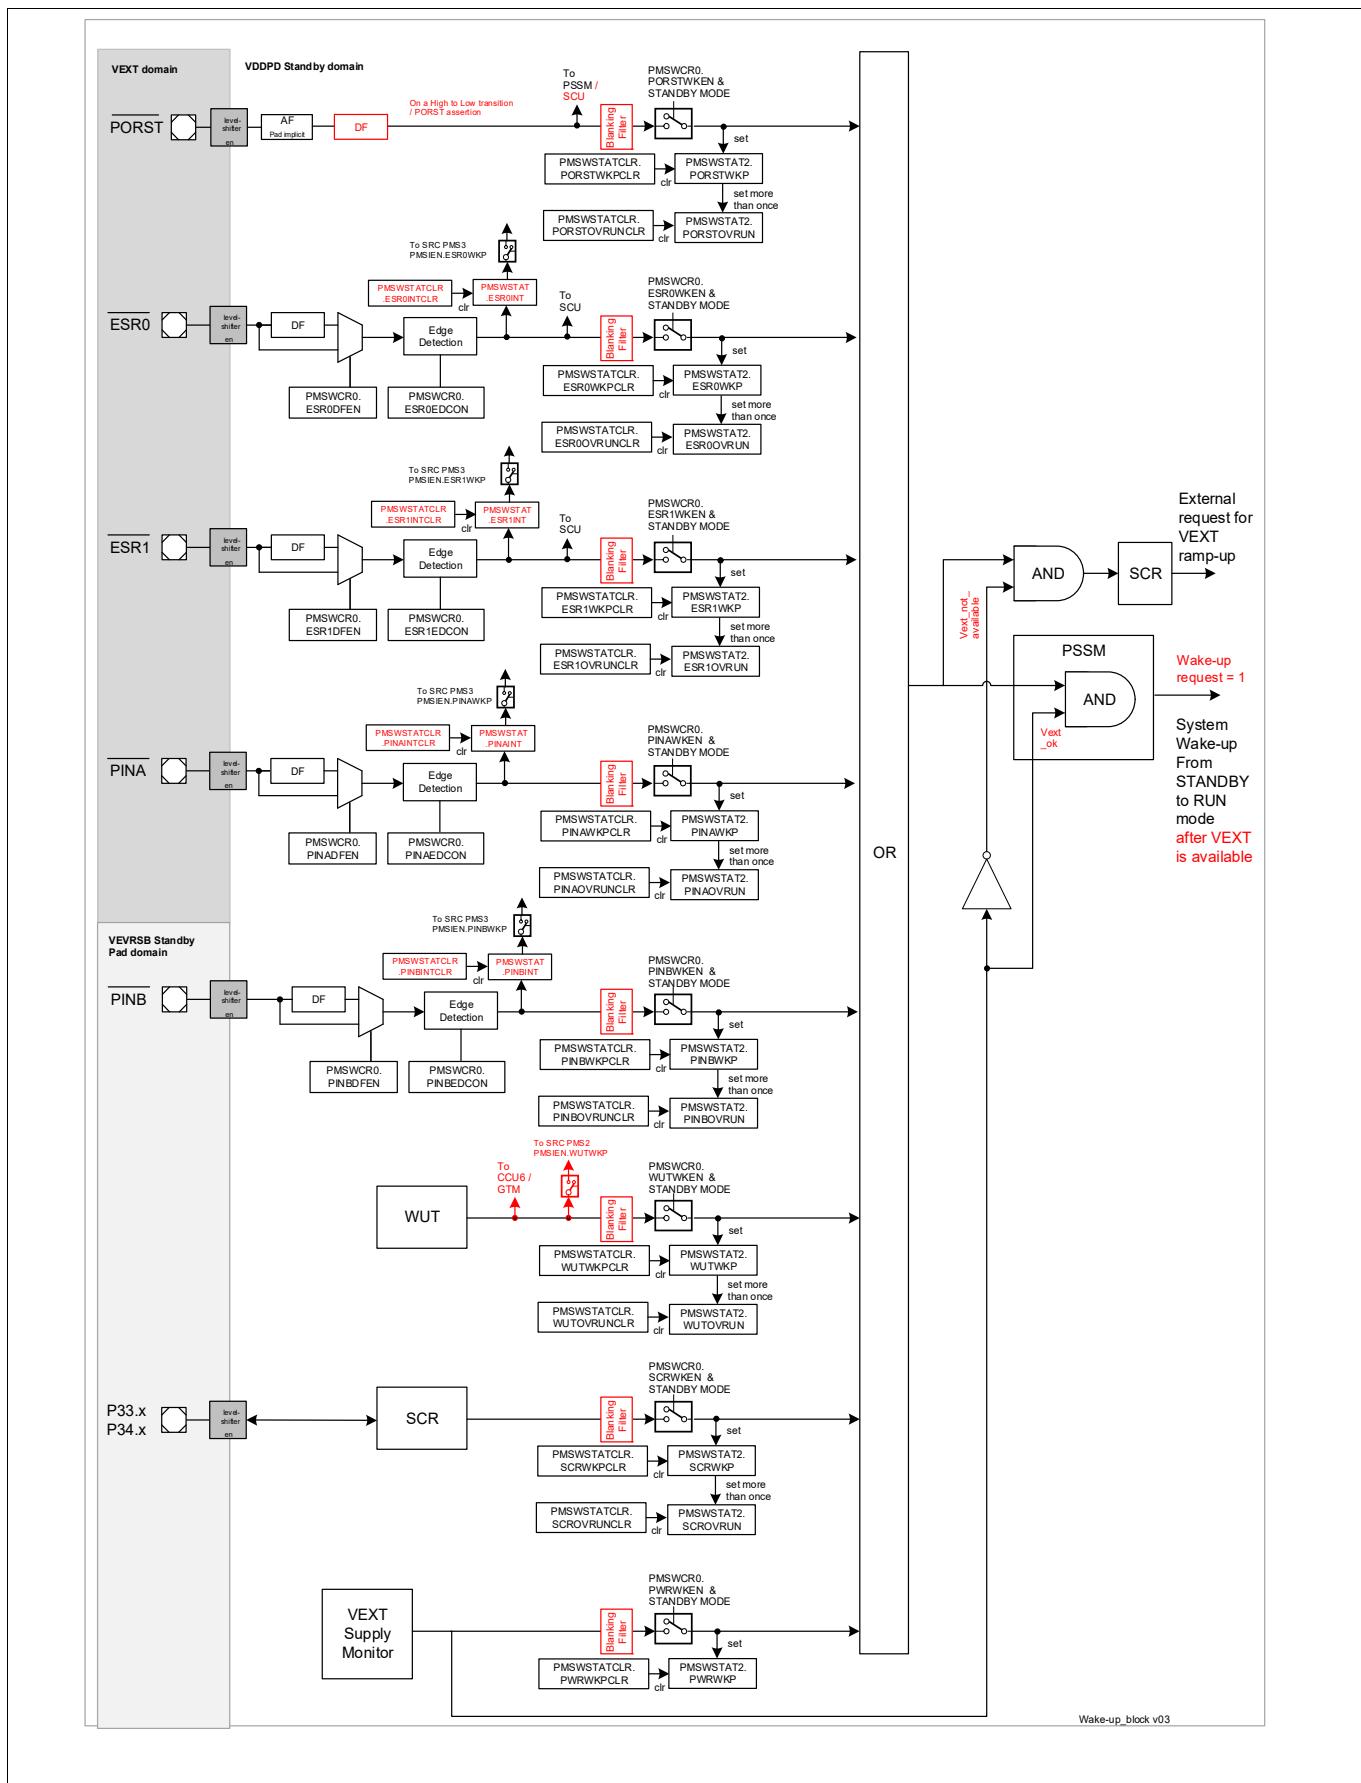

The wake-up event in case of Standby mode where both VEVRSB and VEXT domain supplied may happen after the blanking filter time has expired on following events. ESRx / PINx edge, WUT underflow or SCR wakeup is ignored during the time between Enter\_Standby state till blanking filter expiry. xWKP / xOVRUN flags are only set during Standby mode after Blanking Filter expiry when the respective wake-up event happens.

## Power Management System (PMS)

- ESR1 edge transition (NMI trap): **PMSWSTAT2.ESR1WKP** set on wake-up. **PMSWSTAT2.ESR1OVRUN** set to indicate overrun behavior in case of multiple un-serviced wake-ups.
- Pin A or Pin B edge transition (P14.1 or P33.12): **PMSWSTAT2.PINxWKP** set on wake-up. **PMSWSTAT2.PINxOVRUN** set to indicate overrun behavior in case of multiple un-serviced wake-ups.
- Wake-up from SCR via register STDBYWKP.SCRWKP in turn caused by following events. **PMSWSTAT2.SCRWKP** set on wake-up. **PMSWSTAT2.SCROVRUN** set to indicate overrun behavior in case of multiple un-serviced wake-ups.
  - Edge transitions at the shared ports
  - RTC interrupt
  - SCR watchdog overflow
  - Selected interrupts from communication modules
  - ADCOMP analog channel compare event.
- Wake-up from WUT

The main EVRC and EVR33 regulators are ramped up on wake-up based on the earlier latched configuration in **PMSWSTAT.HWCFCGEVR** register bits. On wake-up, all pads are either in tristate or are connected to pull-ups as indicated in **PMSWSTAT.TRIST** register bit. ESR0 behavior is indicated in **PMSWSTAT.ESR0TRIST** register bit. If Standby RAM was supplied during Standby state, it is indicated in **PMSWSTAT2.STBYRAM** register bits. Additional RAM integrity checks may be carried out after wake-up. RSTSTAT.STBYR bit indicates that the supply was reliable during Standby. The wake-up and over-run status flags are set in **PMSWSTAT2** register and shall be cleared by **PMSWSTATCLR** register. The wake-up time is nearly the same as the normal boot time as EVR need to be started and firmware need to be consequently executed.

## Power Management System (PMS)

**Figure 120 Wake-up Overview**

## Power Management System (PMS)

### 11.2.3.4.12 Exiting Standby Mode - Power Fail or Reset event

A power fail event of the Standby supply (VEVRSB pin) during Standby mode may inevitably result in the loss of Standby RAM contents. Consequently, LVD reset event is issued and the Standby domain is set into reset. EVR Pre-regulator under-voltage violation is indicated in RSTSTAT.STBYR flag which can be used as an indication whether Standby supply fail had happened and Standby RAM contents are reliable. Cold PORST flags RSTSTAT.SWD, EVRC and EVR33 would always be set after wake-up from STANDBY mode as these domains may be devoid of power during STANDBY to eliminate leakage current. It is recommended to keep a copy of the critical data also in Dflash in order to mitigate the effects if unwanted power fail events cannot be avoided.

In case of VEXT supply wake-up, PORST pin, ESRx pins and PIN A input are not evaluated during Standby mode as it is supplied by VEXT domain which is switched off during the STANDBY mode. In case VEXT domain is supplied during STANDBY mode, the Standby domain is woken up on PORST assertion depending on **PMSWCR0.PORSTWKEN** bit. **PMSWCR0.PORSTWKEN** is by default set to 1 to ensure wake-up on PORST assertion during STANDBY mode. The SCR may also set into reset simultaneously depending on **PMSWCR4.PORSTREQ** bit. The device boots up ramping up the regulators followed by firmware execution similar to a normal device start-up. On PORST wake-up, **PMSWSTAT2.PORSTWKP** event flag is set providing information as to the wake-up source. It should be taken care after wake-up to clear the event flags via **PMSWSTATCLR.PORSTWKPCCLR** register. In case new PORST wake-up events are captured while **PMSWSTAT2.PORSTWKP** flags are still set, then **PMSWSTAT2.PORSTOVRRUN** flags are set to indicate an overrun state owing to consecutive un-serviced wake-up events. The overrun flag is cleared via **PMSWSTATCLR.PORSTOVRUNCLR** bit.

The Standby RAM contents are kept intact after a wake-up caused by PORST assertion. In case of VDD supply under-voltage condition during wake-up phase, it is ensured that the Standby RAM is kept supplied by VDDPD until VDD is back in operational range to avoid Standby RAM data loss or corruption during transition. Reset is propagated to external devices via the ESR0 pin on exit from Standby mode depending on **PMSWCR5.ESR0TRIST** configuration. Firmware may elongate ESR0 reset output depending on Flash configuration.

Additional PORST digital filter activated via **PMSWCR5.PORSTDF** bit provides additional spike filtering of at least tPORSTDF duration to provide enhanced immunity against spurious spikes. This is in addition to the inherent analog PORST filter delay of the PORST pad / pin as documented in the datasheet. After cold PORST the additional PORST digital filter delay is by default inactive. If VEXT is supplied, PORST (high to low) during Standby state after blanking filter expiry triggers wake-up.

**Table 302 PORST pin assertion behavior on PMS and SCR subsystem during power modes**

Reaction to PORST pin assertion	RUN mode SLEEP mode	STANDBY mode
No reaction	No effect on PMS domain. No reaction on SCR if <b>PMSWCR4.PORSTREQ</b> = 0 but an SCR_NMI is triggered via the PMSWCR2.RST bit.	No effect on PMS domain if <b>PMSWCR0.PORSTWKEN</b> = 0. No reaction on SCR if <b>PMSWCR4.PORSTREQ</b> = 0
Wake-up	No effect on PMS or SCR domain as the system is already awake	PMS Standby to RUN transition takes place on PORST assertion when VEXT is supplied if <b>PMSWCR0.PORSTWKEN</b> =1(default)
Reset	No reset of PMS domain SCR is reset if <b>PMSWCR4.PORSTREQ</b> = 1 (default)	No reset of PMS domain SCR is reset if <b>PMSWCR4.PORSTREQ</b> = 1 (default)

## Power Management System (PMS)

### 11.2.3.5 Load Jump Sequencing and Voltage Droop

Load jumps lead to consequent voltage overshoots / undershoots which need to be limited within the regulator dynamic specification and operational bounds of the supply rail. The initial phase after the load jump is buffered by the external capacitor which consequently leads to a linear discharge of the capacitor. Consequently the regulator feedback loop recognizes the deviation in voltage and reacts to the jump by changing the control output. The dimensioning of the capacitor results mainly from the load jump amplitude, ESR of the capacitor, the permissible voltage deviation and reaction time of the regulator. The capacitor size in turn has a tangible impact on BOM cost and PCB space. Minimizing peak-to-peak voltage deviation in the face of such large dynamic changes in load current need to be actively managed if large amounts of output capacitance are to be avoided.

If  $V_{DD}$  supply is generated by the internal EVRC regulator, the voltage transients owing to load jumps on core  $V_{DD}$  supply rail need to be restricted within  $V_{DD\_SETPOINT} + 8\% - 6\%$ . This includes a static accuracy of  $V_{DD\_SETPOINT} \pm 2\%$  and consequently  $+ 6\% - 4\%$  remaining for dynamic regulation.

In case of external  $V_{DD}$  supply, the voltage transients owing to load jumps on core  $V_{DD}$  supply rail need to be restricted within  $V_{DD\_SETPOINT} \pm 5\%$ . This includes a static accuracy of  $V_{DD\_SETPOINT} \pm 2\%$  and consequently  $\pm 3\%$  remaining for dynamic regulation.

Load jumps may be triggered by software or user driven actions or asynchronous hardware events. During software triggered non reset events, it is recommended to limit the load jumps ( $dIEXT/dt$ ,  $dIDD/dt$ ) to a maximum of 100 mA with 100  $\mu$ s settling time. For example, during clock ramp-up phase it is recommended to limit the clock switching steps so as not to violate this limit.

#### Handling load jump hardware events triggered asynchronously - Resets and NMI

In case of typical application load jump events, triggered asynchronously, like Non Maskable Interrupts and reset events, namely application, system and warm power-on reset requests, measures are built in to ensure that voltage overshoots are kept within bounds by load sequencing mechanisms or by means of register configuration.

In case of an NMI event, during RUN mode or waking up from SLEEP mode, the device may activate a large number of hitherto dormant circuits and wake-up the CPUs simultaneously resulting in a large change in load current. To avoid a large load jump on an NMI event, it needs to be ensured that only one CPU is triggered by the NMI or woken out of SLEEP mode and that other CPUs are still in IDLE mode. The other CPUs are consequently started one after another with adequate delay in between during start-up phase. The active CPU woken up on an NMI request is selected based on TRAPDIS0 and TRAPDIS1 register configurations.

In case of an Application Reset, System Reset or warm Power-On Reset request, the port pins are immediately set into reset state. Consequently the CPUs are ramped down in a sequence during the first 80  $\mu$ s immediately after the warm reset request. Finally after 180  $\mu$ s after reset request, the asynchronous reset event is issued to the device allowing to limit the maximum warm reset load jump to roughly half of the total dynamic IDD (IDDRAIL minus IDDPORST) current. It needs to be ensured that the VEXT, VDDP3 and VDD supply voltages are above the minimum operational voltage limits during the total reset phase of 180  $\mu$ s after warm reset request not to trigger a cold power-fail reset. Larger overshoots are tolerable during and after reset phase for a certain cumulated time but must be limited to operational and absolute maximum voltage ratings as documented in the datasheet.

Load jump events caused by asynchronous failure events like PLL loss of lock or external oscillator watchdog event may lead to overshoots which cannot be sequenced owing to the inherent nature of failure.

#### Handling simultaneous load jump requests triggered by Software

Software triggered Load Jump events include ramping up / down of various system clock frequencies, activating additional CPUs, Power mode transitions, CPU throttling and idle requests, MTU Memory tests, LBIST tests and so forth.

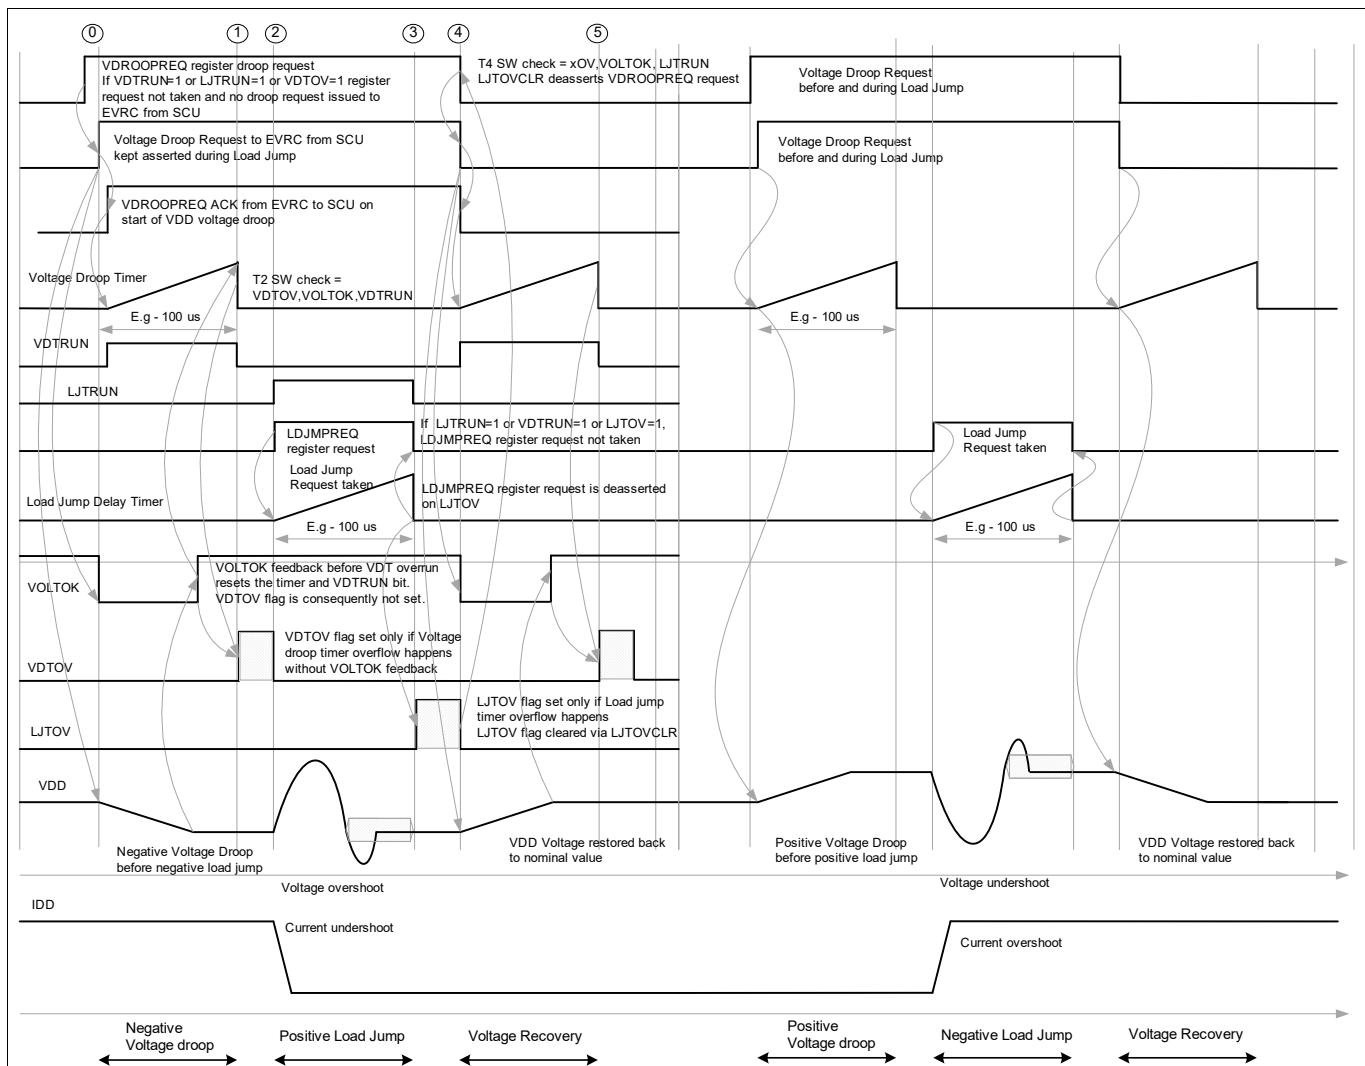

## Power Management System (PMS)

In case of software triggered events, it is possible to prepare by lowering or raising the voltage setpoint before the load jump is issued. A negative voltage droop may be done before a negative load jump and a positive voltage droop before a positive load jump respectively. Thus negative load jumps leading to voltage overshoots is compensated partly by the negative voltage droop and likewise positive load jumps leading to voltage undershoots is compensated partly by the positive voltage droop as shown in [Figure 121](#). The voltage droop is configured through SCU\_PMTCSR0.SDSTEP register bits. The voltage droop in positive or negative direction is issued via SCU\_PMTCSR3.VDROOPREQ register bits. In case a current Vdroop request is not active or the Voltage Droop Timer is not currently running indicated via SCU\_PMTCSR3.VDTRUN or the Load Jump Timer is not currently running indicated via SCU\_PMTCSR2.LJTRUN, a new Vdroop request is taken. Once a new voltage droop request is issued, **EVRSTAT**.SDVOK is reset and TC3xx need to wait for a certain time till the regulator has settled on the new value which is realized using a Voltage Droop Timer. Once the regulator has settled on the new value, **EVRSTAT**.SDVOK status bit is set again indicating the end of the Voltage Droop transition and SCU\_PMTCSR3.VDTRUN and SCU\_PMTCSR3.VDTCNT is reset by hardware. If SDVOK status bit is set by EVRC before compare match of VDT has occurred, VDTOV overflow bit is not set and overrun interrupt is not generated. The Voltage Droop Timer compare value is configured in SCU\_PMTCSR1.VDTCV register bits and the current value is indicated in SCU\_PMTCSR3.VDTCNT register bits. In case of a compare match, the overflow SCU\_PMTCSR3.VDTOV bit is set if enabled via SCU\_PMTCSR0.VDTOVEN register bits. In this case, overflow bit has to be explicitly cleared via SCU\_PMTCSR3.VDTOVCLR before a new request can be taken to support a sequential polling based approach. Furthermore, interrupt maybe activated on an overflow if SCU\_PMTCSR0.VDTOVIEN is enabled.

Simultaneous software triggered load jump events can be likewise avoided by checking whether a Load Jump is ongoing or the Load Jump Timer is currently running. The Load Jump Request is issued by triggering a compare and swap operation on SCU\_PMTCSR2 register. A CPU will access data from SCU\_PMTCSR2 register and will compare the current value with an expected value. The expected value is that there is no load jump currently ongoing and VDTRUN bit state is 0. If there is a match, the CPU will make the swap by setting SCU\_PMTCSR2.LDJMPREQ variable and starting the timer. Obviously if multiple CPUs are making this operation simultaneously only one CPU will succeed and others will fail the compare and swap operation when the Load Jump Timer would be running. The idea is to prevent multiple CPUs from doing load jumps simultaneously by treating Load Jump as a critical section and ensuring that only a single CPU can check and issue a load jump request atomically. Once a load jump request is taken, a timer is started and other CPUs have to wait till the regulator output has been restored to the setpoint value and ensures adequate regulator reaction time. The other CPUs are not blocked during the waiting period instead they can continue with some other operations or try to make the request again at a later point of time.

Thus negative load jumps and positive load jumps are followed by a blanking period using a Load Jump Timer as shown in [Figure 121](#). The Load Jump Timer is configured through SCU\_PMTCSR0 register. The load jump request is issued via SCU\_PMTCSR2.LDJMPREQ register bits. If a current Load Jump request is not active or the Load Jump Timer is not currently running indicated via SCU\_PMTCSR2.LJTRUN or the Voltage Droop Timer is not currently running indicated via SCU\_PMTCSR3.VDTRUN, a new Load Jump request is taken. Once a new Load Jump request is issued, the device needs to wait for a certain time till the regulator has reacted to the jump which is realized using a Load Jump Timer. The Load Jump Timer compare value is configured in SCU\_PMTCSR1.LJTCV register bits and the current value is indicated in SCU\_PMTCSR2.LJTCNT register bits. In case of a compare match, the overflow SCU\_PMTCSR2.LJTOV bit is set if enabled via SCU\_PMTCSR0.LJTOVEN register bits. In this case, overflow bit has to be explicitly cleared via SCU\_PMTCSR2.LJTOVCLR before a new request can be taken to support a sequential polling based approach. Furthermore, an interrupt maybe activated on an overflow if SCU\_PMTCSR0.LJTOVIEN is enabled. Overflow bit is routed to an OS interrupt to schedule the next current jump. Overflow bit maybe masked or used in the compare and swap operation if SCU\_PMTCSR0.LJTOVEN is set to ensure that explicit clear of the time out has happened before issuing a new request. SCU\_PMTCSR2.LJTOVCLR also clears SCU\_PMTCSR3.VDROOPREQ and SCU\_PMTCSR2.LDJMPREQ request.

**Power Management System (PMS)**

### 11.2.3.6 Core Die Temperature Sensor (DTSC)

The Core Die Temperature Sensor (DTSC) generates a measurement result that indicates directly the current temperature. The DTSC measures the temperature with an accuracy within ( $T_{NL} + T_{CALACC}$ ) parameter limits within the TSR temperature range documented in the datasheet. The result of the measurement is updated periodically in DTSCSTAT.RESULT register bit field with a resolution less than 1/5th of a degree Kelvin. The Die Temperature Sensor is available after an application reset release on a device start-up and temperature measurements are carried out continuously during normal RUN / SLEEP modes once DTSC is enabled. The Die Temperature Sensor and DTSLIM and DTSCSTAT registers are reset on an application reset.

The DTSC is enabled via DTSLIM.DTSEN register bitfield. The DTS start-up is completed after a nominal 20us delay after DTSLIM.DTSEN is set. After an ongoing temperature measurement is completed, DTSCSTAT.RESULT bit field is updated coherently with the new value. An interrupt service request (SRC\_SCUERU3) can be generated after a measurement is completed. DTS bandgap status is reflected in DTSLIM.BGPOK status flag. The DTS accuracy and measurement time is defined in the Data Sheet. The DTSLIM register shall be updated before enabling DTSC via DTSLIM.DTSEN register bitfield.

Die temperature upper and lower limits are configured in DTSLIM.UPPER and LOWER register bits. On violation of these limits, DTSLIM.UOF and LLU status bits are set and alarms are forwarded to core SMU. After start-up or application reset, the DTSC limits have to be re-configured appropriately depending on the application before alarm reactions from SMU are activated. Only when a new DTSC conversion result is available, the DTSC comparators are consequently triggered to check the actual DTSCSTAT.RESULT against the upper and lower limits.

DTSCCON and DTSCBGOCTRL register can be also changed after DTSC is enabled on the fly for test purposes.

## Power Management System (PMS)

### 11.3.1.1 Safety Flip-Flops

Safety flip-flops are special flip-flops that implement a hardware mechanism capable to detect single event effects that may lead to single event upsets (bit flip). The configuration and control registers that are implemented with safety flip-flops are:

- **EVRRSTCON**
- **EVRTRIM**
- **EVRMONCTRL**
- **EVRMONFILT**
- **EVRUVMON**
- **EVROVMON**
- **EVRUVMON2**
- **EVROVMON2**
- **HSMUVMON**
- **HSMOVMON**
- **EVROSCCTRL**
- **EVRSDCTRL0**
- **EVRSDCTRL1**
- **EVRSDCTRL2**
- **EVRSDCTRL3**
- **EVRSDCTRL4**
- **EVRSDCTRL5**
- **EVRSDCTRL6**
- **EVRSDCTRL7**
- **EVRSDCTRL8**
- **EVRSDCTRL9**
- **EVRSDCTRL10**
- **EVRSDCTRL11**
- **EVRSDCOEFF0**
- **EVRSDCOEFF1**
- **EVRSDCOEFF2**
- **EVRSDCOEFF3**
- **EVRSDCOEFF4**
- **EVRSDCOEFF5**

## Power Management System (PMS)

### 11.3.1.2 Power Supply Generation and Monitoring Control Registers

This section describes the kernel registers of the PMS module. Most of PMS kernel register names described in this section will be referenced in other parts of the Target Specification by the module name prefix “PMS\_”. All PMS registers are placed in the VDDPD Pre-Regulator domain. After a cold PORST, these registers may return the default isolation value or the updated value by the Firmware. Otherwise, a read will provide the value of the most recent write operation. In PMS subsystem some registers are reset with cold PORST which encompasses predominantly registers with EVR power generation and primary and secondary monitoring functions. This ensures that certain registers are not erroneously updated and the system does not end up in permanent reset situation. The registers covering standby and infrastructure functions however are reset with the EVR LVD (Low Voltage Detector Reset) master reset.

Tricore atomic instructions (LDMST, ST.T, SWAP.W, SWAPMASK.W, CMPSWAP.W) only write back bits that are changing their level. This leads to the fact that bits that are already set cannot be written with a 1 when using RMW instructions. No problem exists when using direct write instructions (e.g. ST.W). This affects the status bits in register DTSIM.LLU and UOF bits which are cleared by writing 1s.

#### Identification Register

<b>ID</b>															
<b>Identification Register</b>															
<b>(0008<sub>H</sub>) Application Reset Value: 00E8 C001<sub>H</sub></b>															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
<b>MODNUMBER</b>															
r															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
<b>MODTYPE</b>								<b>MODREV</b>							
r								r							

Field	Bits	Type	Description
<b>MODREV</b>	7:0	r	<b>Module Revision Number</b> This bit field indicates the revision number of the PMS module.
<b>MODTYPE</b>	15:8	r	<b>Module Type</b> This bit field is fixed coded as C0 <sub>H</sub> . It defines a 32-bit module.
<b>MODNUMBER</b>	31:16	r	<b>Module Number</b> This bit field defines the module identification number. The identification number for the PMS is 00E8 <sub>H</sub> .

#### EVR Status Register

The status registers EVRSTAT, EVRADCSTAT, EVRMONSTAT1, EVRMONSTAT2 and EVRSDSTAT0 are updated during Start-up and after every EVRx closed loop cycle with the actual status and therefore the read value may differ from the reset value. The over-voltage and under-voltage event flag signals are reported to SMU.EMM unit. An alarm for the upper and lower bound is supported in the SMU.EMM unit.

## Power Management System (PMS)

Field	Bits	Type	Description
EVRC	0	rh	<b>EVRC status</b> This bit is set if the internal EVRC regulator is currently active. EVRC is activated if HWCFG[2] pin level is latched high during start-up phase. 0 <sub>B</sub> EVRC is inactive. 1 <sub>B</sub> EVRC is active.
OVC	1	rh	<b>VDD Over-voltage event flag</b> This bit is set if VDD secondary voltage monitor recognizes a over-voltage event. An alarm is raised to the SMU and the status bit remains set until violation disappears. 0 <sub>B</sub> No Over-voltage condition or event active. 1 <sub>B</sub> VDD Over-voltage condition event indication as configured in EVROVMON / EVRMONCTRL register.
EVR33	2	rh	<b>EVR33 status</b> This bit is set if the internal EVR33 LDO regulator is active. EVR33 is activated if HWCFG[1] pin level is latched high during start-up phase. 0 <sub>B</sub> EVR33 is inactive. 1 <sub>B</sub> EVR33 is active.
OV33	3	rh	<b>VDDP3 Over-voltage event flag</b> This bit is set if VDDP3 secondary voltage monitor recognizes a over-voltage event. An alarm is raised to the SMU and the status bit remains set until violation disappears. 0 <sub>B</sub> No over-voltage condition or event active. 1 <sub>B</sub> VDDP3 Over-voltage event indication as configured in EVROVMON / EVRMONCTRL register.
OVSWD	4	rh	<b>VEXT Over-voltage event flag</b> This bit is set if VEXT secondary voltage monitor recognizes an over-voltage event. An alarm is raised to the SMU and the status bit remains set until violation disappears. 0 <sub>B</sub> No over-voltage condition or event active. 1 <sub>B</sub> VEXT Over-voltage event indication as configured in EVROVMON / EVRMONCTRL register.

## Power Management System (PMS)

Field	Bits	Type	Description
<b>UVC</b>	5	rh	<p><b>VDD Under-voltage event flag</b></p> <p>This bit is set if VDD secondary voltage monitor recognizes a under-voltage event. An alarm is raised to the SMU and the status bit remains set until violation disappears.</p> <p>0<sub>B</sub> No under-voltage condition or event active. 1<sub>B</sub> VDD Under-voltage event indication as configured in EVRUVMON / EVRMONCTRL register.</p>
<b>UV33</b>	6	rh	<p><b>VDDP3 Under-voltage event flag</b></p> <p>This bit is set if VDDP3 secondary voltage monitor recognizes a under-voltage event. An alarm is raised to the SMU and the status bit remains set until violation disappears.</p> <p>0<sub>B</sub> No under-voltage condition or event active. 1<sub>B</sub> VDDP3 Under-voltage event indication as configured in EVRUVMON / EVRMONCTRL register.</p>
<b>UVSWD</b>	7	rh	<p><b>VEXT Under-voltage event flag</b></p> <p>This bit is set if VEXT secondary voltage monitor recognizes an under-voltage event. An alarm is raised to the SMU and the status bit remains set until violation disappears.</p> <p>0<sub>B</sub> No under-voltage condition or event active. 1<sub>B</sub> VEXT Under-voltage event indication as configured in EVRUVMON / EVRMONCTRL register.</p>
<b>SYNCLCK</b>	8	rh	<p><b>EVRC Synchronization Input Locked status(sd_sync_in_locked_o)</b></p> <p>This bitfield indicates the current synchronization status of EVRC SMPS regulator to external DCDCSYNCI input signal. When the EVRC switching frequency/ edge is locked to the synchronization input, the SYNCLCK bit is set to HIGH indicating the locked state. When the synchronization is lost owing to frequency deviations beyond MAXDEV or the feature is disabled via SYNCEN, the SYNCLCK bit is set to LOW.</p> <p>This EVRC Synchronization status is indicated in EVRSDSTAT0.SYNCLCK status bits.</p> <p>0<sub>B</sub> EVRC regulator runs on internal configured switching frequency and is not currently synchronized to external DCDCSYNCI input signal. 1<sub>B</sub> EVRC regulator switching frequency and VGATE output edge is currently synchronized to external DCDCSYNCI input signal.</p>
<b>EVR33VOK</b>	9	rh	<p><b>EVR33 Regulator Voltage OK status</b></p> <p>This bit is set after the soft ramp-up time of the EVR33 voltage OK ramp detector has elapsed and is not based on the measured VDDP3 voltage at the end of ramp-phase..</p> <p>0<sub>B</sub> EVR33 ramp-up time has not elapsed. 1<sub>B</sub> EVR33 ramp-up time has elapsed.</p>
<b>RSTC</b>	13	rh	<p><b>EVRC Reset Trigger</b></p> <p>0<sub>B</sub> No cold reset trigger signal is active after spike filter and core VDD voltage output is above the selected reset trim value. 1<sub>B</sub> A cold reset trigger signal is active after spike filter and core VDD voltage output is below the selected reset trim value.</p>

## Power Management System (PMS)

Field	Bits	Type	Description
<b>RST33</b>	14	rh	<b>EVR33 Reset Trigger</b> 0 <sub>B</sub> No cold reset trigger signal is active after spike filter and 3.3 V VDDP3 voltage output is above the selected reset trim value. 1 <sub>B</sub> A cold reset trigger signal is active after spike filter and 3.3 V VDDP3 voltage output is below the selected reset trim value.
<b>RSTSVD</b>	15	rh	<b>EVR SWD Reset Trigger</b> 0 <sub>B</sub> No cold reset trigger signal is active after spike filter and VEXT voltage input is above the selected reset trim value. 1 <sub>B</sub> A cold reset trigger signal is active after spike filter and VEXT voltage input is below the selected reset trim value.
<b>EVRCSHLV</b>	16	rh	<b>Short to ground</b> This bit is set if a short condition to ground has been detected. The measured EVRC output is below the operational supply range and the upper controller limits are reached. The feature is supported only during closed loop operation or EVRCMOD = 00b. 0 <sub>B</sub> No short to ground detected on VDD rail. 1 <sub>B</sub> Short to ground detected on VDD rail.
<b>EVRCSHHV</b>	17	rh	<b>Short to supply</b> This bit is set if a short condition to supply has been detected. The measured EVRC output exceeds the allowed supply range and the lower controller limits are reached. The feature is supported only during closed loop operation or EVRCMOD = 00b. 0 <sub>B</sub> No short to supply detected on VDD rail. 1 <sub>B</sub> Short to supply detected on VDD rail.
<b>EVR33SHLV</b>	18	rh	<b>Short to ground</b> This bit is set if a short condition to ground has been detected. The measured EVR33 output is below the operational supply range and the lower gate drive threshold voltage driving P ch. MOSFET is reached. 0 <sub>B</sub> No short to ground detected on VDDP3 rail. 1 <sub>B</sub> Short to ground detected on VDDP3 rail.
<b>EVR33SHHV</b>	19	rh	<b>Short to supply</b> This bit is set if a short condition to supply has been detected. The measured EVR33 output exceeds the allowed supply range and the upper gate drive threshold voltage driving P ch. MOSFET is reached. 0 <sub>B</sub> No short to supply detected on VDDP3 rail. 1 <sub>B</sub> Short to supply detected on VDDP3 rail.
<b>SWDLVL</b>	20	rh	<b>VEXT External Supply Level Status</b> This bit indicates that the VEXT voltage has dropped below ~4 V to indicate EVRC parameter switch to differentiate 5V or 3.3V external supply. A hysteresis of ~120 mV is implemented on this detector. 0 <sub>B</sub> VEXT external supply is above the threshold. 1 <sub>B</sub> VEXT external supply is below the threshold.

## Power Management System (PMS)

Field	Bits	Type	Description
<b>SDVOK</b>	21	rh	<p><b>EVRC Regulator Voltage OK status</b></p> <p>This bit is set by the EVRC voltage OK detector to indicate that the new regulator output value has been reached. This bit is reset incase EVRTRIM, SDVOUTSEL or SDVOUTTRIM values are adapted to scale core voltage and is set when the new output setpoint is reached. This bit is also reset incase droop compensation is requested before a load jump event. A time out period of x us shall be waited when polling SDVOK bit.</p> <ul style="list-style-type: none"> <li><math>0_B</math> EVRC regulator setpoint voltage has not been reached.</li> <li><math>1_B</math> EVRC regulator setpoint voltage is reached and VDD voltage is ok.</li> </ul>

### EVR Secondary Monitor Control Register

The default setting after reset is that over-voltage indication is notified via an SMU alarm when the over-voltage threshold is crossed in a lower to higher voltage transition. Overvoltage monitors use greater than equal compare if xOVMOD=01b or 11b and less than equal compare if xOVMOD=10b

The default setting after reset is that under-voltage indication is notified via an SMU alarm when the under-voltage threshold is crossed in a higher to lower voltage transition. Under voltage monitors use greater than equal compare if xUVMOD=01b and less than equal compare if xUVMOD=10b or 11b

It can be configured in EVRMONCTRL register to generate an interrupt when the over- under-voltage thresholds are crossed in either direction. This may be used to notify when the violation condition disappears with respect

## Power Management System (PMS)

to secondary voltage monitoring. Interrupt is generated on low to high transition of the EVRSTAT monitoring bits incase of xOVMOD=01b or 10b and interrupt is generated on any transition incase of xOVMOD=11b.

### EVR Secondary Monitor Filter Register

The assertion of alarm takes place when xFIL consecutive values are violating the threshold. Incase one of the values is not violating the threshold , the spike filter is reset. For renewed assertion of the alarm to take place, a repeated set of xFIL consecutive values violating the threshold are required.

#### EVRMONFILT

## Power Management System (PMS)

### EVR Secondary Under-voltage Monitor Register

A programmable threshold with upper and lower voltage bounds can be defined in EVROVMON and EVRUVMON registers for monitoring EVRC and EVR33 regulator outputs. Gain and Offset corrected thresholds can be evaluated from datasheet VxxMON parameters

#### EVRUVMON

Field	Bits	Type	Description
SDFREQSPRD	15:0	rw	<b>Frequency Spread Threshold(freqsp_coeff_i)</b> This bit field defines the additional frequency spread to the nominal EVRC regulator switching frequency during operation
SDFREQ	27:16	rw	<b>Regulator Switching Frequency or Over-sampling Factor(m0osfl_fact_i+m0osfh_fact_i)</b> This bit field configures the EVRC regulator switching frequency during closed loop operation. The switching frequency is equal to (100 MHz / (SDFREQ+1)) value. SDFREQ represents the corresponding over-sampling factor or clock cycles in a period. 037 <sub>H</sub> 1.82 MHz (100 MHz/(54+1)) SMPS switching frequency 07D <sub>H</sub> 0.8 MHz (100 MHz/(124+1)) SMPS switching frequency
NGOFF	28	rw	<b>NMOS level during OFF state(drvslo_ngoff_i)</b> This bit field configures the state of N ch. MOSFET driver during start-up and shut-down phases. 0 <sub>B</sub> TRISTATE 1 <sub>B</sub> LOW
PGOFF	29	rw	<b>PMOS level during OFF state(drvslo_pgoff_i)</b> This bitfield configures the state of Pch. MOSFET driver during start-up and shut-down phases. 0 <sub>B</sub> HIGH 1 <sub>B</sub> TRISTATE

## Power Management System (PMS)

Field	Bits	Type	Description
UP	30	rwh	<p><b>Update request for SMPS register values</b></p> <p>This bitfield triggers the update of the current register values from PMS-FPI EVRC registers to the local SMPS module registers.</p> <p>It shall be ensured that ALL EVRSDCTRLx and EVRSDCOEFFx registers have correct and coherent values across the various registers before the update request is issued. In case of singular register update, the other register values should match and be consistent. After a cold PORST, the UP bit is set as default reset value to ensure that the complete SMPS regulator parameter set is set back to its reset state. Consequently, the UP bit is reset and a read delivers 0. The parameter update via UP bit is not allowed in start-up and low power mode.</p> <p>0<sub>B</sub> No action is undertaken. 1<sub>B</sub> A new complete EVRC parameter set is transferred to the SMPS module. All EVRSDCTRLx and EVRSDCOEFFx register contents are transferred.</p>
LCK	31	rh	<p><b>Lock Status</b></p> <p>This bit indicates if the register can be updated with a new value or if the register is locked and a write action from the bus side has no effect.</p> <p>0<sub>B</sub> The register is unlocked and can be updated 1<sub>B</sub> The register is locked and cannot be updated</p>

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
<b>SVOTH</b>								<b>SVINTH</b>							
rw								rw							

Field	Bits	Type	Description
<b>SVINTH</b>	7:0	rw	<b>Vin threshold to switch between SINCLO or SINCHI.(svinth_thres_i)</b> This bit field specifies the threshold to decide on the ramp-up increment during startup. If Vin is below the threshold, SINCLO is taken as ramp-up increment, else if Vin is equal or above the threshold, SINCHI is taken as ramp-up increment. The threshold is compared to the FF-ADC counter value, without offset.
<b>SVOTH</b>	15:8	rw	<b>Vout threshold to switch from open loop start-up to closed loop mode.(svoth_thres_i)</b> This bit field specifies the threshold to decide when to switch from open-loop mode to closed-loop mode during startup. If Vout is below the threshold, open-loop ramp up is executed. if Vout is equal or above the threshold, closed-loop PWM in start-up configuration is executed. The threshold is compared to the low pass filtered FB-ADC counter value, without offset. The switch happens only in one direction during startup and the system does not switch back into start-up mode even if threshold is crossed in other direction.
<b>SINCLO</b>	18:16	rw	<b>Increment for low input voltage.(sinc_sinclo_i)</b> This bitfield specifies the increment of the on-time during open-loop ramp-up during startup. If Vin is below the threshold (SVINTH), SINCLO is taken as ramp-up increment. if Vin is equal or above the threshold (SVINTH), SINCHI is taken as ramp-up increment
<b>SINCHI</b>	22:20	rw	<b>Increment for high input voltage.(sinc_sinchi_i)</b> This bitfield specifies the increment of the on-time during open-loop ramp-up during startup. If Vin is below the threshold (SVINTH), SINCLO is taken as ramp-up increment. if Vin is equal or above the threshold (SVINTH), SINCHI is taken as ramp-up increment
<b>LCK</b>	31	rh	<b>Lock Status</b> This bit indicates if the register can be updated with a new value or if the register is locked and a write action from the bus side has no effect. 0 <sub>B</sub> The register is unlocked and can be updated 1 <sub>B</sub> The register is locked and cannot be updated
<b>0</b>	19, 30:23	r	<b>Reserved</b> Read as 0; should be written with 0.

				<b>SCRRS T</b>	<b>SCRW DT</b>	<b>SCREC C</b>	<b>0</b>								<b>SCRINT</b>
r				rwh	rwh	rwh	r				rh				

Field	Bits	Type	Description
<b>SCRINT</b>	7:0	rh	<b>Data exchange from Standby Controller to PMS main domain.</b> This bit field allows fast data exchange from SCR to PMS/CPUx. The data maybe read by CPUx consequent to an interrupt from the SCR to decode the interrupt. Incase SCR is enabled, at the end of the SCR Firmware routine, a value of 80H is set in SCRINT register to indicate that SCR has finished executing the startup code.
<b>SCRECC</b>	9	rwh	<b>SCR RAM ECC error / reset flag</b>  Note: <i>The flag is set by SCR and cleared by explicit write to the register bit. The flag is not cleared by SCR. While the SCR is being reset triggered by SCR RAM ECC error, this flag is set and clearing the flag is not possible for that duration.</i>  0 <sub>B</sub> No ECC error / reset reported by SCR. 1 <sub>B</sub> ECC error / reset was detected in SCR RAM.
<b>SCRWDT</b>	10	rwh	<b>SCR Watchdog Timer error / reset flag</b>  Note: <i>The flag is set by SCR and cleared by explicit write to the register bit. The flag is not cleared by SCR. While the SCR is being reset triggered by SCR watchdog, this flag is set and clearing the flag is not possible for that duration.</i>  0 <sub>B</sub> No WDT error / reset reported by SCR. 1 <sub>B</sub> WDT timer error / reset reported by SCR.
<b>SCRRST</b>	11	rwh	<b>SCR Software reset flag</b>  Note: <i>The flag is set by SCR and cleared by explicit write to the register bit. The flag is not cleared by SCR. While the SCR is being reset triggered by SCR software, this flag is set and clearing the flag is not possible for that duration.</i>  0 <sub>B</sub> No reset occurred in SCR. 1 <sub>B</sub> A reset has occurred in SCR.

## Power Management System (PMS)

Field	Bits	Type	Description
<b>TCINT</b>	23:16	rw	<b>Data exchange from PMS main domain to Standby Controller.</b> This bit field allows fast data exchange from PMS to SCR. The data may be read by SCR consequent to an interrupt request (TCINTREQ) from PMS/CPUx to SCR to decode the interrupt.
<b>TCINTREQ</b>	24	rwh	<b>SW Interrupt request from PMS to Standby Controller.</b> Setting this bit triggers an interrupt to the 8 bit Standby controller.
<b>SMURST</b>	25	rh	<b>SMU Reset indication flag</b> $0_B$ No reset was issued by SMU. $1_B$ SMU issued an application or system reset.
<b>RST</b>	26	rh	<b>Application or System Reset indication flag</b> $0_B$ No application or system reset occurred. $1_B$ An application or system reset has occurred.

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
<b>WUTREL</b>															
rw															

Field	Bits	Type	Description
<b>WUTREL</b>	23:0	rw	<b>WUT reload value.</b> The counter starts counting down from WUTREL value. The current value of counter is indicated in WUTCNT. On WUTCNT underflow, a reload WUTCNT = WUTREL takes place in auto reload mode.
<b>WUTEN</b>	27	rw	<b>WUT enable</b> This bit enables the Wake-up Timer. The status bit PMSWSTAT.WUTEN is set once Wake-up Timer is enabled. $0_B$ Wake-up timer (WUT) disable request $1_B$ Wake-up timer (WUT) enable request.

## Power Management System (PMS)

Field	Bits	Type	Description
<b>BUSY</b>	28	rh	<b>Lock Status - LCK</b> This bit indicates that the register is busy owing to ongoing bus access. The register can be updated with a new value when BUSY bit is cleared. The register requires synchronization to the 70kHz clock domain on a register update. 0 <sub>B</sub> The register can be updated. 1 <sub>B</sub> The register update is ongoing. A write action may stall bus access for the time duration BUSY bit is set.
<b>WUTDIV</b>	29	rw	<b>WUT clock divider</b> A write to this register bitfield may trigger immediate update irrespective of the status of BUSY bit. 0 <sub>B</sub> Wake-up timer (WUT) clock = fSB = 70 KHz clock. 1 <sub>B</sub> Wake-up timer (WUT) clock = fSB (70 KHz) / 210.
<b>WUTMODE</b>	30	rw	<b>WUT mode selection</b> This bit configures the Wake-up Timer mode. The status bit PMSWSTAT.WUTMODE is respectively updated. A write to this register bitfield may trigger immediate update irrespective of the status of BUSY bit. 0 <sub>B</sub> Wake-up timer (WUT) auto reload mode selected 1 <sub>B</sub> Wake-up timer (WUT) auto stop mode selected.
<b>0</b>	26:24, 31	r	<b>Reserved</b> Read as 0; should be written with 0.

### Standby WUT Counter Register

**PMSWUTCNT****Standby WUT Counter Register****(00DC<sub>H</sub>)****LVD Reset Value: 0000 0000<sub>H</sub>**

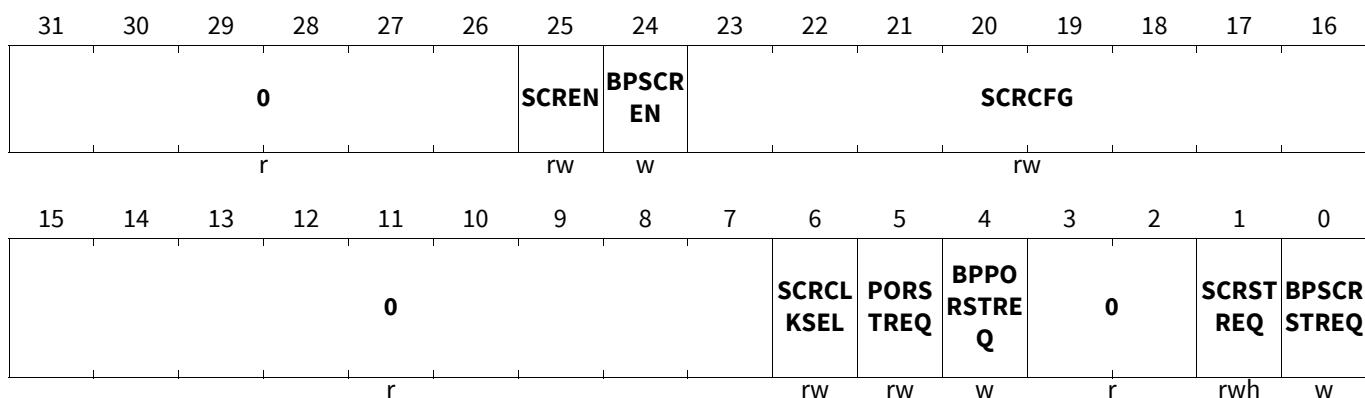

Field	Bits	Type	Description
<b>WUTCNT</b>	23:0	rh	<b>WUT counter value.</b> The current WUT counter value is indicated in this register bitfield. The WUTCNT value may have a deviation of 3 additional clock cycles to the expected counter value owing to synchronization overheads. The WUT clock is based on standby 70 kHz clock with ~ + - 30% variation. The counter depending on the mode can run through a RUN to STANDBY to RUN mode transition without interruption.
<b>0</b>	31:24	r	<b>Reserved</b> Read as 0; should be written with 0.

## Power Management System (PMS)

### Standby and Wake-up Control Register 4

#### PMSWCR4

#### Standby and Wake-up Control Register 4

(00C4<sub>H</sub>)Reset Value: [Table 373](#)

Field	Bits	Type	Description
<b>BPSCRSTREQ</b>	0	w	<b>Standby Controller Reset request enable - SCRSTEN</b> $0_B$ Bit SCRSTREQ is not updated $1_B$ Bit SCRSTREQ can be updated
<b>SCRSTREQ</b>	1	rwh	<b>Standby Controller Reset request</b> $0_B$ No request for main reset of the 8 bit Standby Controller. $(evr\_scr\_rst\_req\_i)$ $1_B$ 8 bit Standby Controller reset request.
<b>BPPORSTREQ</b>	4	w	<b>Bit Protection for PORSTREQ - PORSTEN</b> $0_B$ Bit PORSTREQ is not updated $1_B$ Bit PORSTREQ can be updated
<b>PORSTREQ</b>	5	rw	<b>SCR Reset behavior on warm PORST in Normal RUN / SLEEP mode</b> $0_B$ 8 bit Standby Controller is not reset when warm PORST pin is asserted. $1_B$ 8 bit Standby Controller is reset when warm PORST pin is asserted. warm PORST usage in normal and standby mode.
<b>SCRCLKSEL</b>	6	rw	<b>Default Clock selection on Standby Mode Entry</b> $0_B$ 100MHz oscillator can be enabled or disabled based on request from Standby Controller. By default 100 MHz Oscillator is requested by SCR in Standby Mode. $1_B$ 100MHz oscillator is always active irrespective of SCR requests. Thus both 70 KHz Oscillator and 100 MHz oscillator are active in Standby Mode.

## Power Management System (PMS)

Field	Bits	Type	Description
<b>SCRCFG</b>	23:16	rw	<p><b>Hardware configuration of the 8 bit SCR controller.</b></p> <p><b>Note:</b> Any change in SCRCFG is followed by a SCRSTREQ reset request of the 8 bit controller to start off in the chosen mode. ## Power Management System (PMS)

**Table 373 Reset Values of PMSWCR4**

Reset Type	Reset Value	Note
LVD Reset	0000 0020 <sub>H</sub>	
After SSW execution	0200 0020 <sub>H</sub>	The Reset Value is updated by SSW only after cold power-on reset and not after warm resets. SCR is initialized/started upon cold power-on reset which is not identified as exit from stand-by mode.

### Standby and Wake-up Control Register 5

Additional PORST digital filter activated via PORSTDF bit provides additional spike filtering of at least tPORSTDF duration to provide enhanced immunity against spurious spikes. This is in addition to the inherent analog PORST filter delay of the PORST pad / pin as documented in the datasheet. After cold PORST this delay is by default inactive.

## Power Management System (PMS)

Field	Bits	Type	Description
<b>ESR0WKP</b>	0	rh	<b>ESR0 Wake-up flag</b> In case wake-up was triggered by ESR0 pin during STANDBY, this flag is set. The bit shall be cleared explicitly after wakeup via PMSWSTATCLR.ESR0WKPCR bit before next STANDBY entry. 0 <sub>B</sub> No wake-up event detected on ESR0 input during STANDBY. 1 <sub>B</sub> An event as defined by PMSWCR0. ESR0EDCON detected on ESR0 input.
<b>ESR1WKP</b>	1	rh	<b>ESR1 Wake-up flag</b> In case wake-up was triggered by ESR1 pin during STANDBY, this flag is set. The bit shall be cleared explicitly after wakeup via PMSWSTATCLR.ESR1WKPCR bit before next STANDBY entry. 0 <sub>B</sub> No wake-up event detected on ESR1 input during STANDBY. 1 <sub>B</sub> An event as defined by PMSWCR0. ESR1EDCON detected on ESR1 input.
<b>PINAWKP</b>	2	rh	<b>Pin Wake-up flag</b> In case wake-up was triggered by PINA pin during STANDBY, this flag is set. The bit shall be cleared explicitly after wakeup via PMSWSTATCLR.PINAWKPCR bit before next STANDBY entry. 0 <sub>B</sub> No wake-up event detected on Pin A input during STANDBY. 1 <sub>B</sub> An event as defined by PMSWCR0. PINAEDCON detected on Pin A input.
<b>PINBWKP</b>	3	rh	<b>Pin B Wake-up flag</b> In case wake-up was triggered by PINB pin during STANDBY, this flag is set. The bit shall be cleared explicitly after wakeup via PMSWSTATCLR.PINBKPCR bit before next STANDBY entry. 0 <sub>B</sub> No wake-up event occurred on the Pin B input during STANDBY. 1 <sub>B</sub> An event as defined by PMSWCR0. PINBEDCON detected on Pin B input.
<b>PWRWKP</b>	4	rh	<b>Wake-up event on VEXT Supply ramp-up</b> In case wake-up was triggered by VEXT ramp-up pin during STANDBY, this flag is set. The bit shall be cleared explicitly after wakeup via PMSWSTATCLR.PWRWKPCR bit before next STANDBY entry. 0 <sub>B</sub> No VEXT supply wake-up event detected. 1 <sub>B</sub> VEXT Monitor threshold exceeded on VEXT supply ramp-up leading to System Wake-up from STANDBY.
<b>SCRWKP</b>	5	rh	<b>SCR Wake-up flag</b> In case wake-up is triggered by SCR to the main controller during STANDBY, this flag is set. The bit shall be cleared explicitly after wakeup via PMSWSTATCLR.SCRWKPCR bit before next STANDBY entry. 0 <sub>B</sub> No SCR wake-up event detected. 1 <sub>B</sub> A SCR wake-up event occurred.

## Power Management System (PMS)

Field	Bits	Type	Description
<b>PORSTWKP</b>	6	rh	<b>PORST Wake-up flag</b> In case wake-up was triggered by PORST pin during STANDBY, this flag is set. The bit shall be cleared explicitly after wakeup via PMSWSTATCLR.PORSTWKPCR bit before next STANDBY entry. 0 <sub>B</sub> No wake-up event detected on PORST input during STANDBY if enabled via PMSWCR0.PORSTWKEN bit. 1 <sub>B</sub> A wake-up event detected on PORST input if enabled via PMSWCR0.PORSTWKEN bit.
<b>WUTWKP</b>	7	rh	<b>WUT Wake-up flag</b> In case wake-up was triggered by Wake-up timer during STANDBY, this flag is set. The bit shall be cleared explicitly after wakeup via PMSWSTATCLR.WUTWKPCR bit before next STANDBY entry. 0 <sub>B</sub> No wake-up event detected due to WUT underflow. 1 <sub>B</sub> A wake-up event from STANDBY was detected due to WUT underflow.
<b>ESR0OVRUN</b>	8	rh	<b>ESR0 Overrun status flag</b> This flag indicates that a consecutive ESR0 wake-up event occurred while ESR0WKP flag was already set during STANDBY. The bit shall be cleared explicitly after wakeup via PMSWSTATCLR.ESR0OVRUNCLR bit before next STANDBY entry. 0 <sub>B</sub> No overrun condition detected on ESR0 input. 1 <sub>B</sub> An overrun condition detected on ESR0 input.
<b>ESR1OVRUN</b>	9	rh	<b>ESR1 Overrun status flag</b> This flag indicates that a consecutive ESR1 wake-up event occurred while ESR1WKP flag was already set during STANDBY. The bit shall be cleared explicitly after wakeup via PMSWSTATCLR.ESR1OVRUNCLR bit before next STANDBY entry. 0 <sub>B</sub> No overrun condition detected on ESR1 input. 1 <sub>B</sub> An overrun condition detected on ESR1 input.
<b>PINAOVRUN</b>	10	rh	<b>Pin A Overrun status flag</b> This flag indicates that a consecutive PINA wake-up event occurred while PINAWKP flag was already set during STANDBY. The bit shall be cleared explicitly after wakeup via PMSWSTATCLR.PINAOVRUNCLR bit before next STANDBY entry. 0 <sub>B</sub> No overrun condition detected on Pin A input. 1 <sub>B</sub> An overrun condition detected on Pin A input.
<b>PINBOVRUN</b>	11	rh	<b>Pin B Overrun status flag</b> This flag indicates that a consecutive PINB wake-up event occurred while PINBWKP flag was already set during STANDBY. The bit shall be cleared explicitly after wakeup via PMSWSTATCLR.PINBOVRUNCLR bit before next STANDBY entry. 0 <sub>B</sub> No overrun condition detected on Pin B input. 1 <sub>B</sub> An overrun condition detected on Pin B input.

## Power Management System (PMS)

Field	Bits	Type	Description
<b>VDDSTBYEN</b>	12	rh	<p><b>Standby Entry Enable status on VDD Supply ramp-down - VDDSTBYWKEN</b></p> <p>This bit indicates that Standby Entry may be triggered on a VDD Supply undervoltage event (VDDUV). This is supported only when Standby domain is supplied separately by VEVRSB Standby supply pin. This bit is updated when PMSWCRO.VDDSTBYWKEN bit is updated.</p> <p>0<sub>B</sub> 0 Standby Entry on VDD supply ramp-down is disabled. 1<sub>B</sub> 1 Standby Entry is enabled on a VDD Supply undervoltage event (SWDUV). Blanking filter active on Standby mode entry.</p>
<b>SCROVRUN</b>	13	rh	<p><b>SCR Overrun status flag</b></p> <p>This flag indicates that a consecutive SCR wake-up event occurred while SCRWKP flag was already set during STANDBY. The bit shall be cleared explicitly after wakeup via PMSWSTATCLR.SCROVRUNCLR bit before next STANDBY entry.</p> <p>0<sub>B</sub> No overrun condition detected of SCR wake-up event. 1<sub>B</sub> An overrun condition detected of SCR wake-up event.</p>
<b>PORSTOVRUN</b>	14	rh	<p><b>PORST Overrun status flag</b></p> <p>This flag indicates that a consecutive PORST wake-up event occurred while PORSTWKP flag was already set during STANDBY. The bit shall be cleared explicitly after wakeup via PMSWSTATCLR.PORSTOVRUNCLR bit before next STANDBY entry.</p> <p>0<sub>B</sub> No overrun condition detected on PORST input if enabled via PMSWCRO.PORSTWKEN bit. 1<sub>B</sub> An overrun condition detected on PORST input if enabled via PMSWCRO.PORSTWKEN bit.</p>
<b>WUTOVRUN</b>	15	rh	<p><b>WUT Overrun status flag</b></p> <p>This flag indicates that a consecutive WUT wake-up event occurred while WUTWKP flag was already set during STANDBY. The bit shall be cleared explicitly after wakeup via PMSWSTATCLR.WUTOVRUNCLR bit before next STANDBY entry. WUTREL need to be greater than 10 during Standby mode to be able to latch consecutive WUT underflow events and update the WUTOVRRUN register bitfield.</p> <p>0<sub>B</sub> No overrun condition detected of WUT events. 1<sub>B</sub> An overrun condition detected of WUT events.</p>

## Power Management System (PMS)

Field	Bits	Type	Description																												
<b>STBYRAM</b>	18:16	rh	<p><b>Standby RAM Supply status</b></p> <p>This bit field indicates whether Standby RAM was supplied during Standby Mode and to infer status after a wake-up event. This bit is updated when PMSWCR0.STBYRAMSEL is set.</p> <p><b>Note:</b> <i>All other bit combinations are reserved. In case of VDDPD Standby supply fail or VEVRSB supply fail leading to LVD reset (indicated also in RSTSTAT.STBYR), the STBYRAM status bit is reset to 000<sub>B</sub> to indicate that Standby RAM contents may be corrupted.</i></p> <p>000<sub>B</sub> Standby RAM is not supplied.      001<sub>B</sub> Standby RAM (CPU0 dLMU RAM Lower Half) is supplied.      010<sub>B</sub> Standby RAM (CPU0 dLMU RAM) is supplied.      100<sub>B</sub> Standby RAM (CPU1 dLMU RAM) is supplied.      111<sub>B</sub> Standby RAMs (CPU0 dLMU &amp; CPU1 dLMU) are supplied.</p>																												
<b>VEXTSTBYEN</b>	19	rh	<p><b>Standby Entry Enable status on VEXT Supply ramp-down - VEXTSTBYWKEN</b></p> <p>This bit indicates that Standby Entry may be triggered on a VEXT Supply undervoltage event (SWDUV). ## Power Management System (PMS)

Field	Bits	Type	Description
<b>ESR0WKEN</b>	24	rh	<b>ESR0 Wake-up enable status</b> This bit indicates that ESR0 is enabled to trigger wake-up from Standby. This bit is updated when PMSWCR0.ESR0WKEN bit is updated. $0_B$ Wake-up from Standby via ESR0 is disabled. $1_B$ Wake-up from Standby via ESR0 is enabled.
<b>ESR1WKEN</b>	25	rh	<b>ESR1 Wake-up enable status</b> This bit indicates that ESR1 is enabled to trigger wake-up from Standby. This bit is updated when PMSWCR0.ESR1WKEN bit is updated. $0_B$ Wake-up from Standby via ESR1 is disabled. $1_B$ Wake-up from Standby via ESR1 is enabled.
<b>PINAWKEN</b>	26	rh	<b>Pin A Wake-up enable status</b> This bit indicates that PINA is enabled to trigger wake-up from Standby. This bit is updated when PMSWCR0.PINAWKEN bit is updated. $0_B$ Wake-up from Standby via PINA is disabled. $1_B$ Wake-up from Standby via PINA is enabled.
<b>PINBWKEN</b>	27	rh	<b>Pin B Wake-up enable status</b> This bit indicates that PINB is enabled to trigger wake-up from Standby. This bit is updated when PMSWCR0.PINBWKEN bit is updated. $0_B$ Wake-up from Standby via PINB is disabled. $1_B$ Wake-up from Standby via PINB is enabled.
<b>PWRWKEN</b>	28	rh	<b>Standby Wake-up Enable status on VEXT Supply ramp-up</b> This bit indicates that VEXT detector is enabled to trigger wake-up from Standby during VEXT supply ramp-up after blanking filter time has expired. This is supported only when Standby domain is supplied separately by VEVRSB Standby supply pin. This bit is updated when PMSWCR0.PWRWKEN bit is updated. $0_B$ Wake-up on VEXT supply ramp-down disabled. Blanking filter configuration has no effect. $1_B$ Standby Wake-up on VEXT supply ramp-up is enabled after blanking filter expiry.
<b>SCRWKEN</b>	29	rh	<b>Standby Controller Wake-up Enable status</b> This bit indicates that SCR is enabled to trigger wake-up from Standby. This bit is updated when PMSWCR0.SCRWKEN bit is updated. $0_B$ Wake-up from Standby via SCR is disabled. $1_B$ Wake-up from Standby via SCR is enabled.
<b>PORSTWKEN</b>	30	rh	<b>PORST pin Wake-up enable status from Standby</b> This bit indicates that wake-up via PORST pin is enabled during STANDBY mode. This bit is updated when PMSWCR0. PORSTWKEN bit is updated. $0_B$ System wake-up via PORST pin is disabled. $1_B$ System wake-up via PORST pin is enabled.
<b>WUTWKEN</b>	31	rh	<b>WUT Wake-up enable status</b> This bit indicates that WUT is enabled to trigger wake-up from Standby. This bit is updated when PMSWCR0.WUTWKEN bit is updated. $0_B$ Wake-up from Standby via WUT is disabled. $1_B$ Wake-up from Standby via WUT is enabled.

#### 11.3.2.1 Power Management Control and Status Registers

This section describes the kernel registers of the PMS module in SCU address space. Most of PMS kernel register names described in this section will be referenced in other parts of the Target Specification by the module name prefix “SCU\_”. The set of registers used for Power Management control the issue of power modes, manage wake-up configuration and provide status information on mode transitions and modules. The request for Idle, Sleep or Standby mode is issued via PMCSR<sub>x</sub> registers.

Tricore atomic instructions (LDMST, ST.T, SWAP.W, SWAPMASK.W, CMPSWAP.W) only write back bits that are changing their level. This leads to the fact that bits that are already set cannot be written with a 1 when using RMW instructions. No problem exists when using direct write instructions (e.g. ST.W). This affects the status bits in register DTSCSTAT.LLU, UOF and INT bits which are cleared by writing 1s.

Field	Bits	Type	Description
LOWER	11:0	rw	<b>DTSC Lower Limit</b> This bit field defines the lower limit of the DTSC temperature check. The DTSC measurement result is compared against this value and if the measurement result is less than or equal to the configured LOWER bitfield value; flag LLU is set.

## Power Management System (PMS)

Field	Bits	Type	Description
<b>BGPOK</b>	13	rh	<b>DTSC Bandgap OK</b> This bitfield indicates that the bandgap reference for the Core Die Temperature Sensor (DTSC) is available and ok. 0 <sub>B</sub> DTSC Bandgap is not ok. 1 <sub>B</sub> DTSC Bandgap is ok.
<b>EN</b>	14	rw	<b>DTSC Enable</b> This bitfield enables the Core Die Temperature Sensor (DTSC). The bitfield is reset on an application reset. 0 <sub>B</sub> DTSC is disabled 1 <sub>B</sub> DTSC is enabled
<b>LLU</b>	15	rwh	<b>DTSC Lower Limit Underflow</b> When this bit is set the related SMU DTSC alarm trigger is generated. This bit has to be written with zero in order to clear it. Writing a one has no effect. This bit is set when a DTSC measurement is finished and the result is below the lower limit (i.e. DTSCLIM.LOWER). 0 <sub>B</sub> No temperature underflow was detected 1 <sub>B</sub> A temperature underflow was detected
<b>UPPER</b>	27:16	rw	<b>DTSC Upper Limit</b> This bit field defines the upper limit of the DTSC temperature check. The DTSC measurement result is compared against this value and if the measurement result is greater than or equal to the configured UPPER bitfield value; flag UOF is set.
<b>INTEN</b>	28	rw	<b>DTSC Interrupt Enable</b> This bitfield enables the Core Die Temperature Sensor (DTSC) interrupt. The bitfield is reset on an application reset. 0 <sub>B</sub> DTSC Interrupt is disabled 1 <sub>B</sub> DTSC Interrupt is enabled
<b>INT</b>	30	rwh	<b>DTSC Interrupt status flag</b> This bit is set when SMU DTSC interrupt is generated when a DTSC measurement is finished. This bit is cleared by writing a zero. Writing a one has no effect. 0 <sub>B</sub> No DTSC interrupt is generated 1 <sub>B</sub> DTSC interrupt is generated
<b>UOF</b>	31	rwh	<b>DTSC Upper Limit Overflow</b> When this bit is set, the related SMU DTSC alarm trigger is generated. This bit has to be written with zero in order to clear it. Writing a one has no effect. This bit is set when a DTSC measurement is finished and the result is exceeding the upper limit (i.e. DTSCLIM.UPPER). 0 <sub>B</sub> No temperature overflow was detected 1 <sub>B</sub> A temperature overflow was detected
<b>0</b>	12, 29	r	<b>Reserved</b> Read as 0; should be written with 0.

## Power Management System (PMS)

### Power Management Transition Control and Status Register 0

#### PMTRCSR0

**Power Management Transition Control and Status Register 0(0198<sub>H</sub>)**

**Cold PowerOn Reset Value: 0000**

**0000<sub>H</sub>**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
										<b>VDTCL R</b>	<b>VDTST P</b>	<b>VDTST RT</b>	<b>VDTO VIEN</b>	<b>VDTO VEN</b>	<b>VDTEN</b>
0	LPSLP EN				0					w	rw	rwh	rw	rw	rw

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
										<b>LJTCL R</b>	<b>LJTST P</b>	<b>LJTST RT</b>	<b>LJTOV IEN</b>	<b>LJTOV EN</b>	<b>LJTEN</b>
	SDSTEP					0				w	rw	rwh	rw	rw	rw

Field	Bits	Type	Description
<b>LJTEN</b>	0	rw	<b>Load Jump Timer Enable</b> This bit field enables the usage of load jump timer. 0 <sub>B</sub> Load Jump Timer inactive 1 <sub>B</sub> Load Jump Timer active
<b>LJTOVEN</b>	1	rw	<b>Load Jump Timer Overflow Enable</b> This bit field enables the update of LJTOV status bit on timer overflow or time out. 0 <sub>B</sub> LJTOV bit is not updated on a Load Jump Timer overflow. 1 <sub>B</sub> LJTOV bit is updated on a Load Jump Timer overflow.
<b>LJTOVIEN</b>	2	rw	<b>Load Jump Timer Overflow Interrupt Enable</b> This bit field enables the activation of interrupt on timer overflow or time out. 0 <sub>B</sub> LJTOV interrupt is inactive. 1 <sub>B</sub> LJTOV interrupt is activated on a Load Jump Timer overflow.
<b>LJTSTRT</b>	3	rwh	<b>Load Jump Timer Start</b> This bit field starts Load jump timer. This is intended for test purposes. The LJTSTRT remains set on a write and is cleared when LJTOV bit is set if LJTOVEN bit is enabled. 0 <sub>B</sub> Load Jump Timer status not changed. 1 <sub>B</sub> Load Jump Timer started.
<b>LJTSTP</b>	4	rw	<b>Load Jump Timer Stop</b> This bit field stops Load jump timer. This is intended for test purposes. The LJTSTP remains set on a write and is to be explicitly cleared by software. The LJTSTP stops the counter at the current value and timer re-starts from that value when LJTSTP is cleared and LJTSTRT is set. 0 <sub>B</sub> Load Jump Timer status not changed. 1 <sub>B</sub> Load Jump Timer stopped.

## Power Management System (PMS)

Field	Bits	Type	Description
LJTCLR	5	w	<b>Load Jump Timer Clear</b> This bit field clear Load jump timer count. This is intended for test purposes. This bit resets LJT and clears LJTRUN if LJTEN bit is set. 0 <sub>B</sub> Load Jump Count status not changed. 1 <sub>B</sub> Load Jump Timer Count cleared.
SDSTEP	15:12	rw	<b>Droop Voltage Step(vdroop_step_i)</b> This bit field defines the voltage offset for droop compensation on a load jump to the EVRC setpoint value. The request is made via <b>PMTRCSR3.VDROOPREQ</b> on an anticipated load jump with a voltage offset equal to the SDSTEP x 5 mV. The droop step is a positive offset if VDROOPREQ = 01b and is a negative offset if VDROOPREQ = 10b and no offset is applied if VDROOPREQ = 00b. Maximum Droop = 80 mV.
VDTEN	16	rw	<b>Voltage Droop Timer Enable</b> This bit field enables the usage of Voltage Droop timer. 0 <sub>B</sub> Voltage Droop Timer inactive 1 <sub>B</sub> Voltage Droop Timer active
VDTOVEN	17	rw	<b>Voltage Droop Timer Overflow Enable</b> This bit field enables the update of VDTOV status bit on timer overflow or time out. 0 <sub>B</sub> VDTOV bit is not updated on a Voltage Droop Timer overflow. 1 <sub>B</sub> VDTOV bit is updated on a Voltage Droop Timer overflow.
VDTOVIEN	18	rw	<b>Voltage Droop Timer Overflow Interrupt Enable</b> This bit field enables the activation of interrupt on timer overflow or time out. 0 <sub>B</sub> VDTOV interrupt is inactive. 1 <sub>B</sub> VDTOV interrupt is activated on a Voltage Droop Timer overflow.
VDTSTRT	19	rwh	<b>Voltage Droop Timer Start</b> This bit field starts Voltage Droop timer. This is intended for test purposes. The VDTSTRT remains set on a write and is cleared when VDTOV bit is set if VDTOVEN bit is enabled. 0 <sub>B</sub> Voltage Droop Timer status not changed. 1 <sub>B</sub> Voltage Droop Timer started.
VDTSTP	20	rw	<b>Voltage Droop Timer Stop</b> This bit field stops Voltage Droop timer. SCU cancels the droop request via signal sd_droop_cntr_i = 00. This is intended for test purposes. The VDTSTP remains set on a write and is to be explicitly cleared by software. The VDTSTP stops the counter at the current value and timer re-starts from that value when VDTSTP is cleared and VDTSTRT is set. 0 <sub>B</sub> Voltage Droop Timer status not changed. 1 <sub>B</sub> Voltage Droop Timer stopped.
VDTCLR	21	w	<b>Voltage Droop Timer Clear</b> This bit field clear Voltage Droop timer count. This is intended for test purposes. This bit resets VDT and clears VDTRUN if VDTEN bit is set. 0 <sub>B</sub> Voltage Droop Count status not changed. 1 <sub>B</sub> Voltage Droop Timer Count cleared.

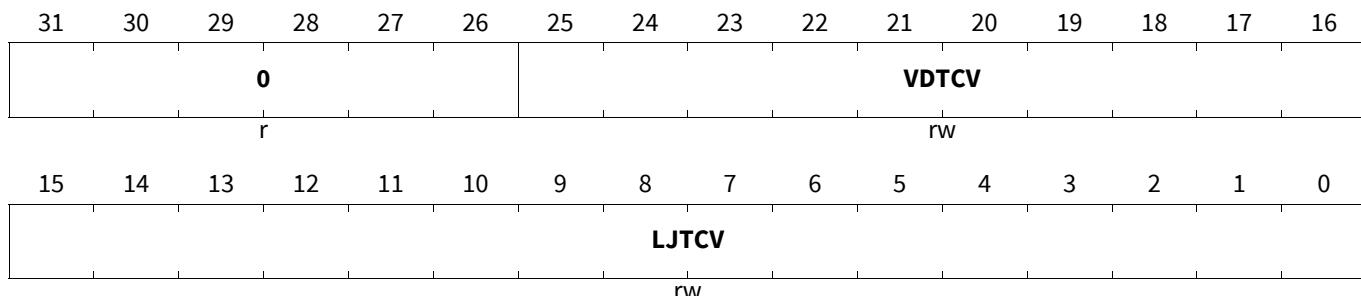

## Power Management System (PMS)

Field	Bits	Type	Description
LPSLPEN	29	rw	<b>EVRC Low Power Mode activation on a Sleep Request</b> PMS: This bit field enables the activation of LPM EVRC mode on a sleep request. PMSLE: Reserved, no function (no LPM for SC-DCDC EVRC). 0 <sub>B</sub> PMS: EVRC remains in normal operation mode during and after a sleep request. PMSLE: Reserved. 1 <sub>B</sub> PMS: LPM mode activated on a sleep request. PMSLE: Reserved.
0	11:6, 28:22, 31:30	r	<b>Reserved</b> Read as 0; should be written with 0.

## Power Management Transition Control and Status Register 1

### PMTRCSR1

**Power Management Transition Control and Status Register 1(019C<sub>H</sub>)**      **Cold PowerOn Reset Value: 0000 0000<sub>H</sub>**

Field	Bits	Type	Description
LJTCV	15:0	rw	<b>Load Jump Timer Compare Setpoint Value</b> This bit field defines the compare setpoint value of Load Jump timer. The compare event would lead to LJTOV bit being set and LJT interrupt being raised. The LJTRUN status bit, LDJMPREQ bit and LJTCNT value is reset to 0 on a compare event. X us is the compare value. LSB =1 us. Total range = 65.5 ms
VDTCV	25:16	rw	<b>Voltage Droop Timer Compare Setpoint Value</b> This bit field defines the compare setpoint value of Voltage Droop timer. The compare event would lead to VDTOV bit being set and VDT interrupt being raised. The VDTRUN status bit, VDROOPREQ bit and VDTCNT value is reset to 0 on a compare event. X us is the compare value. LSB =1 us. Total range = 1023 us
0	31:26	r	<b>Reserved</b> Read as 0; should be written with 0.

## Power Management System (PMS)

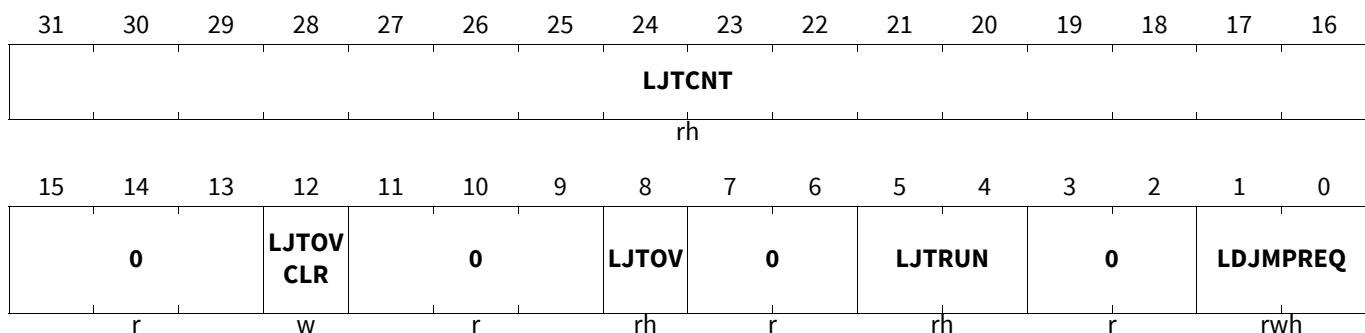

### Power Management Transition Control and Status Register 2

#### PMTRCSR2

**Power Management Transition Control and Status Register 2(01A0<sub>H</sub>)**

**Cold PowerOn Reset Value: 0000**

**0000<sub>H</sub>**

Field	Bits	Type	Description
<b>LDJMPREQ</b>	1:0	rwh	<p><b>Load Jump Request</b></p> <p>This bit requests a Load Jump consequently leading to Load Jump Timer start and LJTRUN bit being set if LJTEN=1. The request is not taken if LJTRUN bit is already in set state and LJT is currently running. The request is not taken if VDTRUN bit is already in set state and VDT is currently running. The request is also not taken if (LJTOV bit is set AND LJTOVEN bit is enabled). The request is also not taken if (VDTOV bit is set AND VDTOVEN bit is enabled). The LDJMPREQ bit is cleared on a compare overflow.</p> <p><i>Note:</i> All other bit combinations are reserved.</p> <p>00<sub>B</sub> Load Jump Timer inactive 01<sub>B</sub> Load Jump Request made and taken. Load Jump Timer activated.</p>
<b>LJTRUN</b>	5:4	rh	<p><b>Load Jump Timer Run Status</b></p> <p>This status bit indicates that the Load Jump timer is currently running and a Load Jump is currently taking place. The LJTRUN bit is cleared on a compare overflow.</p> <p><i>Note:</i> All other bit combinations are reserved.</p> <p>00<sub>B</sub> Load Jump and Load Jump Timer inactive 01<sub>B</sub> A SW triggered Load Jump active and Load Jump Timer active 10<sub>B</sub> A HW triggered Load Jump active and Load Jump Timer active (reserved for future)</p>

## Power Management System (PMS)

Field	Bits	Type	Description
LJTOV	8	rh	<b>Load Jump Timer Overflow Status</b> This status bit indicates that the Load Jump timer compare match has happened. If LJTOVEN bit is enabled, then LJTOV can only be cleared explicitly via LJTOVCLR bit. If LJTOVEN bit is disabled, LJTOV is cleared on a taken Load Jump Request (A new Load Jump request is taken only if both LJT & VDT are not currently running and no active Load Jump request is being processed). LJTOV being set will lead to an interrupt if LJTOVIEN is enabled. 0 <sub>B</sub> Load Jump Timer compare overflow has not happened. 1 <sub>B</sub> Load Jump Timer compare overflow has happened.
LJTOVCLR	12	w	<b>Load Jump Timer Overflow Status Clear</b> This bit clears LJTOV status bit and sets VDROOPREQ and LDJMPREQ to 0 if LJTOVEN bit is enabled. This bit always reads as 0. 0 <sub>B</sub> This clear bit has no effect on Load Jump Timer overflow flag. 1 <sub>B</sub> Load Jump Timer overflow flag is cleared.
LJTCNT	31:16	rh	<b>Load Jump Timer Value</b> This bit field reflects the current Load Jump timer value. LJTCNT value is cleared on timer overflow and on a taken Load Jump Request X us is the compare value. LSB = 1 us. Total range = 65.5 ms
0	3:2, 7:6, 11:9, 15:13	r	<b>Reserved</b> Read as 0; should be written with 0.

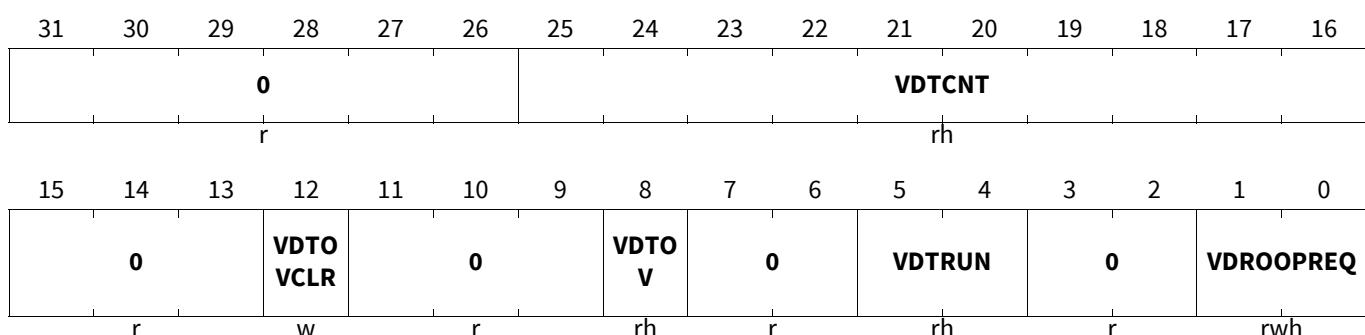

## Power Management Transition Control and Status Register 3

### PMTRCSR3

#### Power Management Transition Control and Status Register 3(01A4<sub>H</sub>)

Cold PowerOn Reset Value: 0000

0000<sub>H</sub>

## Power Management System (PMS)

Field	Bits	Type	Description
<b>VDROOPREQ</b>	1:0	rwh	<p><b>Voltage Droop Request</b></p> <p>This bit requests a Voltage Droop consequently leading to Voltage Droop Timer start and VDTRUN bit being set if VDTEN=1. The request is not taken if VDTRUN bit is already in set state and VDT is currently running. The request is also not taken if (VDTOV bit is set AND VDTOVEN bit is enabled). The droop step is a positive offset if sd_droop_cntr_i = 01 and is a negative offset if sd_droop_cntr_i = 10 and no offset is applied if sd_droop_cntr_i = 00 and is applied immediately.</p> <ul style="list-style-type: none"> <li>00<sub>B</sub> Voltage Droop and Voltage Droop Timer inactive</li> <li>01<sub>B</sub> A Positive Voltage Droop Request made and taken. ### 11.4 IO Interfaces

The following table defines the signals connecting the PMS to other modules and the outside world.

Note that not all signals may be used in all members of the family. Consult the product specific appendix to see the available connections.

**Table 379 List of PMS Interface Signals**

Interface Signals	I/O	Description
HWCFG1IN	in	<b>HWCFG1 pin input</b> Hardware configuration 1 input for activation of EVR33 regulator.
HWCFG2IN	in	<b>HWCFG2 pin input</b> Hardware configuration 2 input for activation of EVRC regulator.
HWCFG4IN	in	<b>HWCFG4 pin input</b> Hardware configuration 4 input for test purposes.
HWCFG5IN	in	<b>HWCFG5 pin input</b> Hardware configuration 5 input for test purposes.
HWCFG6IN	in	<b>HWCFG6 pin input</b> Hardware configuration 6 input for activation of tri-state.
TESTMODEIN	in	<b>TESTMODE pin input</b> Test mode pin input to enable entry into test modes
PORSTIN	in	<b>PORST pin input</b> PORST pin input to trigger warm PORST
PORSTOUT	in	<b>PORST pin output</b> Cold PORST strong pull down control output to drive PORST pin low in case of primary monitor undervoltage events
PORSTWKPD	in	<b>PORST pad weak pull down control output</b> PORST weak pull down control to keep PORST weakly pulled low in case of bond wire breakage. The pull down is inactive to avoid additional current during STANDBY mode
ESR0PORST	out	<b>ESR0 control output during PORST activation</b> Warm PORST signal connected to ESR0 pad to ensure that ESR0 pad is asserted when PORST pin is asserted to propagate the reset
ESR0WKP	in	<b>ESR0 pin input</b> ESR0 pin input for wakeup from STANDBY mode
ESR1WKP	in	<b>ESR1 pin input</b> ESR1 pin input for wakeup from STANDBY mode

## Power Management System (PMS)

**Table 379 List of PMS Interface Signals (cont'd)**

Interface Signals	I/O	Description
PINAWKP	in	<b>PINA ( P14.1) pin input</b> P14.1 pin input for wakeup from STANDBY mode
PINBWKP	in	<b>PINB (P33.12) pin input</b> P33.12 pin input for wakeup from STANDBY mode
VGATE1P	out	<b>DCDC P ch. MOSFET gate driver output</b>
VGATE1N	out	<b>DCDC N ch. MOSFET gate driver output</b>
DCDCSYNCO	out	<b>DC-DC synchronization output</b>
WUTUFLOW	out	<b>WUT counter underflow signal to CCU6/GTM</b> WUT Underflow output to support WUT calibration
DCDCSYNCGTM	in	<b>DCDC synchronization signal input from GTM</b> Synchronisation input from GTM module to EVRC SMPS regulator
DCDCSYNCCU	in	<b>DCDC synchronization signal input from CCU6</b> Synchronisation input from CCU6 (CCU60 COUT63) module to EVRC SMPS regulator
VDDMLVL	out	<b>VDDM monitor signal to Converter</b> Signal indicating whether VDDM is supplied with 5V or 3.3V. 0: VDDM = 5V 1: VDDM = 3.3V.

## Power Management System (PMS)

### 11.5 Revision History

#### 11.5.1 Changes from AURIX 2G PMS V2.2.19 onwards

**Table 380 Revision History**

Reference	Change to Previous Version	Comment
V2.2.28		
<a href="#">Page 120</a>	Corrected VIN formula in the bit-field description of EVRSDSTAT0.ADCFBCV. ADCFBCV value includes trimming, thus subtracting to obtain VIN.	
<a href="#">Page 88</a>	Corrected VIN formula and related explanation in the bit-field descriptions of EVRADCSTAT.ADCCV, EVRADCSTAT.ADC33V, and EVRADCSTAT.ADCSWDV by removing the EVRTRIM2 ADC offset part (ADCOFFS does not need to be considered for the calculation of the output voltage, production test trimming makes sure to set the ADCOFFS correctly).	
<a href="#">Page 38</a>	Added a statement that the user shall not modify the default values of the EVRRSTCON register.	
<a href="#">Page 9</a>	Added to the description of the LVD reset release at T1 that VEVRSB is above the VLDRSTSB level.	
<a href="#">Page 11</a>	Added to the description of the LVD reset release at T1 that VEVRSB is above the VLDRSTSB level.	
<a href="#">Page 13</a>	Added to the description of the LVD reset release at T1 that VEVRSB is above the VLDRSTSB level.	
<a href="#">Page 15</a>	Added to the description of the LVD reset release at T1 that VEVRSB is above the VLDRSTSB level.	
<a href="#">Page 82</a>	Corrected list of registers with Safety Flip-Flops by removing EVRRSTHYS and DTSLIM registers.	
<a href="#">Page 38</a>	Enabled description of the HSMUVMON and HSMOVMON thresholds and documented that alarms are routed not only to the HSM module, but also to the SMU.	
<a href="#">Page 20</a>	Changed name of the DTS interrupt service request from SRC_DTS to SRC_PMSDTS, to match the name in the Interrupt Router specification.	
<a href="#">Page 78</a>	Enabled section on Core Die Temperature Sensor (DTSC).	
<a href="#">Page 47</a>	Corrected figure by adding DTSC interrupt event to SCR_SCUERU3 source and SRC_PMSDTS interrupt source with DTS interrupt event.	
<a href="#">Page 46</a>	Corrected name of the MONBIST control register for MONBIST enabling, by changing “MONBISTSTAT.TESTEN” to “MONBISTCTRL.TESTEN”	
<a href="#">Page 18</a>	Added statement that EVROSCCTRL register shall not be modified by application SW and that additional compensation can be enabled via EVROSCCTRL.OSCTEMPOFFS and EVROSCCTRL.OSCTRIMEN bits.	
<a href="#">Page 40</a>	Added statement that EVRUVMON2.VDDMLVLSEL bit-field shall not be modified by application SW and that its default value shall be kept with any updates of the undervoltage monitoring thresholds.	

## Power Management System (PMS)

**Table 380 Revision History (cont'd)**
