## Power Management System for Low-End (PMSLE)

### 12 Power Management System for Low-End (PMSLE)

This chapter describes Power Supply Generation and Power Management in TC3xx in following sections:

- Power Supply Infrastructure and Supply Start-up (see [Section 12.2.1](#))
  - Supply Mode Selection (see [Section 12.2.1.1](#))
  - Supply Ramp-up and Ramp-down Behavior (see [Section 12.2.1.2](#))
  - Independent Supply domain for Regulators and Monitors (see [Section 12.2.1.3.1](#))
  - Reference Voltage Generation (see [Section 12.2.1.3.2](#))
  - 100 MHz Back-up Clock (see [Section 12.2.1.3.3](#))
  - Die Temperature Measurement (see [Section 12.2.1.4](#))
- Power Supply Generation and Monitoring (see [Section 12.2.2](#))
  - VDDP3 Supply Generation
    - Linear Regulator Mode (EVR33) (see [Section 12.2.2.1](#))
    - External Supply Modes (see [Section 12.2.2.4](#))
  - VDD Supply Generation
    - Step-down Regulator (EVRC) (see [Section 12.2.2.2](#))
    - External Supply Modes (see [Section 12.2.2.4](#))
  - Supply Voltage Monitoring (see [Section 12.2.2.5](#))
    - Primary under-voltage monitors and Cold PORST (see [Section 12.2.2.5.1](#))
    - Secondary over- and under-voltage monitors and alarm generation (see [Section 12.2.2.5.2](#))
    - Built In Self Tests (PBIST and MONBIST) (see [Section 12.2.2.5.3](#) and [Section 12.2.2.5.4](#))
  - Interrupts (see [Section 12.2.2.6](#))
  - OCDS Interface (see [Section 12.2.2.7](#))
- Power Management (see [Section 12.2.3](#))
  - Idle Mode (see [Section 12.2.3.2](#))
  - Sleep Mode (see [Section 12.2.3.3](#))
  - Standby Mode (see [Section 12.2.3.4](#))
  - Wake-up Timer (WUT) (see [Section 12.2.3.4.7](#))
  - Standby ControlleR (SCR) Interface (see [Section 12.2.3.4.6](#))
  - Load Jump Sequencing and Voltage Droop (see [Section 12.2.3.5](#))
- Power Management System Register Tables
  - PMS Power Management Register Table (see [Page 80](#))
  - SCU Power Management Register Table (see [Page 175](#))

## Power Management System for Low-End (PMSLE)

### 12.1 Overview

On-chip linear and switch mode voltage regulators are implemented in TC3xx thereby enabling a single source power supply concept. The external nominal system supply from external regulator may be either 5 V or 3.3 V. The Embedded Voltage Regulators (EVR33 & EVRC) in turn generate the VDDP3 and VDD supply voltages required internally for the core, flash and port domains. EVRC regulator is implemented as a SMPS regulator and generates core supply either from 5 V or 3.3 V external supply. EVR33 regulator is implemented always as a LDO regulator and is required only in case of 5 V external supply.

Depending on the chosen EVR mode, the actual power consumption, EMI requirements and thermal constraints of the system; additional external components like MOSFETs, inductors and capacitors may be required. It is also possible to supply all voltages (VEXT, VDDP3 and VDD) externally ensuring compliance to the legacy supply concept.

All supply and generated voltages are monitored for brownout conditions by primary monitors setting the device into cold power-on reset state in case of violation. All supply and generated voltages are monitored again redundantly by secondary monitors against programmable over-voltage and under-voltage levels. If these levels are violated, either an interrupt or an alarm to the SMU may be generated.

All internal supplies except analog supplies (VAREFx & VDDM) may be supplied by the EVR33 & EVRC. The analog supply domain is separated from the main EVR supply domain and can be supplied by separate external regulators or trackers. It is possible to have a mixed supply scheme with a 5 V ADC domain (VAREFx = VDDM = 5 V) and the remaining system running on 3.3 V supply (VEXT = VDDP3 = 3.3 V).

### 12.2 Functional Description

#### 12.2.1 Power Supply Infrastructure and Supply Start-up

##### 12.2.1.1 Supply Mode Selection

The choice of the supply scheme at startup is based on the latched status of HWCFG[2:1] pins before cold PORST release and is indicated by [PMSWSTAT](#).HWCFGEVR status flags. Following supply modes are supported and are further enumerated in [Table 381](#).

- Single source 5 V supply level ( $VEXT = 5\text{ V}$ ) is supported in following topologies.
  - EVRC in SMPS mode with external flying capacitor and EVR33 in LDO mode with internal pass devices.
- Single source 3.3 V supply level ( $VEXT = VDDP3 = 3.3\text{ V}$ ) is supported in following topologies.
  - EVRC in SMPS mode with external flying capacitor and EVR33 is inactive.
- Supplies are provided externally and the respective EVRs are in disabled state.
  - 5 V ( $VEXT$ ) and 1.25 V ( $VDD$ ) supplied externally. EVR33 in LDO mode with internal pass devices.
  - 5 V ( $VEXT$ ) and 3.3 V ( $VDDP3$ ) supplied externally. EVRC in SMPS mode with external flying capacitor.
  - 5 V ( $VEXT$ ), 3.3 V ( $VDDP3$ ) and 1.25 V ( $VDD$ ) are all supplied externally.

EVRC is enabled or disabled at startup via the HWCFG[2] configuration pin. In case EVRC is selected, VCAP0 and VCAP1 pins shall be connected to an external flying capacitor as shown in [Figure 132](#).

## Power Management System for Low-End (PMSLE)

EVR33 is enabled or disabled at startup via the HWCFG[1] configuration pin. In case of single source 3.3 V supply, EVR33 is disabled and VDDx3 & VEXT pins are supplied externally by 3.3 V. EVR33 LDO uses internal pass devices distributed on the chip.

The allowed ranges of supplies among different supply rails during different power modes are documented in [Table 382](#) and [Table 383](#). The allowed combinations of nominal external supply voltages among different supply rails are documented in [Table 384](#). All externally provided supplies must be available and be stable before warm PORST reset release by external regulator(s).

HWCFG [2:1] are latched during supply ramp-up and the respective regulators are consequently started. The latched values are stored in PMSWSTAT.HWCFGEV register bits. The latched values are retained through a cold PORST and are only reset if EVR LVD (Low Voltage Detector) reset is asserted. HWCFG signals are filtered through a spike / glitch filter and are monitored for a constant level over a 28us - 115us nominal debouncing period before the value is considered as valid so as to ensure reliable operation in noisy environment. The current state of EVRs are reflected in EVRSTAT.EVRx3 flags. For small package variants, some of the HWCFG configuration pins may be absent and both EVRs are activated by default at startup.

HWCFG[6] pin is latched during early VEXT supply ramp-up ( $VEXT < VDDPPA$ ) to decide and set the default reset state of port pins as early as possible. During the initial ramp-up phase of VEXT and VEVRSB supply voltage from 0V up to VDDPPA limit, the voltage levels of pins are undefined till the transistor threshold voltages are reached. After VDDPPA limit, the pins behave as inputs with pull-up if HWCFG[6] = 1 or are in tristate if HWCFG[6] = 0. During the later stage of ramp-up, the latched HWCFG[6] value is stored in PMSWSTAT.TRIST register bit.

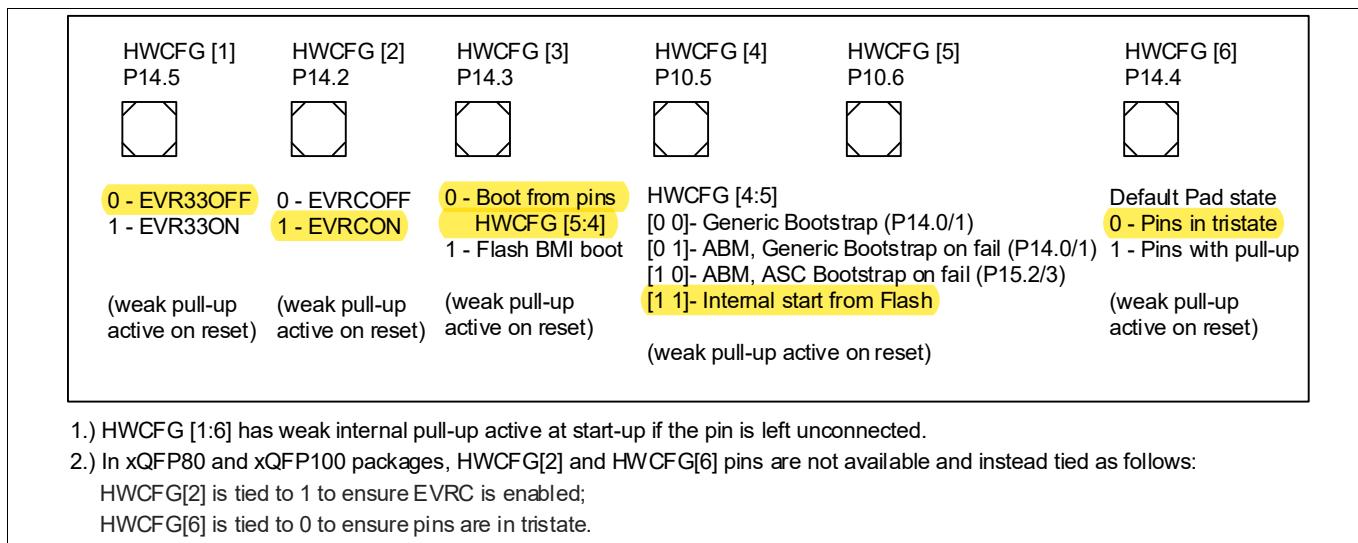

HWCFG [1,2,3,6] pins have weak internal pull-up active at start-up irrespective of HWCFG [6] pin level to ensure that the device boots with a defined configuration if HWCFG [1,2,3,6] pins are left unconnected. HWCFG [1,2,3,6] pins are only latched by the PMS on every initial supply ramp-up and are not re-latched during warm reset events (warm PORST, system or application resets) or on exit from Standby mode. All HWCFG pins are latched on internal reset release additionally (between 100us – 180us after warm reset assertion) and the status is stored redundantly in STSTAT register by SCU.

- HWCFG[6] and HWCFG[1,2] are recognized as high when the respective pin is open or pulled up to VEXT supply with pull device  $> 2\text{ k}\Omega$  and  $< 4.7\text{ k}\Omega$  on the external system.
- HWCFG[6] and HWCFG[1,2] are recognized as low when the respective pin is pulled down to GND with pull device  $> 2\text{ k}\Omega$  and  $< 4.7\text{ k}\Omega$  on the external system.

The lower limit of the pull resistance is derived from the overload and short specification (see data sheet) in case of a short event.

Regardless of the HWCFG[6] setting, the VEXT-buffered PU1 pads (see the PU1 buffer type in the data sheet) are set into tristate after standby mode entry.

## Power Management System for Low-End (PMSLE)

**Figure 122 Hardware Configuration (HWCFG) pins**

d.)	01 <sub>B</sub>	VCAPO/VCAP1 pins can be left open.	VEXT & VEVRSB = 5.0 V external supply. VDDM = VAREFx = 5V or 3.3V external supply. VFLEX = 5 V or 3.3 V. VDDP3 and VDDFL3 supplied by EVR33. VDD = 1.25 V external supply.	5 V & 1.25 V external supply. EVRC inactive. EVR33 in LDO mode. 5 V or 3.3 V ADC domain. 5 V or 3.3 V Flexport domain. Standby Mode is supported and 1.25V supply shall be switched off by external regulator after Standby state is entered.

**Power Management System for Low-End (PMSLE)**
**Table 381 Supply Mode and Topology selection (cont'd)**

No.	HWCFG [2,1] <sup>1)</sup>	VCAP0 VCAP1 <sup>2)</sup>	Supply Pin Voltage Level / Source <sup>3)</sup>	Selected Supply Scheme
e.)	10 <sub>B</sub>	VCAP0/VCAP1 pins connected to external flying capacitor.	VEXT, VEVRSB, VDDP3, VFLEX and VDDFL3 = 3.3V external supply. VDDM = VAREFx = 5V or 3.3V external supply. VDD supplied by EVRC.	3.3 V single source supply. EVRC in SMPS mode. EVR33 inactive. 5 V or 3.3 V ADC domain. 3.3 V Flexport domain. Standby Mode supported.
			VEXT & VEVRSB = 5.0 V external supply. VDDP3, VFLEX and VDDFL3 = 3.3V external supply. VDDM = VAREFx = 5V or 3.3V external supply. VDD supplied by EVRC.	5 V & 3.3 V external supply. EVRC in SMPS mode. EVR33 inactive. 5 V or 3.3 V ADC domain. 5 V or 3.3 V Flexport domain. Standby Mode is supported and 3.3V supply shall be switched off by external regulator after Standby state is entered.
h.)	00 <sub>B</sub>	VCAP0/VCAP1 pins can be left open.	VEXT & VEVRSB = 5.0 V external supply. VDDM = VAREFx = 5V or 3.3V external supply. VFLEX = 5 V or 3.3 V external supply. VDDP3 and VDDFL3 = 3.3V external supply. VDD = 1.25 V external supply.	5 V, 3.3 V and 1.25 V are supplied externally. EVRC and EVR33 inactive. 5 V or 3.3 V ADC domain. 5 V or 3.3 V Flexport domain. Standby Mode is supported and 3.3V and 1.25V supplies shall be switched off by external regulator after Standby state is entered.

- 1) if HWCFG[2,1] pins are left unconnected, it is ensured that EVR33 and EVRC are active owing to the internal weak pull-up active by default after start-up/cold PORST.
- 2) VCAPx pins are dedicated for SMPS Switch capacitor regulator and cannot be used as port pins, In SMPS mode, the VCAPx shall be connected with a flying capacitor between the pins. In case EVRC is disabled, the VCAP pins may be left open or may be connected with a small decoupling capacitor. VCAP pins shall not be connected to ground as ESD diodes start conducting.
- 3) Only Nominal supply voltage values of respective rails are indicated in the table. The tolerances of the supply voltages are documented in datasheet.

**Power Management System for Low-End (PMSLE)**
**Table 382 5 V Nominal Supply : Voltage variations at independent supply rails during system modes**

Supply Rails	<b>VEXT = VEVRSB = 5V Nominal Voltage Level</b>				<b>VEXT = VEVRSB = 3.3V Nominal Voltage Level</b>	
$V_{EVRSB}$	5 V <sup>2)</sup>				3.3 V	
$V_{EXT}$	5 V				3.3 V	
$V_{FLEX}$ <sup>3)</sup>	5 V	3.3 V	5 V	3.3 V	3.3 V	
$V_{DDM}$ <sup>4)</sup>	5 V				5 V <sup>5)</sup>	3.3 V
$V_{DDP3}$ <sup>6)</sup>	3.3 V (external supply or generated by EVR33 )				3.3 V (external supply or generated by EVR33 )	
$V_{DD}$	1.25 V (external supply or generated by EVRC )				1.25 V (external supply or generated by EVRC )	
$V_{DDSB}$ <sup>7)</sup>	1.25 V (external supply or generated by EVRC )				1.25 V (external supply or generated by EVRC )	

- 1) All supply rails shall have ramped up to their minimum voltage operational limits as documented in the datasheet before warm PORST reset release. It is not allowed to leave any supply rail un supplied after warm PORST reset release.
- 2) VEVRSB supply rail can be ramped down during VEVRSB Standby mode to 2.6 V minimum voltage.
- 3) VFLEX supply rail provides supply to ports P11 and P12 and can be supplied with nominal 3.3V supply when remaining ports are supplied with nominal 5V. VFLEX maybe supplied by the same external supply source connected also to VEXT supply rail. VFLEX supply level shall be less than or equal to VEXT supply level.
- 4) VDDM analog supply and VAREFx analog reference supply shall have the same supply level. It is recommended to supply VDDM and VAREFx from the same external supply source with filters.
- 5) VDDM supplies only a part of analog pins. For shared analog pins supplied by VEXT (P00) and VEVRSB (P33), the voltage levels of the resepective analog channels would be bounded by the respective supply voltages when they are lower than the VDDM / VAREF voltages.
- 6) EVR33 is designed to supply the current required only by VDDP3 rail and the associated modules requiring 3.3V supply. It is not intended to supply VFLEX pad currents from 3.3V VDDP3 rail when EVR33 generates VDDP3 supply.
- 7) VDDSB shall be connected to VDD rail and supplied together in case of non emulation devices.

## Power Management System for Low-End (PMSLE)

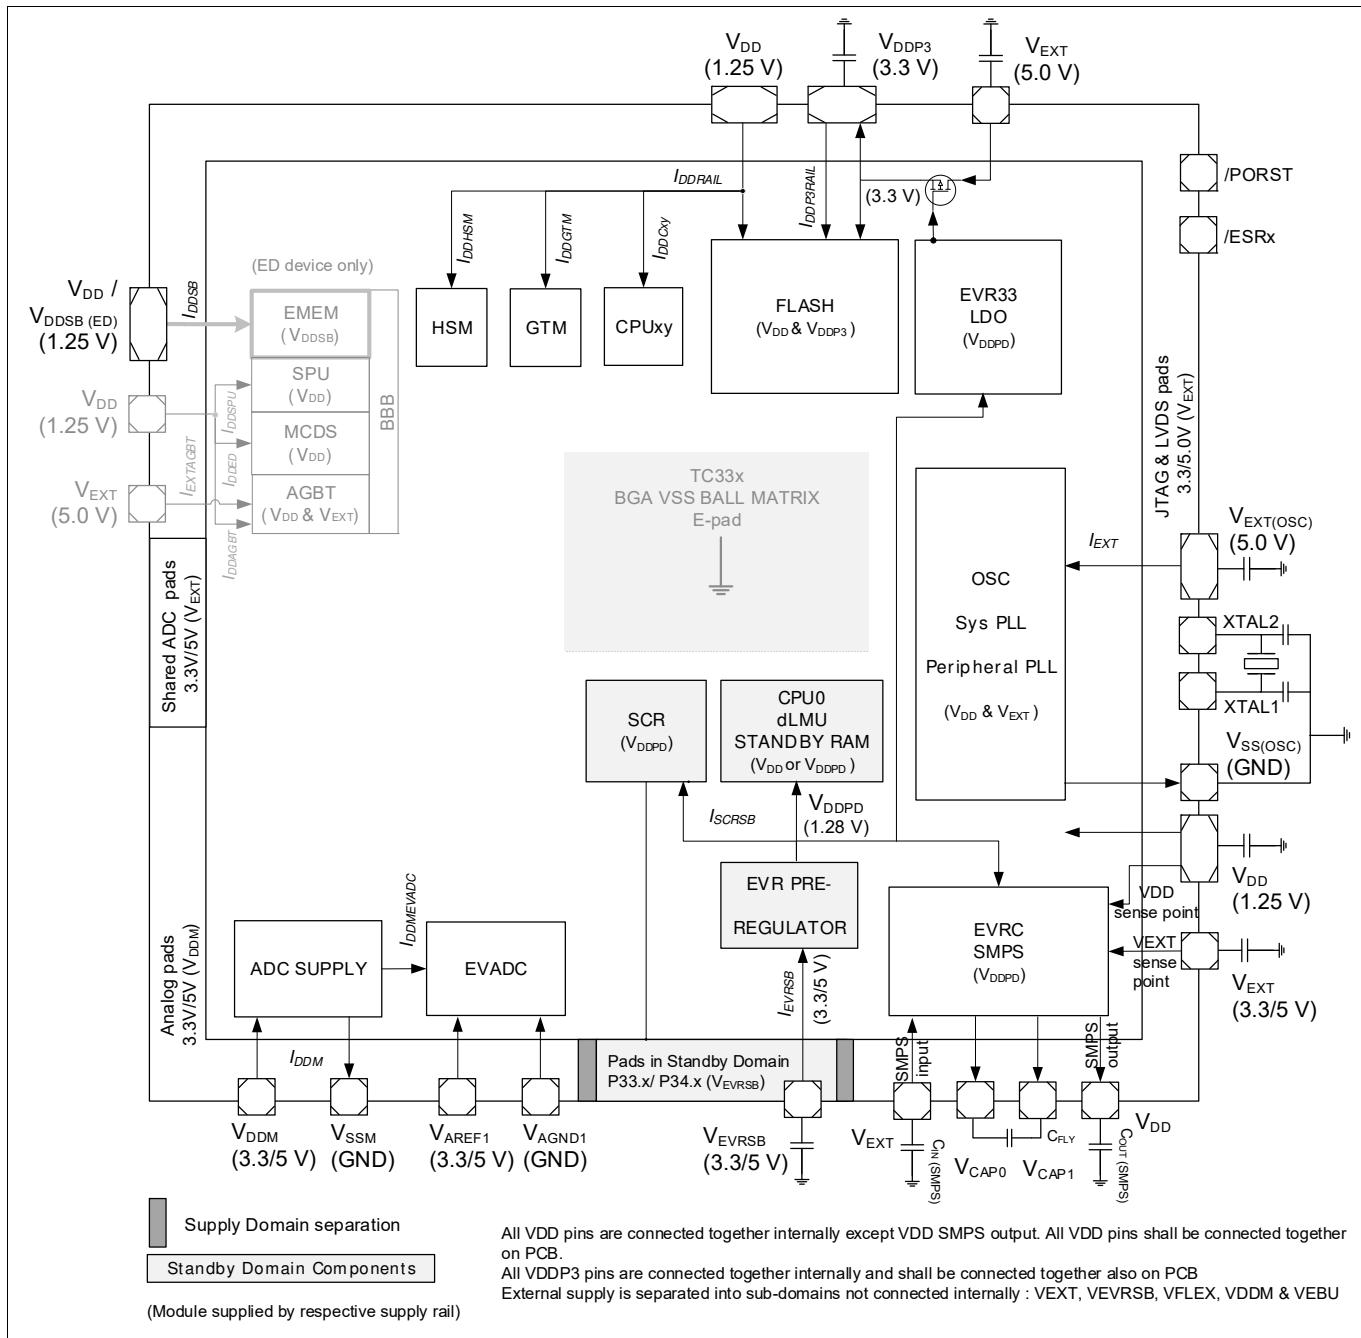

Figure 123 TC33x Supply Pins and Module Connectivity

## Power Management System for Low-End (PMSLE)

### 12.2.1.2 Supply Ramp-up and Ramp-down Behavior

#### 12.2.1.2.1 Single Supply mode (a)

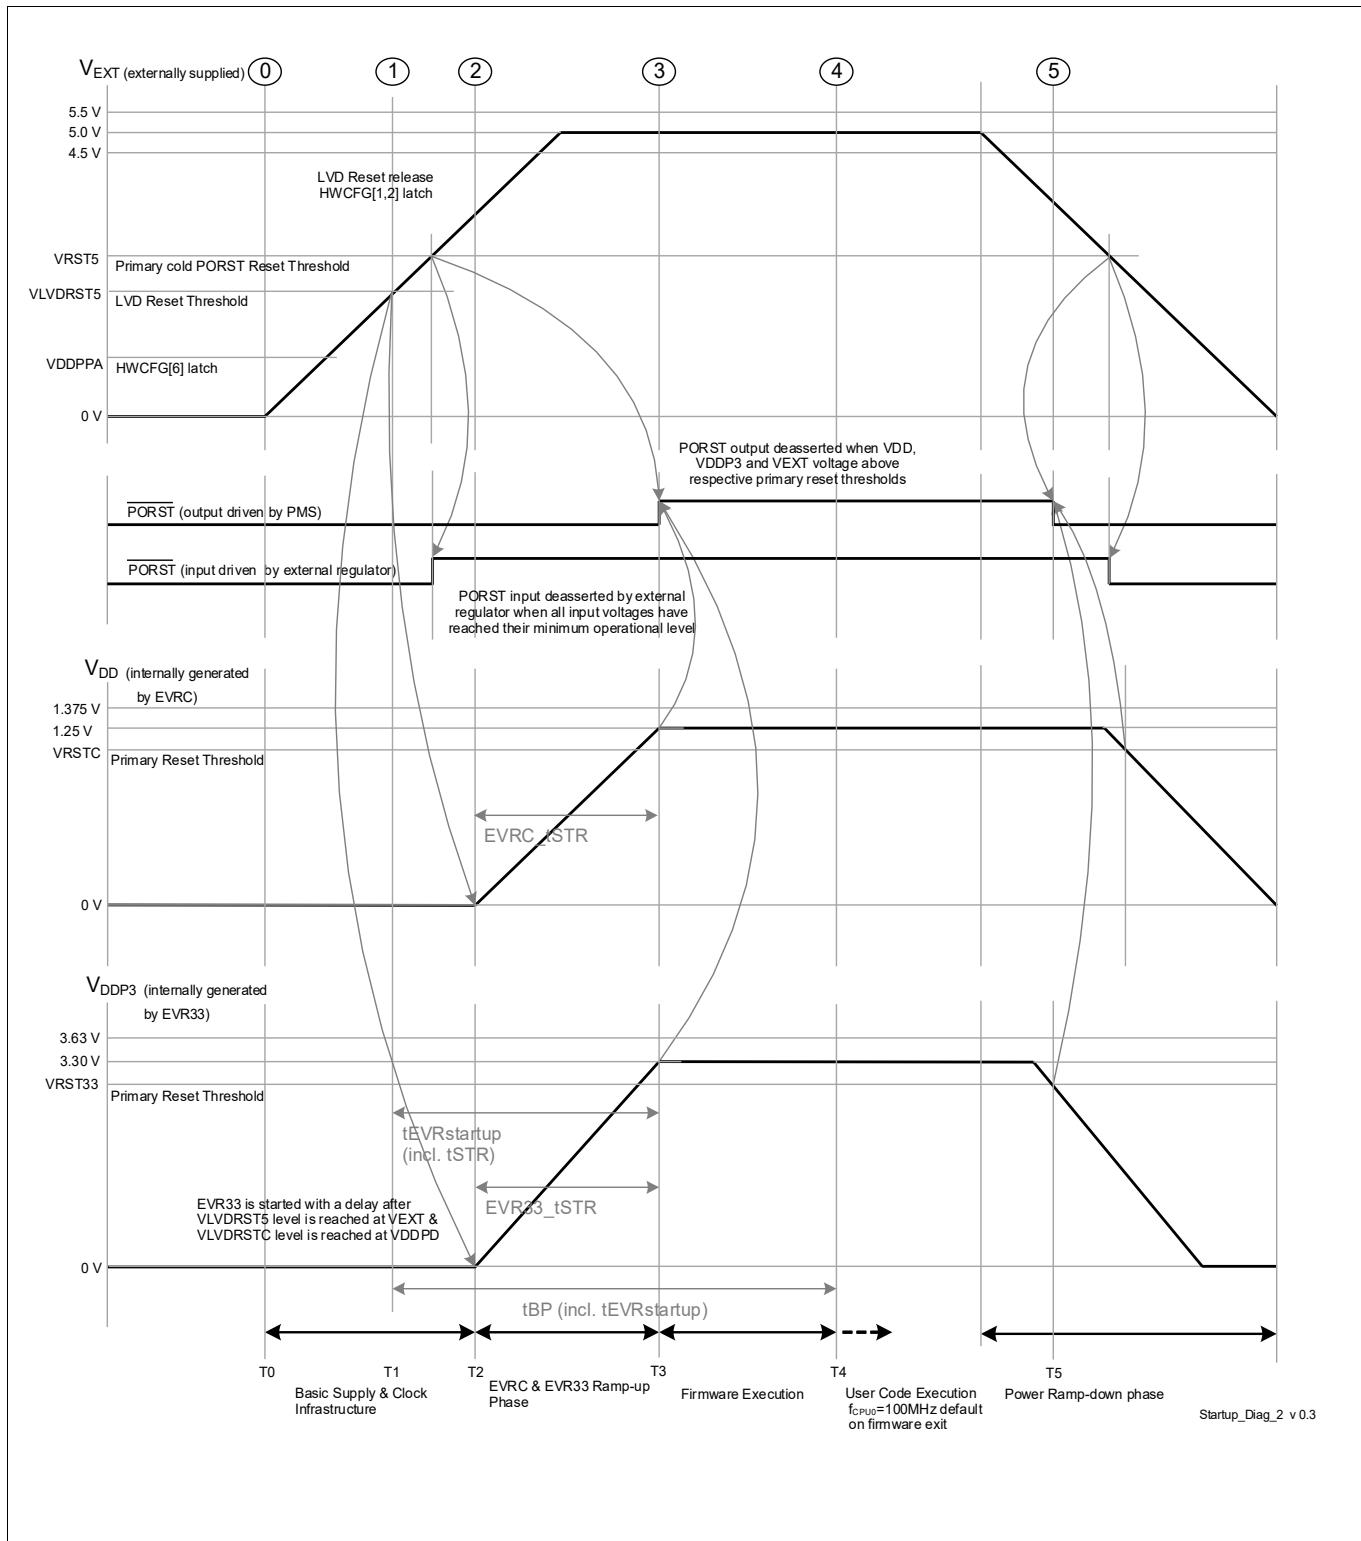

Figure 124 Single Supply mode (a) - VEXT (5 V) single supply

## Power Management System for Low-End (PMSLE)

VEXT = 5 V single supply mode. VDD and VDDP3 are generated internally by the EVRC and EVR33 internal regulators.

- The rate at which current is drawn from the external regulator ( $dI_{EXT}/dt$ ) is limited during the basic infrastructure and EVRx regulator start-up phase (T0 up to T3) to a maximum of 100 mA with 50  $\mu$ s settling time. Start-up slew rates for supply rails shall comply to datasheet parameter SR. The slope is defined as the maximal tangential slope between 0% to 100% voltage level. Actual waveform may not represent the specification.
- Furthermore it is also ensured that the current drawn from the regulator ( $dI_{DD}/dt$ ) is limited during the Firmware start-up phase (T3 up to T4) to a maximum of 100 mA with 100  $\mu$ s settling time.
- PORST is active/asserted when either PORST (input) or PORST (output) is active/asserted.
- PORST (input) active means that the reset is held active by external agents by pulling the PORST pin low. It is recommended to keep the PORST (input) asserted until the external supply is above the respective primary reset threshold.
- PORST (output) active means that  $\mu$ C asserts the reset internally and drives the PORST pin low thus propagating the reset to external devices. The PORST (output) is asserted by the  $\mu$ C when atleast one among the three supply domains (VDD, VDDP3 or VEXT) violate their primary under-voltage reset thresholds. The PORST (output) is de-asserted by the  $\mu$ C when all supplies are above their primary reset thresholds and the basic supply and clock infrastructure is available. During reset release at T3, the load jump of upto 150 mA ( $dI_{DD}$ ) is expected.
- The power sequence as shown in [Figure 124](#) is enumerated below
  - T1 up to T2 refers to the period in time when basic supply and clock infrastructure components are available as the external supply ramps up. The bandgap and internal clock sources are started .The supply mode is evaluated based on the HWCFG[2:1,6] pins. These events are initiated after LVD reset release at T1. LVD reset is released when both input voltages VEXT and VEVRSB are above VLVRST5 and VLVRSTSB levels respectively. Internal pre-regulator VDDPD voltage is above VLVRSTC level.
  - T2 refers to the point in time where consequently a soft start of EVRC and EVR33 regulators are initiated. PORST (input) does not have any affect on EVR33 or EVRC output and regulators continue to generate the respective voltages though PORST is asserted and the device is in reset state. The generated voltage follows a soft ramp-up over the tSTR (datasheet parameter) time to avoid overshoots.
  - T3 refers to the point in time when all supplies are above their primary reset thresholds denoted by VRST5, VRST33 and VRSTC supply voltage levels. EVRC and EVR33 regulators have ramped up. PORST (output) is de-asserted and HWCFG[3:5] pins are latched on PORST rising edge by SCU. Firmware execution is initiated. The time between T1 and T3 is documented as tEVRstartup (datasheet parameter).
  - T4 refers to the point in time when Firmware execution is completed and User code execution starts with CPU0 at a default frequency of 100 MHz. The time between T0 and T4 is documented as tBP (datasheet parameter).
  - T5 refers to the point in time during the ramp-down phase when at least one of the externally provided or generated supplies (VDD, VDDP3 or VEXT) drop below their respective primary under-voltage reset thresholds.

## Power Management System for Low-End (PMSLE)

### 12.2.1.2.2 Single Supply mode (e)

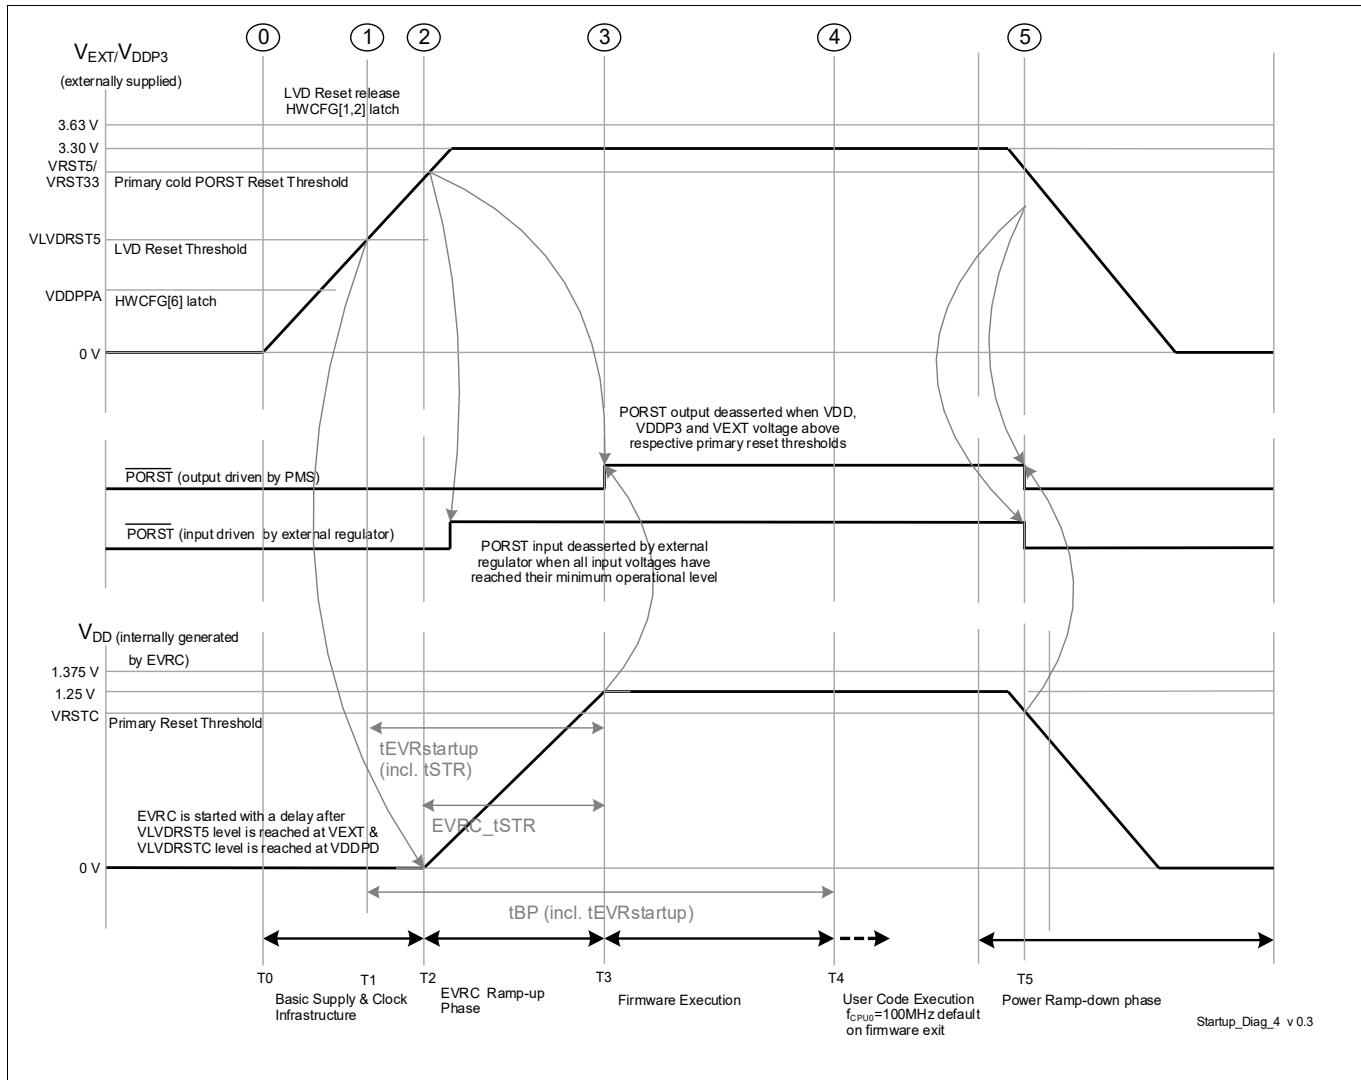

Figure 125 Single Supply mode (e) - ( $V_{EXT}$  &  $V_{DDP3}$ ) 3.3 V single supply

$V_{EXT} = V_{DDP3} = 3.3$  V single supply mode.  $V_{DD}$  is generated internally by the EVRC regulator.

- The rate at which current is drawn from the external regulator ( $dI_{EXT} / dt$ ) is limited in the Start-up phase (T2 up to T3) to a maximum of 100 mA with 50  $\mu$ s settling time. Start-up slew rates for supply rails shall comply to datasheet parameter SR. The slope is defined as the maximal tangential slope between 0% to 100% voltage level. Actual waveform may not represent the specification.
- PORST is active/asserted when either PORST (input) or PORST (output) is active/asserted.
- PORST (input) active means that the reset is held active by external agents by pulling the PORST pin low. It is recommended to keep the PORST (input) asserted until the external supply is above the respective primary reset threshold.
- PORST (output) active means that  $\mu$ C asserts the reset internally and drives the PORST pin low thus propagating the reset to external devices. The PORST (output) is asserted by the  $\mu$ C when at least one among the three supply domains ( $V_{DD}$ ,  $V_{DDP3}$  or  $V_{EXT}$ ) violate their primary under-voltage reset thresholds. The PORST (output) is de-asserted by the  $\mu$ C when all supplies are above their primary reset thresholds and the

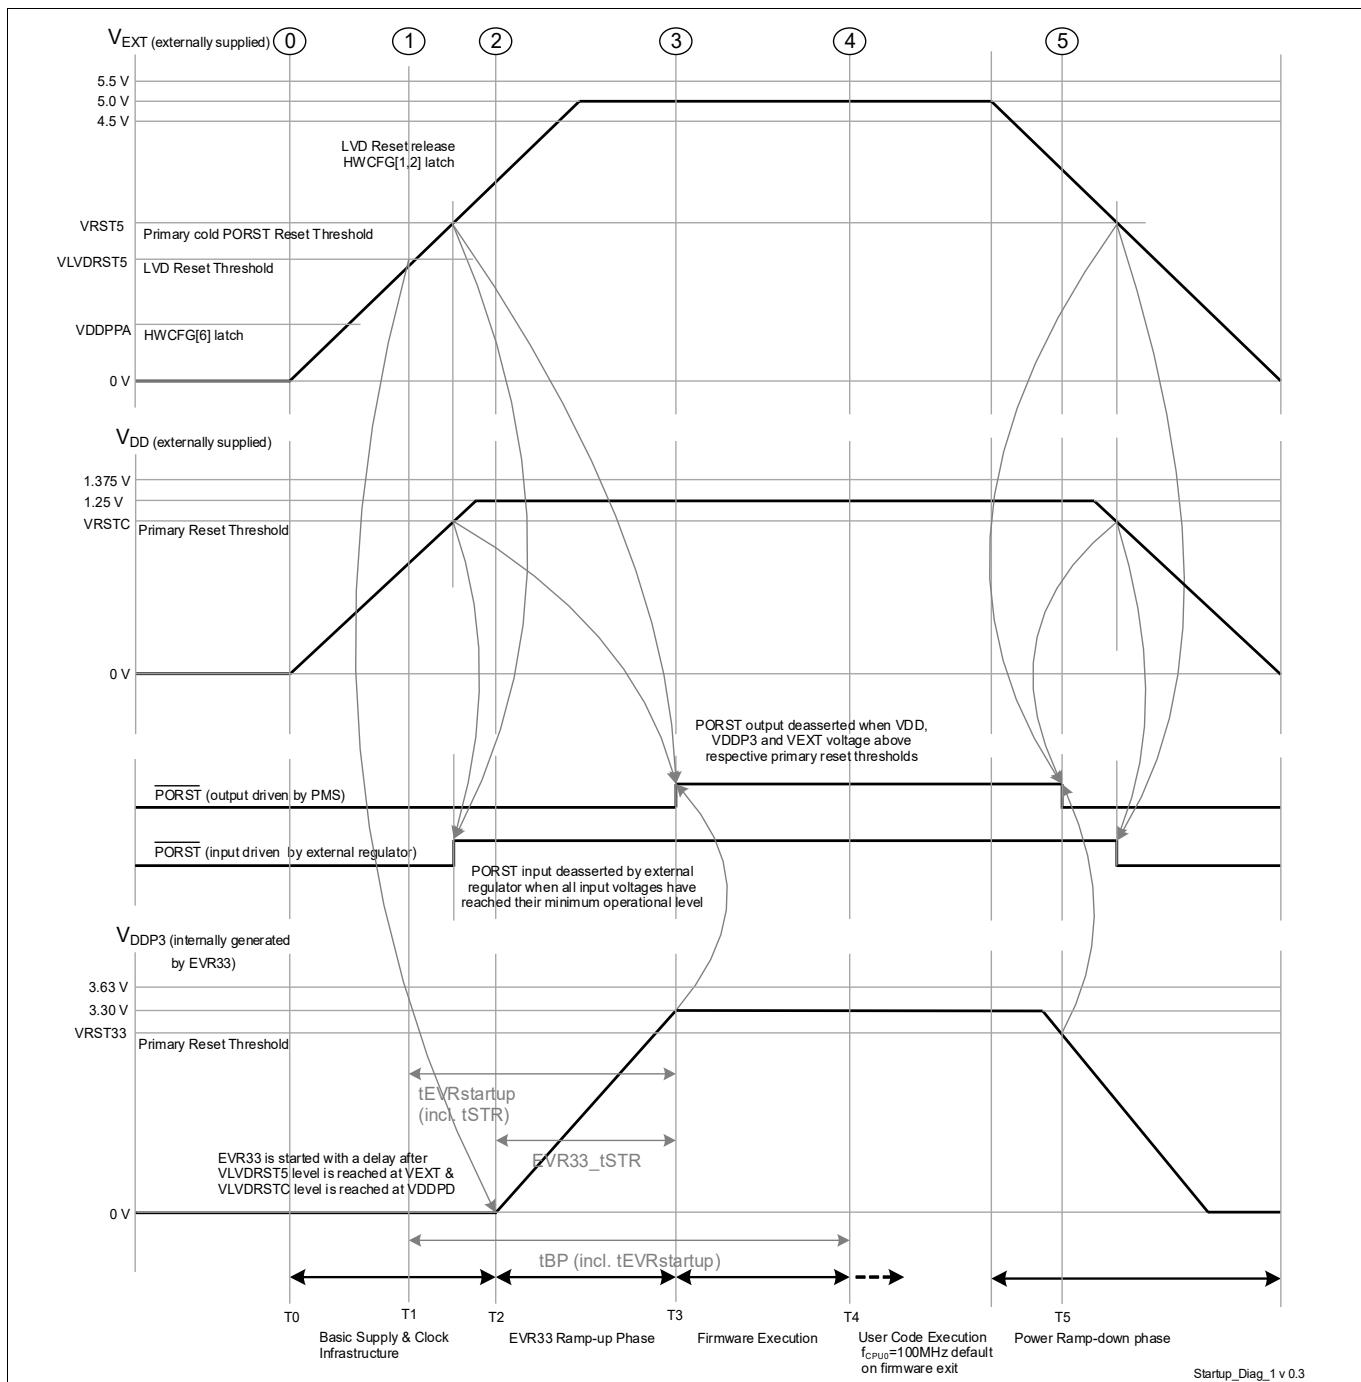

## Power Management System for Low-End (PMSLE)

basic supply and clock infrastructure is available. During reset release at T3, the load jump of upto 150 mA (dIDD) is expected.

- The power sequence as shown in [Figure 125](#) is enumerated below
  - T1 up to T2 refers to the period in time when basic supply and clock infrastructure components are available as the external supply ramps up. The bandgap and internal clock sources are started .The supply mode is evaluated based on the HWCFG[2:1,6] pins. These events are initiated after LVD reset release at T1. LVD reset is released when both input voltages VEXT and VEVRSB are above VLDRST5 and VLDRSTSB levels respectively. Internal pre-regulator VDDPD voltage is above VLDRSTC level.
  - T2 refers to the point in time where consequently a soft start of EVRC regulator is initiated. PORST (input) does not have any affect on EVRC output and regulators continue to generate the respective voltages though PORST is asserted and the device is in reset state. The generated voltage follows a soft ramp-up over the tSTR (datasheet parameter) time to avoid overshoots.
  - T3 refers to the point in time when all supplies are above their primary reset thresholds denoted by VRST5, VRST33 and VRSTC supply voltage levels. EVRC regulator has ramped up. PORST (output) is de-asserted and HWCFG[3:5] pins are latched on PORST rising edge by SCU. Firmware execution is initiated. The time between T1 and T3 is documented as tEVStartup (datasheet parameter).
  - T4 refers to the point in time when Firmware execution is completed and User code execution starts with CPU0 at a default frequency of 100 MHz. The time between T0 and T4 is documented as tBP (datasheet parameter).
  - T5 refers to the point in time during the ramp-down phase when at least one of the externally provided or generated supplies (VDD, VDDP3 or VEXT) drop below their respective primary under-voltage reset thresholds.

## Power Management System for Low-End (PMSLE)

### 12.2.1.2.3 External Supply mode (d)

**Figure 126 External Supply mode (d) - VEXT and VDD externally supplied**

VEXT = 5 V and VDD supplies are externally supplied. 3.3V is generated internally by the EVR33 regulator.

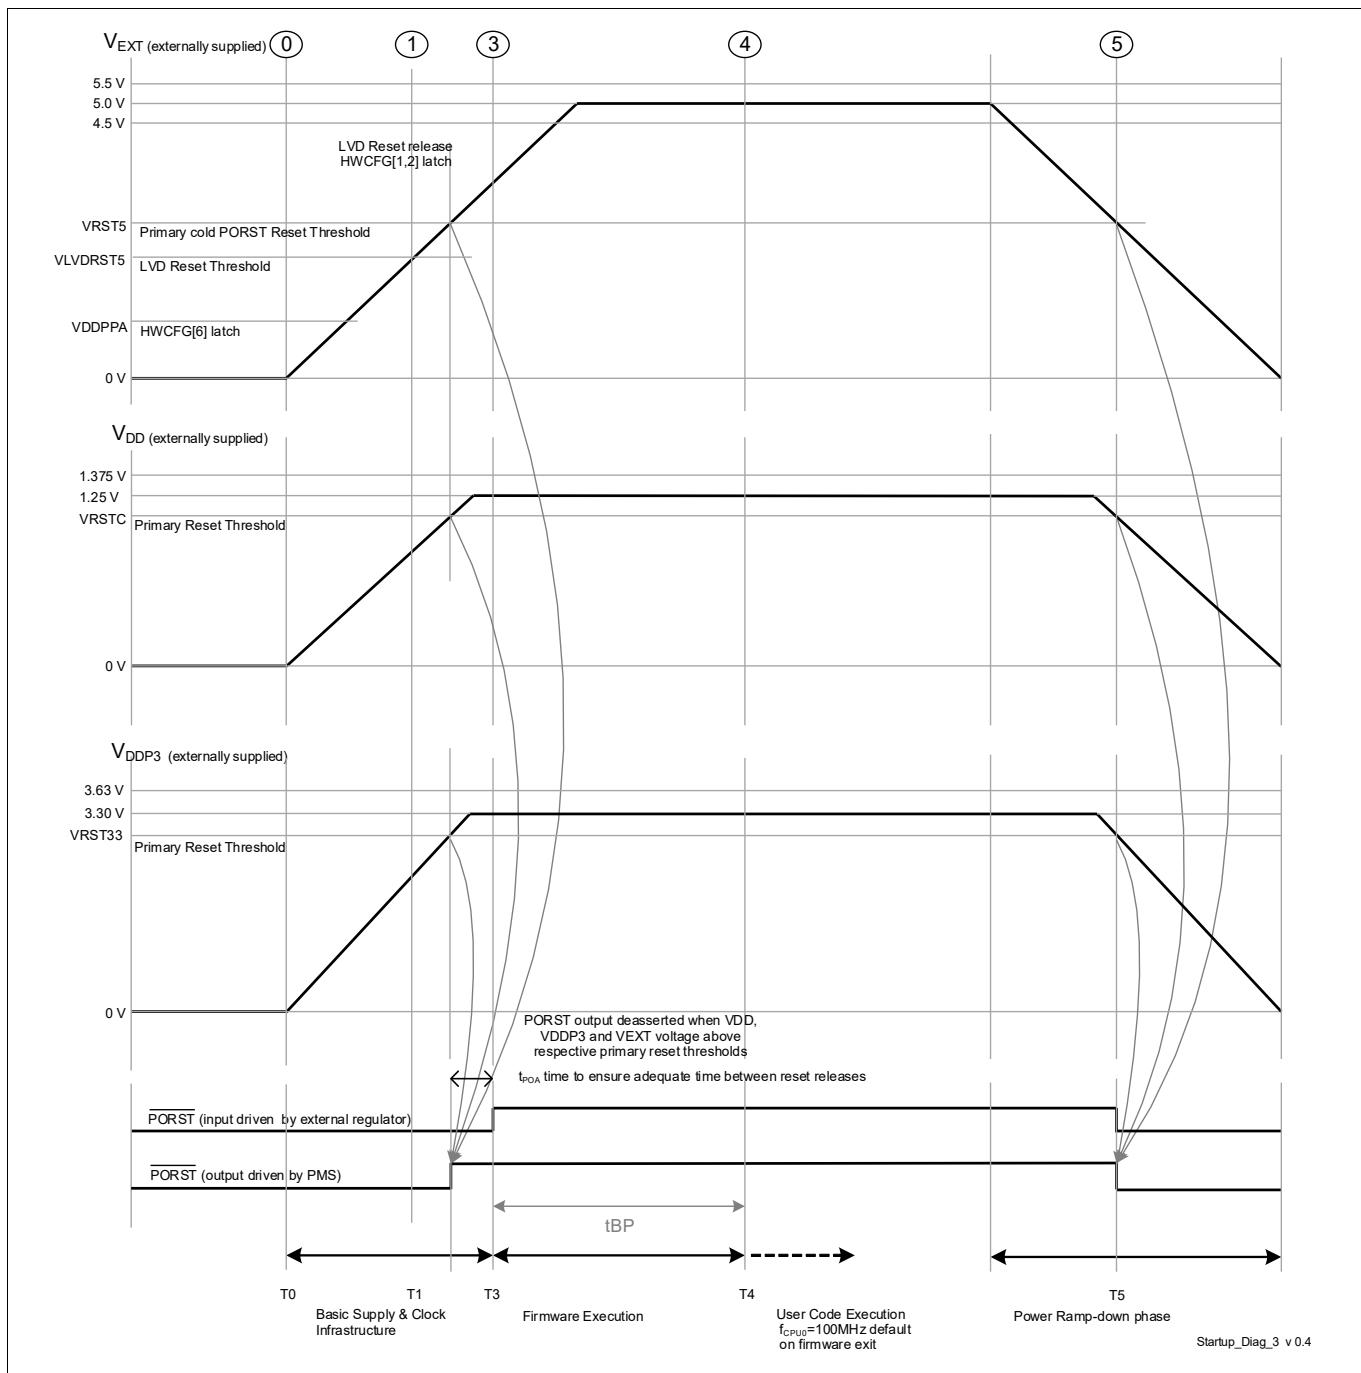

- External supplies VEXT and VDD may ramp-up or ramp-down independent of each other with regards to start, rise and fall time(s). Start-up slew rates for supply rails shall comply to datasheet parameter SR. The slope is defined as the maximal tangential slope between 0% to 100% voltage level. Actual waveform may not represent the specification. It is expected that during start-up, VEXT ramps up before VDD rail. In case VDD voltage rail is ramped up before VEXT; VDD supply overshoots during start-up shall be limited within the operational voltage range.

## Power Management System for Low-End (PMSLE)

- The rate at which current is drawn from the external regulator ( $dI_{EXT}/dt$  or  $dI_{DD}/dt$ ) is limited in the Start-up phase to a maximum of 100 mA with 100  $\mu$ s settling time.
- PORST is active/asserted when either PORST (input) or PORST (output) is active/asserted.
- PORST (input) active means that the reset is held active by external agents by pulling the PORST pin low. It is recommended to keep the PORST (input) asserted until all the external supplies are above their primary reset thresholds.
- PORST (output) active means that  $\mu$ C asserts the reset internally and drives the PORST pin low thus propagating the reset to external devices. The PORST (output) is asserted by the  $\mu$ C when at least one among the three supply domains (VDD, VDDP3 or VEXT) violate their primary under-voltage reset thresholds. The PORST (output) is de-asserted by the  $\mu$ C when all supplies are above their primary reset thresholds and the basic supply and clock infrastructure is available. During reset release at T3, the load jump of up to 150 mA ( $dI_{DD}$ ) is expected.
- The power sequence as shown in [Figure 126](#) is enumerated below
  - T1 up to T2 refers to the period in time when basic supply and clock infrastructure components are available as the external supply ramps up. The bandgap and internal clock sources are started. The supply mode is evaluated based on the HWCFG[2:1,6] pins. These events are initiated after LVD reset release at T1. LVD reset is released when both input voltages VEXT and VEVRSB are above VLVRST5 and VLVRSTSB levels respectively. Internal pre-regulator VDDPD voltage is above VLVRSTC level.
  - T2 refers to the point in time where consequently a soft start of EVR33 regulator is initiated. PORST (input) does not have any affect on EVR33 output and regulators continue to generate the respective voltages though PORST is asserted and the device is in reset state. The generated voltage follows a soft ramp-up over the tSTR (datasheet parameter) time to avoid overshoots.
  - T3 refers to the point in time when all supplies are above their primary reset thresholds denoted by VRST5, VRST33 and VRSTC supply voltage levels. EVR33 regulators has ramped up. PORST (output) is de-asserted and HWCFG[3:5] pins are latched on PORST rising edge by SCU. Firmware execution is initiated. The time between T1 and T3 is documented as tEVStartup (datasheet parameter).
  - T4 refers to the point in time when Firmware execution is completed and User code execution starts with CPU0 at a default frequency of 100 MHz. The time between T0 and T4 is documented as tBP (datasheet parameter).
  - T5 refers to the point in time during the ramp-down phase when at least one of the externally provided or generated supplies (VDD, VDDP3 or VEXT) drop below their respective primary under-voltage reset thresholds.

## Power Management System for Low-End (PMSLE)

### 12.2.1.2.4 External Supply mode (h)

**Figure 127 External Supply mode (h) - VEXT, VDDP3 & VDD externally supplied**

All supplies, namely VEXT, VDDP3 & VDD are externally supplied.

- External supplies VEXT, VDDP3 & VDD may ramp-up or ramp-down independent of each other with regards to start, rise and fall time(s). Start-up slew rates for supply rails shall comply to datasheet parameter SR. The slope is defined as the maximal tangential slope between 0% to 100% voltage level. Actual waveform may not represent the specification. It is expected that during start-up, VEXT ramps up before VDDP3 and VDD rails. If smaller voltage rails are ramped up before VEXT; VDD and VDDP3 supply overshoots during start-up shall be limited within the operational voltage ranges of the respective rails.

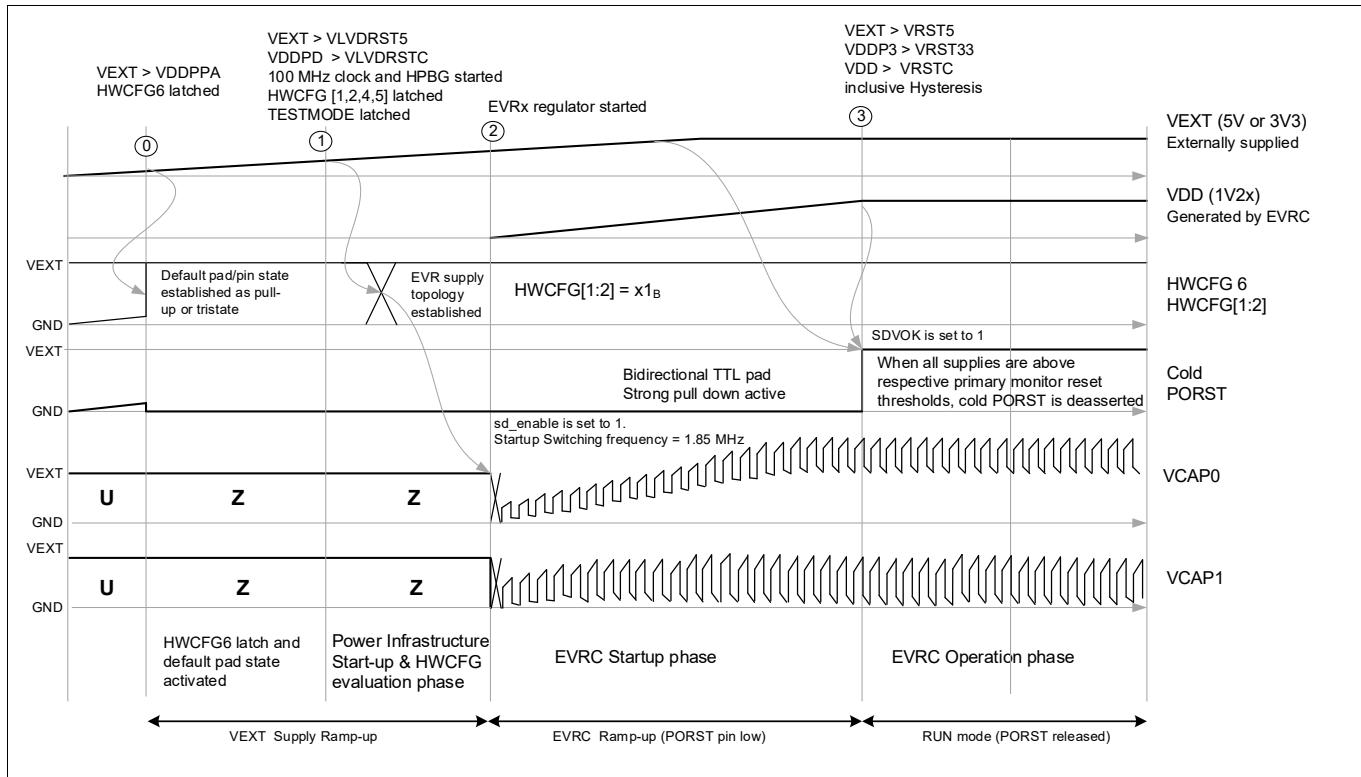

## Power Management System for Low-End (PMSLE)

- The rate at which current is drawn from the external regulator ( $dI_{EXT}/dt$ ,  $dI_{DD}/dt$  or  $dI_{DDP3}/dt$ ) is limited in the Start-up phase to a maximum of 100 mA with 50  $\mu$ s settling time.
- PORST is active/asserted when either PORST (input) or PORST (output) is active/asserted.
- PORST (input) active means that the reset is held active by external agents by pulling the PORST pin low. It is recommended to keep the PORST (input) asserted until all the external supplies are above their primary reset thresholds.
- PORST (output) active means that  $\mu$ C asserts the reset internally and drives the PORST pin low thus propagating the reset to external devices. The PORST (output) is asserted by the  $\mu$ C when at least one among the three supply domains (VDD, VDDP3 or VEXT) violate their primary under-voltage reset thresholds. The PORST (output) is de-asserted by the  $\mu$ C when all supplies are above their primary reset thresholds and the basic supply and clock infrastructure is available. During reset release at T3, the load jump of up to 150 mA ( $dI_{DD}$ ) is expected.
- The power sequence as shown in [Figure 127](#) is enumerated below
  - T1 up to T3 refers to the period in time when basic supply and clock infrastructure components are available as the external supply ramps up. The bandgap and internal clock sources are started. The supply mode is evaluated based on the HWCFG[2:1,6] pins. These events are initiated after LVD reset release at T1. LVD reset is released when both input voltages VEXT and VEVRSB are above VLVRST5 and VLVRSTSB levels respectively. Internal pre-regulator VDDPD voltage is above VLVRSTC level.
  - T3 refers to the point in time when all supplies are above their primary reset thresholds denoted by VRST5, VRST33 and VRSTC supply voltage levels. PORST (output) is de-asserted and HWCFG[3:5] pins are latched on PORST rising edge by SCU. Firmware execution is initiated.
  - T4 refers to the point in time when Firmware execution is completed and User code execution starts with CPU0 at a default frequency of 100 MHz. The time between T0 and T4 is documented as tBP (datasheet parameter).
  - T5 refers to the point in time during the ramp-down phase when at least one of the externally provided supplies (VDD, VDDP3 or VEXT) drop below their respective primary under-voltage reset thresholds.

## Power Management System for Low-End (PMSLE)

### 12.2.1.2.5 EVRC, VCAPx behavior during Start-up

If EVRC regulator is activated via HWCFG[2] = 1, then the behavior of the pins during start-up is as portrayed in **Figure 128**. During VEXT ramp-up, the VCAPx pins are in tristate. Once the HWCFG[2:1] pins are latched and the internal enable signal for the SCDCDC is activated (sd\_enable = 1), EVRC is starting up and the VCAPx pins are driven by the internal switch network at the start-up switching frequency of 1.85 MHz. During the start-up phase, the flying capacitor is charged to the target output voltage and a soft start-up procedure is applied to avoid current overshoots, as described in **Section 12.2.2.2**.

**Figure 128** VCAP behavior during start-up when EVRC regulator is used

## Power Management System for Low-End (PMSLE)

### 12.2.1.3 PMS Infrastructure Components

Power Management System constitutes infrastructure components which need to be started before ramping the EVR33 & EVRC Embedded Voltage Regulators.

- EVR Pre- Regulator (EVRPR)
- 100 MHz Back-up Clock Source (fBACK)
- Secondary High Precision Bandgap reference (SHPBG)
- 70 kHz Standby Clock Source (fSB)
- Primary Low Power Bandgap reference (PLPBG)

#### 12.2.1.3.1 Independent VEVRSB & VDDPD Supply domain and EVR Pre-Regulator (EVRPR)

The objective of the EVRPR is to supply the basic infrastructure components, the Standby domain and certain safety components with a dedicated low-noise independent supply. The EVRPR pre-regulator is supplied directly by the external 5 V or 3.3 V VEVRSB supply. It is implemented as a low drop-out regulator generating the 1.25 V VDDPD internal voltage which is buffered internally and is not routed to any external supply pin. Since EVRPR part is always powered on as long as the external supply is available and also in Standby mode, it is implemented to have low power consumption to meet ISTANDBY current parameter limits in datasheet. The EVRPR supplies the high precision bandgap, the 100 MHz EVR clock source and EVRC / EVR33 regulators as the regulators have to be independent from their generated supplies. The EVRPR also supplies the Standby domain including the Standby RAMs, the Wake-Up Timer, the Standby Controller and a part of the Port domain (Port 33 / 34).

The minimum power detection logic ensures that a minimum voltage level is available on VEXT and VEVRSB external supplies and on the internally generated VDDPD supply via dedicated detectors. The VEXT supply is monitored for minimum VLDRST5 level to ensure that adequate voltage is available to latch HWCFG pins and start EVRC. Likewise, the internal VDDPD supply is monitored for minimum VLDRSTC voltage level by the VDDPD detector with in-built reference. When both conditions are fulfilled the start-up of the EVRPR has been successfully completed and the EVR Low Voltage Detector reset (LVD reset) is released. The 100 MHz clock and high precision bandgap are consequently started. The HWCFG pins are evaluated to establish the supply mode which needs to be activated. Consequently EVRC and EVR33 are started in parallel in a soft ramp-up to ensure a voltage ramp-up with minimal overshoots. In case both EVRC and EVR33 are activated, a normal start-up is completed when both the regulator outputs are stable and operational. Consequently cold PORST reset is released when VEXT, VDDP3 and VDD voltages ramp-ups are complete and the respective voltages are above their minimum operational limits (VRSTxx / VxxPRIUV).

#### 12.2.1.3.2 Reference Voltage Generation : Secondary Bandgap Reference (SHPBG)

The objective of the Secondary High Precision BandGap and Reference current circuitry is to provide an accurate voltage reference and reference currents to various modules. The reference is used by EVRC, EVR33, supply monitors, ADC modules, XTAL Oscillator, Flash, ADC and LVDS Pads.

The secondary high precision bandgap reference is checked against the primary low power bandgap reference or VDDPD voltage to detect bandgap drifts during start-up phase. This is part of the Power BIST ([Section 12.2.2.5.3](#)) which is carried out only during a supply ramp-up.

#### 12.2.1.3.3 100 MHz Back-up Clock Source (fBACK)

The 100 MHz clock source is a precise back-up on-chip clock used by EVRs, firmware and serves as the main system clock during the Start-up phase. It is further used as an independent clock reference for clock monitoring and can be used as a back-up clock in case of loss of lock or crystal failures. After start-up, the 100 MHz clock source has a higher variance in the order of  $\pm 30\%$  and the clock source is later trimmed by the start-up software

---

**Power Management System for Low-End (PMSLE)**

as documented in datasheet. It shall be ensured that the PMS subsystem, boot software / Firmware and the start-up modules are tolerant and functionally robust to this clock variation.

The **EVROSCCTRL** register shall not be modified by the application software, as it is configured by the Start-Up Software in order to trim the back-up oscillator to the specified accuracy limits. Additional compensation for improved accuracy across the temperature range is possible by enabling the dynamic oscillator trimming in the register bits **EVROSCCTRL.OSCTEMPOFFS** and **EVROSCCTRL.OSCTRIMEN**.

---

**Power Management System for Low-End (PMSLE)**

#### 12.2.1.4 Die Temperature Measurement

The Die Temperature Sensor (DTS) generates a measurement result that indicates directly the current temperature. The DTS measures the temperature with an accuracy within ( $T_{NL} + T_{CALACC}$ ) parameter limits within the TSR temperature range documented in the datasheet. The result of the measurement is updated periodically in **DTSSTAT.RESULT** register bit field with a resolution less than 1/5th of a degree Kelvin. The Die Temperature Sensor is available after cold PORST reset release on a device start-up and temperature measurements are carried out continuously during normal RUN / SLEEP modes. The DTS and corresponding registers are not affected by a warm PORST, system or application reset; consequently DTSTAT temperature result from earlier conversion is available for immediate use after any warm reset.

After an ongoing temperature measurement is completed, **DTSSTAT.RESULT** bit field is updated coherently with the new value. An interrupt service request (SRC\_PMSDTS) can be generated after a measurement is completed. The DTS accuracy and measurement time is defined in the Data Sheet.

Die temperature upper and lower limits are configured in **DTSLIM.UPPER** and **LOWER** register bits. On violation of these limits, **DTSLIM.UOF** and **LLU** status bits are set and alarms are forwarded to SMU and HSM. After start-up, the DTS limits have to be re-configured appropriately depending on the application before alarm reactions from SMU or HSM are activated. Only when a new DTS conversion result is available, the DTS comparators are consequently triggered to check the actual **DTSSTAT.RESULT** against the upper and lower limits.

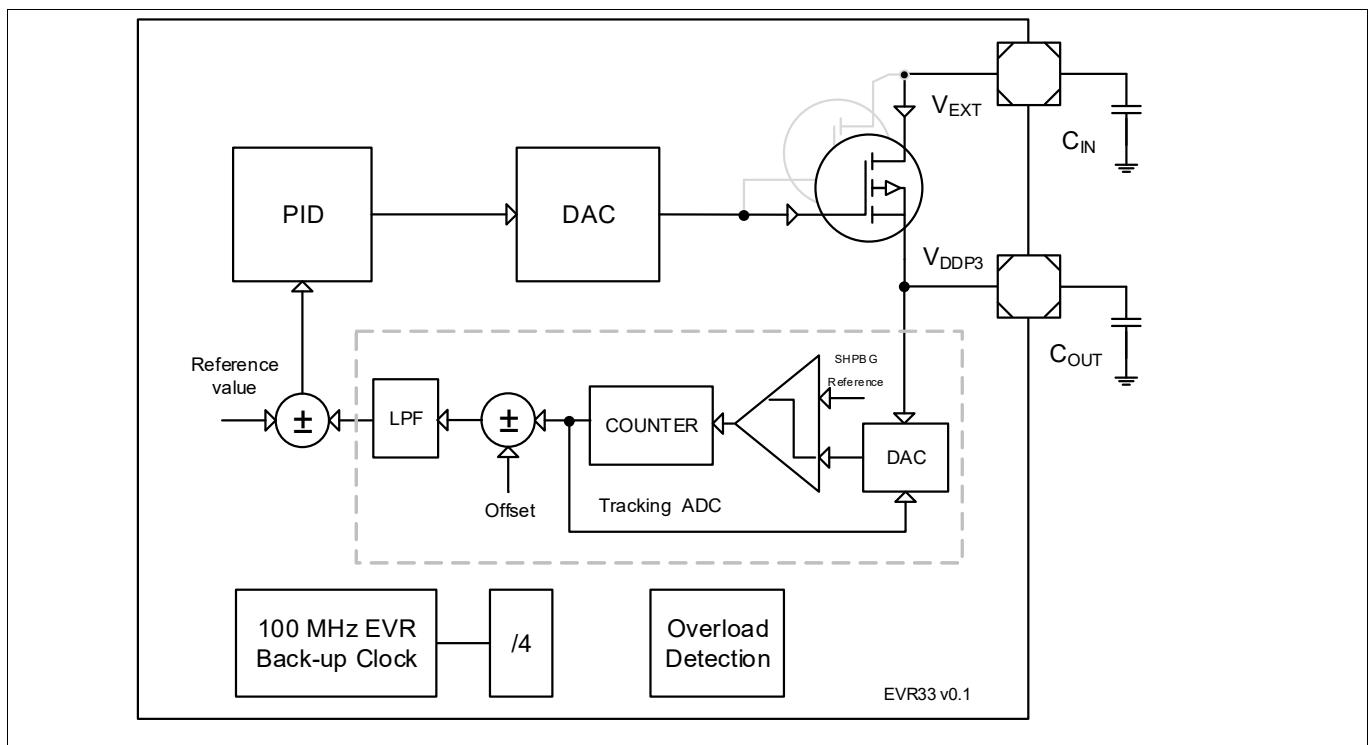

Note: LDMST or SWAPMSK.W should be used only with bit mask enabled for all 'rwh' bits in the **DTSLIM** register.

## Power Management System for Low-End (PMSLE)

### 12.2.2 Power Supply Generation and Monitoring

#### 12.2.2.1 Linear Regulator Mode (EVR33)

The EVR33 regulator supplies the Flash module. EVR33 constitutes a digital regulator, a pass device control unit and a voltage feedback loop. In order to compensate technology and process variations, the ADC and the DAC are device individually trimmed. The EVR33 regulator output voltage ( $V_{DDP3}$ ) is measured by a dedicated ADC using SHPBG reference supply and the result is indicated also in register **EVRADCSTAT.ADC33V**. The closed loop regulation cycle is triggered at the end of the ADC conversion. The error difference is fed to a PID controller and the output of the controller is fed to the DAC to control the gate voltage of the pass devices. The pass device outputs are buffered by external capacitor to handle load transients so as not to violate the operating voltage limits. EVR33 can be individually disabled via HWCFG[1] pin as described in [Chapter 12.2.1.1](#). During the Start-up phase, the setpoint voltage is ramped up in steps over the start-up period to ensure a soft ramp-up of the  $V_{DDP3}$  voltage.

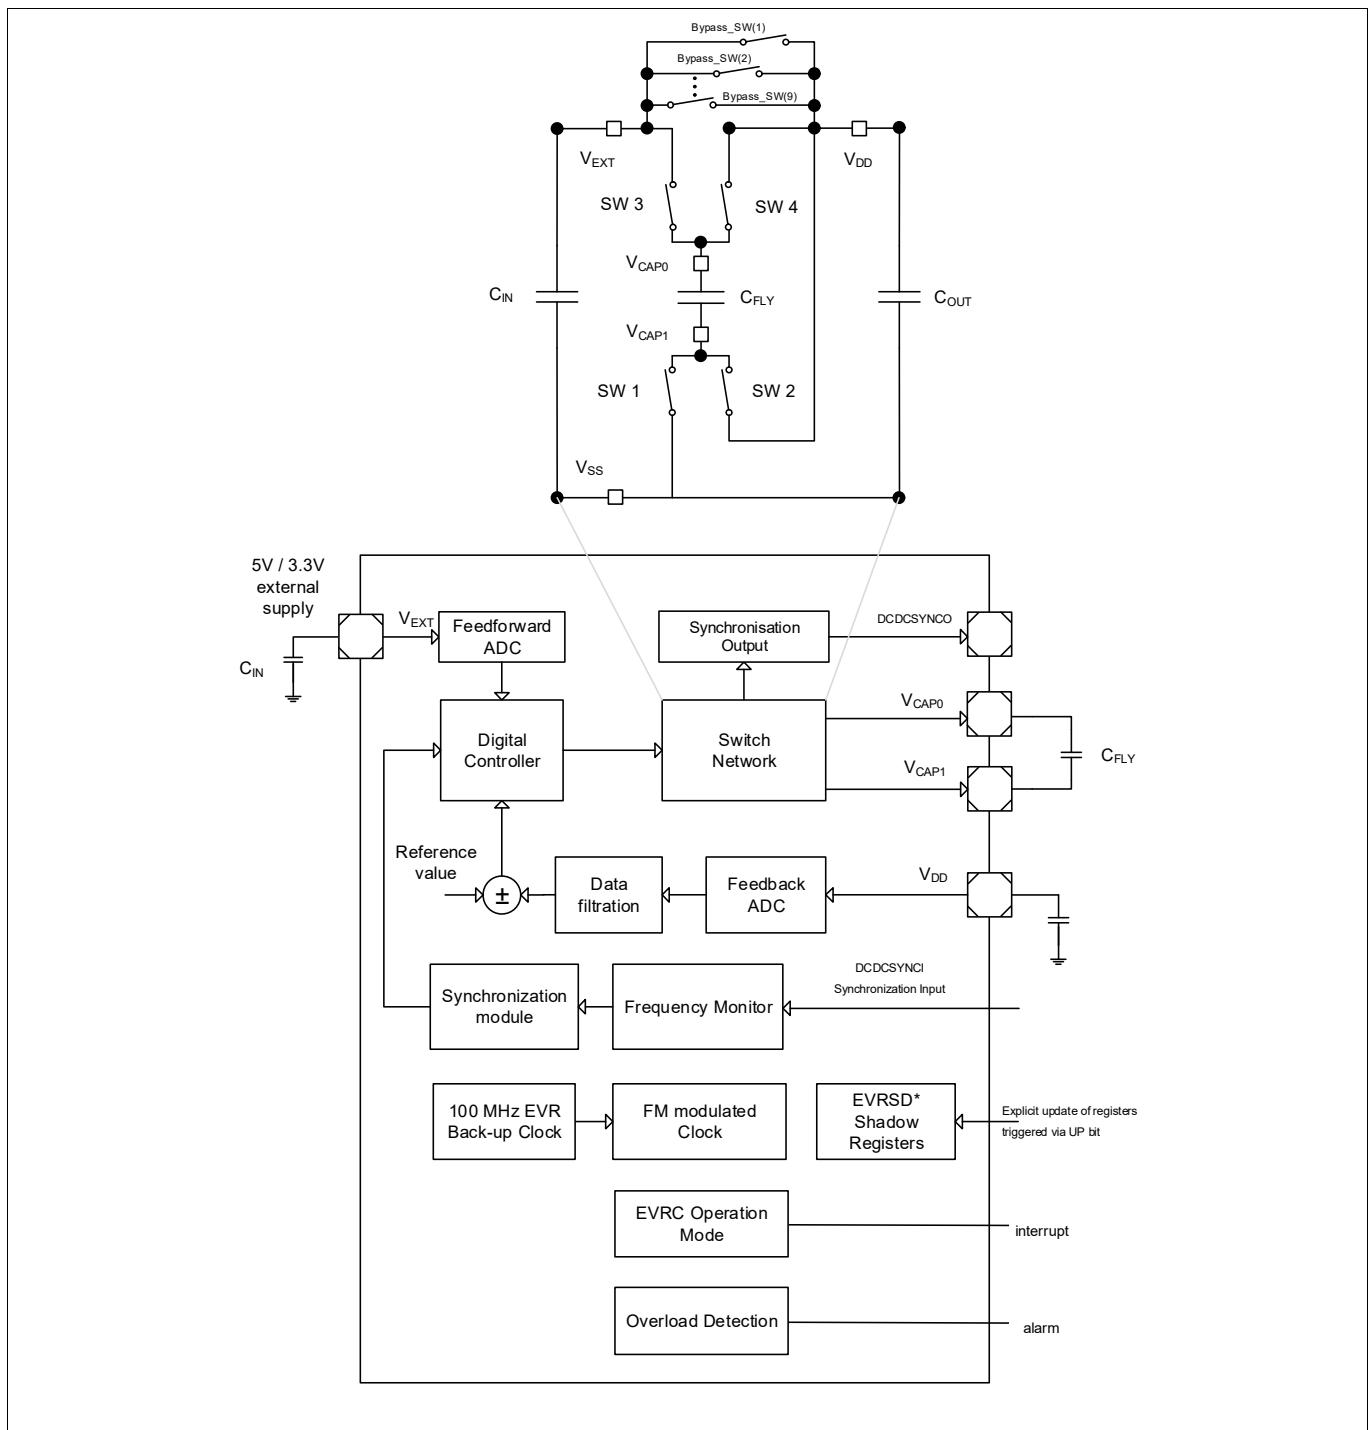

**Figure 129 EVR33 LDO regulator**

## Power Management System for Low-End (PMSLE)

### 12.2.2.2 Switch Capacitor Regulator (EVRC)

The Switch Capacitor SMPS regulator provides a higher efficiency of power conversion compared to the linear voltage regulator concept. However it requires additional external components and injects more switching noise into the system. The integrated switch capacitor regulator modulates internal switches to buffer the energy in capacitors in order to generate a regulated core supply. A flying capacitor and a buffer capacitor is required as shown in [Figure 130](#).

**Figure 130 EVRC Step down regulator**

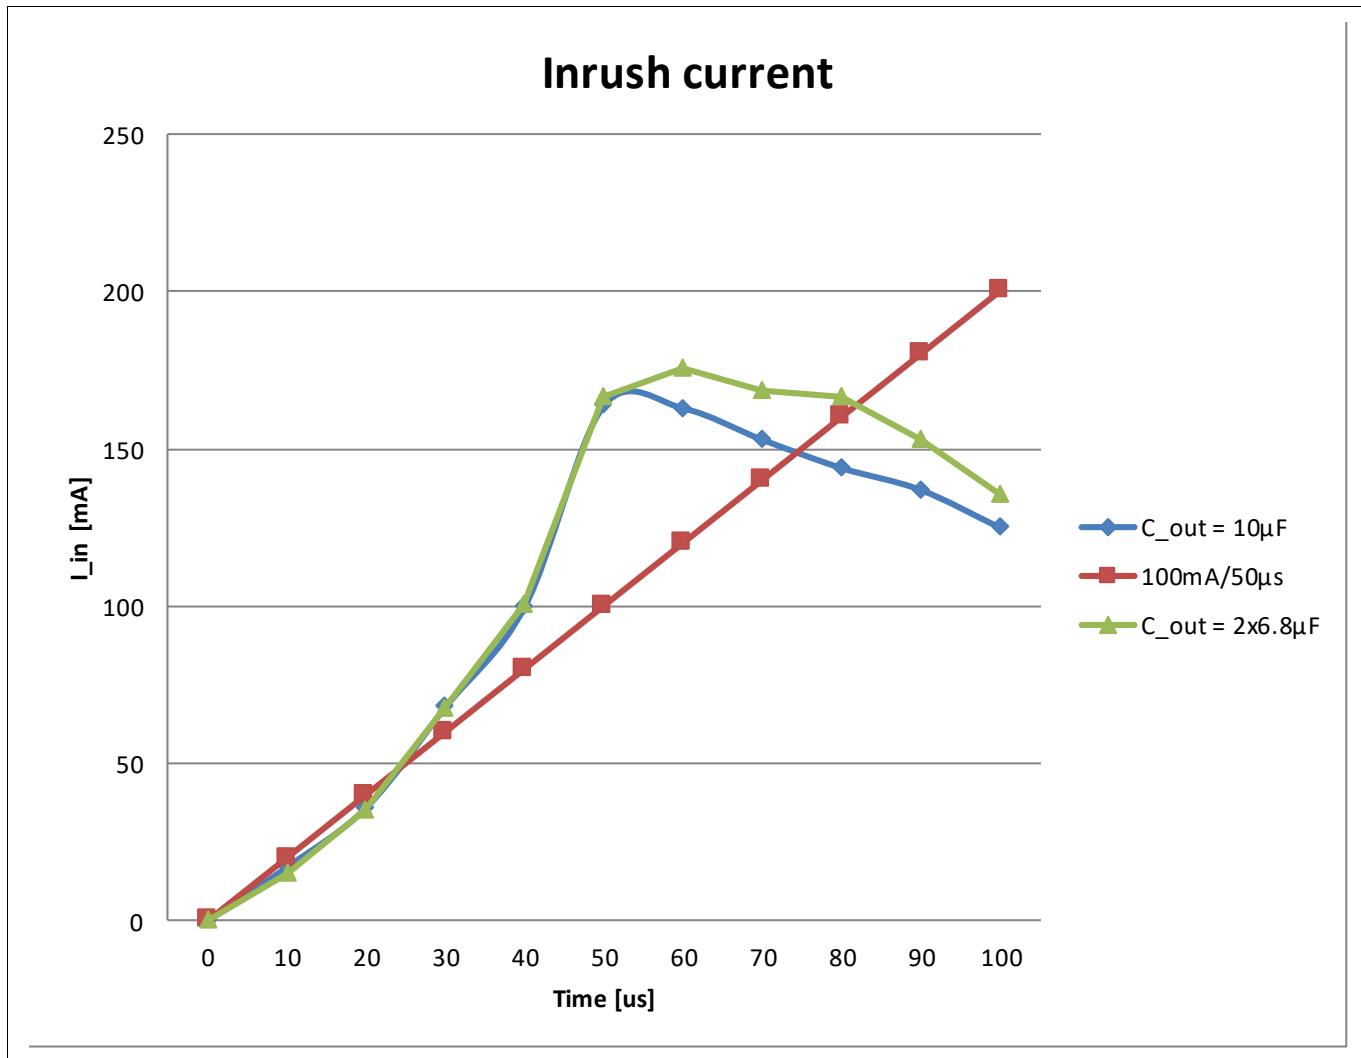

The control strategy involves synchronous switching of the 4 switches at a defined switching frequency in conductance modulation mode thus charging and discharging the switch capacitor network. The regulator

## Power Management System for Low-End (PMSLE)

operates with a fixed conversion ratio of 1/2 in SC mode. The recommended nominal switching frequency is 1.85 MHz in PWM mode and is derived based on efficiency, performance and EMI/EMC trade-off. The nominal switching frequency is configured with a 10 ns switching period resolution at a base frequency of 100 MHz back-up clock. The charge / discharge time are programmable via **EVRSDCTRL1.TON** and **TOFF** fields which inturn determine the switching frequency. The charge and discharge time are kept equal for best ripple performance. The output voltage is measured via the SMPS feedback ADC module and based on the deviation to the reference voltage the controller modulates the conductance value for the next charge / discharge period. The measured output voltage is then fed into the digital filter and provided to the digital controller. The measured core voltage is indicated in **EVRSDSTAT0.ADCFBCV** status bits. The target of the digital controller is to compute the new conductance control output based on the feedback. The conductance value of the previous period is indicated in **EVRSDSTAT0.CONDUCTANCE** status bits. The parameters for the digital controller are programmable. The external VEXT supply is also measured by the Primary SWD/VEXT Monitor ADC to facilitate a parameter switch incase the voltage crosses a threshold and to differentiate between 5 V or 3.3 V external supply case.

During the start-up phase, a soft-startup control strategy is used in order to avoid an overshoot of the output voltage and the charging of the buffer capacitor takes place gradually. During the initial switching periods a different set of coefficients are used in open loop operation. The conductance value is gradually changed to avoid current overshoots and keep the current jumps within 100 mA/50 us. The default switching frequency is 1.85 MHz during open loop start-up phase. The open loop operation ends when the ADC indicates that the output voltage is slightly below the target value. At this point the digital controller is re-configured and the normal closed loop operation begins. After a voltage transient (typically an overshoot), EVRC is ready and regulator output voltage is ok as indicated via **EVRSTAT.SDVOK**. The start-up phase and VCAPx behavior is portrayed in [Figure 128](#). The parameters of the step down regulator is consequently updated by the Firmware after reset release to achieve a more accurate EVRC output voltage and improved performance. The step-down regulator is also later programmed with the values enumerated in [Table 385](#) so as to match the application needs and the components used. A complete parameter update is triggered explicitly by writing to **EVRSDCTRL0.UP** bit and it need to be ensured that all the registers are consistent before triggering the update. The parameter update is not allowed during Start-up Mode. The droop compensation request and droop level value are taken immediately without waiting for a parameter update. During consequent supply ramp-down phase, the step down regulator ensure a graceful shut-down devoid of output voltage overshoots beyond absolute max ratings.

## Power Management System for Low-End (PMSLE)

**Figure 131 EVRC Inrush Current with different  $C_{out}$  values**

The conductance of the switches is, in a first order approximation, proportional to the current provided to the load. The switches are implemented as MOS transistors and the resistance of the active switches sets the maximum current capability. The output voltage VDD is measured with a 8 bit SMPS tracking ADC synchronous to the PWM and sampled twice every switching period. The digitized output voltage is then fed into the digital filter and the new conductance value is appropriately calculated by the PI controller. ADC samples are measured at the end of the charging and discharging phases corresponding to the double sampling scheme. The parameters for the PI controller are programmable.

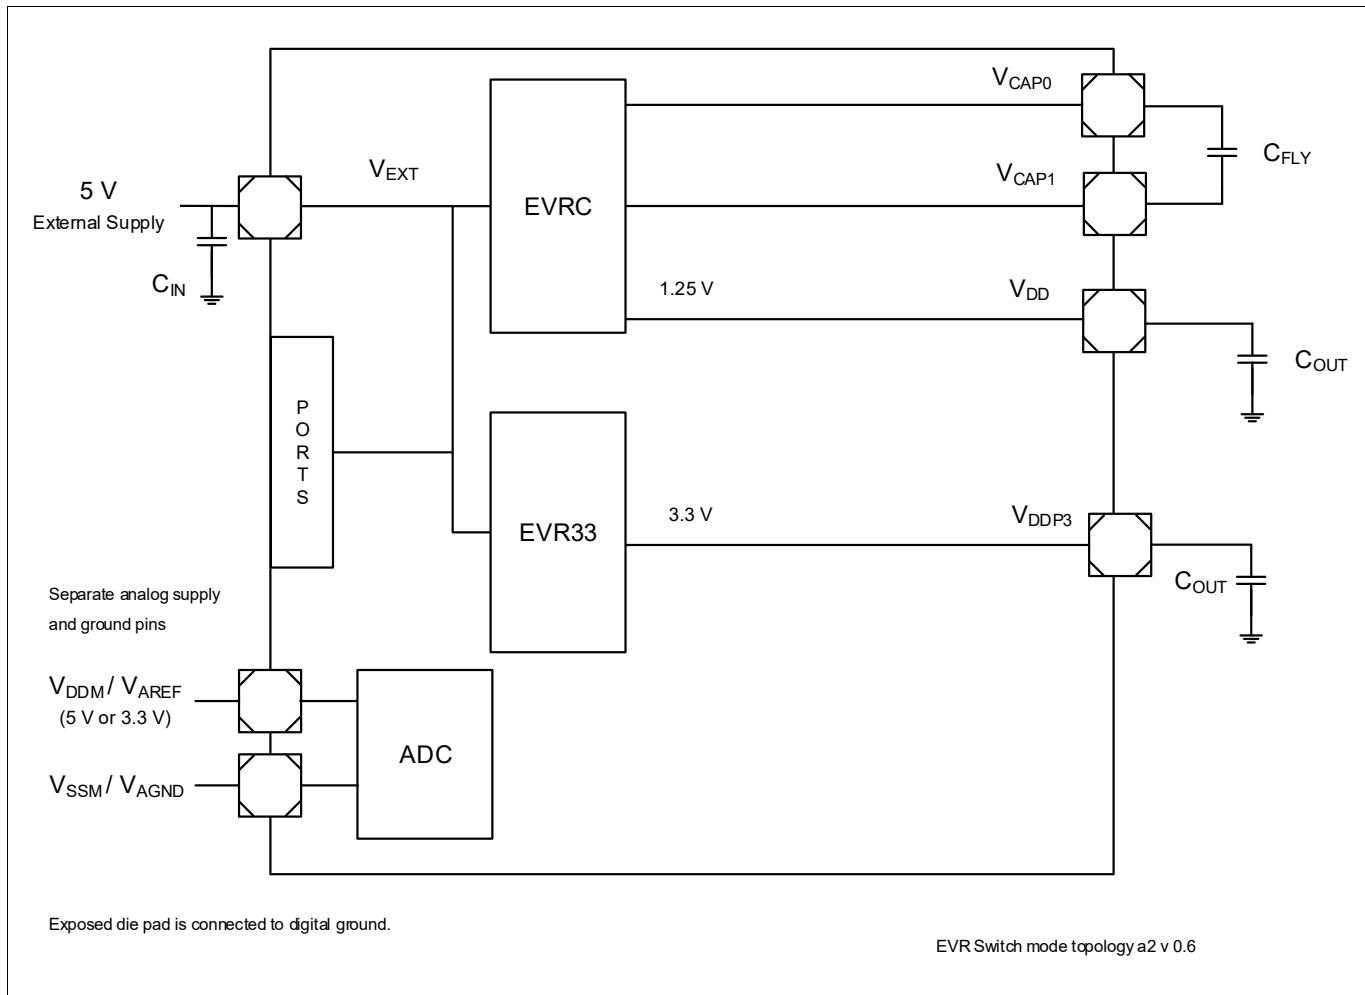

Maximum load current capabilities are limited in SC operational mode by the on-resistance of the switches (implemented using MOS transistors). In order to supply higher load currents, an additional set of bypass switches are implemented, as shown in Figure 11. A total of 9 bypass switches are implemented, adding increasingly higher load current capabilities as follows:

- bypass switch 1, adding 11 mA load current capability
- bypass switch 2, adding 22 mA load current capability
- bypass switches 3-9, each of them adding 44 mA load current capability

The step-down regulator may be informed on anticipated load jumps so that adequate preparation can be made. The controller could lower or raise the output voltage to compensate and thus minimise voltage over-/undershoots owing to a sudden load jump. The management of voltage droop is described in Power Management [Section 12.2.3.5](#)

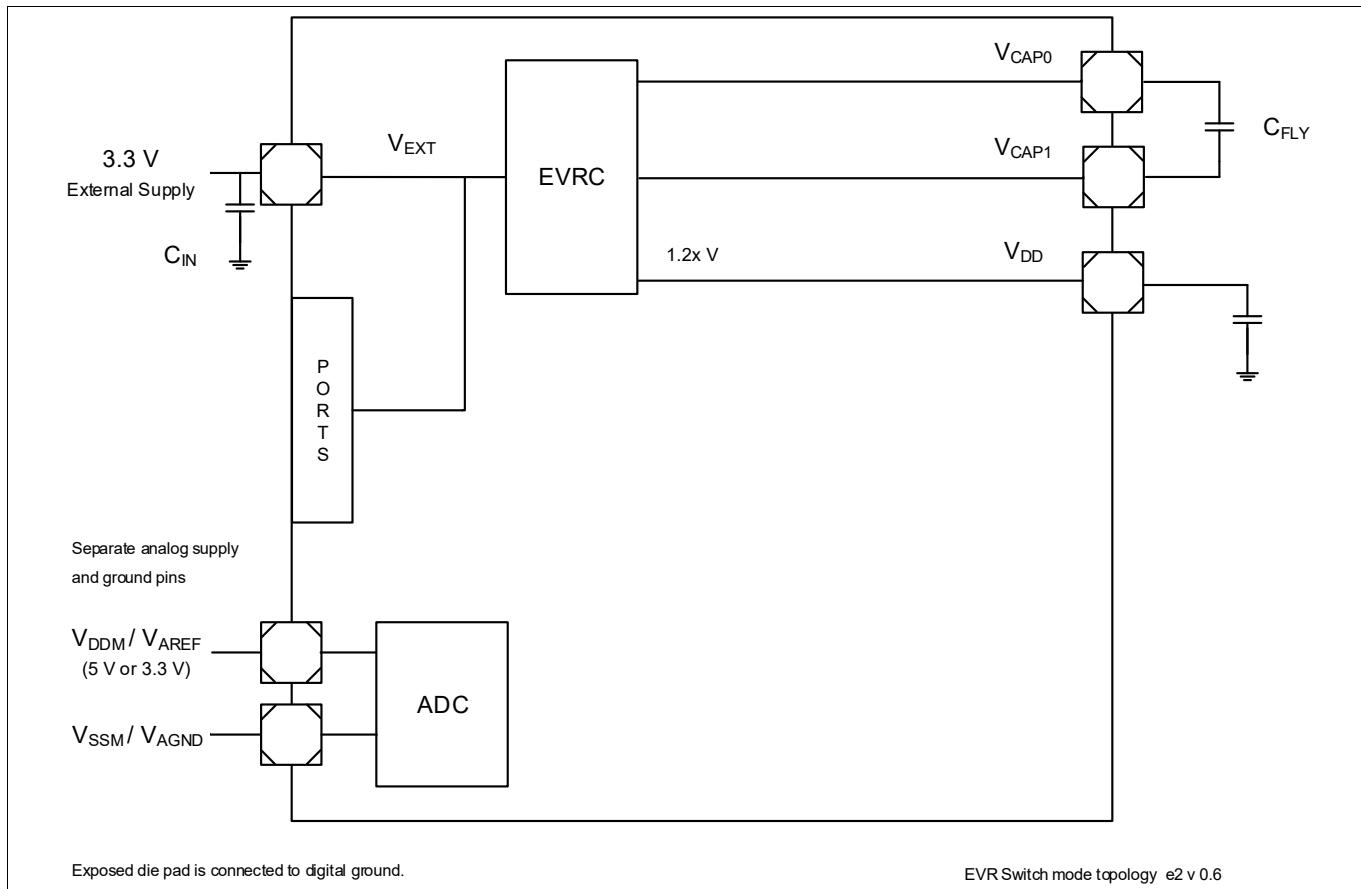

## Power Management System for Low-End (PMSLE)

In case frequency spreading is activated, the charge and discharge times are appended with a uniform random offset once per switching period. This allows to randomize the switching frequency of the SC DCDC regulator within a maximum value. The maximum random offset is bounded by the programmed value in **EVRSDCTRL0.SDFREQSPRD** register field. It is possible to synchronize an external step-down regulator which may run at much lower switching frequencies than the internal regulator. A scaled synchronisation clock output is provided and routed to an external pin (DCDCSYNC output).

**Figure 132 EVR Switch mode topology (a) - 5 V single supply**

## Power Management System for Low-End (PMSLE)

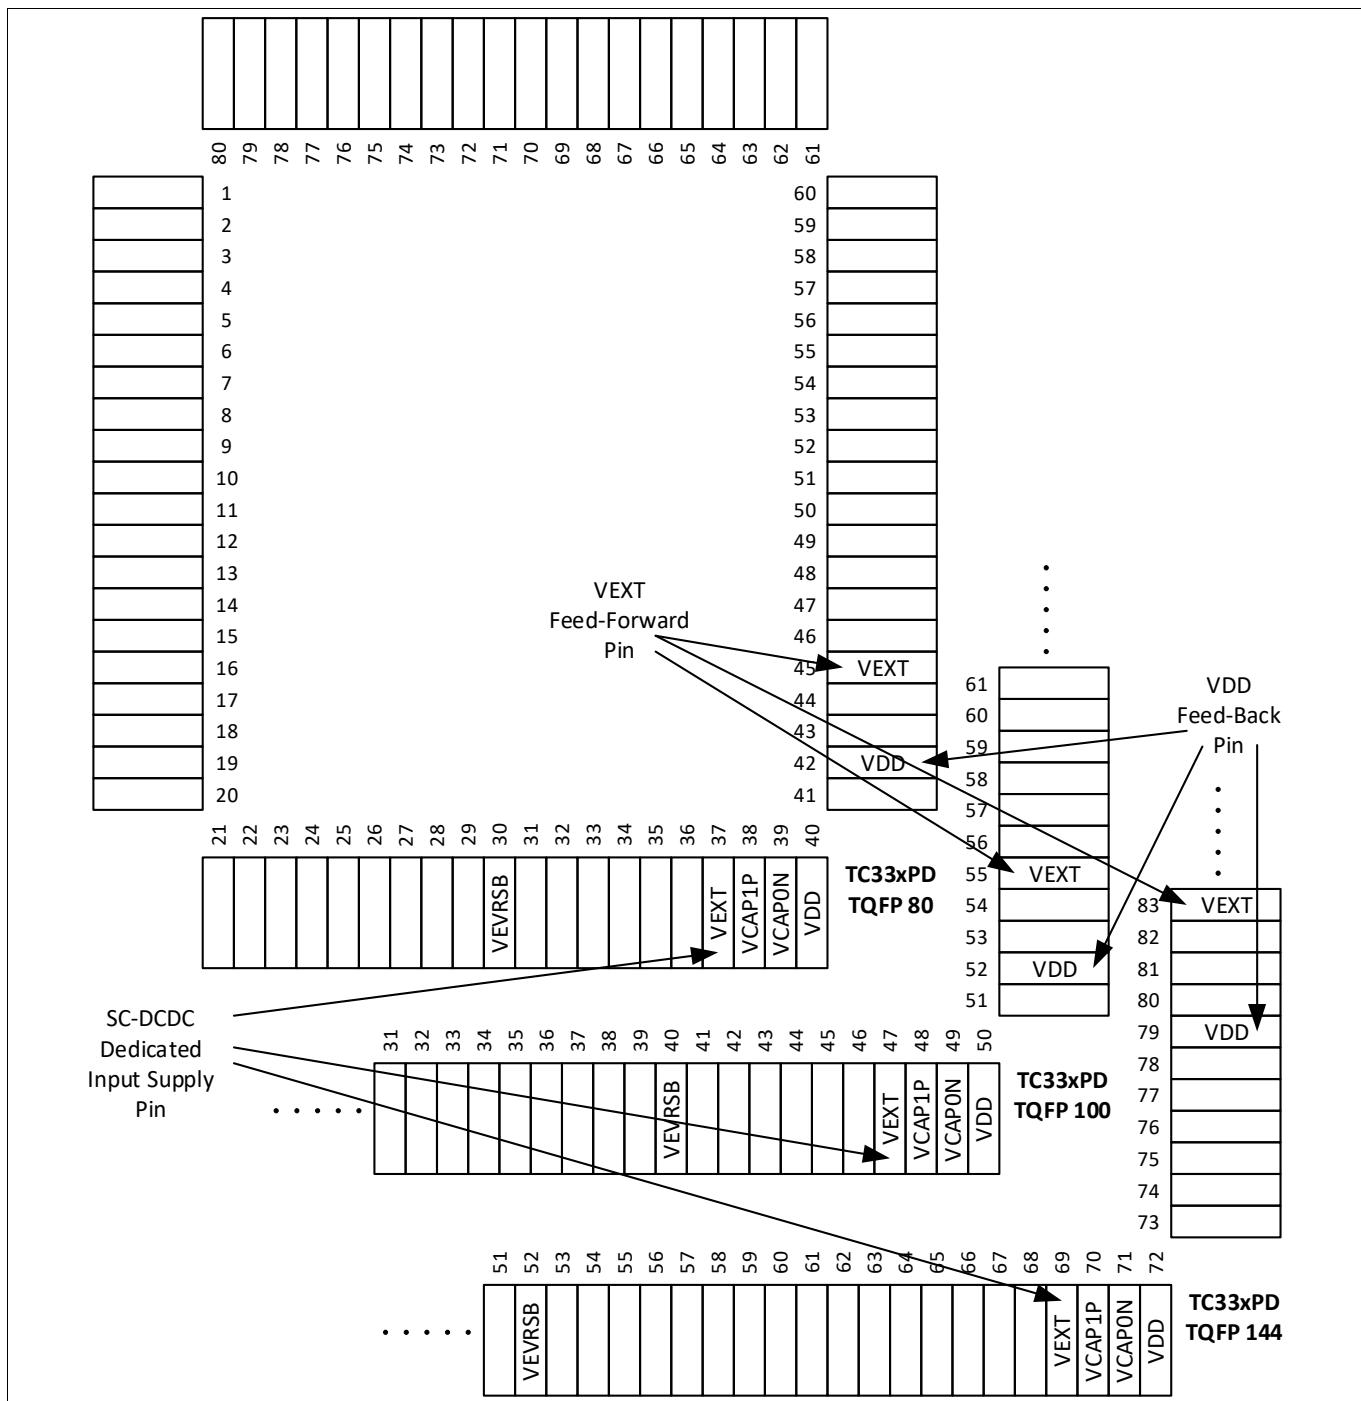

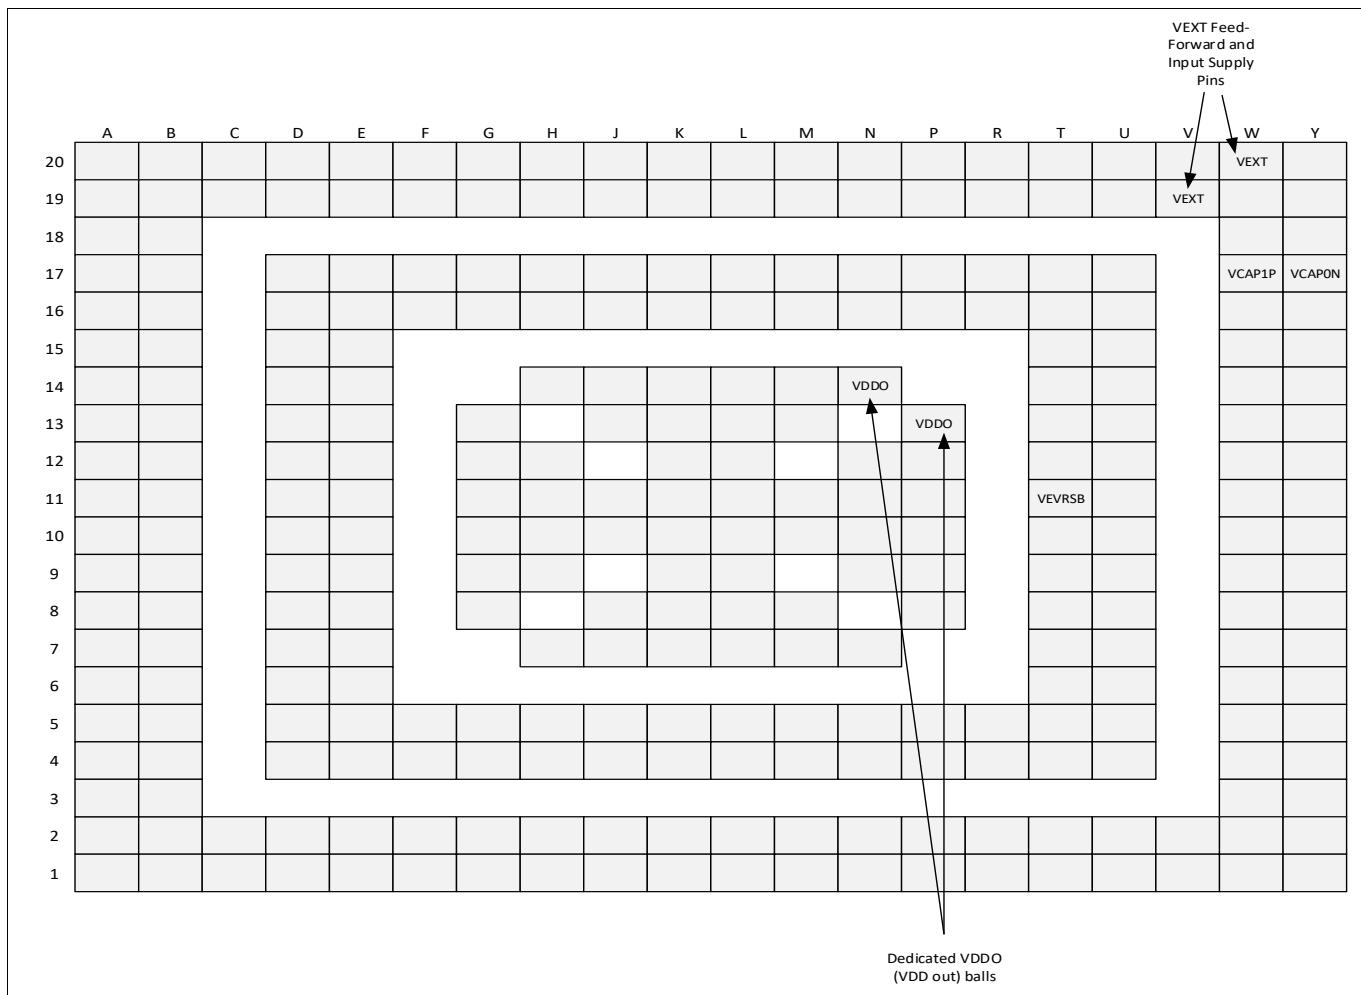

**Figure 133 EVR Switch mode topology (e) - 3.3 V single supply**

In case the current consumption in SC SMPS mode exceeds the switching regulator capabilities as indicated in the datasheet (IMAXSC parameter), bypass switches are automatically activated and a consequent interrupt (SRC\_PMS1) is issued to the system. The switch from the normal SC mode (EVRCMOD = 00b) to bypass switches enabled (EVRCMOD = 01b) is also indicated via **EVRSTAT.EVRCMOD** status bits. The lower bit of **EVRSTAT.EVRCMOD[12]** signal is used to generate the interrupt on SRC\_PMS1 interrupt node on a transition. Toggling of the **EVRSTAT.EVRCMOD** lower bit is expected for load currents around the IMAXSC threshold and multiple interrupts can be triggered as a result.

### 12.2.2.2.1 EVRC Supply Pins

The EVRC SC-DCDC pins, for the QFP and BGA packages, are shown in [Figure 134](#) and [Figure 135](#).

**Power Management System for Low-End (PMSLE)**

**Figure 134 EVRC SC-DCDC Supply Pins for QFP Packages**

**Power Management System for Low-End (PMSLE)**

**Figure 135 EVRC SC-DCDC Supply Pins for BGA Package (LFBGA292)**

In BGA packages, there is no dedicated VDD feedback ball. Instead, the VDD sense pin is connected inside the package to the common VDD plane in the redistribution layer (RDL).

#### 12.2.2.2.2 VDD Connectivity

It shall be ensured that all the VDD pins are connected together on the PCB. The VDD output pin is separated from the VDD feedback sense point pin, as shown in [Figure 123](#).

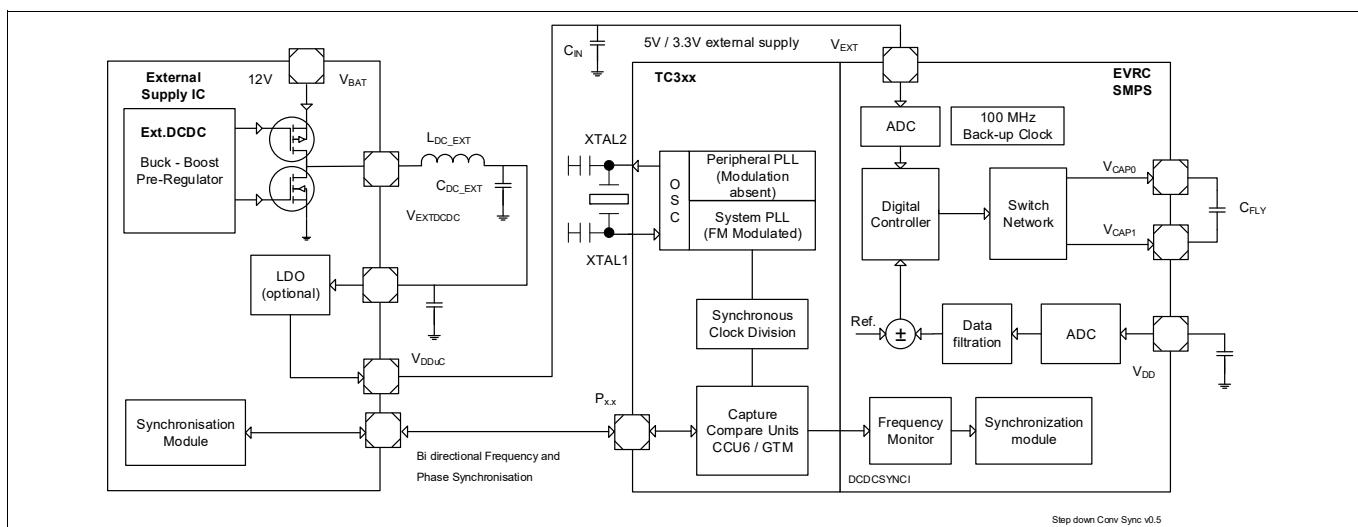

## Power Management System for Low-End (PMSLE)

### 12.2.2.2.3 EVRC Frequency and Phase Synchronization to CCU6/GTM Input

A synchronization input (DCDCSYNCI) is provided to the EVRC SMPS regulator from CCU6 or GTM module to synchronize the frequency and the phase of the internal EVRC regulator to the external DC DC regulator. The CCU6 / GTM module provides / captures two phase synchronised PWM signals; one PWM output to the internal EVRC regulator and the other as either input from or output to an external DC DC regulator using a Port pin as shown in **Figure 136**. The synchronization should only be enabled in trimmed mode, not during start-up or untrimmed mode. The pre-conditions for synchronization are:

- **EVRSDCTRL1.SYNCEN = 1<sub>B</sub>** - synchronization module enabled
- EVRC has finished the start-up phase and operates in trimmed mode.
- The synchronization input frequency range supported is between 1.6 MHz and 2 MHz. The nominal frequency of the synchronization input is 1.85 MHz. Bi-directional signal to/from external regulator is provided by the CCU6 or GTM unit.
- For correct edge detection, the duty cycle of the input synchronization signal shall be at least 20 ns (i.e. two 100 MHz clock cycles).

To disable the synchronization mode, SW shall configure **EVRSDCTRL1.SYNCEN = 0<sub>B</sub>**. The synchronization input source can be selected either from CCU6 or GTM inputs via the **EVRSDCTRL2.SYNCMUXSEL** bit-field.

**Figure 136 EVRC Synchronization Input**

The frequency monitor allows a maximum tolerable deviation of the synchronization input as configured in **EVRSDCTRL2.SYNCMAXDEV** register bit fields. A hysteresis is applied for the locking and unlocking, such that toggling lock behavior is avoided around the frequency monitoring limits as configured in **EVRSDCTRL2.SYNCHYST** hysteresis width register bit field. The DCDC locks to the synchronization signal if its period is within the following range:

- Sync. signal period  $\leq$  540 ns + **EVRSDCTRL2.SYNCMAXDEV** \* 10 ns - **EVRSDCTRL2.SYNCHYST** \* 10 ns
- Sync. signal period  $\geq$  540 ns - **EVRSDCTRL2.SYNCMAXDEV** \* 10 ns + **EVRSDCTRL2.SYNCHYST** \* 10 ns

Synchronization is unlocked when the synchronization signal leaves the hysteresis range, i.e.:

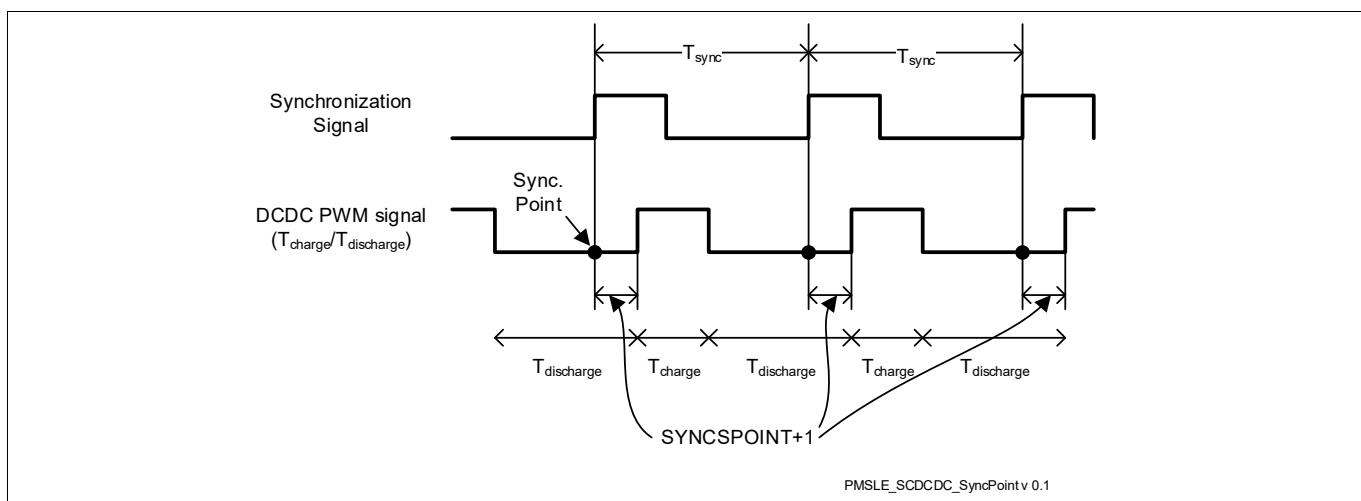

- Sync. signal period  $\geq$  540 ns + **EVRSDCTRL2.SYNCMAXDEV** \* 10 ns
- Sync. signal period  $\leq$  540 ns - **EVRSDCTRL2.SYNCMAXDEV** \* 10 ns

Here, the 540 ns represent the period of the nominal 1.85 MHz frequency (i.e. 54 cycles of 100 MHz) and the SYNCMAXDEV and SYNCHYST parameters are expressed in cycles of 100 MHz (i.e. number of 10 ns slots). The maximum deviation **EVRSDCTRL2.SYNCMAXDEV** can be specified up to 31 and the hysteresis range **EVRSDCTRL2.SYNCHYST** can be specified up to 7.

## Power Management System for Low-End (PMSLE)

The status of the synchronization lock is indicated via **EVRSTAT.SYNCLCK** bit. The loss of Synchronization Lock event is indicated by an interrupt which can be enabled via the **PMSIEN.SYNCLCK** register bit.

A programmable delay is introduced between the rising edge of the external synchronization signal and the rising edge of the DCDC PWM signal, required to safely turn off the discharge switches and perform calculations for the next switching cycle (FB-ADC sampling, conductance evaluation, bypass switch update etc.). This delay can be programmed by the SW in the **EVRSDCTRL6.SYNCSPOINT** bit-field and is expressed as a number of 100 MHz cycles (number of 10 ns slots). The rising edge of the synchronization signal will then be synchronized to the rising edge of the DCDC PWM signal - **EVRSDCTRL6.SYNCSPOINT** - 1, thus the delay between the signals is **SYNCSPOINT+1** cycles. This delay defines the Synchronization Point and is illustrated in [Figure 137](#).

**Figure 137 Synchronization Point between External Synchronization Signal and DCDC PWM Signal**

The synchronization point shall be set during the discharge phase, to allow turning off the discharge switches. The minimum setting for **EVRSDCTRL6.SYNCSPOINT** is 7, thus the minimum delay between the signals is 8 cycles (i.e. 80 ns). The reset value of **EVRSDCTRL6.SYNCSPOINT** is 8 and the SW shall never program a value below 7. The maximum delay is determined by the programmed discharge time (see the **EVRSDCTRL1.TOFF** setting).

### Synchronization Lock Procedure

- After the completion of the start-up phase, all EVRC parameters are configured as per the intended configuration. The **EVRSDCTRL2.SYNCMAXDEV** and **SYNCHYS** bit fields are configured. Frequency spreading, if required, can be activated in the **EVRSDCTRL0.SDFREQSPRD** register field. If frequency spreading is enabled (i.e. **EVRSDCTRL0.SDFREQSPRD > 0**), it is applied also during the synchronized state, however by increasing or decreasing only the charge phase by a random number of 100 MHz cycles within the programmed range (since the rising edges of the PWM and the input signal must remain in sync).
- A synchronization input signal is provided and configured in GTM / CCU6 module and is selected via **EVRSDCTRL2.SYNCMUXSEL** bit field. GTM LCDCDCOUT signal is selected via the LCDCDCOUTSEL register in GTM module. In case of CCU60, only COUT63 is routed. A phase shifted signal may be provided to the external DCDC regulator.
- When no load / line transients are ongoing, **EVRSDCTRL1.SYNCEN** bit is set to initiate the Synchronization Lock procedure.
- The frequency of the incoming synchronization signal is monitored for a single period consequently after **EVRSDCTRL1.SYNCEN** bit is set. At least one input period is required to evaluate whether the input frequency is valid. A parameter update is required to transfer the synchronization enable information.
- There are two locking options available, configurable via the **EVRSDCTRL6.SYNCLCKOPT** bit:
  - **EVRSDCTRL6.SYNCLCKOPT = 0<sub>B</sub>** - fast locking option (typical duration is 1-2 switching cycles)

## Power Management System for Low-End (PMSLE)

- **EVRSDCTRL6.SYNCLCKOPT = 1<sub>B</sub>** - slow locking option (typical duration is 4-8 switching cycles)
- Fast locking can cause an undershoot of the output voltage. The reset setting is 1<sub>B</sub> (slow locking) and is the recommended option for all applications where the synchronization locking time is not critical, to avoid the possible undershoots. A smooth synchronization is achieved by optimizing the frequency and phase correction depending on the moment of the rising edge of the synchronization signal.
- When the synchronization is completed, the DCDC switching frequency and phase is altered and locked to the incoming signal.
- When the DCDC switching frequency is locked to the synchronization input, the **EVRSTAT.SYNCLCK** status bit is set into locked state indicating the completion of the lock procedure.

### Synchronization Un-Lock Procedure

- The **EVRSDCTRL1.SYNCEN** bit shall be reset to initiate the Synchronization unlock procedure.
- As soon as synchronization is disabled via **EVRSDCTRL1.SYNCEN**, the **EVRSTAT.SYNCLCK** status bit toggles into unlocked state. The Synchronization unlock interrupt is generated if enabled (via **PMSIEN.SYNCLCK**).
- The synchronization input signal is consequently deactivated from GTM / CCU6 module via **EVRSDCTRL2.SYNCMUXSEL** bit field. The phase shifted signal to the external DCDC regulator from GTM / CCU6 is also deactivated.

### Synchronization Un-Lock Event

- In case the frequency of the input synchronization signal violates the allowed limits (respectively more than nominal period + maximum deviation or is less than nominal period - maximum deviation), the EVRC unlocks and continues operation with the programmed charge/discharge times.
- As soon as the synchronization is lost, the **EVRSTAT.SYNCLCK** bit toggles into unlocked state. The Synchronization unlock interrupt is generated if enabled (via **PMSIEN.SYNCLCK**).
- A re-lock is triggered when the incoming signal period is less than (nominal period + maximum deviation - sync hysteresis) or more than (nominal period - maximum deviation + sync hysteresis).

## Power Management System for Low-End (PMSLE)

### 12.2.2.3 Components and Layout

The efficiency of EVR is influenced by the characteristics of the selected components and also the placement and routing of the components on the PCB. The additional external components for the SC SMPS regulator constitute a flying capacitor (1 uF) and a buffer capacitor (10 uF). An input capacitor (4,7 uF) is required in case of SC SMPS mode to limit the input current ripple. The trace impedances and distances to the external components should be in principle as small as possible. The component requirements are documented in the datasheet and recommendations are also provided in application notes.

In case of usage of Emulation devices, it should be taken care that the component choice also considers the current additionally drawn by Emulation RAM and additional modules.

Component characteristics would be recommended in the datasheet and is also documented in [Table 385](#).

It shall be ensured that all the VDD pins are connected together when using SC DCDC regulator. The VDD output pin adjacent to the VCAP pins is separated from the VDD feedback sense pin as shown [Figure 123](#) and needed to be connected together for proper functioning of regulator closed loop.

It should be taken care that each supply pin in QFP packages or a pair of supply pins in BGA packages has a decoupling capacitor close to the pins. Supply pins belonging to a common supply rail shall be connected together after the respective decoupling capacitors and shall be buffered by an additional larger capacitor based on the constraints of the regulator which supplies the rail. In case of EVR33 and EVRC regulator, recommended buffer capacitors are enumerated in [Table 385](#). It should be taken care to have a low trace resistance to the decoupling capacitors and buffer capacitors for better performance and EMI / EMC behavior. The dimensioning of the buffer capacitors is based predominantly on the load jumps triggered during reset events and stability criteria of the regulator.

**Table 385 EVRC Regulator Component Reference**

No.	Condition	Optimal Register Value (Modes a & e)	Components (Package)
1.)	IDD < 400 mA fDCDC = 1,85 MHz VEXT < 3.3 V	Use default reset values.	Output Capacitor - (10 uF nominal) CGA6M3X7R1C106K (1210) - t.b.c. Input Capacitor - (4.7 uF nominal) CGA4J1X7R1E475K (0805) - t.b.c. CGA4J3X7R1C475K (0805) - t.b.c. Flying Capacitor - (1 uF nominal) CGA3E1X7R1E105K (0603) - t.b.c. CGA3E1X7R1C105K (0603) - t.b.c.
2.)	IDD < 400 mA fDCDC = 1,85 MHz VEXT < 5 V	Use default reset values.	Output Capacitor - (10 uF nominal) CGA6M3X7R1C106K (1210) - t.b.c. Input Capacitor - (4.7 uF nominal) CGA4J1X7R1E475K (0805) - t.b.c. CGA4J3X7R1C475K (0805) - t.b.c. Flying Capacitor - (1 uF nominal) CGA3E1X7R1E105K (0603) - t.b.c. CGA3E1X7R1C105K (0603) - t.b.c.

## Power Management System for Low-End (PMSLE)

### 12.2.2.4 External Supply Modes

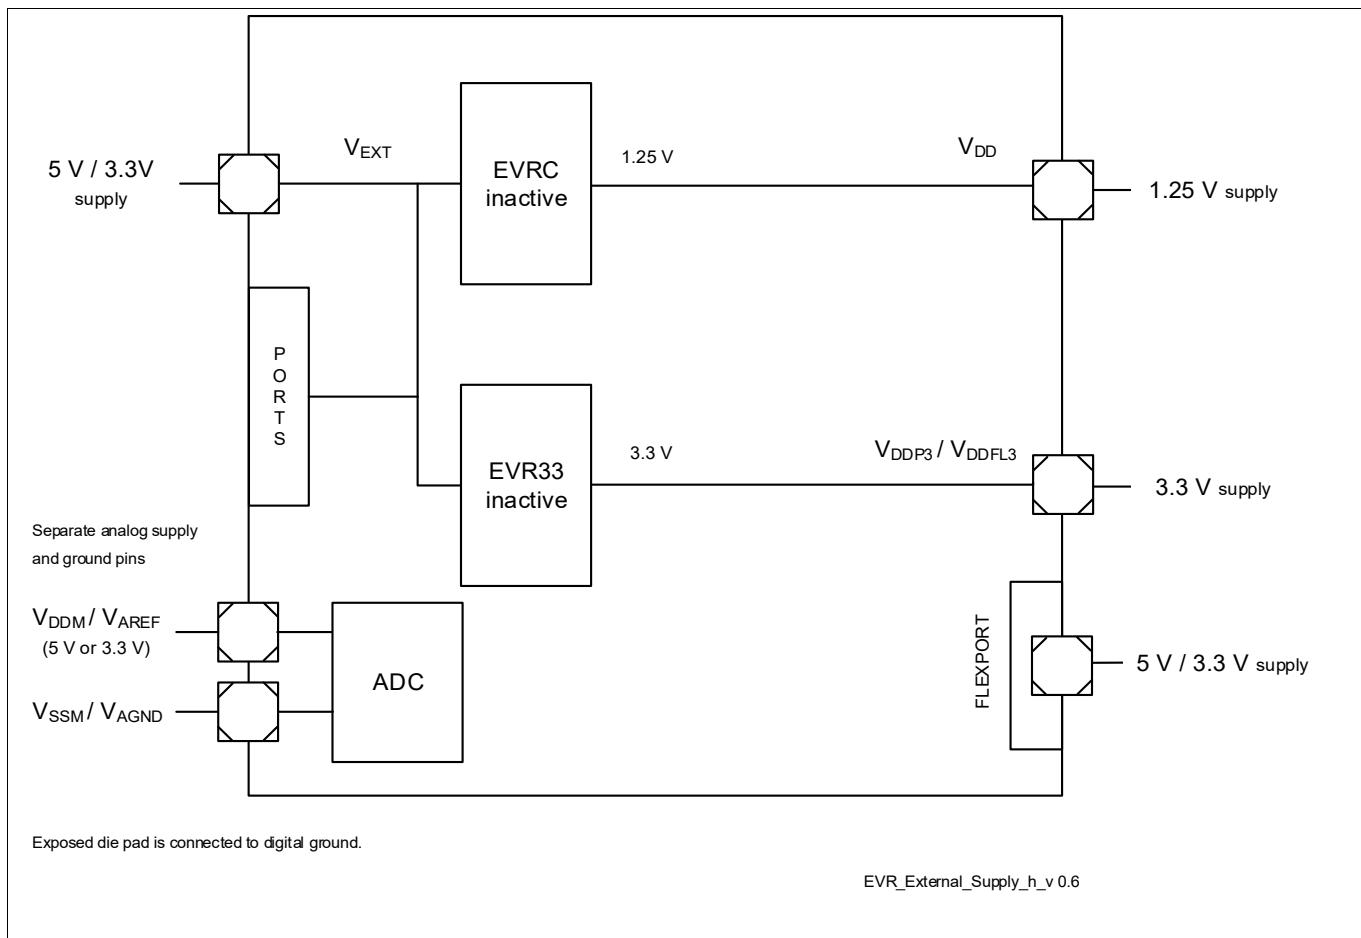

The external supply modes involve deactivating any or both of the EVRC and EVR33 regulators. In this mode, EVR33 is disabled via the HWCFG[1] configuration pin and the EVRC is disabled via the HWCFG[2] configuration pin respectively.

Following external supply modes are supported.

- VEXT = 5 V and VDD supplied externally. VDDP3 is generated using the EVR33 regulator as shown in [Figure 138](#).
- VEXT = 5 V or 3.3 V and VDDP3 is supplied externally. VDD is generated using the EVRC regulator.
- VEXT, VDDP3 and VDD are all supplied externally as shown in [Figure 139](#).

**Figure 138 External Supply mode (d) - VEXT and VDD externally supplied**

**Power Management System for Low-End (PMSLE)**

**Figure 139 External Supply mode (h) -  $V_{EXT}$ ,  $V_{DDP3}$  and  $V_{DD}$  externally supplied**

## Power Management System for Low-End (PMSLE)

### 12.2.2.5 Supply Voltage Monitoring

The PMS module implements a staggered voltage monitoring build upon a primary and a secondary monitor providing adequate redundancy to meet safety requirements. The primary monitor ensures that the micro controller is put into a cold PORST reset state when the lowest operational voltage thresholds are violated. The secondary monitor serves as an additional safety monitor providing over- and under-voltage alarms for multiple supply rails. Monitors are realized using dedicated 8 bit ADC converters and result comparators.

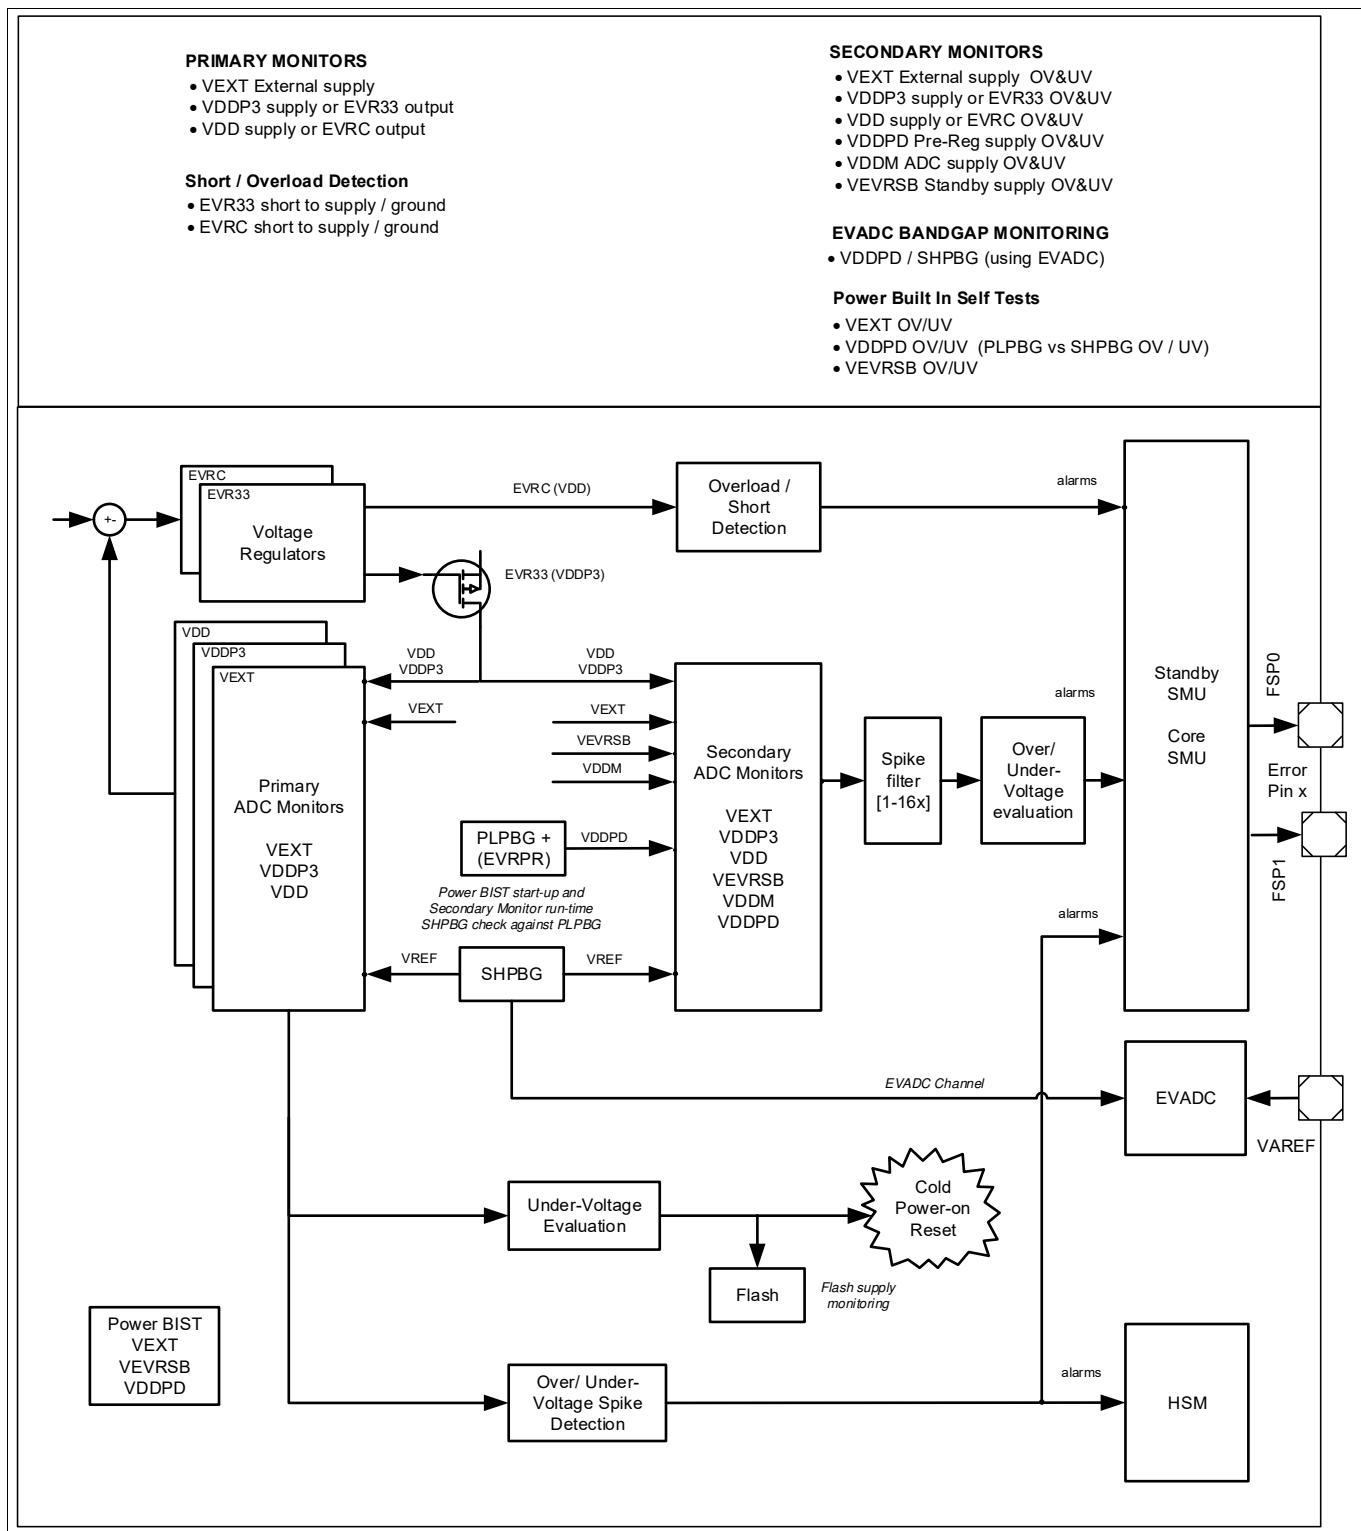

Figure 140 Supply Monitor Overview

## Power Management System for Low-End (PMSLE)

### 12.2.2.5.1 Primary under-voltage monitors and Cold PORST

Primary under-voltage monitoring of the external VEXT supply, VDDP3 / EVR33 supply and VDD / EVRC supply are inherently carried out to ensure proper functioning of the system. The thresholds for the primary monitors represent the lowest possible thresholds for the correct functioning of the system. The threshold and tolerance is documented in datasheet as VxxPRIUV parameter. In case of violation of these thresholds, cold PORST is activated and PORST pin is pulled low (strong current sink) thus setting the device into reset state. Following the reset release and firmware boot, it can be inferred from STBYR, EVRC, EVR33 or SWD bits in RSTSTAT register as to whether the violation of these thresholds led to the previous reset. The primary under-voltage monitoring is kept active even if the respective EVRs have been disabled and the supply is provided externally as shown in **Table 387**. The thresholds are trimmed and the monitoring is activated or deactivated via the **EVRRSTCON** register. The user shall not modify the default values of the **EVRRSTCON** register, as any alteration of the primary reset monitoring violates the operational conditions of the microcontroller and may lead to unexpected behavior during the dynamic undershoot regulation or during the power down sequence.

The cold PORST is asserted when the supply voltage drops below **EVRRSTCON.RSTxTRIM** value. During cold PORST reset release, to avoid consecutive toggling PORST during slow supply ramp-ups, a voltage hysteresis is supported. The cold PORST is de-asserted or released when the supply rises above (**EVRRSTCON.RSTxTRIM** + Hysteresis) value. The PORST pin is driven low for a minimum nominal time of 10 us on recognition of cold PORST irrespective whether the voltages have been immediately restored so that there is adequate time to recognise it externally.

Further more, additional power-on detectors are available for VEVRSB supply (supplied by VEXT), VEXT supply (supplied by VEVRSB) and VDDPD internal supply (via VDDPD POR monitor) to ensure a proper minimum-power detection, robust start-up and standby operation. Undervoltage of VDDPD internal supply and external VEXT supply will lead to the assertion of the LVD (Low Voltage Detector) reset. Undervoltage of external VEVRSB supply will lead to the assertion of the LVD reset indirectly via the VDDPD POR monitor as VDDPD is generated from VEVRSB. Assertion of LVD reset is reflected in RSTSTAT.STBYR bit and can be evaluated in the next start-up. After a normal supply start-up, only STBYR and PORST bits in RSTSTAT register are set.

The primary Supply WatchDog (SWD monitor) monitors the ramp-up of external VEXT supply voltage and keeps the micro controller in cold Power On Reset state as long as the supply has not reached the operational region. Likewise, it also allows detecting ramp-down or brown out conditions of external supply so that the device can be brought into a cold Power On Reset state when the voltage has dropped below the lowest operational threshold. Nevertheless, It is recommended to monitor externally all supplies generated external to the micro controller and to assert PORST reset pin in case of violation of the lowest operational limits. The pass device dropout voltage should be taken into consideration when setting these limits. In case of 5 V nominal external supply and 3.3 V in turn being generated by the internal EVR33 LDO regulator, the external supply shall maximum drop during normal RUN mode considering adequate pass device dropout as documented in datasheet.

The external VEXT supply, VDD / EVRC and VDDP3 / EVR33 supplies are measured by Primary Monitor ADCs and the measured value is updated in **EVRADCSTAT** register after conversion completion at every PMS clock cycle.

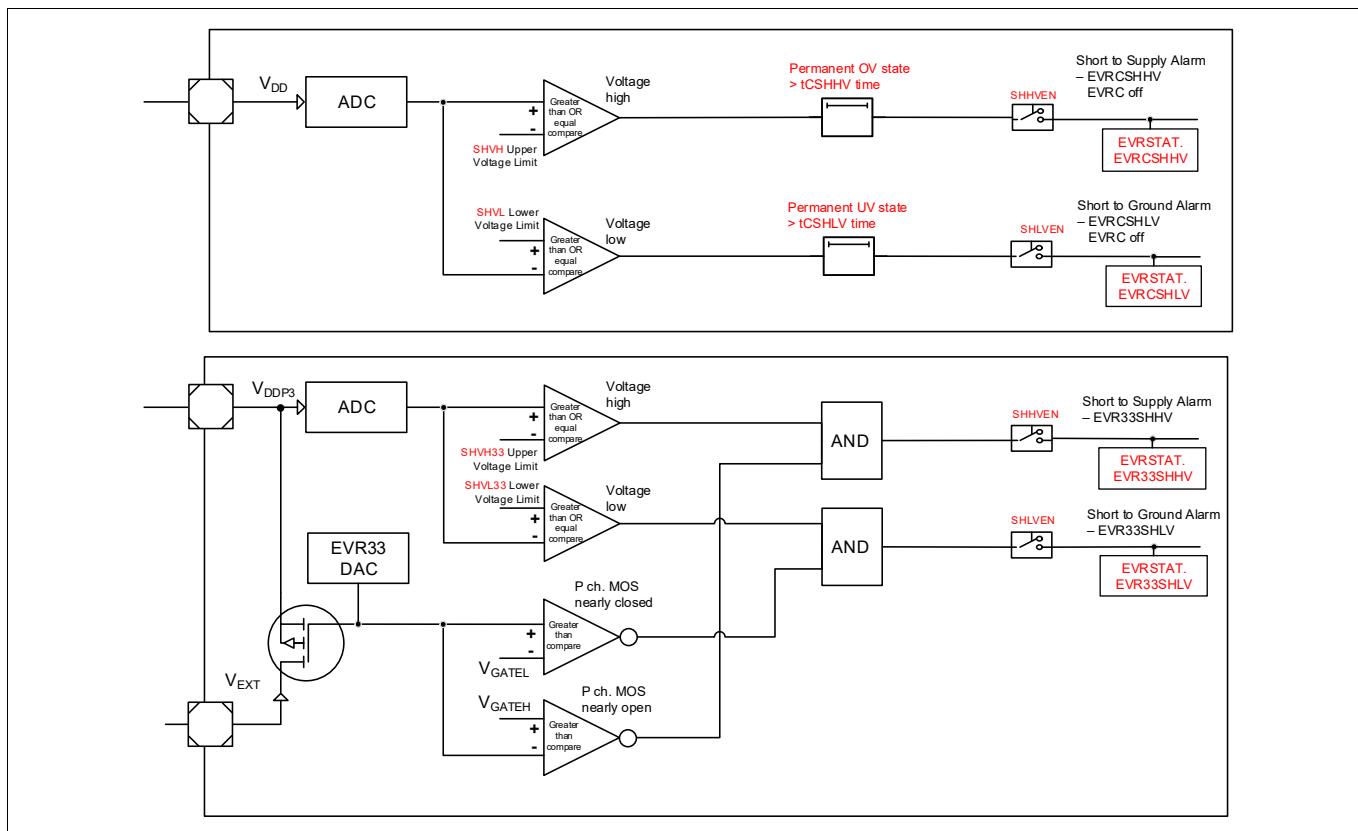

In case of primary monitor violation, respective status bits are set to indicate the event as shown in **Table 387**. These bits maybe evaluated during consequent start-up after cold power-fail reset to recognize which among the supply rails had the power-fail.

The violation of the primary under-voltage and over-voltage operational limits of VEXT, VDDP3 and VDD supply rails is communicated to the HSM module. HSM module may lock access to EVR registers via SLCK bit so that supply generation cannot be influenced by other masters. This is to ensure that trojan programs do not manipulate the supplies to gain access to the system. VEXT, VDDP3 and VDD rail primary monitor measurements are compared with **HSMOVMON** and **HSMUVMON** thresholds and alarms are routed to HSM module and to the SMU (as shown in **Figure 140**). The violations are indicated in **EVRADCSTAT** status flags. The unfiltered primary monitor ADC measurements are used to detect power spikes on the main supply rails and consequently alarms are provided to HSM and SMU. Each primary monitor ADC tracking speed is bounded by the maximum supply

## Power Management System for Low-End (PMSLE)

slope of a single LSB step every nominal 25 MHz ADC clock cycle. This results in a maximum tracking speed of 500V/ms (20mV LSB/40ns) for VEXT SWD primary monitor, 375V/ms (15mV LSB/40ns) for VDDP3 primary monitor. A voltage based short detection scheme is enabled for EVRC via **EVRSDCTRL9.SHLVEN** / **SHHVEN** register bit fields. The short detection scheme for EVRC output is as portrayed in [Figure 141](#). VDD FBADC result is compared against SHVL and SHHV thresholds. If the low voltage or high voltage condition occurs continuously for more than tCSHLV or tCSHHV duration, the respective voltage alarms are activated and are indicated by **EVRSTAT.EVRxSHHV** and **EVRSTAT.EVRxSHLV** register status bits. If the low voltage or high voltage condition disappears before tCSHLV or tCSHHV expiry, then tCSHLV or tCSHHV timers are reset. The recovery from EVRC short switch-off state is possible only with a renewed ramp-up of VEVRSB and VEXT supply rails. EVRC Short signal is filtered for 6 consecutive values using a spike filter and the filtered signal leads to EVRC switch off.

A short detection scheme may be activated for EVR33 via **EVR33CON.SHLVEN** / **SHHVEN** bits. The short detection scheme for EVR33 is portrayed in [Figure 141](#). Short to higher voltage is deduced when the voltage regulator control output or pass device gate voltage has saturated at the lower limit and at the same time the regulator voltage output has crossed the absolute maximum limit. Short to lower voltage is deduced when the voltage regulator control output or pass device gate voltage has saturated at the upper limit and at the same time the regulator voltage output has stayed at the minimum limit. In both cases the respective alarms are activated and indicated by **EVRSTAT.EVR33SHHV** and **EVRSTAT.EVR33SHLV** register bits.

**Figure 141** Short to Supply and Ground Detection

## Power Management System for Low-End (PMSLE)

### 12.2.2.5.2 Secondary over- and under-voltage monitors and alarm generation

Additional secondary over-voltage and under-voltage monitoring against programmable thresholds is provided for all supplied and generated voltages. The secondary monitors are based on a secondary bandgap reference independent from the primary band-gap reference. The monitored voltages include the external VEXT supply voltage, VDDP3 / EVR33 supply, VDD / EVRC supply, external VEVRSB supply voltage, external VDDM ADC supply voltage and the internally generated VDDPD Pre- Regulator output voltage as shown in [Figure 143](#) and [Figure 144](#). The secondary voltage monitors are kept active even if the respective EVRs have been disabled and the supply is provided externally as shown in [Table 387](#). In case of a threshold violation, an SMU alarm event is generated. The threshold and tolerance is documented in datasheet as VxxMON parameter.

The secondary monitor violation is notified depending on the direction of voltage transition as programmed in [EVROMONCTRL](#) register. The appropriate thresholds for voltage monitoring can be programmed in the [EVROVMON](#), [EVROVMON2](#), [EVRUVMON](#) and [EVRUVMON2](#) registers. These can be calculated by linear interpolation based on multiple voltage levels and corresponding thresholds provided in VxxMON datasheet parameters. In case of an active monitoring violation, respective status flags are set in the [EVRSTAT](#) register. It can be inferred from OVC, OV33, OVSWD, OVPRE, OVS and OVDDM bits in [EVRSTAT](#) register as to whether over-voltage thresholds for the respective voltage domains were violated. Likewise, it can be inferred from UVC, UV33, UVSWD, UVPRE, UVSB and UVDDM bits in [EVRSTAT](#) register as to whether under-voltage thresholds were violated. The respective status bits may be evaluated to differentiate between an over-voltage or an under-voltage event and to recognize which supply rail had triggered the alarm event to SMU as shown in [Table 387](#). The secondary monitor measurement latency to measure all 6 supply rails is documented in datasheet as tMON parameter. The supply rails are converted one after another in a continuous scan mode. It is also possible to deactivate individually the secondary monitors in [EVROMONCTRL](#) register. If the respective OVMOD and UVMOD bits are set to 00, then the ADC conversion for the particular supply rail is skipped by the Secondary Monitor and (tMON/6) time is respectively reduced from the total conversion time.

The [EVRUVMON2.VDDMLVLSEL](#) bit-field shall not be modified by the application software (as it is not related to the secondary monitoring thresholds). The application SW shall always read out the default value of [EVRUVMON2.VDDMLVLSEL](#) and write it back unmodified together with any new undervoltage monitoring threshold information in the [EVRUVMON2](#) register.

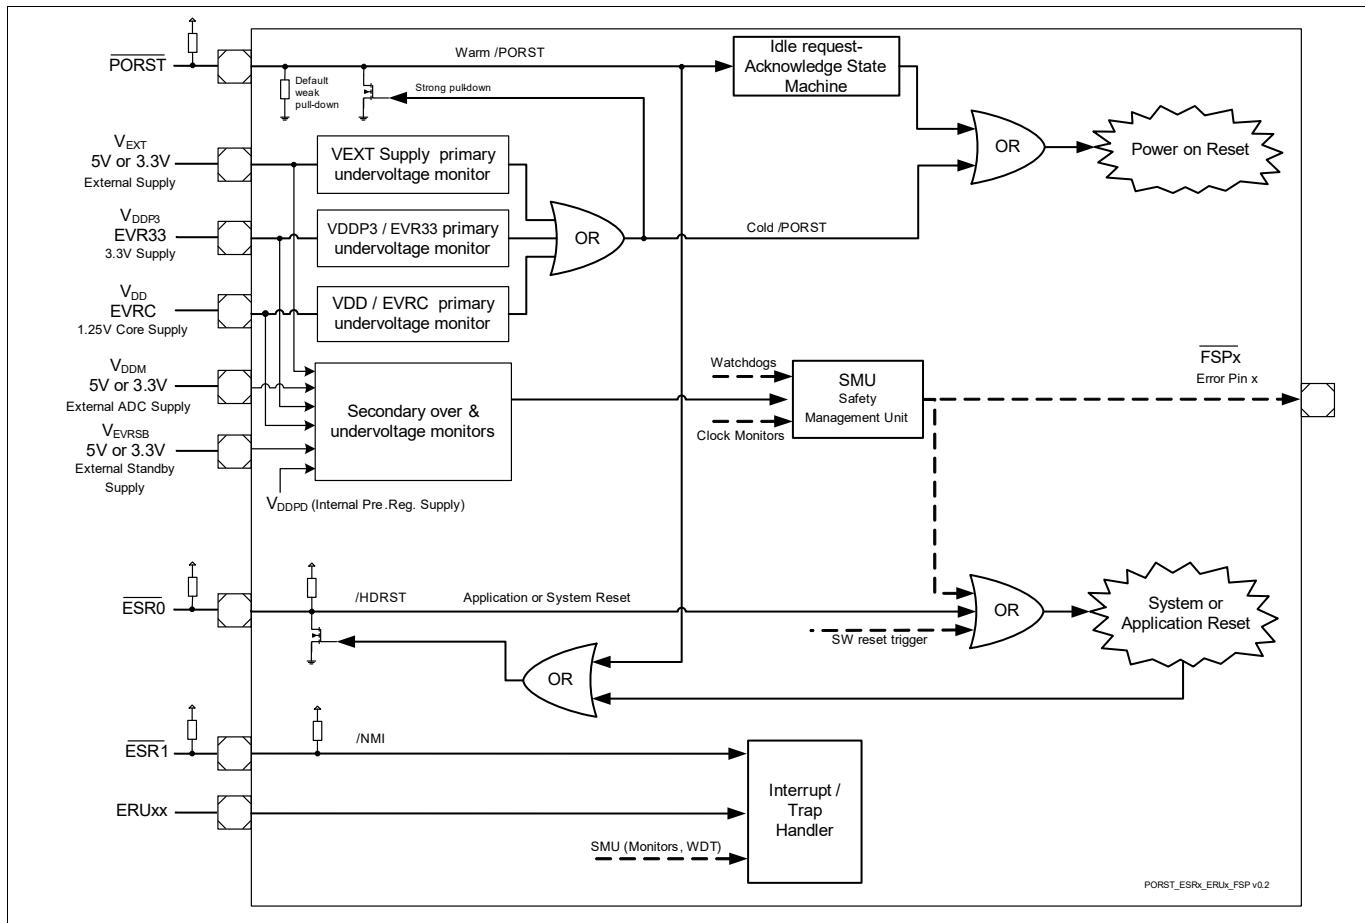

The monitored voltages, namely the VEXT, VDDP3, VDD, VDDPD, VEVRSB, and VDDM supplies are measured by Secondary Monitor ADCs and the actual measured value is updated in [EVROMONSTAT1](#) and [EVROMONSTAT2](#) register after conversion completion at regular intervals. Spike filtering of consecutive ADC results are used to generate alarm to SMU and also used for the filtered values indicated in [EVROMONSTAT1 / EVROMONSTAT2](#) registers as configured via adjustable filter coefficients in [EVROMONFILT.xx FIL](#) bit fields. In case VDDM supply voltage drops below 500 mV outside the operational limits, then Secondary monitor stops converting and the activity counter [EVROMONSTAT1.ACTVCNT](#) freezes at the last value.

In case of over-voltage supply alarms, it may be ensured that the supply to the device is switched off to avoid damage. The Error Pin Fail Safe Protocol ensures that the over-voltage condition is communicated to the external regulator even when TC3xx is in warm reset state.

After start-up, it may happen that supply over- or under-voltage alarms may already have been triggered depending on residual start-up voltages or supply dynamics. Likewise during [EVROMONCTRL](#) or [EVROMONFILT](#) reconfigurations, spurious alarms may be raised depending on filter state and changed configuration. Therefore before activating SMU alarm generation or triggering latent fault supply alarm tests, the secondary monitors and filters need to be completely reset. It need to be ensured that SMU alarms and associated interrupts are foremost deactivated in [EVROMONCTRL](#) / [EVROMONFILT](#) / [PMSIEN](#) registers, then filters are cleared via [EVROMONFILT.CLRFIL](#) = 1, alarms and interrupts are then consequently re-configured to the intended voltage level and filter settings in [EVROMONCTRL](#) / [EVROMONFILT](#) registers followed by activation of filters via [EVROMONFILT.CLRFIL](#) = 0. A delay time of 4 us has to be awaited before alarm activation after configuration is changed in [EVROMONCTRL](#) / [EVROMONFILT](#) registers.

## Power Management System for Low-End (PMSLE)

In case of application and system resets, PMS alarms happening during the respective reset shutdown and release will be reflected in SMU\_stdby AGX alarm status registers and consequently SMU\_stdby FSP reaction may be triggered if so configured in SMU\_stdby AGFSP.FEx registers. On the contrary, PMS alarms occurring during warm reset phase will be not be latched in SMU\_core AGX alarm status registers as they are in reset state. Furthermore, alarms which have occurred during the reset phase would not be consequently forwarded to the SMU\_core on reset release.

## Power Management System for Low-End (PMSLE)

Monitoring tolerances and levels are specified in datasheet section EVR : Supply monitoring

**Figure 144 Voltage Monitoring - VEVRSB, VDDM & VDDPD**

## Power Management System for Low-End (PMSLE)

### 12.2.2.5.3 Power Built In Self Test at Start-up (PBIST)

A Power Built-In-Self-Test (PBIST) at start-up allows the testing of supply levels, power functions and voltage monitors before cold PORST reset release.

The internal EVRPR Pre-regulator VDDPD voltage based on the primary low power bandgap (PLPBG) is tested using secondary monitor ADC against the secondary bandgap (SHPBG) at supply ramp-up. This allows to monitor the bandgap voltages against each other during start-up and the device continue to remain in reset state till the test has passed. During runtime, bandgap monitoring is realised by VDDPD monitoring using secondary monitor ADC and alarm is raised to SMU in case of VDDPD over and under-voltage event.

VEVRSB and VEXT voltage levels are checked using secondary monitor ADC before starting the regulators in PBIST state. In case the voltages are not within the limits, the device reset state is not deasserted. Furthermore, the PBIST test is passed and reset state is deasserted when VDDM supply voltage is above 500 mV.

After EVRC and EVR33 regulators are ramped up, additional overvoltage and undervoltage checks are carried out for VEVRSB ( $5,84V / 2,75V \pm 5\%$ ), VEXT ( $5,84V / 2,75V \pm 5\%$ ), VDDP3 ( $3,81V / 2,0V \pm 5\%$ ), VDD ( $1,46V / 1,0V \pm 5\%$ ) and VDDPD ( $1,46V / 1,0V \pm 5\%$ ) rails before cold PORST reset release in PBIST2 state. The limits are the default reset values of **EVROVMON**, **EVROVMON2**, **EVRUVMON** and **EVRUVMON2** registers.

A PBIST\_Off pad has been added to disable only the PBIST check as an implementation risk mitigation measure. The default state after reset is that the pad is pulled low which activates PBIST check during Start-up and Standby transitions. If the pad level is high, then the PBIST check is always skipped during Start-up and Standby PBIST and PBIST2 states.

### 12.2.2.5.4 Secondary Monitor and Standby SMU Built in Self Test (MONBIST)

After reset release, MONBIST for the secondary monitors and alarm generation path may be carried out by user software. Secondary Monitor BIST ensures a higher latent fault coverage for the secondary monitors and the associated alarm and error pin fault logic routed to the Standby SMU. The MONBIST can be triggered during start-up via MONBISTCTRL.TSTEN register bit in Standby SMU module. During ongoing MONBIST, PMS SFF test shall not be triggered. MONBIST test takes less than 25 us execution time. The procedure is as follows :

- The Standby SMU shall be enabled via SMUEN register bitfield for MONBIST functionality.
- The MONBISTCTRL.TSTCLR bit shall be set foremost to clear all the flags and reset the test logic. This clears TSTEN, TSTRUN, TSTDONE, TSTOK, SMUERR and PMSERR bits.
- **EVRMONFILT** is set to 0x20000000 to clear the filter and to activate 1 x spike filter.
- **EVRMONCTRL** is set to 0xa5a5a5 to activate Over-voltage and Under-voltage alarms.
- The corresponding Over-voltage and Under-voltage interrupts are disabled by clearing **PMSIEN**.OVx/UVx register bit fields.
- FSP reaction on alarms are disabled by setting AGFSP.FEx to 0.
- CMD.FSP0EN and CMD.FSP1EN configuration bits are cleared to avoid spurious Error pin activation during MONBIST.
- CMD.ASCE is set to ensure that all pending alarms are cleared in AGx registers.
- **EVRMONFILT** is set back to 0x00000000 before enabling MONBIST to ensure alarm propagation.
- Consequently the MONBIST is enabled via MONBISTCTRL.TSTEN register bit.
- The MONBISTSTAT.TSTRUN register bit is set to indicate an ongoing test by MONBIST logic.
- Once the test is completed, MONBISTSTAT.TSTDONE bit is set and MONBISTSTAT.TSTRUN bit is cleared.
- The MONBISTSTAT.TSTOK bit indicates that the test was successfully completed.
- The MONBISTSTAT.SMUERR and MONBISTSTAT.PMSERR bits indicate that errors were detected during the MONBIST.

---

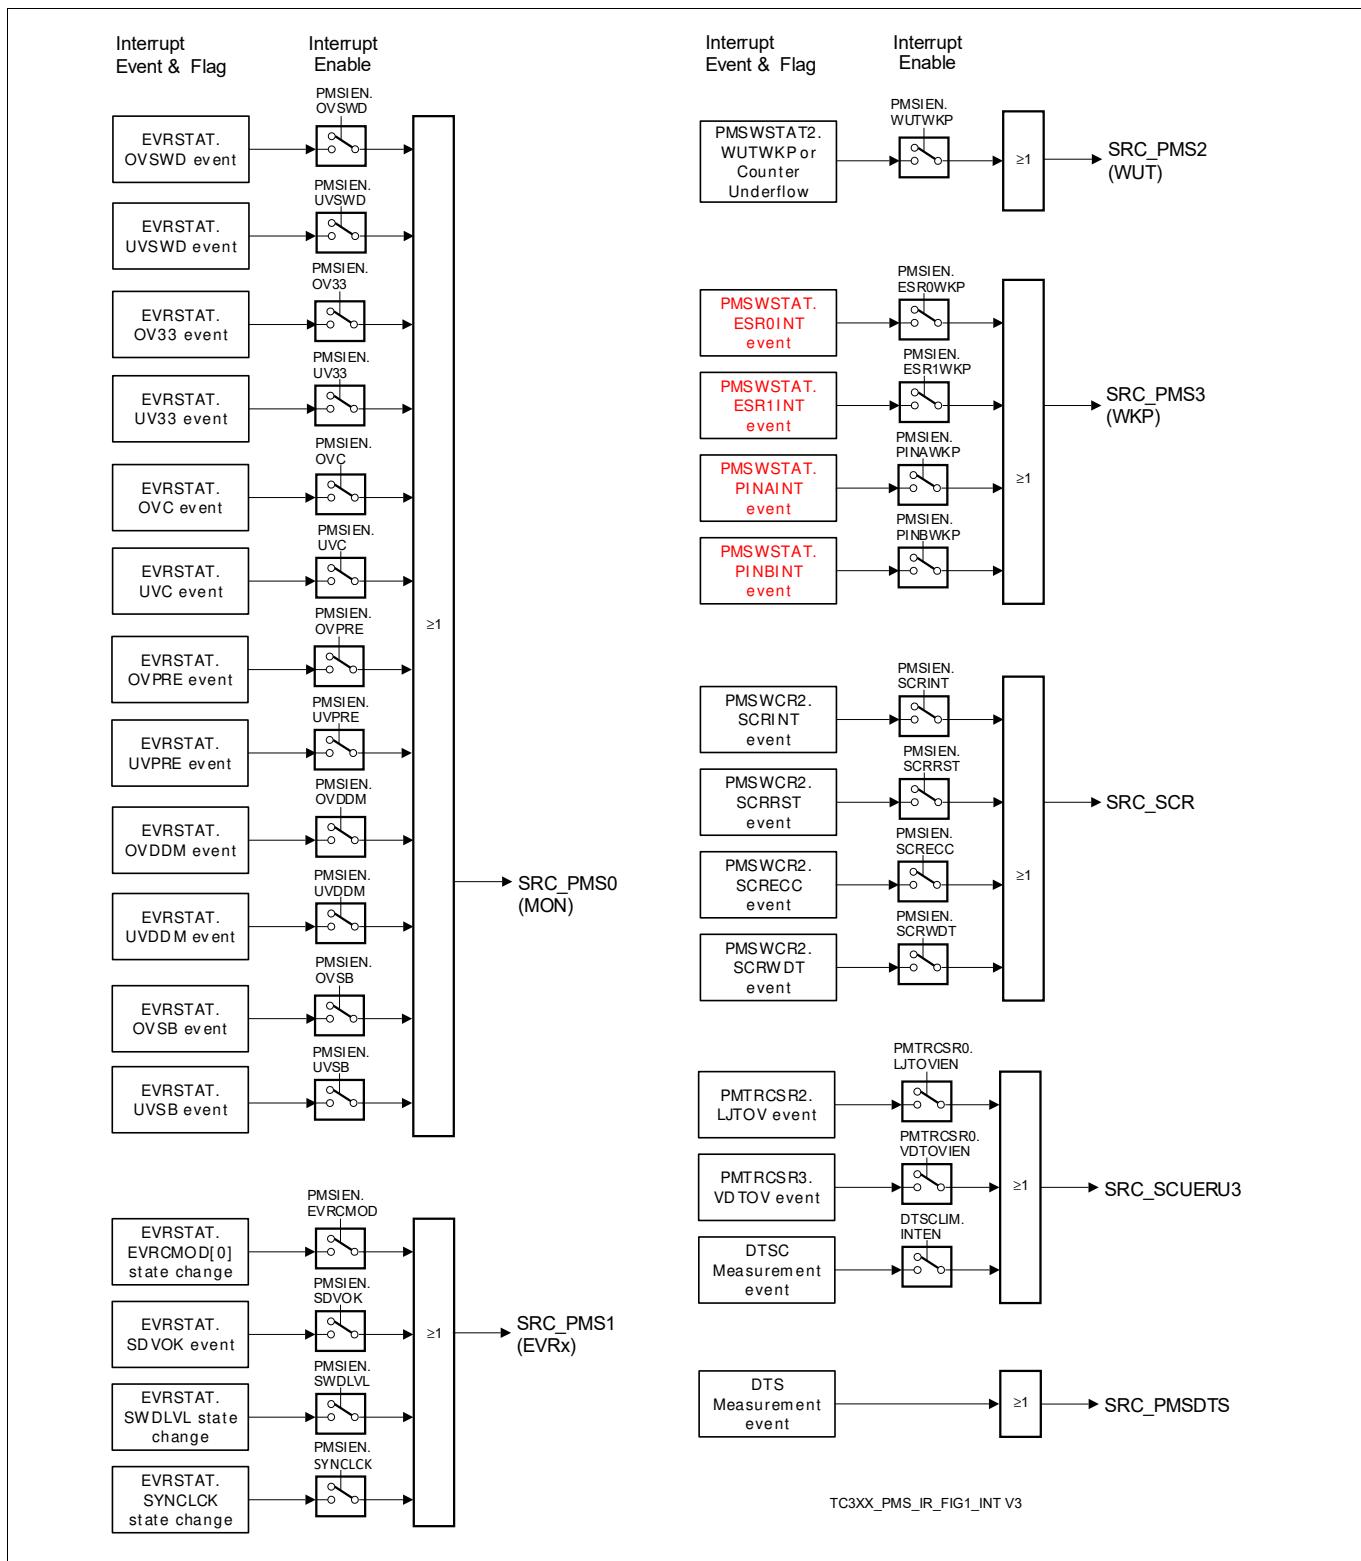

**Power Management System for Low-End (PMSLE)**

- FSPERR bit shall be cleared after MONBIST before enabling FSP reaction. If alarms happened during MONBIST, status registers may be updated and shall be cleared before Standby SMU initialization. TSTEN bit is cleared at the end of MONBIST.

## Power Management System for Low-End (PMSLE)

### 12.2.2.6 Interrupts

Following events may be configured to lead to interrupts routed to Interrupt Router in Normal Run and Sleep System modes. If enabled by the related interrupt enable bit in register **PMSIEN**, an interrupt pulse can be generated on one of the service request outputs (SRC\_PMS0, SRC\_PMS1, SRC\_PMS2, SRC\_PMS3, SRC\_SCR, SRC\_SCUERU3). Interrupts are forwarded from PMS to IR module within 4 fspb clock cycles after the occurrence of the event.

**Figure 145 Interrupt Sources and Events**

## Power Management System for Low-End (PMSLE)

### 12.2.2.7 OCDS Trigger Bus (OTGB) Interface

#### PMS OTGB Features

- Voltage signals and ADC outputs
  - Primary VDD, VDDP3 and VEXT voltage monitor outputs
  - Primary EVRC (SMPS) core voltage feedback ADC output
  - Secondary VDD, VDDP3 and VEXT voltage monitor outputs
  - EVRPR / VDDPD voltage monitor output
  - VEVRSB Standby supply voltage monitor output
  - VDDM ADC supply voltage monitor output
  - DTS temperature output
- EVR control outputs
  - EVR33 regulator DAC control output
  - EVRC switching control output driving the switches
  - EVRC Regulator output and internal signals
  - Wake-up timer count
  - PMS and SCR register interface signals

The PMS module has two 16 bit ([Table 388](#)) trigger sets which are selected with the **OTSS** register. The trigger sets can be arbitrarily mapped to OTGB0/1 busses. Refer OCDS chapter for more details.

**Table 388 PMS Trigger Sets**

Trigger Set	Details
<a href="#">TS16_ADCMON Monitor Trigger Set</a>	<a href="#">Table 389</a>
<a href="#">TS16_EVRCON Control Trigger Set</a>	<a href="#">Table 390</a>

The PMS trigger signals relate to the 100 MHz internal back-up clock, which can be different to the OTGB/OTGM clock. It should be taken care that the triggers and associated signals are synchronised to SPB clock domain.

#### 12.2.2.7.1 ADC Monitor and Voltage Trigger Sets

ADC Monitor Trigger Sets consist of the important voltage signals measured by various PMS ADC monitors. The multiplexer allows to map arbitrary and different signal groups to the high and the low byte of a 16 bit Trigger Set. In addition it is possible to use one or two 16 bit Trigger Sets with this flexibility. All this is controlled with **OTSCO**.

**Power Management System for Low-End (PMSLE)**
**Table 389 TS16\_ADCMON Monitor Trigger Set**

<b>Bits</b>	<b>Name</b>	<b>Description</b>
[7:0]	SG0	8 bit Analog output from selected Analog monitors
		PRADCCV Primary Core / VDD voltage monitor output
		PRADC33V Primary VDDP3 voltage monitor output
		PRADCSWDV Primary VEXT voltage monitor output
		PRADCFBCV Primary EVRC SMPS core voltage feedback output
		SECADCCV Secondary Core / VDD voltage monitor output
		SECADC33V Secondary VDDP3 voltage monitor output
		SECADCSWDV Secondary VEXT voltage monitor output
		SECADCPRE EVRPR / VDDPD voltage monitor output
		SECADCSB VEVRSB standby voltage monitor output
		SECADCVDDM VDDM ADC voltage monitor output
		DTSRESULTL DTS Temperature output [7:0]
		DTSRESULTH DTS Temperature output [11:8]
[15:8]	SG1	Independent selection with same options as for Bits [7:0]

**12.2.2.7.2 EVR Control output Trigger Sets**

EVRCON Control Trigger Sets consist of the important control outputs of various regulators in PMS subsystem. All this is controlled with **OTSC1**.

**Table 390 TS16\_EVRCON Control Trigger Set**

<b>Bits</b>	<b>Name</b>	<b>Description</b>
[15:0]	EVR33OUT	EVR33 regulator DAC control output
	CONDUCTANCE	EVRC conductance value as indicated in <b>EVRSSTATO.CONDUCTANCE</b>
	EVRCOUT	Array of EVRC regulator signals from the SMPS module selected via DMOND multiplexer.
	WUTCNT	Wake-up timer count ([23:15] reduced to 15th bit)
	TCINT [7:0] SCRINT [15:8]	PMS and SCR output and input bus interface

## Power Management System for Low-End (PMSLE)

### 12.2.3 Power Management

#### 12.2.3.1 Power Management Overview

The Power Management scheme allows activation of power down modes so that the system operates with the minimum required power for the corresponding application state. A progressive reduction in power consumption is achieved by invoking Idle, Sleep or Standby modes respectively. The Idle mode is specific to each individual CPU where as Sleep and Standby modes influence the complete system.

As shown in [Table 391](#), there are two power modes available for each CPU:

- CPU Run Mode
- CPU Idle Mode

**Table 391 CPU Power Management**

Mode	Description
<b>Run Mode</b>	The CPU clock is active and code is being executed.
<b>Idle Mode</b>	<p>CPU may enter Idle Mode on following events:</p> <ul style="list-style-type: none"> <li>• On a SW Idle request issued by setting register bits PMCSR<sub>x</sub>.REQSLP = 01<sub>B</sub> when CPU has no active tasks to perform.</li> <li>• On a SW Idle request (PMCSR<sub>y</sub>.REQSLP = 01<sub>B</sub>) issued by another CPU.</li> </ul> <p>The CPU code execution is halted and CPU clock is disabled in Idle state. The peripherals continue to remain active. CPU RAM memories (PSPR / DSPr / DLMU) are accessible to other bus masters and peripherals.</p> <p>CPU may exit Idle mode on following events:</p> <ul style="list-style-type: none"> <li>• When an interrupt occurs on a CPU returning the CPU to Run Mode.</li> <li>• When a trap occurs like an NMI trap event.</li> <li>• When the CPU watchdog or Safety watchdog timer overflow events trigger an SMU alarm in turn leading to a CPU interrupt.</li> <li>• When a MSB bit wrap of the CPU Watchdog counter takes place.</li> <li>• When a Application reset, System reset or any higher reset occurs.</li> <li>• On a SW Run request (PMCSR<sub>x</sub>.REQSLP = 00<sub>B</sub>) issued by another CPU.</li> </ul>

As shown in [Table 392](#), there are three main power modes available for the system:

- System Run Mode
- System Sleep Mode
- System Standby Mode

Furthermore, flexible reduction of power consumption is possible through following measures:

- Reduction of individual CPU power consumption by means of CPU clock scaling.
- Disabling the module clock by setting bit DISR in module CLC register if the module need not be active at the current point of time.
- Reducing the system frequency without changing individual peripheral clocks.
- Reducing individual peripheral clock frequency without changing system clock frequency. Main peripherals are provided with independent clocks separate from main system SRI and SPB clocks.

## Power Management System for Low-End (PMSLE)

**Table 392 System Power Management**

Mode	Description
<b>Run Mode</b>	At least one master CPU has not requested Sleep Mode or Standby mode and is in Run mode. All peripheral modules are active.
<b>Sleep Mode</b>	<p>System may enter Sleep Mode on following events:</p> <ul style="list-style-type: none"> <li>• On a SW Sleep request issued by setting PMCSR<sub>x</sub>.REQSLP = 10<sub>B</sub> by the master CPU. CPU code execution is halted and CPU Idle state is entered. Peripherals are set into sleep state if so configured in the respective CLCx.EDIS bit. Ports retain their earlier programmed state.</li> </ul> <p>System may exit Sleep mode on following events:</p> <ul style="list-style-type: none"> <li>• When an interrupt or trap occurs on the master CPU.</li> <li>• When an NMI trap event takes place.</li> <li>• When the CPU watchdog or Safety watchdog timer overflow events trigger an SMU alarm leading in turn to a master CPU interrupt.</li> <li>• When a MSB bit wrap of master CPU Watchdog counter takes place.</li> <li>• When an Application reset, System reset or any higher reset occurs.</li> </ul>

## Power Management System for Low-End (PMSLE)

**Table 392 System Power Management (cont'd)**

Mode	Description
Standby Mode (VEVRSB and VEXT supplied)	<p>System may enter Standby Mode on following events if so configured:</p> <ul style="list-style-type: none"> <li>• Standby entry on a SW Standby request issued by setting PMCSR<sub>x</sub>.REQSLP= 11<sub>B</sub> by the master CPU.</li> <li>• Standby entry on an ESR1 (NMI) assertion event. ESR1 (NMI) function doesn't require involvement of interrupt subsystem if configured as the standby entry trigger.</li> </ul> <p>The Standby domain constituting the Standby RAM, the 8 bit Standby Controller, shared ports and the wake-up unit remain actively supplied. The power to the rest of the chip is completely switched off. VEXT and VEVRSB rails remain supplied during Standby mode. VDDP3 and VDD supply rails are switched off.</p> <p>System may exit Standby mode on following events:</p> <ul style="list-style-type: none"> <li>• when a wake-up edge is detected on selected pins / ESR1.</li> <li>• when a wake-up edge is detected on ESR0.</li> <li>• when a wake-up request is issued by the 8 bit Standby Controller (SCR).</li> <li>• when a wake-up request is issued by Wake-up timer.</li> <li>• when PORST pin is asserted.</li> </ul>
Standby Mode (Only VEVRSB supplied)	<p>System may enter Standby Mode on following events if so configured:</p> <ul style="list-style-type: none"> <li>• Standby entry on a secondary under-voltage event during VEXT supply ramp-down.</li> <li>• Standby entry on an ESR1 (NMI) assertion event.</li> <li>• Standby entry on a SW Standby request issued by setting PMCSR<sub>x</sub>.REQSLP= 11<sub>B</sub> by the master CPU.</li> </ul> <p>The Standby domain constituting the Standby RAM and the 8 bit Standby Controller and Ports 33 and 34 remain actively supplied. The power to the rest of the chip is completely switched off. Only VEVRSB standby supply pin remain powered during Standby mode. VEXT, VDDP3 and VDD supply rails are switched off. SCR, WUT, Standby RAM supply maybe active or inactive during Standby mode.</p> <p>System may exit Standby mode on following event:</p> <ul style="list-style-type: none"> <li>• when VEXT supply ramps up</li> <li>• when a wake-up request is issued by SCR and VEXT is available.</li> <li>• when a wake-up request is issued by Wake-up timer and VEXT is available.</li> <li>• when a wake-up edge is detected on Pin B.</li> </ul>

## Power Management System for Low-End (PMSLE)

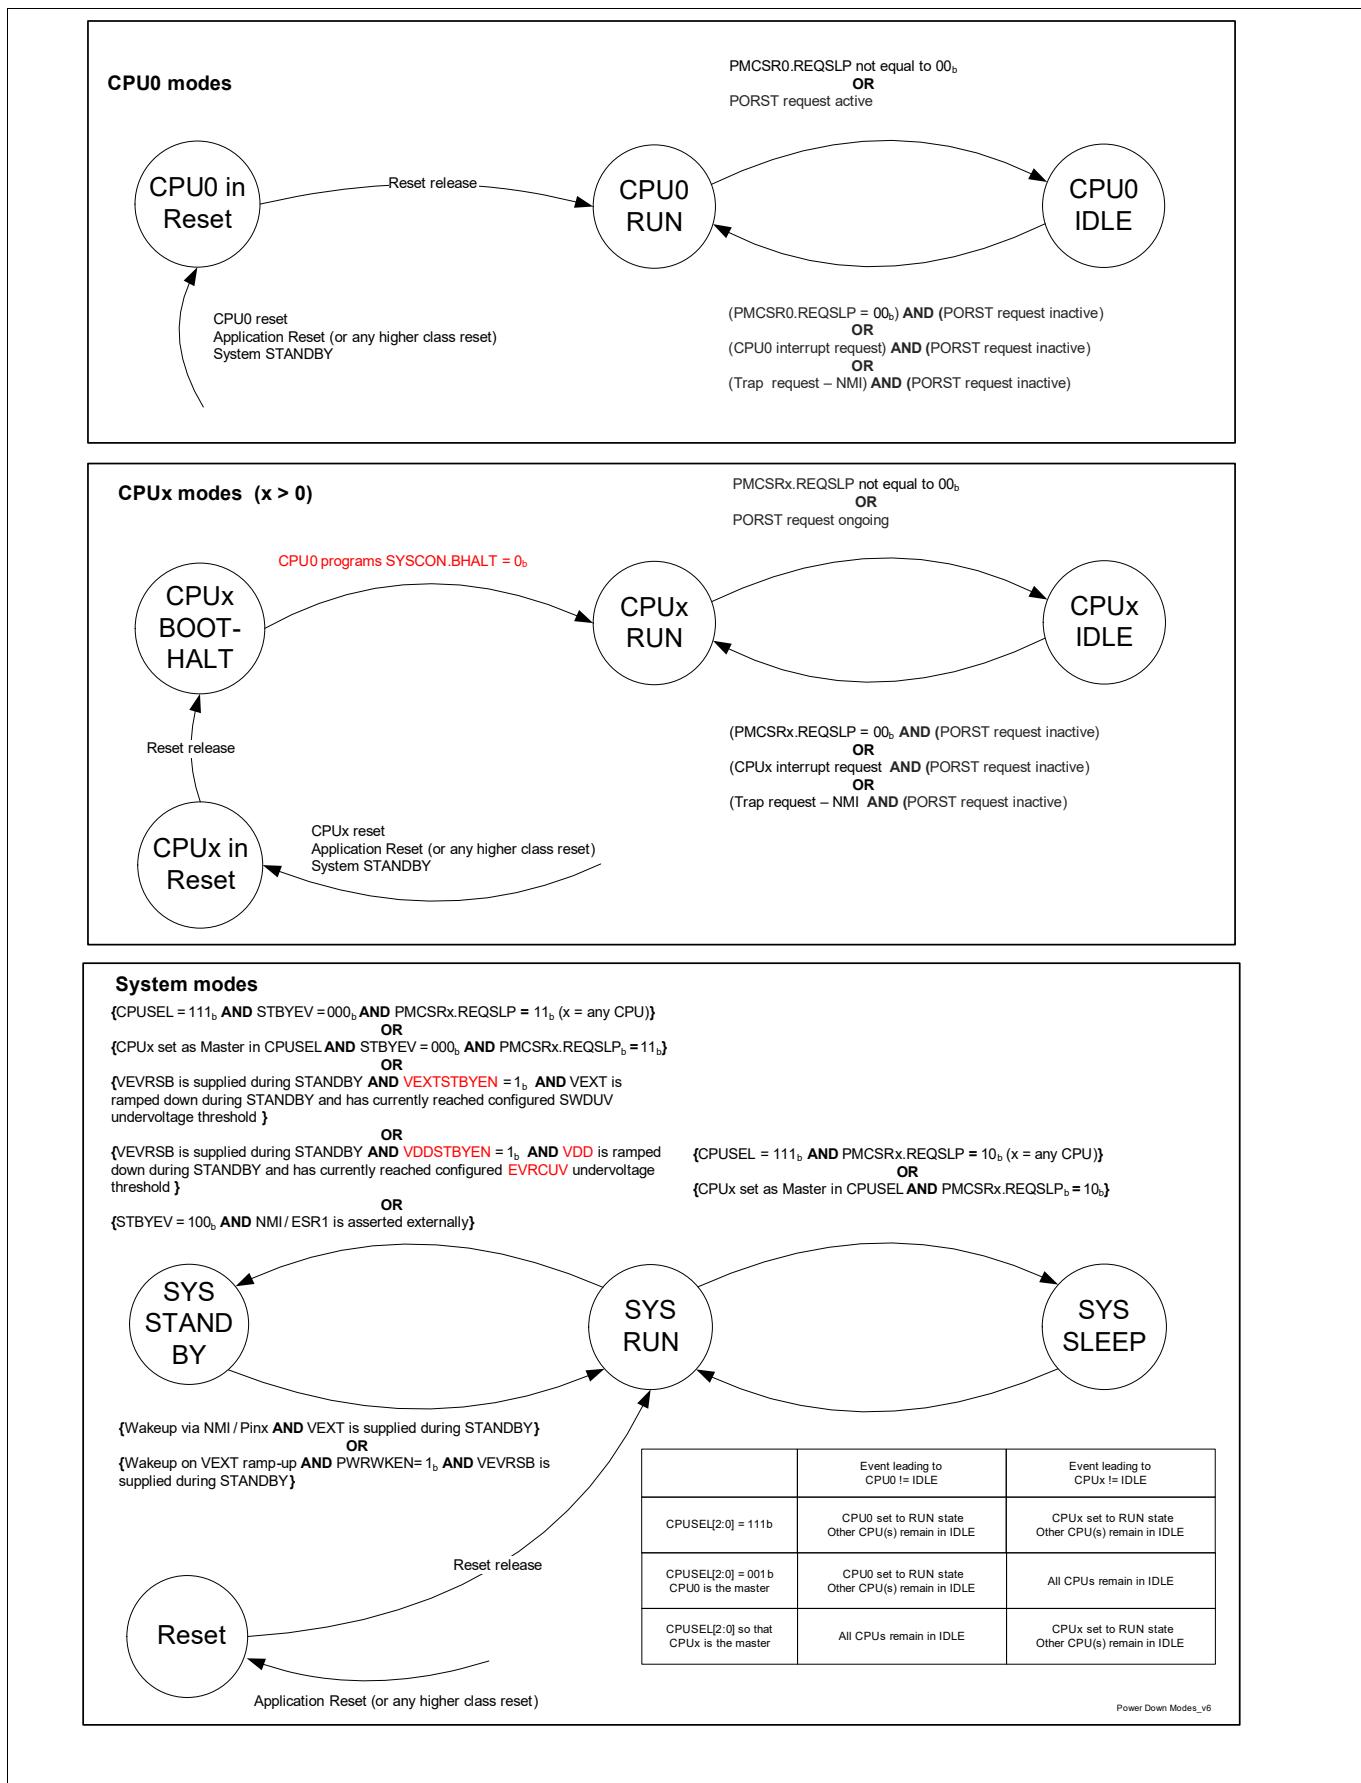

Figure 146 Power down modes and transitions

## Power Management System for Low-End (PMSLE)

### 12.2.3.2 Idle Mode

In case there are no active tasks to perform, a CPU may be requested to enter Idle mode during runtime by writing to the respective PMCSR<sub>x</sub> register and setting the bit field REQSLP = 01<sub>B</sub>.

#### 12.2.3.2.1 Entering Idle Mode :

Following events can invoke a CPU<sub>x</sub> Idle request

- CPU<sub>x</sub> setting itself in Idle by writing its own PMCSR<sub>x</sub> register: The respective PMCSR<sub>x</sub> register shall be accessed by setting CPU<sub>x</sub> ENDINIT = 0<sub>B</sub> and consequently writing the bit field REQSLP = 01<sub>B</sub>. The Idle transition takes place only when CPU<sub>x</sub> ENDINIT = 1<sub>B</sub> is set back again. This ensures that a CPU<sub>x</sub> does not enter Idle mode when it's WDTx is in Time-Out mode and ENDINIT<sub>x</sub> = 0<sub>B</sub> to avoid wake-up on a consequent WDT time-out. Safety ENDINIT mechanism shall not be used by a CPU to set itself into Idle to avoid wake-up on a Safety WDT time-out. Idle mode may also be simultaneously triggered for additional CPUs based on SCU\_PMSWCR1.CPUIDLSEL configuration.
- Masters except CPU<sub>x</sub> setting CPU<sub>x</sub> into Idle (e.g.- CPU[y]): The PMCSR<sub>x</sub> register shall be accessed by such masters by setting Safety ENDINIT = 0<sub>B</sub>. The Idle request is issued immediately on setting PMCSR<sub>x</sub>.REQSLP = 01<sub>B</sub>. The device no longer waits for Safety ENDINIT = 1<sub>B</sub> to be set back to trigger Idle transition. It need to be taken care to grant access via ACCEN register as required by application.

The CPU watchdog may be disabled or slowed down by reprogramming the timers before triggering Idle request via Software. On an Idle request, the CPU finishes its current operations and sends an acknowledge signal back to the Power Management unit. It then enters an inactive state in which the CPU clocks and the respective DMI and PMI memory units are shut off. It is recommended to reduce respective CPU clocks via CPU<sub>x</sub>DIV register bit field before issuing Idle request.

#### 12.2.3.2.2 State during Idle mode

During Idle Mode, memory accesses to the DMI, PMI and DLMU from other bus masters cause these units to wake-up automatically to handle these transactions. When memory transactions are complete, the DMI, PMI and DLMU return to Idle state again. Once Idle Mode is entered, the state is reflected in PMCSR<sub>x</sub>.PMST status bits.

**Table 393 CPU[x] Idle Mode Entry Sequence, Behavior and Status Indication**

Condition	CPU[x] writes PMCSR[x].REQSLP = 01 <sub>B</sub>	Masters except CPU <sub>x</sub> (e.g.- CPU[y]) writes PMCSR[x].REQSLP = 01 <sub>B</sub>	CPU[y] writes PMCSR[y].REQSLP = 01 <sub>B</sub>
CPU[x] enters Idle Mode	A CPU[x] should be able to set itself into Idle.  CE[x] = 0 <sub>B</sub> SE = 0 <sub>B</sub> or 1 <sub>B</sub> PMCSR[x].REQSLP= 01 <sub>B</sub> CPU[x] Idle Entry happens when CE[x] = 1 <sub>B</sub> is set. If CE[x] = 1 <sub>B</sub> during PMCSR[x] write; FPI error issued and request is not taken.	A CPU[y] or (other masters except CPU[x]) should be able to set another CPU[x] into Idle if it has SE rights.  SE = 0 <sub>B</sub> CE[x] = 0 <sub>B</sub> or 1 <sub>B</sub> PMCSR[x].REQSLP= 01 <sub>B</sub> CPU[x] Idle Entry happens immediately. If SE = 1 <sub>B</sub> during PMCSR[x] write; FPI error issued and request is not taken.	CPUIDLSEL = y+1 is already set by a CPU having SE rights before.  CE[y] = 0 <sub>B</sub> SE = 0 <sub>B</sub> or 1 <sub>B</sub> PMCSR[y].REQSLP= 01 <sub>B</sub> All CPUs go into IDLE. when CE[y] = 1 <sub>B</sub> is set. If CE[y] = 1 <sub>B</sub> during PMCSR[y] write; FPI error issued and request is not taken.

## Power Management System for Low-End (PMSLE)

**Table 393 CPU[x] Idle Mode Entry Sequence, Behavior and Status Indication (cont'd)**

Condition	CPU[x] writes PMCSR[x].REQSLP = 01 <sub>B</sub>	Masters except CPUx (e.g.- CPU[y]) writes PMCSR[x].REQSLP = 01 <sub>B</sub>	CPU[y] writes PMCSR[y].REQSLP = 01 <sub>B</sub>
CPU[x] during Idle Mode	PMCSR[x].REQSLP= 01 <sub>B</sub> PMCSR[x].PMST= 011 <sub>B</sub> PMSTAT0.CPU[x] & LS= 0 <sub>B</sub>	PMCSR[x].REQSLP= 01 <sub>B</sub> PMCSR[x].PMST= 011 <sub>B</sub> PMSTAT0.CPU[x] & LS= 0 <sub>B</sub>	PMCSR[ALL].REQSLP= 01 <sub>B</sub> PMCSR[ALL].PMST= 011 <sub>B</sub> PMSTAT0.CPU[ALL]&LS= 0 <sub>B</sub>
CPU[x] exits Idle mode	PMCSR[x].REQSLP= 00 <sub>B</sub> PMCSR[x].PMST= 001 <sub>B</sub> PMSTAT0.CPU[x] & LS= 0 <sub>B</sub>	PMCSR[x].REQSLP= 00 <sub>B</sub> PMCSR[x].PMST= 001 <sub>B</sub> PMSTAT0.CPU[x] & LS= 0 <sub>B</sub>	PMCSR[x].REQSLP= 00 <sub>B</sub> PMCSR[x].PMST= 001 <sub>B</sub> PMSTAT0.CPU[x] & LS= 0 <sub>B</sub>

### 12.2.3.2.3 Exiting Idle mode

In Idle mode, the CPU will return to Run mode in response to the following wake-up events:

- An interrupt / trap received from an interrupt / trap source mapped to the CPU.
- An NMI trap request is received to wake-up the corresponding CPUs.
- A MSB bit wrap of the corresponding CPU Watchdog counter occurs.
- Setting the register bits PMCSR<sub>x</sub>.REQSLP = 00<sub>B</sub> to set the CPU<sub>x</sub> into Run mode.

The system enters reset state on an Application, System reset or any higher reset. If it is woken by a watchdog timer overflow event routed via the SMU to the CPU or by an NMI or by an interrupt, the CPU will immediately vector to the appropriate interrupt / trap handler.

CPU module reset will not result in exit from Idle mode if it was already in Idle state before. An explicit wake-up event has to happen before CPU is in run state again.

### 12.2.3.3 Sleep Mode

Sleep mode allows a progressive reduction of power consumption by gating the clocks of selected peripherals and keeping bare minimum modules active at their minimum clock frequencies during the Sleep state. Sleep mode maybe used to cater to Pretended Networking or ECU Degradation requirements. The clocks to a module maybe disabled individually using the respective CLCx.DISR register bits. Alternatively the clocks to selected peripherals may be simultaneously gated on a common sleep request if respective CLCx.EDIS register bits are cleared. The power consumption during Sleep state is predominantly dominated by the device leakage as power to the modules in core domain are not switched off. The dynamic core current component is reduced to the minimum as most of the module clocks are gated.

#### 12.2.3.3.1 Entering Sleep Mode

System may be requested to enter Sleep mode via software by master CPU by writing to the CPU's PMCSR<sub>x</sub> register and setting the bit field PMCSR<sub>x</sub>.REQSLP = 10<sub>B</sub>.

An example sequence for Sleep mode is enumerated below :

- The CLCx.EDIS register bit shall be cleared for all peripherals intended to be inactive in Sleep mode.
- All CPUs except the master CPU may be put into IDLE state. The respective watchdogs may be disabled or re-configured for slower modes. This allows to sequence the CPU load jumps before going into sleep mode
- Master CPU code execution maybe switched from Flash to PSPR RAM if required. Flash module may be explicitly set into Sleep state.
- The analog modules EVADC and EDSADC maybe switched off if not required to be active in Sleep state.
- It should be ensured to select the individual clocks from Clock Control Unit for peripherals which need to remain active during Sleep mode as shown in **Table 394**. Certain communication and timer peripherals have

## Power Management System for Low-End (PMSLE)

clocks independent from the system frequencies, namely SRI and SPB clocks, to allow the possibility to bypass the system PLL. In such cases, the System PLL is switched into bypass mode and consequently the DCO would be switched off. Peripheral clock will continue to run clocking the modules active during sleep mode. The system clock frequencies, namely SRI and SPB clocks, maybe then reduced to the minimum possible values via the low power divider and / or Kx divider to reduce the current consumption. In some cases the respective peripherals may be clocked directly from external crystal / resonator depending on application.

- The interrupt control unit provides the infrastructure for wake-up from sleep state and therefore need to be kept active with a minimum SPB bus frequency. The respective module wakeup interrupts are routed to master CPU to wake-up on an interrupt event.
- Sleep Mode may be entered as a unanimous decision of all the CPUs when ALL of the PMCSR<sub>x</sub> registers in the system request it AND SCU\_PMSWCR1.CPUSEL = 111<sub>B</sub>. Sleep Mode may also be entered based on a singular decision of a master CPU based on the configuration of the CPUSEL register. The PMCSR<sub>x</sub> register shall be accessed by setting CPU<sub>x</sub> ENDINIT = 0<sub>B</sub>. The Sleep request is issued only after CPU<sub>x</sub> ENDINIT bit is set back again. Safety ENDINIT mechanism shall not be used by a CPU<sub>x</sub> to issue Sleep request. The master CPU watchdog may also be disabled or slowed down before issuing a Sleep request.

### 12.2.3.3.2 State during Sleep Mode

Sleep Mode is disabled for a unit if CLCx.EDIS bit is set. The sleep request is ignored in this case and the corresponding unit continues normal operation as intended. If CLCx.EDIS is cleared, the clock of the module is gated. CPU Idle state is entered for all the CPUs as described in the previous section. All ports retain their earlier programmed state. The current consumption during Sleep mode is documented in datasheet.

**Table 394 Module activity and configuration during Sleep mode**

Module active during Sleep mode	Module and Clock State during Sleep Mode
MCAN	<p>Peripheral PLL active providing module clock (e.g. - f MOD = 20MHz - 40MHz).          Module may alternatively run on f OSC0 allowing also complete switch off of the Peripheral PLL.          Module FIFO and DMA allows autonomous handling of messages without involvement of CPU for a minimal amount of CAN messages.          System PLL may be switched into low power mode.          f SRI and f SPB clocks are reduced to (e.g. - ~1-2 MHz) via LPDIV and / or Kx dividers (available only in B step).          System PLL may also be switched off and switched to Back-up clock depending on application (available only in B step).          Wake-up on CAN wake-up message identifier via CAN interrupt.</p>
ASCLIN	<p>Peripheral PLL active providing module clock (e.g. - f MOD = 20MHz).          Module may alternatively run on f OSC0 allowing also switch off of the Peripheral PLL.          System PLL may be switched into low power mode.          f SRI and f SPB clocks are reduced to (e.g. - ~1-2 MHz) via LPDIV and / or Kx dividers.          Module FIFO and DMA allows autonomous handling of messages without involvement of CPU for a minimal amount of LIN frames.          System PLL may also be switched off and switched to Back-up clock depending on application.          Wake-up on LIN wake-up frame via ASCLIN interrupt.</p>

**Power Management System for Low-End (PMSLE)**
**Table 394 Module activity and configuration during Sleep mode (cont'd)**

<b>Module active during Sleep mode</b>	<b>Module and Clock State during Sleep Mode</b>
GPT12	<p>Peripheral PLL is disabled.</p> <p>System PLL may be switched into low power mode.</p> <p>f SRI and f SPB clocks are reduced to (e.g. - ~1-2 MHz) via LPDIV and / or Kx dividers depending on application. Module clock (e.g - f MOD ~1-2 MHz) is derived from f SPB clock.</p> <p>System PLL may also be switched off and switched to Back-up clock depending on application.</p> <p>Wake-up on timer overflow or capture event via GPT12 interrupt.</p>
CCU6	<p>Peripheral PLL is disabled.</p> <p>System PLL may be switched into low power mode.</p> <p>f SRI and f SPB clocks are reduced to (e.g. - ~1-2 MHz) via LPDIV and / or Kx dividers depending on application. Module clock (e.g - f MOD ~1-2 MHz) is derived from f SPB clock.</p> <p>System PLL may also be switched off and switched to Back-up clock depending on application.</p> <p>Wake-up on timer overflow or capture event via CCU6 interrupt.</p>
QSPI	<p>Peripheral PLL active providing module clock (e.g - f MOD = 20MHz).</p> <p>System PLL may be switched into low power mode.</p> <p>f SRI and f SPB clocks are reduced to (e.g. - ~1-2 MHz) via LPDIV and / or Kx dividers.</p> <p>Services external watchdog if required by application. A timer module maybe used to trigger DMA or fill the FIFO allowing autonomous handling of messages without involvement of CPU.</p> <p>Wake-up in case of fault diagnosis of external device via a QSPI interrupt.</p>
Ethernet MAC	<p>Ethernet PHY active and provides module clock (e.g - f MOD = 25MHz) to the asynchronous part to decode the magic packet. Wake-up on magic packet via ETH interrupt.</p> <p>Alternatively PHY may trigger a wakeup directly via GPIO edge capture.</p> <p>Peripheral PLL may be disabled.</p> <p>System PLL may be switched into low power mode.</p> <p>f SRI, f SPB &amp; f ETH clocks are reduced to (e.g. - ~1-2 MHz) via LPDIV and / or Kx dividers.</p> <p>System PLL may also be switched off and switched to Back-up clock depending on application.</p>
I2C	<p>Peripheral PLL active providing module clock (e.g - f MOD = 20MHz).</p> <p>System PLL may be switched into low power mode.</p> <p>f SRI and f SPB clocks are reduced to (e.g. - 5 MHz) via LPDIV and / or Kx dividers.</p> <p>External communication remains active.</p>

## Power Management System for Low-End (PMSLE)

**Table 394 Module activity and configuration during Sleep mode (cont'd)**

Module active during Sleep mode	Module and Clock State during Sleep Mode
Pin Wake-up ESR1 (NMI)	Peripheral PLL is disabled. System PLL bypassed. f SRI, f SRI clocks reduced to (e.g. - ~1-2 MHz) via LPDIV / Kx dividers. System PLL may also be switched off and switched to Back-up clock depending on application. Wake-up on Edge / Level detection on pin routed to ERUx, ESR1 (NMI) or PORT module via SCU interrupts or polling Port registers on an active timer interrupt.
WUT	Peripheral PLL is disabled. System PLL bypassed. f SRI, f SRI clocks reduced to (e.g. - ~1-2 MHz) via LPDIV / Kx dividers. System PLL may also be switched off as module clock is derived from Back-up clock Wake-up on timer overflow via WUT interrupt.

### 12.2.3.3.3 Exiting Sleep Mode

The system will exit Sleep mode on any wake-up event that causes any master CPU to exit Idle Mode depending on CPUSEL configuration. Only the master CPU associated with the interrupt wake-up event would be set into Run mode (REQSLP = RUN, PMST = RUN). Other CPUs will remain in Idle (REQSLP = SLEEP, PMST = IDLE). An NMI trap event will wake-up the respective CPU as configured in TRAPDIS0 and TRAPDIS1 registers. A MSB bit wrap of the corresponding master CPU Watchdog counter would also wake-up the master CPU. The response of the CPU to being woken up from Sleep Mode is also the same as for Idle Mode. Peripheral units that have entered Sleep Mode will switch back to their selected Run Mode operation. Wake-up latency from Sleep mode depends mainly on the extent of clock ramp-up required after wake-up keeping the load jump constraints. If DCO or PLL is switched off, the wake-up latency would include the time to power and lock the PLL. The sequence after wake-up is dependent on the entry sequence and mainly constitutes ramping back the clock system, activating analog and Flash modules, switching from RAM to Flash execution and activating additional CPUs. The time taken between interrupt trigger availability until CPU has woken up and is executing next instruction is less than 3 SPB + 20 SRI clock cycles.

**Power Management System for Low-End (PMSLE)**
**Table 395 System Sleep Mode Entry Sequence, Behavior and Status Indication**

<b>Condition</b>	<b>Master CPU[x] writes PMCSR[x].REQSLP = 10<sub>B</sub></b>	<b>CPU[y] writes PMCSR[x].REQSLP = 10<sub>B</sub></b>	<b>All CPU[y] writes respective PMCSR[y].REQSLP = 10<sub>B</sub></b>
System enters Sleep Mode	A CPUx should be able to trigger SLEEP mode if CPUSEL = x+1 <sub>B</sub> is already set by a CPU having SE rights before.  CE[x] = 0 <sub>B</sub> SE = 0 <sub>B</sub> or 1 <sub>B</sub> PMCSR[x].REQSLP= 10 <sub>B</sub> System enters SLEEP mode when CE[x] = 1 <sub>B</sub> is set. If CE[x] = 1 <sub>B</sub> during PMCSR[x] write; FPI error issued and request is not taken.	CPU[y] is not authorised to trigger Sleep Mode and therefore this is an error case.  CPUx is configured to trigger SLEEP mode via CPUSEL = x+1 <sub>B</sub> . SE = 0 <sub>B</sub> CE[x] = 0 <sub>B</sub> or 1 <sub>B</sub> PMCSR[x].REQSLP= 10 <sub>B</sub>	CPUSEL = 111 <sub>B</sub> is already set by a CPU having SE rights before. ## Power Management System for Low-End (PMSLE)

### 12.2.3.4 Standby Mode

The Standby domain constitutes the Standby RAM, the 8 bit Standby Controller, the Power Management unit, the Pin Wake-up unit, the Wake-up timer, the VEXT supply monitor and basic infrastructure components. The Standby domain is supplied by the EVRPR pre-regulator and is by default clocked by the 70 kHz internal low power clock source in Standby Mode. The 3.3V / 5V dedicated external Standby supply pin VEVRSB supplies the EVRPR pre-regulator and the Port domain P33.x / P34.x during the Standby mode when VEXT supply is switched off.

Following Standby topologies are supported with respective events which may trigger Standby mode entry and exit based on SCU\_PMSWCR1.STBYEV and **PMSWCR0.xWKEN** bits.

#### 12.2.3.4.1 Standby Mode with only VEVRSB domain supplied and VEXT domain switched off

As shown in **Figure 147**, only the Standby domain and Port domain P33.x/P34.x continue to be supplied by the separate VEVRSB supply pin during Standby mode. The main VEXT supply is switched off in Standby state. Consequently the rest of the PORT domain except P33.x/P34.x is devoid of supply.

**Figure 147 Standby domain supplied via a separate dedicated supply pin VEVRSB**

Standby Entry is triggered by following events :

- Standby entry on a secondary under-voltage event during VEXT supply ramp-down if configured in **PMSWCR0.VEXTSTBYEN** bits.
- Standby entry on SW request (PMCSR<sub>x</sub>.REQSLP = 11<sub>B</sub>) if configured via SCU\_PMSWCR1.STBYEV register bit field. The Standby request is issued only after CPU<sub>x</sub> ENDINIT bit is set back again. Safety ENDINIT mechanism shall not be used by a CPU<sub>x</sub> to issue Standby request. Standby entry on ESR1 (NMI) edge event if configured via SCU\_PMSWCR1.STBYEV register bit field.

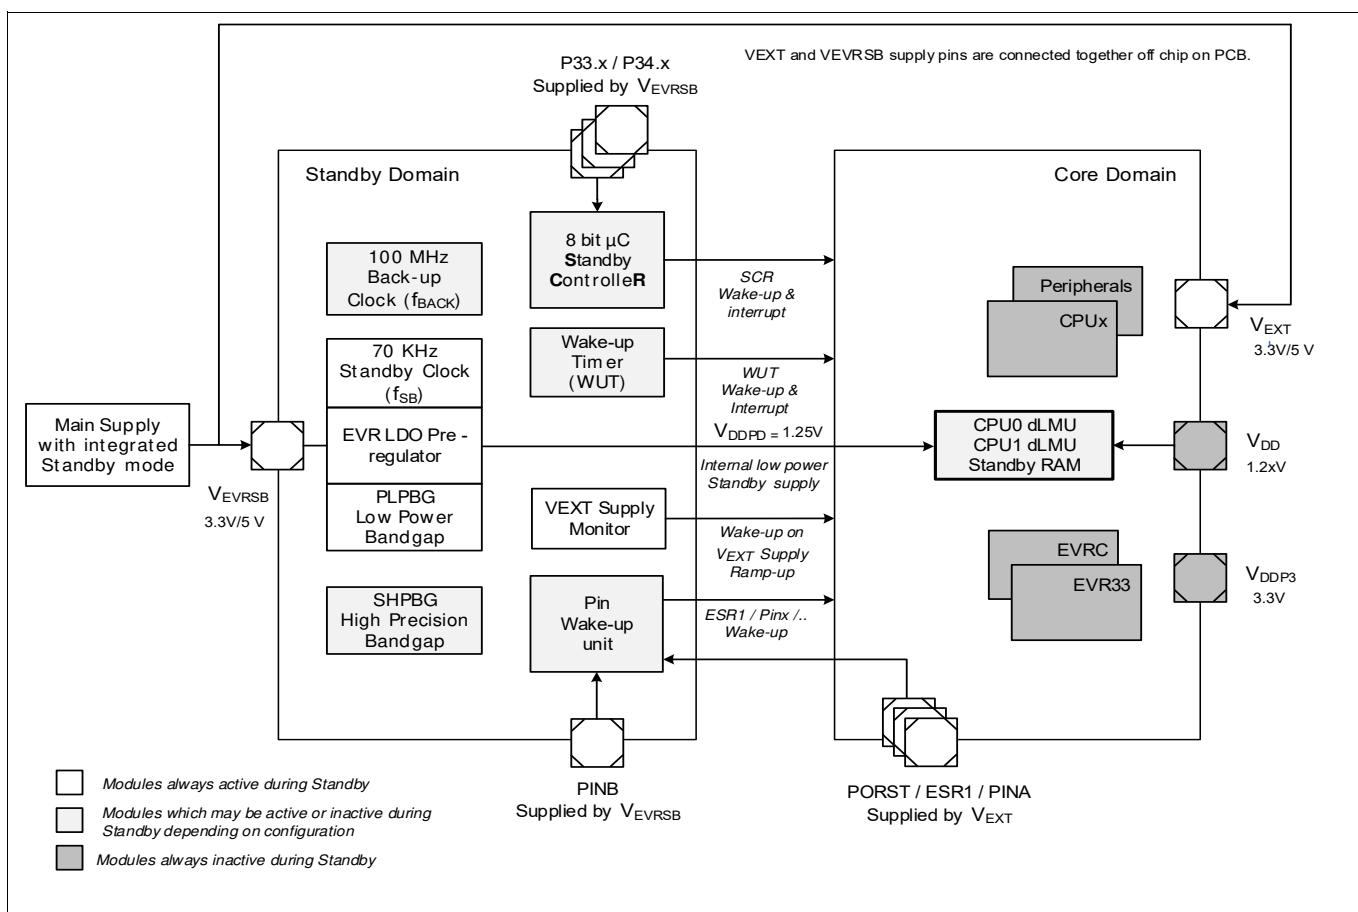

Standby Wake-up is triggered by following events after blanking filter time expiry :

## Power Management System for Low-End (PMSLE)

- Wake-up is triggered when main VEXT supply ramps-up again if configured via **PMSWCRO.PWRWKEN** enable bit.
- Wake-up is triggered by Standby Controller if configured via **PMSWCRO.SCRWKEN** enable bit provided VEXT supply has already ramped-up before. Standby controller can also request for VEXT ramp-up to external regulator.
- Wake-up via Wake-up Timer if configured via **PMSWCRO.WUTWKEN** enable bit provided VEXT has already ramped-up before.
- Wake-up via Pin B if configured via **PMSWCRO.PINBWKEN** enable bit provided VEXT has already ramped-up before.
- It is to be noted that wake-up via PORST, Pin A, ESR0 & ESR1 pins which are in turn supplied by VEXT is not supported during STANDBY as VEXT is not supplied. Therefore it is required to disable the respective **PMSWCRO.xWKEN** bits.

### 12.2.3.4.2 Standby Mode with both VEXT and VEVRSB supplied via common supply rail.

As shown in **Figure 148**, the Standby domain and the complete Pad domain including P33.x/P34.x, PORST, ESRx and PINx continue to be supplied by (VEVRSB + VEXT) supply rail during Standby mode. This allows additional wake-up possibility via PORST, ESRx and PINx pins but at the cost of higher power consumption during Standby mode.

**Figure 148 Standby domain supplied via a common supply rail connected to both VEXT and VEVRSB**

Standby Entry is triggered by following events

- Standby entry on a secondary under-voltage event during VEXT supply ramp-down if configured in **PMSWCRO.VEXTSTBYEN** bits.

## Power Management System for Low-End (PMSLE)

- Standby entry on SW request (PMCSR<sub>x</sub>.REQSLP = 11<sub>B</sub>) if configured via SCU\_PMSWCR1.STBYEV register bit field. The Standby request is issued only after CPU<sub>x</sub> ENDINIT bit is set back again. Safety ENDINIT mechanism shall not be used by a CPU<sub>x</sub> to issue Standby request.

- Standby entry on ESR1 (NMI) edge event if configured via SCU\_PMSWCR1.STBYEV register bit field.

Standby Wake-up is triggered by following events after blanking filter time expiry :

- Wake-up via NMI / Pinx: Wake-up on rising, falling or any edge of ESR1, Pin A or Pin B pins if configured via **PMSWCRO**.ESRxWKEN / PINxWKEN register bit fields.
- Wake-up is triggered by Standby Controller if configured via **PMSWCRO**.SCRWKEN enable bit.
- Wake-up via Wake-up Timer if configured via **PMSWCRO**.WUTWKEN enable bit.
- Wake-up via PORST pin if configured via **PMSWCRO**.PORSTWKEN enable bit.

### 12.2.3.4.3 Standby RAM

The Standby RAM constitutes ECC protected DLMU RAM of CPU0 (Block 0 and Block 1) and DLMU RAM of CPU1 (Block 0 and Block 1). The 32Kb Block 0 (lower half) is located at address \*0000H and 32Kb Block 1 (upper half) is located at address \*8000H of the respective address range of the corresponding CPUn DLMU RAM. The RAMs remain supplied during Standby mode if configured in **PMSWCRO**.STBYRAMSEL bits. On wake-up, the status which Standby RAMs remain supplied is reflected in **PMSWSTAT2**.STBYRAM bits. The initial 16 words from the start address of DLMU0/DLMU1 are not retained during standby mode as this memory region is used by start-up software.

The Standby RAM cell array is supplied by a separate supply pin (VEVRSB) during Standby state via the internal EVRPR Pre-Regulator. It shall be ensured that the external standby supply source continues to supply VEVRSB supply pin during Standby state with a supply between 2.6 V up to 5.5 V. Standby supply status is also monitored and indicated via RSTSTAT.STBYR bit which indicates EVRPR or VDDPD supply under-voltage LVD reset. It is to be taken care by the Start-up software after wake-up that Standby RAMs are not initialized if **PMSWSTAT2**.STBYRAM bits are set. Furthermore, if **PMSWCRO**.STBYRAMSEL bit is set to enable Standby RAM function and there was a VDD primary under-voltage (cold PORST) event, it is ensured that the Standby RAM supply is switched back to VDDPD supply rail. This ensures that RAM contents are not corrupted also during main VDD core supply loss.

### 12.2.3.4.4 VEXT Supply Monitor

If Standby mode is entered on a VEXT supply ramp down, the consequent wake-up on VEXT supply ramp up is triggered by the VEXT supply monitor activated by configuring **PMSWCRO**.PWRWKEN bit. The Standby request is issued by the secondary under-voltage monitor on crossing a voltage threshold as configured in **EVRUVMON** and **EVRMONCTRL** registers. Idle request acknowledge sequence issued to modules shall be deactivated on Standby entry by setting SCU\_PMSWCR1.IRADIS bit if VEXT supply is available. The EVR33 and EVRC regulators are switched off and Standby state is entered. Consequently VEXT and VDDM supplies may be ramped down, thus port and analog domains are also devoid of power. Wake-up is triggered when VEXT supply ramps up again and is detected by the VEXT supply monitor in the Standby domain. The detection time of the detector itself on reaching VLVDRST5 level is within 50 us. Nevertheless the complete time for start-up from Standby mode is quite the same as that for normal start-up and is documented tBP parameter in datasheet. VEXT wake-up is recognized as valid only after a minimum delay time has elapsed in Standby state as configured in **PMSWCRO**.BLNKFL register bits. This is to avoid spurious wake-up events owing to residual voltage on VEXT supply due to external buffer capacitors. After a successful wake-up, the register bit **PMSWSTAT**.PWRWKWP is set to indicate wake-up owing to a VEXT supply ramp-up and shall be cleared via **PMSWSTATCLR**.PWRWKPCCLR register bit.

### 12.2.3.4.5 Pin Wake-up Unit

External events may be mapped to ESRx / PINx pins in turn acting as wake-up signals for the system. In Run Mode, ESR1 pin may be used as fault or functional interface for external devices. In Standby Mode, an edge event on the

## Power Management System for Low-End (PMSLE)

ESR1 pin may be configured to trigger wake-up of the main core domain via **PMSWCRO**.ESR1WKEN bit and is reflected in **PMSWSTAT**.ESR1WKEN status flag. It can be configured to trigger a wake-up on rising, falling or both edges via **PMSWCRO**.ESR1EDCON bit. The minimum pulse width of the external wakeup input signal without the digital filter activated shall be atleast 2 clock cycles. Glitches on ESR1 input are filtered out by activating the filter via **PMSWCRO**.ESR1DFEN bit. The reset behavior is documented in External Service Requests chapter in RCU chapter. Additional pins (PINA - P14.1 and PINB - P33.12) may likewise be configured to trigger wake-up via **PMSWCRO**.xEDCON, xDFEN & xWKEN bits. On wake-up, **PMSWSTAT**.ESR1WKP or PINxWKP event flags provide information as to the wake-up source. It should be taken care after wake-up to clear the event flags via **PMSWSTATCLR** register. In case new wake-up events are captured while **PMSWSTAT**.xWKP flags are still set, then **PMSWSTAT**.xOVRRUN flags are set to indicate an overrun state owing to consecutive un-serviced wake-up events.

### 12.2.3.4.6 Standby ContolleR (SCR) Interface

The 8 bit Standby controller (SCR) subsystem constitutes an XC800 core, 8KB XRAM memory, various timer modules, ADC comparator, various communication peripherals and up to 16 shared pins executing autonomous activity during Idle, Sleep and Standby modes. Various Standby functions and periodic monitoring tasks may be encapsulated in the SCR with minimal power consumption overheads.

The SCR is enabled via **PMSWCR4**.SCREN bit and the status is reflected in **PMSWSTAT**.SCR bit. If SCR is disabled via **PMSWCR4**.SCREN bit, it is ensured that SCR 100MHz clock request, pending requests from SCR wake-up sources and other SCR interfaces do not have any effect on the main system. After start-up, CPU0 programs the SCR via FPI interface and copies the code into the internal XRAM.

A reset may be issued to the SCR via **PMSWCR4**.SCRSTREQ register bit. Consequently **PMSWSTAT**.SCRST status register bit is flagged to indicate SCR reset. SCRRST register bit is cleared via **PMSWSTATCLR**.SCRSTCLR bit. **PMSWCR4**.SCRSTREQ register bit is cleared after reset has been issued. The SCR is reset in case of warm PORST assertion based on **PMSWCR4**.PORSTREQ register configuration reflected in PORST register bit during normal RUN and SLEEP modes. The SCR is not affected by an Application or System reset. After reset release, the firmware initializes the SCR subsystem based on the hardware configuration programmed in **PMSWCR4**.SCRCFG bits.

The 20 MHz stand-by clock source is the default SCR clock active in System Standby Mode enabling higher-performance of the SCR subsystem. The SCR clock source may be switched to the internal 20 MHz (derived from the 100 MHz back-up clock) clock source via SCRCLKSEL register bit thus enabling higher performance on the SCR subsystem. Fundamentally SCR is in control of its clock needs and may request a clock switch via CMCON.OSCPD register overruling the behavior configured in SCRCLKSEL register. A watchdog ensures that the clock received after the request is adequate for reliable operation.

SCR PORT module shares a part of the PORT (P33.0 - P33.7, P33.9 - P33.15 and P34.1) domain with the main port system which may be kept active during Standby mode. The SCR ports are supplied by VDDPD and VEVRSB standby supply. The control to these pins need to be allocated explicitly to the SCR via port configuration Pxx\_PCSR register. Unused wake-up pins may be configured as tristate in Standby Mode. Furthermore dedicated wake-up pins, namely ESR0, ESR1, PINA - P14.1 and PINB - P33.12 are also routed to the SCR subsystem to recognise wake-up edges on these pins. When SCREN = 0 is programmed, PINB wakeup is configured as explained in [Section 12.2.3.4.5](#). Alternatively if SCREN=1 is programmed, PINB ownership is to be foremost transferred to SCR and SCR PINB Port configuration need to be set to input.

The SCR XRAM is accessible from the main domain via the FPI interface. Simultaneous access to XRAM via FPI interface and the SCR is arbitrated with SCR having default priority for XRAM access. In case of wake-up from Standby, it is ensured that SCR XRAM is not re-initialised.

An additional register interface with interrupt support using **PMSWCR2** register bit fields for exchange and facilitate status handshake between the two domains. The SCR can make a direct interrupt request to any CPUx by writing to register NMICON.SCRINTTC SCR register bit. An additional 8 bit information maybe written to

## Power Management System for Low-End (PMSLE)

SCRINTEXCHG SCR register which is also transferred to **PMSWCR2**.SCRINT register bit field to decode the interrupt reason. The routing of the interrupt to the service request node need to be enabled via **PMSIEN**.SCRINT register bit.

Likewise any CPU may also trigger a direct interrupt request to the SCR by writing to **PMSWCR2**.TCINTREQ register bit. An additional 8 bit information maybe written to **PMSWCR2**.TCINT register which is likewise transferred to TCINTEXCHG SCR register bit field to decode the interrupt reason on SCR side.

Critical SCR errors / events like XRAM ECC errors, SCR watchdog overflow event and SCR internal reset need to be communicated back to the main core domain via **PMSWCR2**.SCRECC, SCRWD and SCRRST register bits. These events may additionally trigger internal SCR reset if configured in RSTST SCR register. The occurrence of SCRECC, SCRWD and SCRRST events may be routed to interrupt based on **PMSIEN**.SCRECC, SCRWD and SCRRST register bits.

Like-wise resets of the main system, namely application, system and power-on resets, are reflected in **PMSWCR2**.RST register bit and communicated to SCR register MRSTST.RST bit. Furthermore, SMURST is differentiated via **PMSWCR2**.SMURST and communicated to SCR register MRSTST.SMURST bit. Interrupt maybe generated in SCR subsystem when MRSTST register bits are set. The bits are cleared when SCR has latched the information.

During standby mode, the SAR secondary monitor ADC maybe used to carry out analog conversions of up to 4 analog inputs (P33.4, P33.5, P33.6 & P33.7) if requested by SCR. Refer SCR ADCOMP chapter for more details.

During a standby to run mode transition on a wake-up event, the P33 and P34 PCSR.SELx shadow register value retains the programmed value of PCSR.SELx value before standby entry. This is to ensure that SCR continues to have control over the respective P33 and P34 port pins during and after exit from Standby, though the Port register PCSR.SELx value is reset. Only on a consequent explicit write to the register after reset release will a new PCSR.SELx value be taken to switch the Port 33 and P34 control.

The SCR may wake-up the main core domain from Standby state if configured in SCRWKEN register bit. The enabling of SCR wake-up via SCRWKEN should be programmed when SCR is running at 20 MHz. A wake-up request is issued by the SCR SW via SCRWP bit in STDBYWKP register as documented in the SCR SCU chapter. On wake-up of the main core domain, SCRWP event flag is set which shall be cleared via SCRWPCLR register bit.

### 12.2.3.4.7 Wake-up Timer (WUT)

The Wake-up Timer is a basic low power counter which may be used to wake-up the system periodically from Standby mode. The timer may also be used during RUN, IDLE or SLEEP modes. The following list enumerates the salient features.

- 24 bit counter running on 70 kHz clock source with programmable reload value.
- 24 bit counter status register providing the current count value.
- Timer resolution of 70 kHz or (70 kHz / 2<sup>10</sup>) configured via a clock divider.
  - 14.3 us resolution : 14.3 us - 240 s range ± 60% default tolerance
  - 14.3 ms resolution : 14.3 ms - 2.7 days range ± 60% default tolerance
- 2 operating modes :
  - Auto Reload mode - WUT is started and stopped via Software. Automatic reload on counter underflow and triggers a system wake-up.
  - Standby Auto Stop mode - Counter starts counting down from reload value on Standby entry. Counter stops on underflow and triggers a system wake-up.
- Events on WUT counter underflow
  - Interrupt request on SRC\_PMSx (WUT) interrupt node on counter underflow during RUN, IDLE or SLEEP mode.
  - Wake-up trigger on counter underflow during STANDBY mode.

## Power Management System for Low-End (PMSLE)

- Capture trigger on counter underflow to CCU60\_CC60IND, CCU61\_CC60IND and GTM (TIM 0.7) for trimming purpose.
- Over-run indication of consecutive un-serviced wake-up triggers

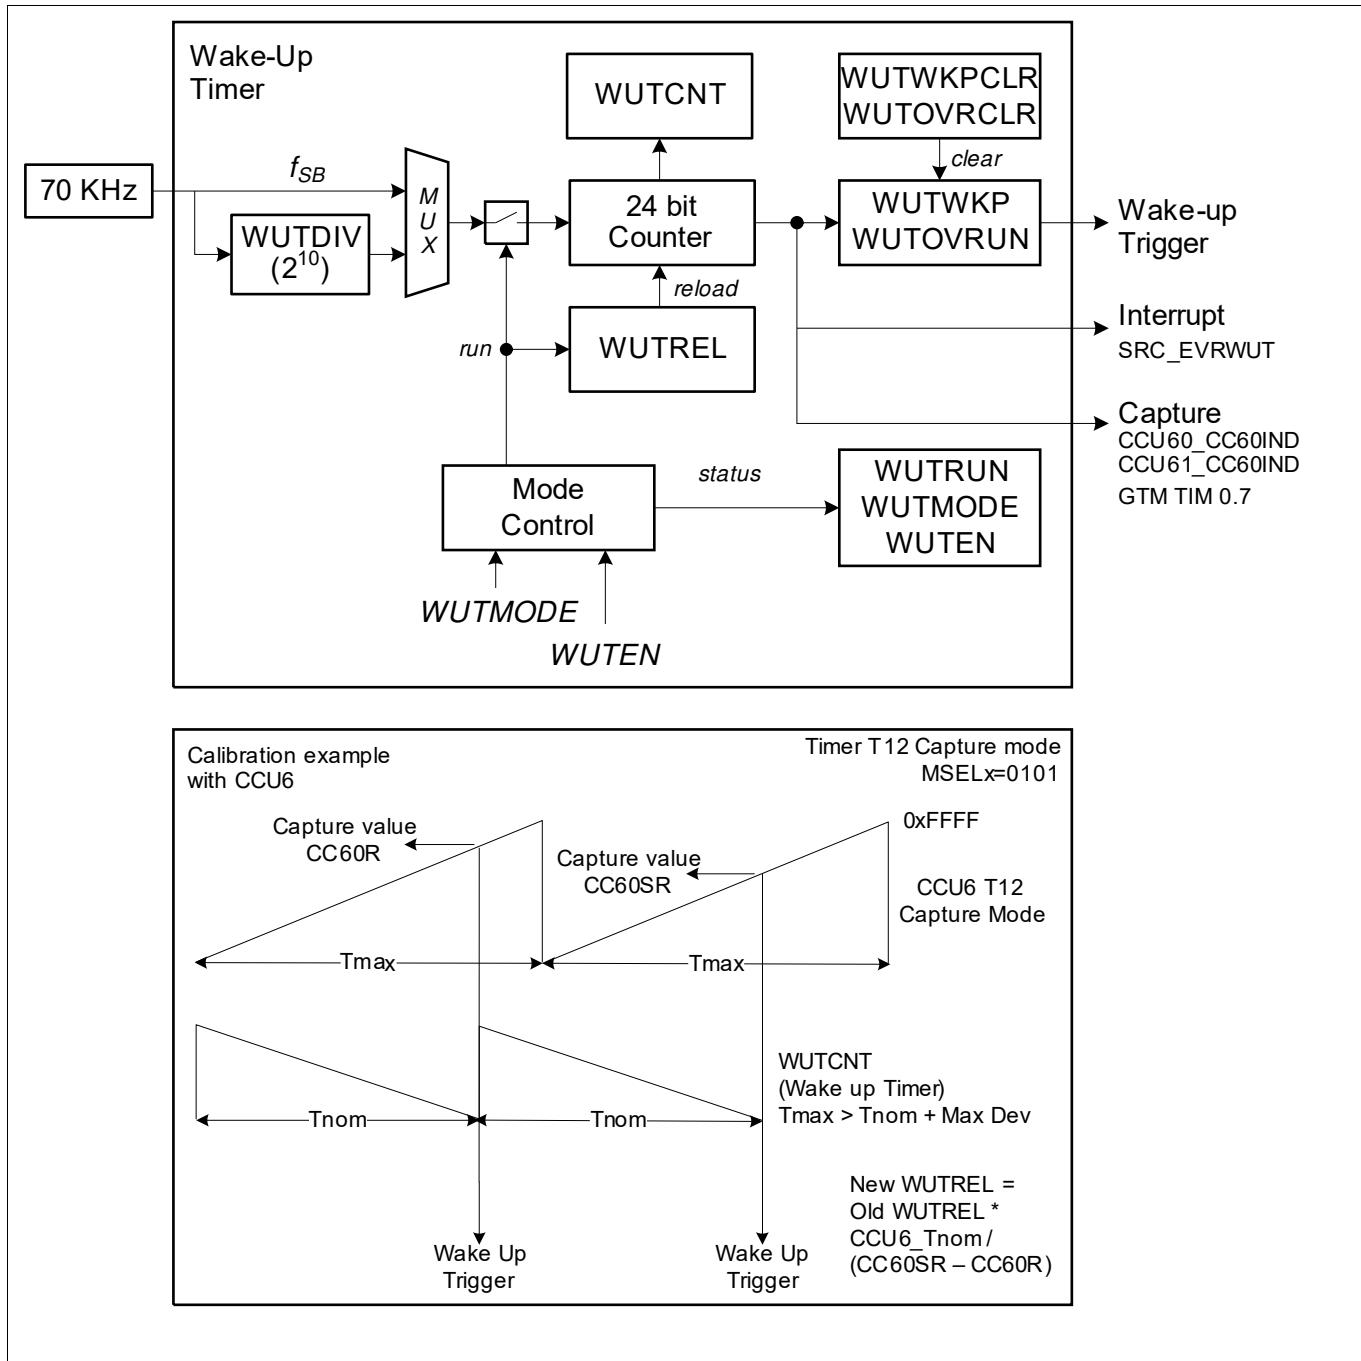

Figure 149 Wake-up Timer (WUT)

## Power Management System for Low-End (PMSLE)

**Table 396 Wake-up Timer Operation and Modes**

WUTEN	WUTMODE	Mode Description
0B	XB	<p>WUT is disabled and counter is stopped.</p> <p><b>PMSWCR3.WUTREL</b> reload value may be updated.</p> <p><b>PMSWSTAT2.WUTCNT,WUTRUN,WUTWKP &amp; WUTOVR</b> flags read 0.</p>
1B	0B	<p>Software Auto Reload mode :</p> <p>WUT starts running when <b>PMSWCR3.WUTEN</b> = 1 and <b>WUTMODE</b> = 0 is set. <b>PMSWCR0.WUTWKEN</b> = 1 is set to activate system wake-up from standby state. <b>PMSWSTAT.WUTRUN</b> bit is set indicating that WUT timer is currently running.</p> <p><b>PMSWUTCNT.WUTCNT</b> bit field indicates the actual counter value. On counter underflow, WUT is automatically reloaded with WUTREL value. During Standby, WUT underflow triggers system wake-up if <b>PMSWSTAT2.WUTWKEN</b> is set and <b>PMSWSTAT2.WUTWKP</b> flag is set. During Run, Idle or Sleep modes, WUT underflow triggers an interrupt request and <b>PMSWSTAT2.WUTWKP</b> flag is set. WUTREL reload value shall not be updated in this state.</p> <p>On wake-up, the <b>PMSWSTAT2.WUTWKP</b> flag shall be cleared by <b>PMSWSTATCLR.WUTWKPCLR</b> bit. In case of un-serviced consecutive counter underflow events, <b>PMSWSTAT2.WUTOVRUN</b> flag is set to indicate an over-run wake-up event.</p> <p>Interrupt over-run event can be detected via SRC.IOV bit during RUN mode.</p>
1B	1B	<p>Standby Auto Stop mode:</p> <p>The mode is selected by setting <b>PMSWCR3.WUTEN</b> = 1, <b>WUTMODE</b> = 1 is set. <b>PMSWCR0.WUTWKEN</b> = 1 is set to activate system wake-up from standby state.</p> <p>WUT starts running only when Standby mode is entered. On counter underflow, WUT stops running and the wake-up of system is triggered and <b>PMSWSTAT2.WUTWKP</b> flag is set.</p> <p>WUT starts running again on the next Standby mode entry. The intention is to have the timer running only during the Standby state.</p> <p><b>PMSWUTCNT.WUTCNT</b> eloads <b>PMSWCR3.WUTREL</b> value on a wake-up.</p> <p><b>PMSWSTAT.WUTRUN</b> reads 0 after a wake-up.</p> <p><b>PMSWCR3.WUTREL</b> reload value shall not be updated in this state.</p> <p>On wake-up, the <b>PMSWSTAT2.WUTWKP</b> flag shall be cleared by <b>PMSWSTATCLR.WUTWKPCLR</b> bit. In case system was woken up by other wake-up triggers while WUT was still running, an interrupt request is generated on WUT underflow. In case of un-serviced consecutive counter underflow events, <b>PMSWSTAT2.WUTOVRUN</b> flag is set to indicate an over-run wake-up event.</p> <p>Interrupt over-run event can be detected via SRC.IOV bit during RUN mode.</p>

In case of timer overflow, an interrupt is issued on the interrupt node SRC\_PMSx (WUT). Wake-up Timer reload value maybe trimmed during Run mode by comparing the time stamp on a WUT underflow captured by a GTM-TIM or CCU6x based on a more precise clock as shown in [Figure 149](#). This allows to compensate on short term the 70 kHz (fSB) clock source variations owing to technology, voltage and temperature.

## Power Management System for Low-End (PMSLE)

### 12.2.3.4.8 Entering Standby Mode (only VEVRSB domain supplied)

The Standby Mode entry may be requested via VEXT supply ramp-down triggered by a secondary SWDUV under-voltage event if configured in **PMSWCR0.VEXTSTBYEN** bits.

The Standby Mode entry may be requested by writing to PMCSR<sub>x</sub> register to set bit field REQSLP = 11<sub>B</sub> or via ESR1 (NMI) assertion as configured in SCU\_PMSWCR1.STBYEV bits.

Standby mode via SW may be entered based on a singular decision from a master CPU based on the configuration in the CPUSEL register. It may also be entered as a unanimous decision of all the CPUs when ALL of the PMCSR<sub>x</sub> registers in the system request it and PMSWCR1.CPUSEL = 111<sub>B</sub>. Each PMCSR<sub>x</sub> register is written by the corresponding CPU<sub>x</sub>.

Before entering Standby mode, modules may be sequentially shut off to avoid large load jumps.

- All peripherals and interrupts associated with CPUs except master CPU are switched off. This is to avoid wake-up of the CPUs once they are put into IDLE state.
- All CPUs except the master CPU are sequentially put into IDLE state. All watchdogs may be disabled or re-configured for slower modes. Peripherals module clocks are switched off in the respective CLC.DISR registers.
- Master CPU frequency reduction in steps compliant to load jump constraints. Master CPU code execution switched from Flash to PSPR RAM. Flash modules may be deactivated.
- System Clock is switched to internal 100 MHz clock source. System PLL & Peripheral PLL are switched off. Clock dividers are programmed to lower values.
- Standby SMU module shall be disabled via CMD\_STDBY.SMUEEN before going into Standby mode.
- SCU\_PMSWCR1.IRADIS bit set to disable Idle Request Acknowledge sequence activation for fast Standby Mode entry. System and Application reset generation possibilities are disabled. Only remaining reset possibility in this phase is via PORST or power-fail
- Standby RAM block selected via **PMSWCR0**.STBYRAMSEL bits. Dcache write back to be executed before Standby entry.
- Select the 70 kHz Standby clock source ( fSB ) via **PMSWCR4**.SCRCLKSEL bits. Configure the blanking filter appropriately via **PMSWCR0**.BLNKFIL bits.
- Configure pad state via **PMSWCR5**.TRISTREQ bit. All pads may be set into tristate or have pull-up device active. Regardless of the **PMSWCR5**.TRISTREQ setting, the VEXT-buffered PU1 pads (see the PU1 buffer type in the data sheet) are set into tristate after standby mode entry. Configure **PMSWCR5**.ESR0TRIST bit to set ESR0 behavior as reset output active or tristate. In case of HWCFG [2:1,6] pins it is recommended to tie them to external pull devices.
- SCR may be kept running before entering the Standby state. The shared ports supplied by VEVRSB are configured either to be in tristate during standby or left to the control of SCR. The enabling of wake-up from SCR via **PMSWCR0**.SCRWKEN should be programmed when SCR is running at 20 MHz.
- Wake-up Timer may also be kept running before entering the Standby state. The wake-up from WUT may be activated via **PMSWCR0**.WUTWKEN bit.
- Wake-up via PORST, Pin A, ESR0 & ESR1 pins is not supported during Standby mode as VEXT will be ramped down on Standby entry. Therefore the respective **PMSWCR0**.PORSTWKEN, PINAWKEN, ESR0WKEN and ESR1WKEN wake-up configuration bits shall be disabled to avoid spurious wake-up triggers. It should be taken care that SCR is not reset on a standby entry by clearing **PMSWCR4**.PORSTREQ bit field.
- Enable wake-up on VEXT supply ramp-up via **PMSWCR0**.PWRWKEN bit. It needs to be ensured that both PWRWKEN and VEXTSTBYEN register bits are both set before entering Standby mode. VEXTSTBYEN register bitfield shall be set to ensure that when VEXT supply is removed during Standby state, no LVD reset is generated consequently exiting from Standby mode.
- In case Standby entry is triggered by VEXT supply ramp down, the threshold is configured in **EVRUVMON**.SWDUVVAL and transition condition in **EVRMONCTRL** register respectively. In case of nominal

## Power Management System for Low-End (PMSLE)

VEXT supply voltage of 5 V, it is recommended to configure SWDUVVAL register bitfield at 4 V for standby entry to have adequate distance to primary reset levels as well as operational region limits. In case of nominal VEXT supply voltage of 3.3V, it is recommended to configure SWDUVVAL register bitfield at 3.1 V for standby entry above primary reset levels. Nevertheless since there is only a minimal margin to reset levels in this case, Standby entry is additionally triggered by the crossing of primary undervoltage limits if VEXTSTBYEN register bit is set to ensure Standby entry in case of fast VEXT slopes. The parasitic diode path from VDDP3 to VEXT will keep the VEXT voltage at (VDDP3 - diode drop), so it should be ensured that SWDUVVAL is configured above (VDDP3 - diode drop) for standby entry if VDDP3 and VEXT supply rails are separately supplied. The selection of only VEXT supply voltage monitoring in **EVRMONCTRL** would reduce the secondary monitor standby entry latency time to (tMON/3). Configure Standby entry event in **PMSWCRO.VEXTSTBYEN** register bit.

- It shall be ensured that the primary under-voltage reset monitors are active before Standby entry is triggered and shall not be disabled in **EVRRSTCON** register.
- The external regulator is communicated to switch off VEXT supply. A controlled ramp-down of VEXT slope during Standby entry is recommended from external regulator (E.g - 0.5V/ms to 1.5V/ms). It need to be ensured that the VEXT supply is ramped below VEXT LVD reset level after standby entry before blanking filter time has expired. This is to avoid an immediate wake-up triggered by the residual VEXT voltage if it is above VEXT LVD reset level after blanking time has expired. It need to be also ensured that VDD and VDDP3 supply rails are consequently switched off after VEXT ramp down to reduce standby current within blanking filter time.
- All xWKP / xOVRUN flags activated by respective xWKEN bits shall be cleared before renewed Standby entry request, otherwise System will remain in Operation state and not enter Standby state. Standby request is issued via VEXT supply undervoltage event or via SW or NMI event. Once Standby entry event is recognised, the primary under-voltage reset generation is disabled and Standby RAM supply is switched from VDD to VDDPD within a single 25 MHz clock cycle. During Standby state entry, the wake-up logic is unable to detect wake-up events for a minimal time period less than 300 ns, therefore it need to be ensured that the wake-up pulse is asserted long enough that wake-up is detected. On entry into Standby mode, blanking filter is activated. The external standby regulator continues to supply the Standby domain via VEVRSB supply pin. Blanking filter is always activated on entry to Enter Standby state.
- Standby request issued via REQSLP bit field or ESR1/NMI event.
- Select required edge configuration in SCU\_ESRCFG1.EDCON if ESR1 is used as a trigger for standby entry.

## Power Management System for Low-End (PMSLE)

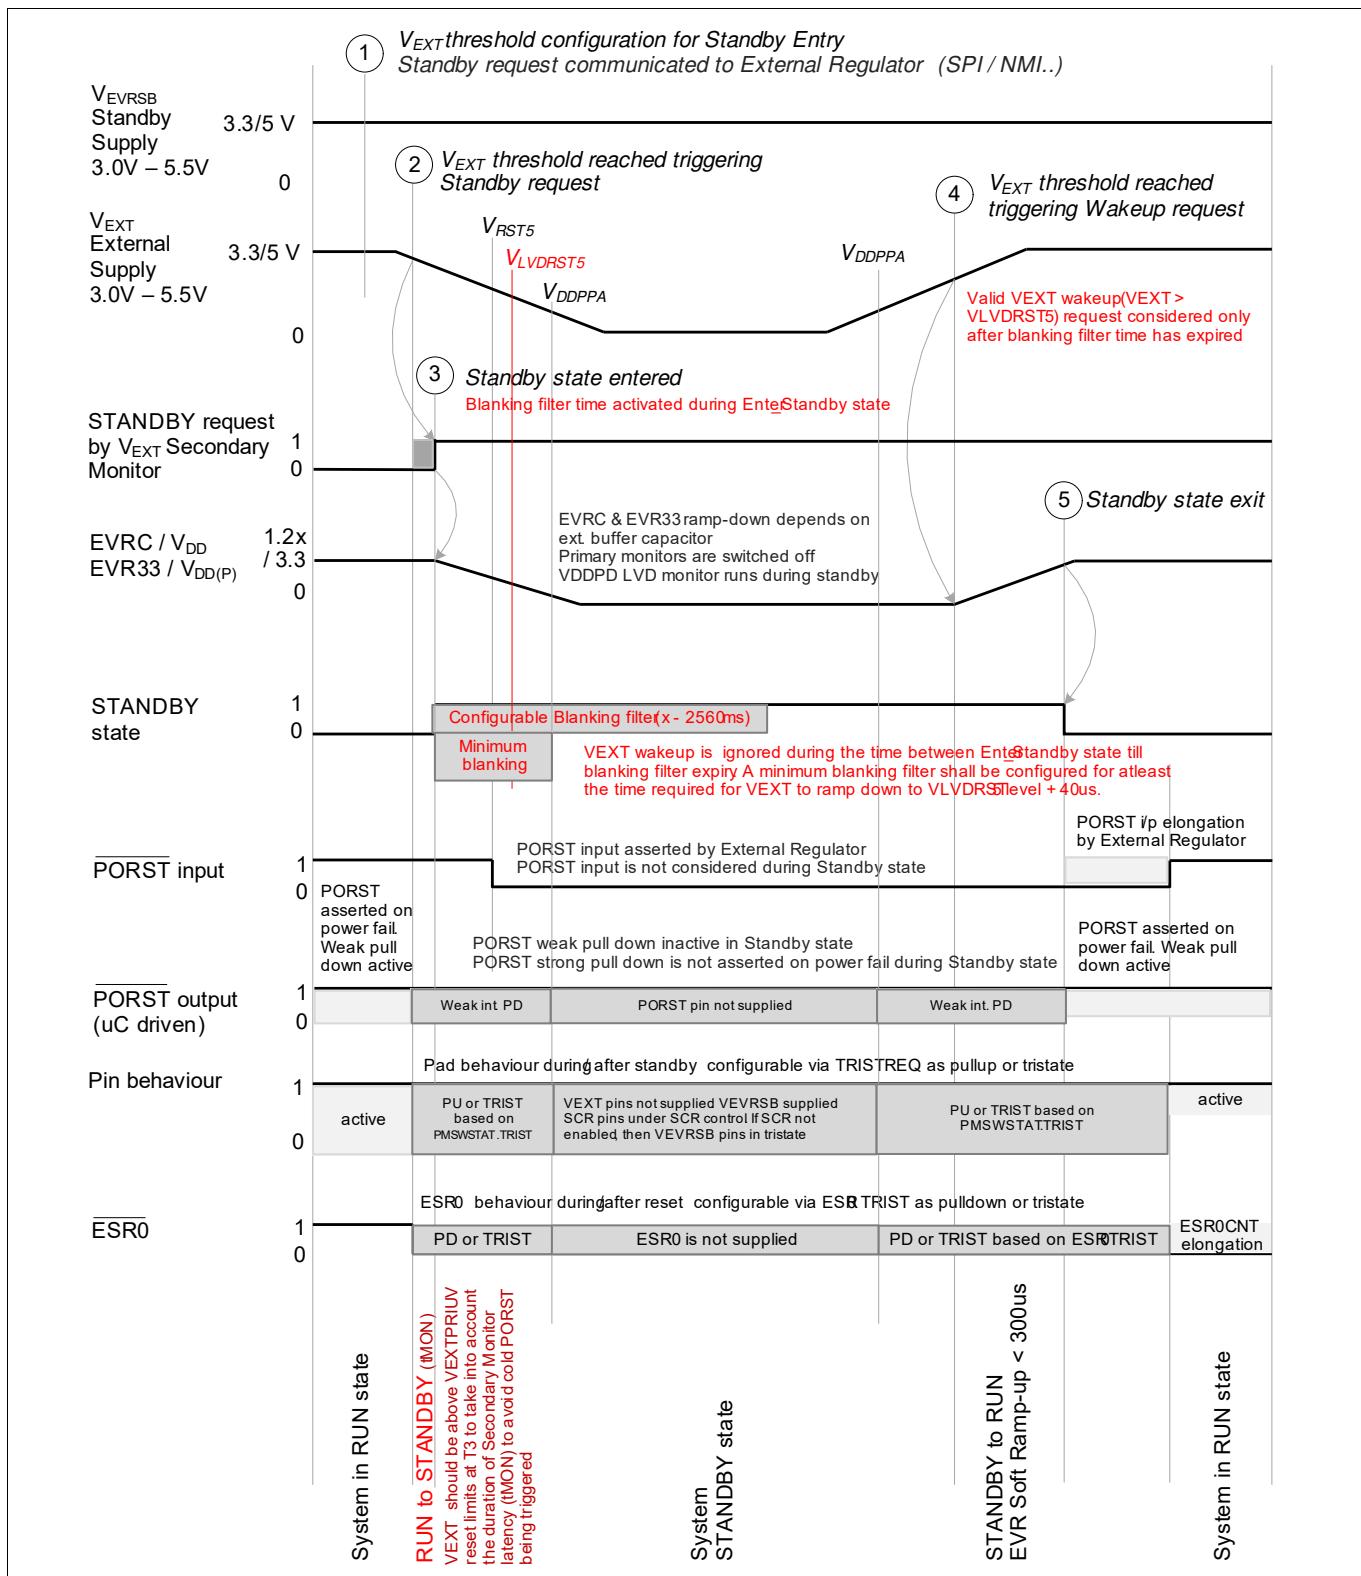

Figure 150 Standby entry on VEXT ramp-down and wake-up on VEXT ramp-up

## Power Management System for Low-End (PMSLE)

### 12.2.3.4.9 Entering Standby Mode (both VEVRSB and VEXT domain supplied)

The Standby Mode entry may be requested by writing to PMCSR<sub>x</sub> register to set bit field REQSLP = 11<sub>B</sub> or via ESR1 (NMI) assertion as configured in SCU\_PMSWCR1.STBYEV bits.

Standby mode via SW may be entered based on a singular decision from a master CPU based on the configuration in the CPUSEL register. It may also be entered as a unanimous decision of all the CPUs when ALL of the PMCSR<sub>x</sub> registers in the system request it and PMSWCR1.CPUSEL = 111<sub>B</sub>. Each PMCSR<sub>x</sub> register is written by the corresponding CPUx.

Before entering standby mode, various modules should be sequentially shut off in a sequence mainly to avoid large current jump on standby entry.

- All peripherals and interrupts associated with CPUs except master CPU are switched off. This is to avoid wake-up of the CPUs once they are put into IDLE state.
- All CPUs except the master CPU are sequentially put into IDLE state. CPU watchdogs may be disabled or re-configured for slower modes. Peripheral module clocks are switched off in respective CLC.DISR registers.
- Master CPU frequency reduction in steps compliant to load jump constraints. Master CPU code execution is switched from Flash to PSPR RAM. Flash modules are deactivated.
- System Clock is switched to the internal 100 MHz clock source. System PLL & Peripheral PLL are switched off. Clock dividers are programmed to lower values.
- Standby SMU module shall be disabled via CMD\_STDBY.SMUEN before going into Standby mode.
- Set SCU\_PMSWCR1.IRADIS bit to disable Idle Request Acknowledge sequence activation for fast Standby Mode entry. This ensures that standby request is not blocked by a pending reset request / sequence.
- Select the Standby RAM block via **PMSWCR0**.STBYRAMSEL bits. Dcache write back to be executed before Standby entry.
- Select the 70 kHz Standby clock source ( fSB ) via **PMSWCR4**.SCRCLKSEL bits. Configure the blanking filter appropriately via **PMSWCR0**.BLNKFIL bits.
- Select the clock source which need to be active on entry into Standby Mode via **PMSWCR4**.SCRCLKSEL bits. Wake-up trigger edge configuration and filter activation is configured via **PMSWCR0**.xxxEDCON and **PMSWCR0**.xxxDFEN bits.
- Configure pad state via **PMSWCR5**.TRISTREQ bit. All pads may either be in tristate or have pull-up devices active. Regardless of the **PMSWCR5**.TRISTREQ setting, the VEXT-buffered PU1 pads (see the PU1 buffer type in the data sheet) are set into tristate after standby mode entry. Configure **PMSWCR5**.ESR0TRIST bit to configure ESR0 behavior as reset output or tristate during Standby and on wake-up. In case of HWCFG [2:1,6] pins it is recommended to tie them to external pull devices.
- Wake-up Timer may also be kept running before entering the Standby state. The wake-up from WUT may be activated via **PMSWCR0**.WUTWKEN bit.
- Enable ESR1 or PINx pins for wake-up via **PMSWCR0**.xxxWKEN bits.
- SCR may be kept running before entering the Standby state. The shared ports supplied by VEVRSB are configured either to be in tristate during standby or left to the control of SCR. The enabling of wake-up from SCR via **PMSWCR0**.SCRWKEN should be programmed when SCR is running at 20 MHz.
- All xWKP / xOVRUN flags activated by respective xWKEN bits shall be cleared before renewed Standby entry request, otherwise System will remain in Operation state and not enter Standby state. Configure Standby Entry event in SCU\_PMSWCR1.STBYEV register bits.
- It shall be ensured that the primary under-voltage reset monitors are active before Standby entry is triggered and shall not be disabled in **EVRRSTCON** register.
- Standby request issued via REQSLP bit field or ESR1/NMI event. An orderly shut down of various sub-systems is triggered to enter Standby mode. Once Standby entry request is recognised, the primary under-voltage

## Power Management System for Low-End (PMSLE)

reset generation is disabled and Standby RAM supply is switched from VDD to VDDPD within a single 25 MHz clock cycle. During Standby state entry, the wake-up logic is unable to detect wake-up events for a minimal time period less than 300 ns, therefore it need to be ensured that the wake-up pulse is asserted long enough that wake-up is detected. Blanking filter is always activated on entry to Enter\_Standby state. It need to be ensured that VDD and VDDP3 supply rails are consequently switched off after entry to standby to reduce standby current.

- Select required edge configuration in SCU\_ESRCFG1.EDCON if ESR1 is used as a trigger for standby entry.

### 12.2.3.4.10 State during Standby Mode

The Standby RAM (DLMU RAM of CPU0 and CPU1), the 8 bit Standby controller, the shared ports and the wake-up logic are kept alive in Standby mode. PORST pin, ESRx pins and PIN A provides wake-up function if VEXT is supplied. In case of wake-up on VEXT supply ramp-up and only VEVRSB is supplied, cold PORST function is resumed only after all supplies have ramped up.

All other pins are set in their default reset state. The default pin behavior during standby and after wake-up may be configured as pull-up or tristate accordingly by TRISTREQ register bit. Regardless of the [PMSWCR5.TRISTREQ](#) setting, the VEXT-buffered PU1 pads (see the PU1 buffer type in the data sheet) are set into tristate after standby mode entry. All pins can be set into tristate except the TESTMODE pin where the internal pull-up is active also during Standby mode. The ESR0 pin may be configured as reset output or tristate during Standby mode by configuring ESR0TRIST bit. The shared port supplied by VEVRSB may retain their state. It need to be ensured by the external regulator that the VEVRSB voltage is within the operational region during Standby state.

The SCR continues to operate as a stand-alone 8 bit controller executing the intended operations. It should be ensured that the shared ports are configured in the corresponding port registers and the ownership of the pins are assigned either to the SCR or the main domain. In case the SCR needs to drive outputs during Standby mode, the default clock may need to be switched from 70 kHz to 20 MHz clock source. The SCR may request the EVR to activate or deactivate the 20 MHz clock. Analog conversions maybe carried out using SCR ADCOMP unit. SCR may be programmed to issue wake-up based on inputs from internal modules or shared pins. When the wake-up of the main core domain is required, the SCR issues a wake-up request via SCRWK bit in STDBYWKP register as documented in the SCR SCU.

### 12.2.3.4.11 Exiting Standby Mode - Wake-up event

The wake-up trigger in case of Standby mode where VEVRSB domain is only supplied may happen

- On a VEXT Supply ramp up after the blanking filter time has expired. SCR may be active. Wake-up can indirectly be triggered via SCR by communicating to external regulator to request the ramp-up of VEXT voltage. The wake-up reason could be any SCR event, Pin B edge transition or WUT Wake-up. Pin B edge transition or WUT Wake-up is also communicated to SCR as shown in [Figure 151](#).

After VEXT wakeup is recognised, it is expected that the VEXT supply is stable afterwards. In case of immediate VEXT powerfail consequent to VEXT wake-up, LVD reset or cold PORST may be triggered.

It is expected that the VEXT Supply has ramped down within the configured blanking filter time. Blanking filter shall be configured for atleast the time required for VEXT to ramp down to VLDRST5 level + 40 us. VEXT wakeup is ignored during the time between Enter Standby state till blanking filter expiry. A wake-up is triggered when the VEXT Supply is above the wake-up threshold of VLDRST5 for a time duration greater than 20 us indicated by event 4 in [Figure 150](#). Wake-up triggered on a VEXT Supply ramp-up is indicated in [PMSWSTAT2.PWRWKP](#) register bit and shall be cleared by [PMSWSTATCLR.PWRWKP](#) clear register bit.

The wake-up event in case of Standby mode where both VEVRSB and VEXT domain supplied may happen after the blanking filter time has expired on following events. ESRx / PINx edge, WUT underflow or SCR wakeup is ignored during the time between Enter\_Standby state till blanking filter expiry. xWKP / xOVRUN flags are only set during Standby mode after Blanking Filter expiry when the respective wake-up event happens.

## Power Management System for Low-End (PMSLE)

- ESR1 edge transition (NMI trap): **PMSWSTAT2.ESR1WKP** set on wake-up. **PMSWSTAT2.ESR1OVRUN** set to indicate overrun behavior in case of multiple un-serviced wake-ups.
- Pin A or Pin B edge transition (P14.1 or P33.12): **PMSWSTAT2.PINxWKP** set on wake-up. **PMSWSTAT2.PINxOVRUN** set to indicate overrun behavior in case of multiple un-serviced wake-ups.
- Wake-up from SCR via register STDBYWKP.SCRWKP in turn caused by following events. **PMSWSTAT2.SCRWKP** set on wake-up. **PMSWSTAT2.SCROVRUN** set to indicate overrun behavior in case of multiple un-serviced wake-ups.
  - Edge transitions at the shared ports
  - RTC interrupt
  - SCR watchdog overflow
  - Selected interrupts from communication modules
  - ADCOMP analog channel compare event.
- Wake-up from WUT

The main EVRC and EVR33 regulators are ramped up on wake-up based on the earlier latched configuration in **PMSWSTAT.HWCFCGEVR** register bits. On wake-up, all pads are either in tristate or are connected to pull-ups as indicated in **PMSWSTAT.TRIST** register bit. ESR0 behavior is indicated in **PMSWSTAT.ESR0TRIST** register bit. If Standby RAM was supplied during Standby state, it is indicated in **PMSWSTAT2.STBYRAM** register bits. Additional RAM integrity checks may be carried out after wake-up. RSTSTAT.STBYR bit indicates that the supply was reliable during Standby. The wake-up and over-run status flags are set in **PMSWSTAT2** register and shall be cleared by **PMSWSTATCLR** register. The wake-up time is nearly the same as the normal boot time as EVR need to be started and firmware need to be consequently executed.

## Power Management System for Low-End (PMSLE)

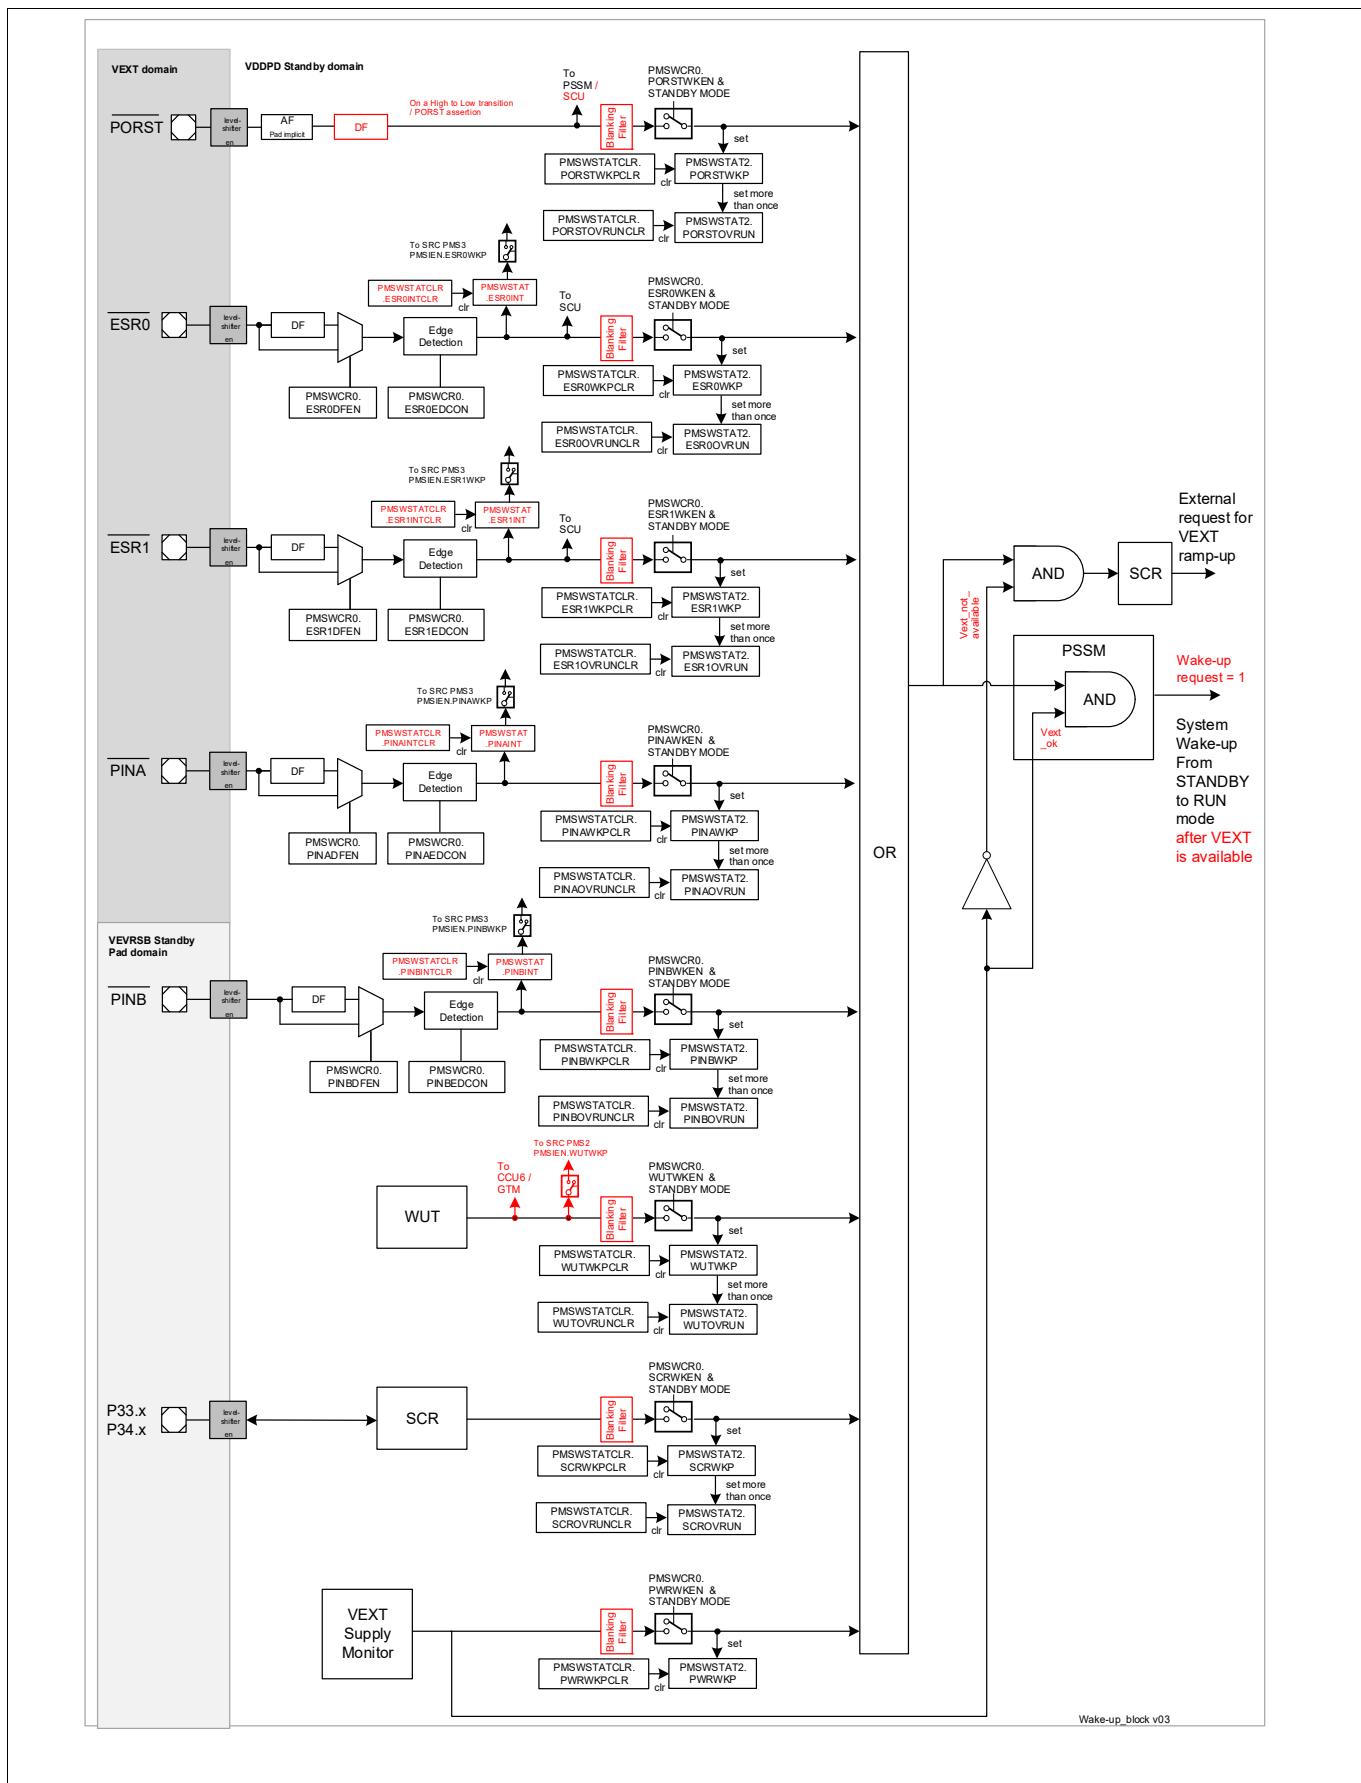

Figure 151 Wake-up Overview

## Power Management System for Low-End (PMSLE)

### 12.2.3.4.12 Exiting Standby Mode - Power Fail or Reset event

A power fail event of the Standby supply (VEVRSB pin) during Standby mode may inevitably result in the loss of Standby RAM contents. Consequently, LVD reset event is issued and the Standby domain is set into reset. EVR Pre-regulator under-voltage violation is indicated in RSTSTAT.STBYR flag which can be used as an indication whether Standby supply fail had happened and Standby RAM contents are reliable. Cold PORST flags RSTSTAT.SWD, EVRC and EVR33 would always be set after wake-up from STANDBY mode as these domains may be devoid of power during STANDBY to eliminate leakage current. It is recommended to keep a copy of the critical data also in Dflash in order to mitigate the effects if unwanted power fail events cannot be avoided.

In case of VEXT supply wake-up, PORST pin, ESRx pins and PIN A input are not evaluated during Standby mode as it is supplied by VEXT domain which is switched off during the STANDBY mode. In case VEXT domain is supplied during STANDBY mode, the Standby domain is woken up on PORST assertion depending on **PMSWCR0.PORSTWKEN** bit. **PMSWCR0.PORSTWKEN** is by default set to 1 to ensure wake-up on PORST assertion during STANDBY mode. The SCR may also set into reset simultaneously depending on **PMSWCR4.PORSTREQ** bit. The device boots up ramping up the regulators followed by firmware execution similar to a normal device start-up. On PORST wake-up, **PMSWSTAT2.PORSTWKP** event flag is set providing information as to the wake-up source. It should be taken care after wake-up to clear the event flags via **PMSWSTATCLR.PORSTWKPCCLR** register. In case new PORST wake-up events are captured while **PMSWSTAT2.PORSTWKP** flags are still set, then **PMSWSTAT2.PORSTOVRRUN** flags are set to indicate an overrun state owing to consecutive un-serviced wake-up events. The overrun flag is cleared via **PMSWSTATCLR.PORSTOVRUNCLR** bit.

The Standby RAM contents are kept intact after a wake-up caused by PORST assertion. In case of VDD supply under-voltage condition during wake-up phase, it is ensured that the Standby RAM is kept supplied by VDDPD until VDD is back in operational range to avoid Standby RAM data loss or corruption during transition. Reset is propagated to external devices via the ESR0 pin on exit from Standby mode depending on **PMSWCR5.ESR0TRIST** configuration. Firmware may elongate ESR0 reset output depending on Flash configuration.

Additional PORST digital filter activated via **PMSWCR5.PORSTDF** bit provides additional spike filtering of at least tPORSTDF duration to provide enhanced immunity against spurious spikes. This is in addition to the inherent analog PORST filter delay of the PORST pad / pin as documented in the datasheet. After cold PORST the additional PORST digital filter delay is by default inactive. If VEXT is supplied, PORST (high to low) during Standby state after blanking filter expiry triggers wake-up.

**Table 397 PORST pin assertion behavior on PMS and SCR subsystem during power modes**

Reaction to PORST pin assertion	RUN mode SLEEP mode	STANDBY mode
No reaction	No effect on PMS domain. No reaction on SCR if <b>PMSWCR4.PORSTREQ</b> = 0 but an SCR_NMI is triggered via the PMSWCR2.RST bit.	No effect on PMS domain if <b>PMSWCR0.PORSTWKEN</b> = 0. No reaction on SCR if <b>PMSWCR4.PORSTREQ</b> = 0
Wake-up	No effect on PMS or SCR domain as the system is already awake	PMS Standby to RUN transition takes place on PORST assertion when VEXT is supplied if <b>PMSWCR0.PORSTWKEN</b> =1(default)
Reset	No reset of PMS domain SCR is reset if <b>PMSWCR4.PORSTREQ</b> = 1 (default)	No reset of PMS domain SCR is reset if <b>PMSWCR4.PORSTREQ</b> = 1 (default)

## Power Management System for Low-End (PMSLE)

### 12.2.3.5 Load Jump Sequencing and Voltage Droop

Load jumps lead to consequent voltage overshoots / undershoots which need to be limited within the regulator dynamic specification and operational bounds of the supply rail. The initial phase after the load jump is buffered by the external capacitor which consequently leads to a linear discharge of the capacitor. Consequently the regulator feedback loop recognizes the deviation in voltage and reacts to the jump by changing the control output. The dimensioning of the capacitor results mainly from the load jump amplitude, ESR of the capacitor, the permissible voltage deviation and reaction time of the regulator. The capacitor size in turn has a tangible impact on BOM cost and PCB space. Minimizing peak-to-peak voltage deviation in the face of such large dynamic changes in load current need to be actively managed if large amounts of output capacitance are to be avoided.

If  $V_{DD}$  supply is generated by the internal EVRC regulator, the voltage transients owing to load jumps on core  $V_{DD}$  supply rail need to be restricted within  $V_{DD\_SETPOINT} + 8\% - 6\%$ . This includes a static accuracy of  $V_{DD\_SETPOINT} \pm 2\%$  and consequently  $+ 6\% - 4\%$  remaining for dynamic regulation.

In case of external  $V_{DD}$  supply, the voltage transients owing to load jumps on core  $V_{DD}$  supply rail need to be restricted within  $V_{DD\_SETPOINT} \pm 5\%$ . This includes a static accuracy of  $V_{DD\_SETPOINT} \pm 2\%$  and consequently  $\pm 3\%$  remaining for dynamic regulation.

Load jumps may be triggered by software or user driven actions or asynchronous hardware events. During software triggered non reset events, it is recommended to limit the load jumps ( $dIEXT/dt$ ,  $dIDD/dt$ ) to a maximum of 100 mA with 50 us settling time. For example, during clock ramp-up phase it is recommended to limit the clock switching steps so as not to violate this limit.

#### Handling load jump hardware events triggered asynchronously - Resets and NMI

In case of typical application load jump events, triggered asynchronously, like Non Maskable Interrupts and reset events, namely application, system and warm power-on reset requests, measures are built in to ensure that voltage overshoots are kept within bounds by load sequencing mechanisms or by means of register configuration.

In case of an NMI event, during RUN mode or waking up from SLEEP mode, the device may activate a large number of hitherto dormant circuits and wake-up the CPUs simultaneously resulting in a large change in load current. To avoid a large load jump on an NMI event, it needs to be ensured that only one CPU is triggered by the NMI or woken out of SLEEP mode and that other CPUs are still in IDLE mode. The other CPUs are consequently started one after another with adequate delay in between during start-up phase. The active CPU woken up on an NMI request is selected based on TRAPDIS0 and TRAPDIS1 register configurations.

In case of an Application Reset, System Reset or warm Power-On Reset request, the port pins are immediately set into reset state. Consequently the CPUs are ramped down in a sequence during the first 80 us immediately after the warm reset request. Finally after 180 us after reset request, the asynchronous reset event is issued to the device allowing to limit the maximum warm reset load jump to roughly half of the total dynamic IDD (IDDRAIL minus IDDPORST) current. It needs to be ensured that the VEXT, VDDP3 and VDD supply voltages are above the minimum operational voltage limits during the total reset phase of 180 us after warm reset request not to trigger a cold power-fail reset. Larger overshoots are tolerable during and after reset phase for a certain cumulated time but must be limited to operational and absolute maximum voltage ratings as documented in the datasheet.

Load jump events caused by asynchronous failure events like PLL loss of lock or external oscillator watchdog event may lead to overshoots which cannot be sequenced owing to the inherent nature of failure.

#### Handling simultaneous load jump requests triggered by Software

Software triggered Load Jump events include ramping up / down of various system clock frequencies, activating additional CPUs, Power mode transitions, CPU throttling and idle requests, MTU Memory tests, LBIST tests and so forth.

## Power Management System for Low-End (PMSLE)

In case of software triggered events, it is possible to prepare by lowering or raising the voltage setpoint before the load jump is issued. A negative voltage droop may be done before a negative load jump and a positive voltage droop before a positive load jump respectively. Thus negative load jumps leading to voltage overshoots is compensated partly by the negative voltage droop and likewise positive load jumps leading to voltage undershoots is compensated partly by the positive voltage droop as shown in [Figure 152](#). The voltage droop is configured through SCU\_PMTCSR0.SDSTEP register bits. The voltage droop in positive or negative direction is issued via SCU\_PMTCSR3.VDROOPREQ register bits. In case a current Vdroop request is not active or the Voltage Droop Timer is not currently running indicated via SCU\_PMTCSR3.VDTRUN or the Load Jump Timer is not currently running indicated via SCU\_PMTCSR2.LJTRUN, a new Vdroop request is taken. Once a new voltage droop request is issued, **EVRSTAT**.SDVOK is reset and TC3xx need to wait for a certain time till the regulator has settled on the new value which is realized using a Voltage Droop Timer. Once the regulator has settled on the new value, **EVRSTAT**.SDVOK status bit is set again indicating the end of the Voltage Droop transition and SCU\_PMTCSR3.VDTRUN and SCU\_PMTCSR3.VDTCNT is reset by hardware. If SDVOK status bit is set by EVRC before compare match of VDT has occurred, VDTOV overflow bit is not set and overrun interrupt is not generated. The Voltage Droop Timer compare value is configured in SCU\_PMTCSR1.VDTCV register bits and the current value is indicated in SCU\_PMTCSR3.VDTCNT register bits. In case of a compare match, the overflow SCU\_PMTCSR3.VDTOV bit is set if enabled via SCU\_PMTCSR0.VDTOVEN register bits. In this case, overflow bit has to be explicitly cleared via SCU\_PMTCSR3.VDTOVCLR before a new request can be taken to support a sequential polling based approach. Furthermore, interrupt maybe activated on an overflow if SCU\_PMTCSR0.VDTOVIEN is enabled.

Simultaneous software triggered load jump events can be likewise avoided by checking whether a Load Jump is ongoing or the Load Jump Timer is currently running. The Load Jump Request is issued by triggering a compare and swap operation on SCU\_PMTCSR2 register. A CPU will access data from SCU\_PMTCSR2 register and will compare the current value with an expected value. The expected value is that there is no load jump currently ongoing and VDTRUN bit state is 0. If there is a match, the CPU will make the swap by setting SCU\_PMTCSR2.LDJMPREQ variable and starting the timer. Obviously if multiple CPUs are making this operation simultaneously only one CPU will succeed and others will fail the compare and swap operation when the Load Jump Timer would be running. The idea is to prevent multiple CPUs from doing load jumps simultaneously by treating Load Jump as a critical section and ensuring that only a single CPU can check and issue a load jump request atomically. Once a load jump request is taken, a timer is started and other CPUs have to wait till the regulator output has been restored to the setpoint value and ensures adequate regulator reaction time. The other CPUs are not blocked during the waiting period instead they can continue with some other operations or try to make the request again at a later point of time.

Thus negative load jumps and positive load jumps are followed by a blanking period using a Load Jump Timer as shown in [Figure 152](#). The Load Jump Timer is configured through SCU\_PMTCSR0 register. The load jump request is issued via SCU\_PMTCSR2.LDJMPREQ register bits. If a current Load Jump request is not active or the Load Jump Timer is not currently running indicated via SCU\_PMTCSR2.LJTRUN or the Voltage Droop Timer is not currently running indicated via SCU\_PMTCSR3.VDTRUN, a new Load Jump request is taken. Once a new Load Jump request is issued, the device needs to wait for a certain time till the regulator has reacted to the jump which is realized using a Load Jump Timer. The Load Jump Timer compare value is configured in SCU\_PMTCSR1.LJTCV register bits and the current value is indicated in SCU\_PMTCSR2.LJTCNT register bits. In case of a compare match, the overflow SCU\_PMTCSR2.LJTOV bit is set if enabled via SCU\_PMTCSR0.LJTOVEN register bits. In this case, overflow bit has to be explicitly cleared via SCU\_PMTCSR2.LJTOVCLR before a new request can be taken to support a sequential polling based approach. Furthermore, an interrupt maybe activated on an overflow if SCU\_PMTCSR0.LJTOVIEN is enabled. Overflow bit is routed to an OS interrupt to schedule the next current jump. Overflow bit maybe masked or used in the compare and swap operation if SCU\_PMTCSR0.LJTOVEN is set to ensure that explicit clear of the time out has happened before issuing a new request. SCU\_PMTCSR2.LJTOVCLR also clears SCU\_PMTCSR3.VDROOPREQ and SCU\_PMTCSR2.LDJMPREQ request.

**Power Management System for Low-End (PMSLE)**

### 12.2.3.6 Core Die Temperature Sensor (DTSC)

The Core Die Temperature Sensor (DTSC) generates a measurement result that indicates directly the current temperature. The DTSC measures the temperature with an accuracy within ( $T_{NL} + T_{CALACC}$ ) parameter limits within the TSR temperature range documented in the datasheet. The result of the measurement is updated periodically in DTSCSTAT.RESULT register bit field with a resolution less than 1/5th of a degree Kelvin. The Die Temperature Sensor is available after an application reset release on a device start-up and temperature measurements are carried out continuously during normal RUN / SLEEP modes once DTSC is enabled. The Die Temperature Sensor and DTSLIM and DTSCSTAT registers are reset on an application reset.

The DTSC is enabled via DTSLIM.DTSEN register bitfield. The DTS start-up is completed after a nominal 20us delay after DTSLIM.DTSEN is set. After an ongoing temperature measurement is completed, DTSCSTAT.RESULT bit field is updated coherently with the new value. An interrupt service request (SRC\_SCUERU3) can be generated after a measurement is completed. DTS bandgap status is reflected in DTSLIM.BGPOK status flag. The DTS accuracy and measurement time is defined in the Data Sheet. The DTSLIM register shall be updated before enabling DTSC via DTSLIM.DTSEN register bitfield.

Die temperature upper and lower limits are configured in DTSLIM.UPPER and LOWER register bits. On violation of these limits, DTSLIM.UOF and LLU status bits are set and alarms are forwarded to core SMU. After start-up or application reset, the DTSC limits have to be re-configured appropriately depending on the application before alarm reactions from SMU are activated. Only when a new DTSC conversion result is available, the DTSC comparators are consequently triggered to check the actual DTSCSTAT.RESULT against the upper and lower limits.

DTSCCON and DTSCBGOCTRL register can be also changed after DTSC is enabled on the fly for test purposes.

## Power Management System for Low-End (PMSLE)

### 12.3 Registers

#### 12.3.1 Register Access Modes

Read and write access to registers and memory locations are sometimes restricted. In memory and register access tables, the terms as defined in **Table 398** are used.

In general, if an access type is not permitted under these rules (e.g. attempted write to R, attempted user mode access to SV, attempted access to E without Endinit, etc.) then a Bus Error will result, unless the access is also marked as nBE (or otherwise stated in the specific module chapter).

**Table 398 Access Terms**

Symbol	Description
BE	Always returns Bus Error (e.g. used on Write Access to indicate a read-only register). Bus error is captured by BCU which in turn generates alarm to SMU.
CEx	Access only when CPUx Endinit is not active (SCU_WDTCPUxCON0.ENDINIT = 0)
E	Access only when any Endinit is inactive (SCU_WDTCPUxCON0.ENDINIT = 0 for any CPUx, or SCU_EICON0.ENDINIT = 0)
P	Access only from Master x (when MOD_ACCEN0.ENx = 1). In case of access violation, bus error is generated which is captured by BCU which in turn generates alarm to SMU.
P0	Access only from Master x (when MOD_ACCEN00.ENx = 1)
P1	Access only from Master x (when MOD_ACCEN10.ENx = 1)
PW	Access only when correct Password
SE	Access only when Safety Endinit is inactive (SCU_WDTSICON0.ENDINIT = 0 or SCU_SEICON.ENDINIT = 0). In case of access with Safety Endinit active, bus error is generated which is captured by BCU which in turn generates alarm to SMU.
ST	Access only when startup (SSW) executes and writable only while bit STCON.STP is cleared.
SV	Access only when PSW = Supervisor Mode. In case of access violation, bus error is generated which is captured by BCU which in turn generates alarm to SMU.
TM	Access only when SCU test mode
U	Access only when PSW = User Mode 0 or 1 Reset Value: Value or bit is not changed by a reset operation.
32	Access only when 32-bit width
32/16	Access only when 32-bit or 16-bit width

**Table 399 Combined Access Conditions**

Symbol	Description
P, U, SV	P and (U or SV)
U, SV	(U or SV)
P, SV, E	P and SV and E
SV, SE	SV and SE
TM, ST	TM or ST

---

**Power Management System for Low-End (PMSLE)**
**Table 400 Other Register Annotations**

<b>Symbol</b>	<b>Description</b>
nBE	Indicates that no Bus Error is generated when accessing this address range, even though it is either an access to an undefined address or the access does not follow the given rules.
nE	Indicates that no Error is generated when accessing this address or address range, even though the access is to an undefined address or address range. True for CPU accesses (MTCR/MFCR) to undefined addresses in the CSFR range.

### 12.3.2.1 Safety Flip-Flops

Safety flip-flops are special flip-flops that implement a hardware mechanism capable to detect single event effects that may lead to single event upsets (bit flip). The configuration and control registers that are implemented with safety flip-flops are:

- [EVRRSTCON](#)
- [EVRTRIM](#)
- [EVRMONCTRL](#)
- [EVRMONFILT](#)
- [EVRUVMON](#)
- [EVROVMON](#)

### 12.3.2.2 Power Supply Generation and Monitoring Control Registers

This section describes the kernel registers of the PMS module. Most of PMS kernel register names described in this section will be referenced in other parts of the Target Specification by the module name prefix “PMS\_”. All PMS registers are placed in the VDDPD Pre-Regulator domain. After a cold PORST, these registers may return the default isolation value or the updated value by the Firmware. Otherwise, a read will provide the value of the most recent write operation. In PMS subsystem some registers are reset with cold PORST which encompasses predominantly registers with EVR power generation and primary and secondary monitoring functions. This ensures that certain registers are not erroneously updated and the system does not end up in permanent reset situation. The registers covering standby and infrastructure functions however are reset with the EVR LVD (Low Voltage Detector Reset) master reset.

Tricore atomic instructions (LDMST, ST.T, SWAP.W, SWAPMASK.W, CMPSWAP.W) only write back bits that are changing their level. This leads to the fact that bits that are already set cannot be written with a 1 when using RMW instructions. No problem exists when using direct write instructions (e.g. ST.W). This affects the status bits in register DTSIM.LLU and UOF bits which are cleared by writing 1s.

#### Identification Register

ID	(0008 <sub>H</sub> )																Application Reset Value: 00E8 C001 <sub>H</sub>								
Identification Register	MODNUMBER																								
	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	r								
	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	r	MODTYPE		MODREV					

Field	Bits	Type	Description
<b>MODREV</b>	7:0	r	<b>Module Revision Number</b> This bit field indicates the revision number of the PMS module.
<b>MODTYPE</b>	15:8	r	<b>Module Type</b> This bit field is fixed coded as C0 <sub>H</sub> . It defines a 32-bit module.

## Power Management System for Low-End (PMSLE)

Field	Bits	Type	Description
<b>MODNUMBER</b>	31:16	r	<b>Module Number</b> This bit field defines the module identification number. The identification number for the PMS is $00E8_H$ .

### EVR Status Register

The status registers EVRSTAT, EVRADCSTAT, EVRMONSTAT1, EVRMONSTAT2 and EVRSDSTAT0 are updated during Start-up and after every EVRx closed loop cycle with the actual status and therefore the read value may differ from the reset value. The over-voltage and under-voltage event flag signals are reported to SMU.EMM unit. An alarm for the upper and lower bound is supported in the SMU.EMM unit.

#### EVRSTAT

**EVR Status Register** (002C<sub>H</sub>) Reset Value: [Table 403](#)

Field	Bits	Type	Description
<b>EVRC</b>	0	rh	<b>EVRC status</b> This bit is set if the internal EVRC regulator is currently active. EVRC is activated if HWCFG[2] pin level is latched high during start-up phase. $0_B$ EVRC is inactive. $1_B$ EVRC is active.
<b>OVC</b>	1	rh	<b>VDD Over-voltage event flag</b> This bit is set if VDD secondary voltage monitor recognizes a over-voltage event. An alarm is raised to the SMU and the status bit remains set until violation disappears. $0_B$ No Over-voltage condition or event active. $1_B$ VDD Over-voltage condition event indication as configured in EVROVMON / EVRMONCTRL register.
<b>EVR33</b>	2	rh	<b>EVR33 status</b> This bit is set if the internal EVR33 LDO regulator is active. EVR33 is activated if HWCFG[1] pin level is latched high during start-up phase. $0_B$ EVR33 is inactive. $1_B$ EVR33 is active.

**Power Management System for Low-End (PMSLE)**

Field	Bits	Type	Description
OV33	3	rh	<p><b>VDDP3 Over-voltage event flag</b></p> <p>This bit is set if VDDP3 secondary voltage monitor recognizes a over-voltage event. An alarm is raised to the SMU and the status bit remains set until violation disappears.</p> <p>0<sub>B</sub> No over-voltage condition or event active. 1<sub>B</sub> VDDP3 Over-voltage event indication as configured in EVROVMON / EVRMONCTRL register.</p>
OVSWD	4	rh	<p><b>VEXT Over-voltage event flag</b></p> <p>This bit is set if VEXT secondary voltage monitor recognizes an over-voltage event. An alarm is raised to the SMU and the status bit remains set until violation disappears.</p> <p>0<sub>B</sub> No over-voltage condition or event active. 1<sub>B</sub> VEXT Over-voltage event indication as configured in EVROVMON / EVRMONCTRL register.</p>
UVC	5	rh	<p><b>VDD Under-voltage event flag</b></p> <p>This bit is set if VDD secondary voltage monitor recognizes a under-voltage event. An alarm is raised to the SMU and the status bit remains set until violation disappears.</p> <p>0<sub>B</sub> No under-voltage condition or event active. 1<sub>B</sub> VDD Under-voltage event indication as configured in EVRUVMON / EVRMONCTRL register.</p>
UV33	6	rh	<p><b>VDDP3 Under-voltage event flag</b></p> <p>This bit is set if VDDP3 secondary voltage monitor recognizes a under-voltage event. An alarm is raised to the SMU and the status bit remains set until violation disappears.</p> <p>0<sub>B</sub> No under-voltage condition or event active. 1<sub>B</sub> VDDP3 Under-voltage event indication as configured in EVRUVMON / EVRMONCTRL register.</p>
UVSWD	7	rh	<p><b>VEXT Under-voltage event flag</b></p> <p>This bit is set if VEXT secondary voltage monitor recognizes an under-voltage event. An alarm is raised to the SMU and the status bit remains set until violation disappears.</p> <p>0<sub>B</sub> No under-voltage condition or event active. 1<sub>B</sub> VEXT Under-voltage event indication as configured in EVRUVMON / EVRMONCTRL register.</p>

## Power Management System for Low-End (PMSLE)

Field	Bits	Type	Description
<b>SYNCLCK</b>	8	rh	<p><b>EVRC Synchronization Input Locked status(<code>sd_sync_in_locked_o</code>)</b></p> <p>This bitfield indicates the current synchronization status of EVRC SMPS regulator to external DCDCSYNCI input signal. When the EVRC switching frequency/ edge is locked to the synchronization input, the SYNCLCK bit is set to HIGH indicating the locked state. When the synchronization is lost owing to frequency deviations beyond MAXDEV or the feature is disabled via SYNCEN, the SYNCLCK bit is set to LOW.</p> <p>This EVRC Synchronization status is indicated in EVRSDSTAT0.SYNCLCK status bits.</p> <ul style="list-style-type: none"> <li>0<sub>B</sub> EVRC regulator runs on internal configured switching frequency and is not currently synchronized to external DCDCSYNCI input signal.</li> <li>1<sub>B</sub> EVRC regulator switching frequency is currently synchronized to external DCDCSYNCI input signal.</li> </ul>
<b>EVR33VOK</b>	9	rh	<p><b>EVR33 Regulator Voltage OK status</b></p> <p>This bit is set after the soft ramp-up time of the EVR33 voltage OK ramp detector has elapsed and is not based on the measured VDDP3 voltage at the end of ramp-phase..</p> <ul style="list-style-type: none"> <li>0<sub>B</sub> EVR33 ramp-up time has not elapsed.</li> <li>1<sub>B</sub> EVR33 ramp-up time has elapsed.</li> </ul>
<b>RSTC</b>	13	rh	<p><b>EVRC Reset Trigger</b></p> <ul style="list-style-type: none"> <li>0<sub>B</sub> No cold reset trigger signal is active after spike filter and core VDD voltage output is above the selected reset trim value.</li> <li>1<sub>B</sub> A cold reset trigger signal is active after spike filter and core VDD voltage output is below the selected reset trim value.</li> </ul>
<b>RST33</b>	14	rh	<p><b>EVR33 Reset Trigger</b></p> <ul style="list-style-type: none"> <li>0<sub>B</sub> No cold reset trigger signal is active after spike filter and 3.3 V VDDP3 voltage output is above the selected reset trim value.</li> <li>1<sub>B</sub> A cold reset trigger signal is active after spike filter and 3.3 V VDDP3 voltage output is below the selected reset trim value.</li> </ul>
<b>RSTSVD</b>	15	rh	<p><b>EVR SWD Reset Trigger</b></p> <ul style="list-style-type: none"> <li>0<sub>B</sub> No cold reset trigger signal is active after spike filter and VEXT voltage input is above the selected reset trim value.</li> <li>1<sub>B</sub> A cold reset trigger signal is active after spike filter and VEXT voltage input is below the selected reset trim value.</li> </ul>
<b>EVRCSHLV</b>	16	rh	<p><b>Short to ground</b></p> <p>This bit is set if a short condition to ground has been detected. The measured EVRC output is below the operational supply range and the upper controller limits are reached. The feature is supported only during closed loop operation or EVRCMOD = 00b.</p> <ul style="list-style-type: none"> <li>0<sub>B</sub> No short to ground detected on VDD rail.</li> <li>1<sub>B</sub> Short to ground detected on VDD rail.</li> </ul>

## Power Management System for Low-End (PMSLE)

Field	Bits	Type	Description
<b>EVRCSHHV</b>	17	rh	<p><b>Short to supply</b></p> <p>This bit is set if a short condition to supply has been detected. The measured EVRC output exceeds the allowed supply range and the lower controller limits are reached. The feature is supported only during closed loop operation or EVRCMOD = 00b.</p> <p><math>0_B</math> No short to supply detected on VDD rail.  <math>1_B</math> Short to supply detected on VDD rail.</p>
<b>EVR33SHLV</b>	18	rh	<p><b>Short to ground</b></p> <p>This bit is set if a short condition to ground has been detected. The measured EVR33 output is below the operational supply range and the lower gate drive threshold voltage driving P ch. MOSFET is reached.</p> <p><math>0_B</math> No short to ground detected on VDDP3 rail.  <math>1_B</math> Short to ground detected on VDDP3 rail.</p>
<b>EVR33SHHV</b>	19	rh	<p><b>Short to supply</b></p> <p>This bit is set if a short condition to supply has been detected. The measured EVR33 output exceeds the allowed supply range and the upper gate drive threshold voltage driving P ch. MOSFET is reached.</p> <p><math>0_B</math> No short to supply detected on VDDP3 rail.  <math>1_B</math> Short to supply detected on VDDP3 rail.</p>
<b>SWDLVL</b>	20	rh	<p><b>VEXT External Supply Level Status</b></p> <p>This bit indicates that the VEXT voltage has dropped below ~4 V to indicate EVRC parameter switch to differentiate 5V or 3.3V external supply. A hysteresis of ~120 mV is implemented on this detector.</p> <p><math>0_B</math> VEXT external supply is above the threshold.  <math>1_B</math> VEXT external supply is below the threshold.</p>
<b>SDVOK</b>	21	rh	<p><b>EVRC Regulator Voltage OK status</b></p> <p>This bit is set by the EVRC voltage OK detector to indicate that the new regulator output value has been reached. This bit is reset incase EVRTRIM, SDVOUTSEL or SDVOUTTRIM values are adapted to scale core voltage and is set when the new output setpoint is reached. This bit is also reset incase droop compensation is requested before a load jump event. A time out period of x us shall be waited when polling SDVOK bit.</p> <p><math>0_B</math> EVRC regulator setpoint voltage has not been reached.  <math>1_B</math> EVRC regulator setpoint voltage is reached and VDD voltage is ok.</p>
<b>EVRCMOD</b>	23:22	rh	<p><b>EVRC Mode</b></p> <p>EVRC Operation Mode. This bit-field indicates the current operation mode of the SC-DCDC: bypass switches disabled, bypass switches enabled.</p> <p><math>00_B</math> SMPS Normal SC Mode: The bypass switches are not active.  <math>01_B</math> SMPS operation with bypass switches activated. High current consumption expected. An interrupt is generated to the application SW if enabled in the PMSIEN register.  <math>10_B</math> Reserved.  <math>11_B</math> Reserved.</p>

**Power Management System for Low-End (PMSLE)**

Field	Bits	Type	Description
<b>OVPRE</b>	24	rh	<p><b>Pre Regulator VDDPD Over-voltage event flag</b></p> <p>This bit is set if VDDPD supply secondary voltage monitor recognizes an over-voltage event. An alarm is raised to the SMU.</p> <p>0<sub>B</sub> No over-voltage condition happened. 1<sub>B</sub> VDDPD Over-voltage event indication as configured in EVROVMON2 register.</p>
<b>OVSB</b>	25	rh	<p><b>Standby Supply or VEVRSB Over-voltage event flag</b></p> <p>This bit is set if VEVRSB supply secondary voltage monitor recognizes an over-voltage event. An alarm is raised to the SMU.</p> <p>0<sub>B</sub> No over-voltage condition happened. 1<sub>B</sub> VEVRSB Over-voltage event indication as configured in EVROVMON2 register.</p>

**Table 411 Reset Values of EVRMONSTAT2**

Reset Type	Reset Value	Note
LVD Reset	0000 0000 <sub>H</sub>	
Cold PORST	0000 0000 <sub>H</sub>	

### EVR Secondary Monitor Control Register

The default setting after reset is that over-voltage indication is notified via an SMU alarm when the over-voltage threshold is crossed in a lower to higher voltage transition. Overvoltage monitors use greater than equal compare if xOVMOD=01b or 11b and less than equal compare if xOVMOD=10b

The default setting after reset is that under-voltage indication is notified via an SMU alarm when the under-voltage threshold is crossed in a higher to lower voltage transition. Under voltage monitors use greater than equal compare if xUVMOD=01b and less than equal compare if xUVMOD=10b or 11b

It can be configured in EVRMONCTRL register to generate an interrupt when the over- under-voltage thresholds are crossed in either direction. This may be used to notify when the violation condition disappears with respect to secondary voltage monitoring. Interrupt is generated on low to high transition of the EVRSTAT monitoring bits incase of xOVMOD=01b or 10b and interrupt is generated on any transition incase of xOVMOD=11b.

### EVRMONCTRL

### EVR Secondary Monitor Filter Register

The assertion of alarm takes place when xFIL consecutive values are violating the threshold. Incase one of the values is not violating the threshold , the spike filter is reset. For renewed assertion of the alarm to take place, a repeated set of xFIL consecutive values violating the threshold are required.

#### EVRMONFILT

##### EVR Secondary Monitor Filter Register

(0070<sub>H</sub>)

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
				VDDMUUVVAL							PREUVVAL				
				rw							rw				

Field	Bits	Type	Description
PREUVVAL	7:0	rw	<b>VDDPD Supply Secondary Monitor Under-voltage threshold</b> This field defines the under-voltage monitoring threshold level of the VDDPD supply or EVRPR output. Ideal Threshold = [(VIN / LSB) + 1] Ideal LSB = 5.7692 mV
VDDMUUVVAL	15:8	rw	<b>VDDM Supply Secondary Monitor Under-voltage threshold</b> This field defines the under-voltage monitoring threshold level of the VDDM ADC supply. Ideal Threshold = [(VIN / LSB) + 1] Ideal LSB = 23.077 mV
SBUVVAL	23:16	rw	<b>VEVRSB Supply Secondary Monitor Under-voltage threshold</b> This field defines the under-voltage threshold level of the external VEVRSB (3.3V / 5V) standby supply monitor. Ideal Threshold = [(VIN / LSB) + 1] Ideal LSB = 23.077 mV.
VDDMLVLSEL	29:24	rw	<b>VDDM Level Select</b> This field defines the under-voltage monitoring threshold level required by EVADC / EDSADC modules to differentiate between 5 V or 3.3 V VDDM supply level to adjust analog behavior to the actual voltage level. The 6 MSB bits of the ADC result is compared against VDDMLVLSEL with 4 LSB hysteresis. Ideal Threshold = [(VIN / LSB) + 1] Ideal LSB = 92.308 mV
SLCK	30	rw	<b>HSM Security Lock</b> If this bit is set, all other bits in this register can no longer be written. Write requests to other bits when SLCK is set will trigger an SLCK access error alarm. This bit can not be cleared by software. SLCK bit can only be set by an access from the HSM master (TAG = 000011 <sub>B</sub> ). A set operation performed by any other master or software is ignored and the bit is kept as cleared. 0 <sub>B</sub> No lock active 1 <sub>B</sub> Lock is active

0		DROOPVL					0				DROOPVH				
r		rw					r				rw				

Field	Bits	Type	Description
DROOPVH	4:0	rw	<b>High VDD Limit for Droop request(droopvh_thres_i)</b> This bitfield defines the VDD high voltage limit above which a positive droop request on VDD voltage shall be ignored. VDD Droop High Limit = 712.5 mV + LSB * (SDVOUTSEL+ SDVOUTTRIM+ DROOPVH); LSB = 5 mV
DROOPVL	12:8	rw	<b>Low VDD Limit for Droop request(droopvl_thres_i)</b> This bitfield defines the VDD low voltage limit below which a negative droop request on VDD voltage shall be ignored. VDD Droop Low Limit = 712.5 mV + LSB * (SDVOUTSEL+ SDVOUTTRIM- DROOPVL); LSB = 5 mV
SYNCMAXDEV	20:16	rw	<b>Maximum Deviation of the Synchronization Input Frequency(synci1_maxdev_i)</b> This bitfield defines the maximum allowed frequency deviation of the synchronization input signal frequency from the programmed nominal DCDC switching frequency (EVRSCTRL0.SDFREQ). Violation of limit leads to loss of synchronization. The frequency window is defined as follows $d f_{MAXDEV} = 100 \text{ MHz} * (2 * SYNCMAXDEV) / (SDFREQ^2 + SYNCMAXDEV^2)$ $SYNCMAXDEV = \text{round} [ (100 \text{ MHz} / d f_{MAXDEV}) - \sqrt{(100 \text{ MHz} / d f_{MAXDEV})^2 - SDFREQ^2} ]$
SYNCHYST	26:24	rw	<b>Lock Unlock Hysteresis Window(synci0_hyst_i)</b> This bitfield defines the hysteresis window for synchronization locking and unlocking. The limit is applied to the period counter running at 100 MHz. Upper unlock condition= SDFREQ + SYNCMAXDEV Upper lock condition= SDFREQ + SYNCMAXDEV - SYNCHYST Lower unlock condition = SDFREQ - SYNCMAXDEV Lower lock condition = SDFREQ - SYNCMAXDEV + SYNCHYST $SYNCHYST = \text{round} [ d f_{HYST} * (SDFREQ \pm SYNCMAXDEV)^2 ] / [ d f_{HYST} * (SDFREQ \pm SYNCMAXDEV) + 100 \text{ MHz} ]$

## Power Management System for Low-End (PMSLE)

Field	Bits	Type	Description
<b>DTLOCONEN</b>	0	rw	<b>Enable Dead time at low conductance(dtlocon_en_i)</b> This bitfield activates the incorporation of dead time between charge and discharge phase when conductance is below 4. The charge and discharge phase are reduced by half of dead time value each.
<b>DTLOCONMIN</b>	6:1	rw	<b>Minimum Charge + Discharge time after Dead time(dtlocon_mintime_i)</b> This bitfield defines the minimum number of SDSWPRDNOM clock cycles for charge + discharge phase after dead time introduction. The minimum setting (duration of charge+discharge phase) is 4 clock cycles.
<b>DTOVERREN</b>	8	rw	<b>Enable Dead time on VDD output voltage error(dtov_en_i)</b> This bitfield activates the incorporation of dead time when VDD output voltage error is above / below threshold DTOVERRMIN. DTOV = (DTOV3V3 / DTOV5V + increment) An increment of 2 clock cycles of dead time is made with respective increase of output voltage error of greater than 3 LSB.
<b>DTOVERRMIN</b>	12:9	rw	<b>Dead time VDD Output Voltage Error Threshold(dtov_thr_i)</b> This bitfield defines the VDD output voltage error threshold beyond which dead time is introduced. The threshold should not be below 3 because error upto 2 can happen during normal operation.
<b>DTOV3V3BASE</b> <b>E</b>	20:16	rw	<b>Dead time 3V3 base value for Output Voltage Error(dtov3v3_base_i)</b> This bitfield defines the base dead time value of SDSWPRDNOM clock cycles introduced when VDD output voltage error is above / below threshold DTOVERRMIN during over / undershoots. DTOV3V3 is selected for nominal VEXT = 3.3V case.
<b>DTOV5VBASE</b>	28:24	rw	<b>Dead time 5V base value for Output Voltage Error(dtov5v_base_i)</b> This bitfield defines the base dead time value of SDSWPRDNOM clock cycles introduced when VDD output voltage error is above / below threshold DTOVERRMIN during over / undershoots. DTOV5V is selected for nominal VEXT = 5V case.
<b>LCK</b>	31	rh	<b>Lock Status</b> This bit indicates if the register can be updated with a new value or if the register is locked and a write action from the bus side has no effect. $0_B$ The register is unlocked and can be updated $1_B$ The register is locked and cannot be updated
<b>0</b>	7, 15:13, 23:21, 30:29	r	<b>Reserved</b> Read as 0; should be written with 0.

### Standby and Wake-up Control Register 5

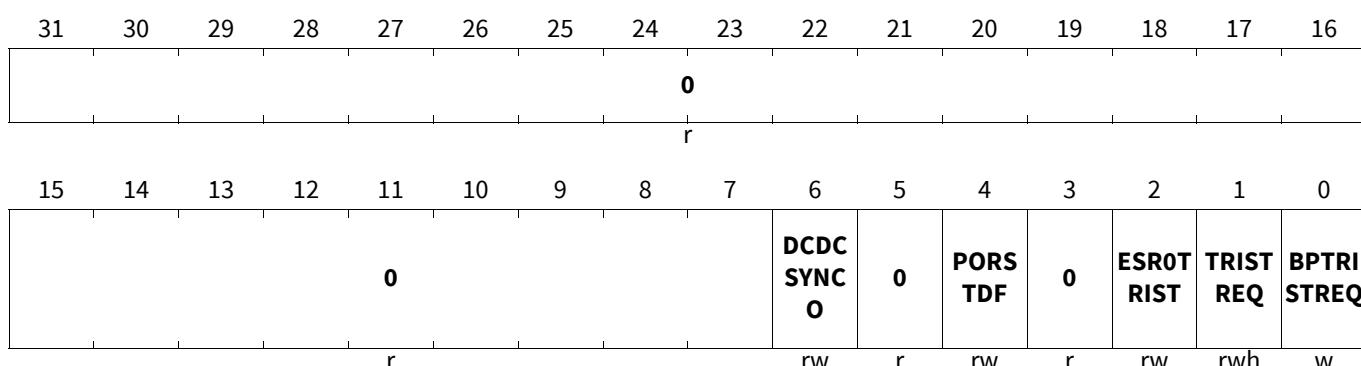

Additional PORST digital filter activated via PORSTDF bit provides additional spike filtering of at least tPORSTDF duration to provide enhanced immunity against spurious spikes. This is in addition to the inherent analog PORST filter delay of the PORST pad / pin as documented in the datasheet. After cold PORST this delay is by default inactive.

## Power Management System for Low-End (PMSLE)

Field	Bits	Type	Description
<b>ESR0WKP</b>	0	rh	<b>ESR0 Wake-up flag</b> In case wake-up was triggered by ESR0 pin during STANDBY, this flag is set. The bit shall be cleared explicitly after wakeup via PMSWSTATCLR.ESR0WKPCR bit before next STANDBY entry. 0 <sub>B</sub> No wake-up event detected on ESR0 input during STANDBY. 1 <sub>B</sub> An event as defined by PMSWCR0. ESR0EDCON detected on ESR0 input.
<b>ESR1WKP</b>	1	rh	<b>ESR1 Wake-up flag</b> In case wake-up was triggered by ESR1 pin during STANDBY, this flag is set. The bit shall be cleared explicitly after wakeup via PMSWSTATCLR.ESR1WKPCR bit before next STANDBY entry. 0 <sub>B</sub> No wake-up event detected on ESR1 input during STANDBY. 1 <sub>B</sub> An event as defined by PMSWCR0. ESR1EDCON detected on ESR1 input.
<b>PINAWKP</b>	2	rh	<b>Pin Wake-up flag</b> In case wake-up was triggered by PINA pin during STANDBY, this flag is set. The bit shall be cleared explicitly after wakeup via PMSWSTATCLR.PINAWKPCR bit before next STANDBY entry. 0 <sub>B</sub> No wake-up event detected on Pin A input during STANDBY. 1 <sub>B</sub> An event as defined by PMSWCR0. PINAEDCON detected on Pin A input.
<b>PINBWKP</b>	3	rh	<b>Pin B Wake-up flag</b> In case wake-up was triggered by PINB pin during STANDBY, this flag is set. The bit shall be cleared explicitly after wakeup via PMSWSTATCLR.PINBKPCR bit before next STANDBY entry. 0 <sub>B</sub> No wake-up event occurred on the Pin B input during STANDBY. 1 <sub>B</sub> An event as defined by PMSWCR0. PINBEDCON detected on Pin B input.
<b>PWRWKP</b>	4	rh	<b>Wake-up event on VEXT Supply ramp-up</b> In case wake-up was triggered by VEXT ramp-up pin during STANDBY, this flag is set. The bit shall be cleared explicitly after wakeup via PMSWSTATCLR.PWRWKPCR bit before next STANDBY entry. 0 <sub>B</sub> No VEXT supply wake-up event detected. 1 <sub>B</sub> VEXT Monitor threshold exceeded on VEXT supply ramp-up leading to System Wake-up from STANDBY.
<b>SCRWKP</b>	5	rh	<b>SCR Wake-up flag</b> In case wake-up is triggered by SCR to the main controller during STANDBY, this flag is set. The bit shall be cleared explicitly after wakeup via PMSWSTATCLR.SCRWKPCR bit before next STANDBY entry. 0 <sub>B</sub> No SCR wake-up event detected. 1 <sub>B</sub> A SCR wake-up event occurred.

## Power Management System for Low-End (PMSLE)

Field	Bits	Type	Description
<b>PORSTWKP</b>	6	rh	<p><b>PORST Wake-up flag</b></p> <p>In case wake-up was triggered by PORST pin during STANDBY, this flag is set. The bit shall be cleared explicitly after wakeup via PMSWSTATCLR.PORSTWKPCR bit before next STANDBY entry.</p> <p>0<sub>B</sub> No wake-up event detected on PORST input during STANDBY if enabled via PMSWCR0.PORSTWKEN bit.</p> <p>1<sub>B</sub> A wake-up event detected on PORST input if enabled via PMSWCR0.PORSTWKEN bit.</p>
<b>WUTWKP</b>	7	rh	<p><b>WUT Wake-up flag</b></p> <p>In case wake-up was triggered by Wake-up timer during STANDBY, this flag is set. The bit shall be cleared explicitly after wakeup via PMSWSTATCLR.WUTWKPCR bit before next STANDBY entry.</p> <p>0<sub>B</sub> No wake-up event detected due to WUT underflow.</p> <p>1<sub>B</sub> A wake-up event from STANDBY was detected due to WUT underflow.</p>
<b>ESR0OVRUN</b>	8	rh	<p><b>ESR0 Overrun status flag</b></p> <p>This flag indicates that a consecutive ESR0 wake-up event occurred while ESR0WKP flag was already set during STANDBY. The bit shall be cleared explicitly after wakeup via PMSWSTATCLR.ESR0OVRUNCLR bit before next STANDBY entry.</p> <p>0<sub>B</sub> No overrun condition detected on ESR0 input.</p> <p>1<sub>B</sub> An overrun condition detected on ESR0 input.</p>
<b>ESR1OVRUN</b>	9	rh	<p><b>ESR1 Overrun status flag</b></p> <p>This flag indicates that a consecutive ESR1 wake-up event occurred while ESR1WKP flag was already set during STANDBY. The bit shall be cleared explicitly after wakeup via PMSWSTATCLR.ESR1OVRUNCLR bit before next STANDBY entry.</p> <p>0<sub>B</sub> No overrun condition detected on ESR1 input.</p> <p>1<sub>B</sub> An overrun condition detected on ESR1 input.</p>
<b>PINAOVRUN</b>	10	rh	<p><b>Pin A Overrun status flag</b></p> <p>This flag indicates that a consecutive PINA wake-up event occurred while PINAWKP flag was already set during STANDBY. The bit shall be cleared explicitly after wakeup via PMSWSTATCLR.PINAOVRUNCLR bit before next STANDBY entry.</p> <p>0<sub>B</sub> No overrun condition detected on Pin A input.</p> <p>1<sub>B</sub> An overrun condition detected on Pin A input.</p>
<b>PINBOVRUN</b>	11	rh	<p><b>Pin B Overrun status flag</b></p> <p>This flag indicates that a consecutive PINB wake-up event occurred while PINBWKP flag was already set during STANDBY. The bit shall be cleared explicitly after wakeup via PMSWSTATCLR.PINBOVRUNCLR bit before next STANDBY entry.</p> <p>0<sub>B</sub> No overrun condition detected on Pin B input.</p> <p>1<sub>B</sub> An overrun condition detected on Pin B input.</p>

**Power Management System for Low-End (PMSLE)**

Field	Bits	Type	Description
<b>VDDSTBYEN</b>	12	rh	<p><b>Standby Entry Enable status on VDD Supply ramp-down - VDDSTBYWKEN</b></p> <p>This bit indicates that Standby Entry may be triggered on a VDD Supply undervoltage event (VDDUV). This is supported only when Standby domain is supplied separately by VEVRSB Standby supply pin. This bit is updated when PMSWCRO.VDDSTBYWKEN bit is updated.</p> <p>0<sub>B</sub> 0 Standby Entry on VDD supply ramp-down is disabled. 1<sub>B</sub> 1 Standby Entry is enabled on a VDD Supply undervoltage event (SWDUV). Blanking filter active on Standby mode entry.</p>
<b>SCROVRUN</b>	13	rh	<p><b>SCR Overrun status flag</b></p> <p>This flag indicates that a consecutive SCR wake-up event occurred while SCRWKP flag was already set during STANDBY. The bit shall be cleared explicitly after wakeup via PMSWSTATCLR.SCROVRUNCLR bit before next STANDBY entry.</p> <p>0<sub>B</sub> No overrun condition detected of SCR wake-up event. 1<sub>B</sub> An overrun condition detected of SCR wake-up event.</p>
<b>PORSTOVRUN</b>	14	rh	<p><b>PORST Overrun status flag</b></p> <p>This flag indicates that a consecutive PORST wake-up event occurred while PORSTWKP flag was already set during STANDBY. The bit shall be cleared explicitly after wakeup via PMSWSTATCLR.PORSTOVRUNCLR bit before next STANDBY entry.</p> <p>0<sub>B</sub> No overrun condition detected on PORST input if enabled via PMSWCRO.PORSTWKEN bit. 1<sub>B</sub> An overrun condition detected on PORST input if enabled via PMSWCRO.PORSTWKEN bit.</p>
<b>WUTOVRUN</b>	15	rh	<p><b>WUT Overrun status flag</b></p> <p>This flag indicates that a consecutive WUT wake-up event occurred while WUTWKP flag was already set during STANDBY. The bit shall be cleared explicitly after wakeup via PMSWSTATCLR.WUTOVRUNCLR bit before next STANDBY entry. WUTREL need to be greater than 10 during Standby mode to be able to latch consecutive WUT underflow events and update the WUTOVRRUN register bitfield.</p> <p>0<sub>B</sub> No overrun condition detected of WUT events. 1<sub>B</sub> An overrun condition detected of WUT events.</p>

## Power Management System for Low-End (PMSLE)

Field	Bits	Type	Description
<b>ESR0WKEN</b>	24	rh	<b>ESR0 Wake-up enable status</b> This bit indicates that ESR0 is enabled to trigger wake-up from Standby. This bit is updated when PMSWCR0.ESR0WKEN bit is updated. 0 <sub>B</sub> Wake-up from Standby via ESR0 is disabled. 1 <sub>B</sub> Wake-up from Standby via ESR0 is enabled.
<b>ESR1WKEN</b>	25	rh	<b>ESR1 Wake-up enable status</b> This bit indicates that ESR1 is enabled to trigger wake-up from Standby. This bit is updated when PMSWCR0.ESR1WKEN bit is updated. 0 <sub>B</sub> Wake-up from Standby via ESR1 is disabled. 1 <sub>B</sub> Wake-up from Standby via ESR1 is enabled.
<b>PINAWKEN</b>	26	rh	<b>Pin A Wake-up enable status</b> This bit indicates that PINA is enabled to trigger wake-up from Standby. This bit is updated when PMSWCR0.PINAWKEN bit is updated. 0 <sub>B</sub> Wake-up from Standby via PINA is disabled. 1 <sub>B</sub> Wake-up from Standby via PINA is enabled.
<b>PINBWKEN</b>	27	rh	<b>Pin B Wake-up enable status</b> This bit indicates that PINB is enabled to trigger wake-up from Standby. This bit is updated when PMSWCR0.PINBWKEN bit is updated. 0 <sub>B</sub> Wake-up from Standby via PINB is disabled. 1 <sub>B</sub> Wake-up from Standby via PINB is enabled.
<b>PWRWKEN</b>	28	rh	<b>Standby Wake-up Enable status on VEXT Supply ramp-up</b> This bit indicates that VEXT detector is enabled to trigger wake-up from Standby during VEXT supply ramp-up after blanking filter time has expired. This is supported only when Standby domain is supplied separately by VEVRSB Standby supply pin. This bit is updated when PMSWCR0.PWRWKEN bit is updated. 0 <sub>B</sub> Wake-up on VEXT supply ramp-down disabled. Blanking filter configuration has no effect. 1 <sub>B</sub> Standby Wake-up on VEXT supply ramp-up is enabled after blanking filter expiry.
<b>SCRWKEN</b>	29	rh	<b>Standby Controller Wake-up Enable status</b> This bit indicates that SCR is enabled to trigger wake-up from Standby. This bit is updated when PMSWCR0.SCRWKEN bit is updated. 0 <sub>B</sub> Wake-up from Standby via SCR is disabled. 1 <sub>B</sub> Wake-up from Standby via SCR is enabled.
<b>PORSTWKEN</b>	30	rh	<b>PORST pin Wake-up enable status from Standby</b> This bit indicates that wake-up via PORST pin is enabled during STANDBY mode. This bit is updated when PMSWCR0. PORSTWKEN bit is updated. 0 <sub>B</sub> System wake-up via PORST pin is disabled. 1 <sub>B</sub> System wake-up via PORST pin is enabled.
<b>WUTWKEN</b>	31	rh	<b>WUT Wake-up enable status</b> This bit indicates that WUT is enabled to trigger wake-up from Standby. This bit is updated when PMSWCR0.WUTWKEN bit is updated. 0 <sub>B</sub> Wake-up from Standby via WUT is disabled. 1 <sub>B</sub> Wake-up from Standby via WUT is enabled.

#### 12.3.3.1 Power Management Control and Status Registers

This section describes the kernel registers of the PMS module in SCU address space. Most of PMS kernel register names described in this section will be referenced in other parts of the Target Specification by the module name prefix “SCU\_”. The set of registers used for Power Management control the issue of power modes, manage wake-up configuration and provide status information on mode transitions and modules. The request for Idle, Sleep or Standby mode is issued via PMCSR<sub>x</sub> registers.

Tricore atomic instructions (LDMST, ST.T, SWAP.W, SWAPMASK.W, CMPSWAP.W) only write back bits that are changing their level. This leads to the fact that bits that are already set cannot be written with a 1 when using RMW instructions. No problem exists when using direct write instructions (e.g. ST.W). This affects the status bits in register DTSCSTAT.LLU, UOF and INT bits which are cleared by writing 1s.

LLU EN BGPO K 0								LOWER							
rwh rw rh r rw								rw							

Field	Bits	Type	Description
LOWER	11:0	rw	<b>DTSC Lower Limit</b> This bit field defines the lower limit of the DTSC temperature check. The DTSC measurement result is compared against this value and if the measurement result is less than or equal to the configured LOWER bitfield value; flag LLU is set.

**Power Management System for Low-End (PMSLE)**

Field	Bits	Type	Description
<b>BGPOK</b>	13	rh	<b>DTSC Bandgap OK</b> This bitfield indicates that the bandgap reference for the Core Die Temperature Sensor (DTSC) is available and ok. 0 <sub>B</sub> DTSC Bandgap is not ok. 1 <sub>B</sub> DTSC Bandgap is ok.
<b>EN</b>	14	rw	<b>DTSC Enable</b> This bitfield enables the Core Die Temperature Sensor (DTSC). The bitfield is reset on an application reset. 0 <sub>B</sub> DTSC is disabled 1 <sub>B</sub> DTSC is enabled
<b>LLU</b>	15	rwh	<b>DTSC Lower Limit Underflow</b> When this bit is set the related SMU DTSC alarm trigger is generated. This bit has to be written with zero in order to clear it. Writing a one has no effect. This bit is set when a DTSC measurement is finished and the result is below the lower limit (i.e. DTSCLIM.LOWER). 0 <sub>B</sub> No temperature underflow was detected 1 <sub>B</sub> A temperature underflow was detected
<b>UPPER</b>	27:16	rw	<b>DTSC Upper Limit</b> This bit field defines the upper limit of the DTSC temperature check. The DTSC measurement result is compared against this value and if the measurement result is greater than or equal to the configured UPPER bitfield value; flag UOF is set.
<b>INTEN</b>	28	rw	<b>DTSC Interrupt Enable</b> This bitfield enables the Core Die Temperature Sensor (DTSC) interrupt. The bitfield is reset on an application reset. 0 <sub>B</sub> DTSC Interrupt is disabled 1 <sub>B</sub> DTSC Interrupt is enabled
<b>INT</b>	30	rwh	<b>DTSC Interrupt status flag</b> This bit is set when SMU DTSC interrupt is generated when a DTSC measurement is finished. This bit is cleared by writing a zero. Writing a one has no effect. 0 <sub>B</sub> No DTSC interrupt is generated 1 <sub>B</sub> DTSC interrupt is generated
<b>UOF</b>	31	rwh	<b>DTSC Upper Limit Overflow</b> When this bit is set, the related SMU DTSC alarm trigger is generated. This bit has to be written with zero in order to clear it. Writing a one has no effect. This bit is set when a DTSC measurement is finished and the result is exceeding the upper limit (i.e. DTSCLIM.UPPER). 0 <sub>B</sub> No temperature overflow was detected 1 <sub>B</sub> A temperature overflow was detected
<b>0</b>	12, 29	r	<b>Reserved</b> Read as 0; should be written with 0.

## Power Management System for Low-End (PMSLE)

### Power Management Transition Control and Status Register 0

#### PMTRCSR0

**Power Management Transition Control and Status Register 0(0198<sub>H</sub>)**

**Cold PowerOn Reset Value: 0000**

**0000<sub>H</sub>**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
										<b>VDTCL R</b>	<b>VDTST P</b>	<b>VDTST RT</b>	<b>VDTO VIEN</b>	<b>VDTO VEN</b>	<b>VDTEN</b>

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
										<b>LJTCL R</b>	<b>LJTST P</b>	<b>LJTST RT</b>	<b>LJTOV IEN</b>	<b>LJTOV EN</b>	<b>LJTEN</b>
	SDSTEP					0				w	rw	rwh	rw	rw	rw

Field	Bits	Type	Description
<b>LJTEN</b>	0	rw	<b>Load Jump Timer Enable</b> This bit field enables the usage of load jump timer. 0 <sub>B</sub> Load Jump Timer inactive 1 <sub>B</sub> Load Jump Timer active
<b>LJTOVEN</b>	1	rw	<b>Load Jump Timer Overflow Enable</b> This bit field enables the update of LJTOV status bit on timer overflow or time out. 0 <sub>B</sub> LJTOV bit is not updated on a Load Jump Timer overflow. 1 <sub>B</sub> LJTOV bit is updated on a Load Jump Timer overflow.
<b>LJTOVIEN</b>	2	rw	<b>Load Jump Timer Overflow Interrupt Enable</b> This bit field enables the activation of interrupt on timer overflow or time out. 0 <sub>B</sub> LJTOV interrupt is inactive. 1 <sub>B</sub> LJTOV interrupt is activated on a Load Jump Timer overflow.
<b>LJTSTRT</b>	3	rwh	<b>Load Jump Timer Start</b> This bit field starts Load jump timer. This is intended for test purposes. The LJTSTRT remains set on a write and is cleared when LJTOV bit is set if LJTOVEN bit is enabled. 0 <sub>B</sub> Load Jump Timer status not changed. 1 <sub>B</sub> Load Jump Timer started.
<b>LJTSTP</b>	4	rw	<b>Load Jump Timer Stop</b> This bit field stops Load jump timer. This is intended for test purposes. The LJTSTP remains set on a write and is to be explicitly cleared by software. The LJTSTP stops the counter at the current value and timer re-starts from that value when LJTSTP is cleared and LJTSTRT is set. 0 <sub>B</sub> Load Jump Timer status not changed. 1 <sub>B</sub> Load Jump Timer stopped.

## Power Management System for Low-End (PMSLE)

Field	Bits	Type	Description
LJTCLR	5	w	<b>Load Jump Timer Clear</b> This bit field clear Load jump timer count. This is intended for test purposes. This bit resets LJT and clears LJTRUN if LJTEN bit is set. 0 <sub>B</sub> Load Jump Count status not changed. 1 <sub>B</sub> Load Jump Timer Count cleared.
SDSTEP	15:12	rw	<b>Droop Voltage Step(vdroop_step_i)</b> This bit field defines the voltage offset for droop compensation on a load jump to the EVRC setpoint value. The request is made via <b>PMTRCSR3.VDROOPREQ</b> on an anticipated load jump with a voltage offset equal to the SDSTEP x 5 mV. The droop step is a positive offset if VDROOPREQ = 01b and is a negative offset if VDROOPREQ = 10b and no offset is applied if VDROOPREQ = 00b. Maximum Droop = 80 mV.
VDTEN	16	rw	<b>Voltage Droop Timer Enable</b> This bit field enables the usage of Voltage Droop timer. 0 <sub>B</sub> Voltage Droop Timer inactive 1 <sub>B</sub> Voltage Droop Timer active
VDTOVEN	17	rw	<b>Voltage Droop Timer Overflow Enable</b> This bit field enables the update of VDTOV status bit on timer overflow or time out. 0 <sub>B</sub> VDTOV bit is not updated on a Voltage Droop Timer overflow. 1 <sub>B</sub> VDTOV bit is updated on a Voltage Droop Timer overflow.
VDTOVIEN	18	rw	<b>Voltage Droop Timer Overflow Interrupt Enable</b> This bit field enables the activation of interrupt on timer overflow or time out. 0 <sub>B</sub> VDTOV interrupt is inactive. 1 <sub>B</sub> VDTOV interrupt is activated on a Voltage Droop Timer overflow.
VDTSTRT	19	rwh	<b>Voltage Droop Timer Start</b> This bit field starts Voltage Droop timer. This is intended for test purposes. The VDTSTRT remains set on a write and is cleared when VDTOV bit is set if VDTOVEN bit is enabled. 0 <sub>B</sub> Voltage Droop Timer status not changed. 1 <sub>B</sub> Voltage Droop Timer started.
VDTSTP	20	rw	<b>Voltage Droop Timer Stop</b> This bit field stops Voltage Droop timer. SCU cancels the droop request via signal sd_droop_cntr_i = 00. This is intended for test purposes. The VDTSTP remains set on a write and is to be explicitly cleared by software. The VDTSTP stops the counter at the current value and timer re-starts from that value when VDTSTP is cleared and VDTSTRT is set. 0 <sub>B</sub> Voltage Droop Timer status not changed. 1 <sub>B</sub> Voltage Droop Timer stopped.
VDTCLR	21	w	<b>Voltage Droop Timer Clear</b> This bit field clear Voltage Droop timer count. This is intended for test purposes. This bit resets VDT and clears VDTRUN if VDTEN bit is set. 0 <sub>B</sub> Voltage Droop Count status not changed. 1 <sub>B</sub> Voltage Droop Timer Count cleared.

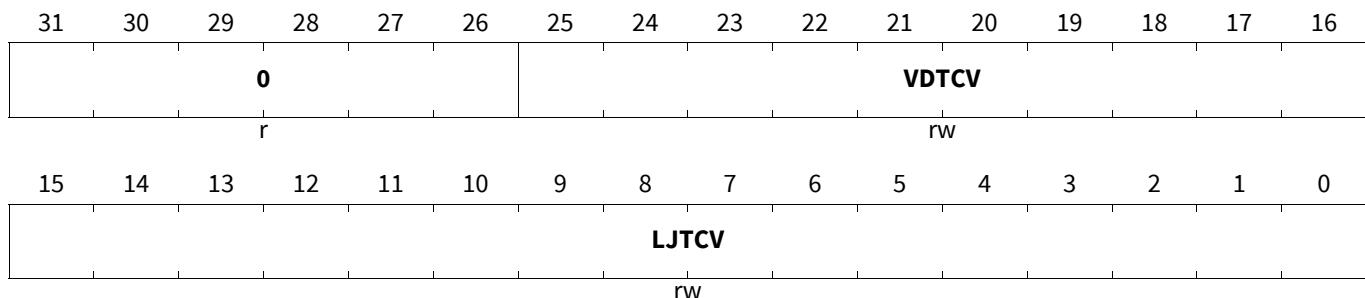

## Power Management System for Low-End (PMSLE)

Field	Bits	Type	Description
LPSLPEN	29	rw	<b>EVRC Low Power Mode activation on a Sleep Request</b> PMS: This bit field enables the activation of LPM EVRC mode on a sleep request. PMSLE: Reserved, no function (no LPM for SC-DCDC EVRC). 0 <sub>B</sub> PMS: EVRC remains in normal operation mode during and after a sleep request. PMSLE: Reserved. 1 <sub>B</sub> PMS: LPM mode activated on a sleep request. PMSLE: Reserved.
0	11:6, 28:22, 31:30	r	<b>Reserved</b> Read as 0; should be written with 0.

## Power Management Transition Control and Status Register 1

### PMTRCSR1

**Power Management Transition Control and Status Register 1(019C<sub>H</sub>)**      **Cold PowerOn Reset Value: 0000 0000<sub>H</sub>**

Field	Bits	Type	Description
LJTCV	15:0	rw	<b>Load Jump Timer Compare Setpoint Value</b> This bit field defines the compare setpoint value of Load Jump timer. The compare event would lead to LJTOV bit being set and LJT interrupt being raised. The LJTRUN status bit, LDJMPREQ bit and LJTCNT value is reset to 0 on a compare event. X us is the compare value. LSB =1 us. Total range = 65.5 ms
VDTCV	25:16	rw	<b>Voltage Droop Timer Compare Setpoint Value</b> This bit field defines the compare setpoint value of Voltage Droop timer. The compare event would lead to VDTOV bit being set and VDT interrupt being raised. The VDTRUN status bit, VDROOPREQ bit and VDTCNT value is reset to 0 on a compare event. X us is the compare value. LSB =1 us. Total range = 1023 us
0	31:26	r	<b>Reserved</b> Read as 0; should be written with 0.

## Power Management System for Low-End (PMSLE)

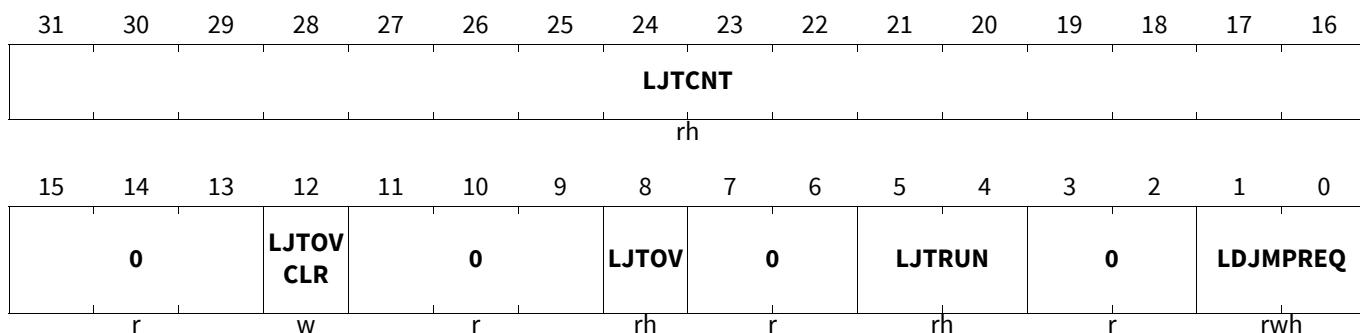

### Power Management Transition Control and Status Register 2

#### PMTRCSR2

**Power Management Transition Control and Status Register 2(01A0<sub>H</sub>)**

**Cold PowerOn Reset Value: 0000**

**0000<sub>H</sub>**

Field	Bits	Type	Description
<b>LDJMPREQ</b>	1:0	rwh	<p><b>Load Jump Request</b></p> <p>This bit requests a Load Jump consequently leading to Load Jump Timer start and LJTRUN bit being set if LJTEN=1. The request is not taken if LJTRUN bit is already in set state and LJT is currently running. The request is not taken if VDTRUN bit is already in set state and VDT is currently running. The request is also not taken if (LJTOV bit is set AND LJTOVEN bit is enabled). The request is also not taken if (VDTOV bit is set AND VDTOVEN bit is enabled). The LDJMPREQ bit is cleared on a compare overflow.</p> <p><i>Note:</i> All other bit combinations are reserved.</p> <p>00<sub>B</sub> Load Jump Timer inactive 01<sub>B</sub> Load Jump Request made and taken. Load Jump Timer activated.</p>
<b>LJTRUN</b>	5:4	rh	<p><b>Load Jump Timer Run Status</b></p> <p>This status bit indicates that the Load Jump timer is currently running and a Load Jump is currently taking place. The LJTRUN bit is cleared on a compare overflow.</p> <p><i>Note:</i> All other bit combinations are reserved.</p> <p>00<sub>B</sub> Load Jump and Load Jump Timer inactive 01<sub>B</sub> A SW triggered Load Jump active and Load Jump Timer active 10<sub>B</sub> A HW triggered Load Jump active and Load Jump Timer active (reserved for future)</p>

## Power Management System for Low-End (PMSLE)

Field	Bits	Type	Description
LJTOV	8	rh	<b>Load Jump Timer Overflow Status</b> This status bit indicates that the Load Jump timer compare match has happened. If LJTOVEN bit is enabled, then LJTOV can only be cleared explicitly via LJTOVCLR bit. If LJTOVEN bit is disabled, LJTOV is cleared on a taken Load Jump Request (A new Load Jump request is taken only if both LJT & VDT are not currently running and no active Load Jump request is being processed). LJTOV being set will lead to an interrupt if LJTOVIEN is enabled. 0 <sub>B</sub> Load Jump Timer compare overflow has not happened. 1 <sub>B</sub> Load Jump Timer compare overflow has happened.
LJTOVCLR	12	w	<b>Load Jump Timer Overflow Status Clear</b> This bit clears LJTOV status bit and sets VDROOPREQ and LDJMPREQ to 0 if LJTOVEN bit is enabled. This bit always reads as 0. 0 <sub>B</sub> This clear bit has no effect on Load Jump Timer overflow flag. 1 <sub>B</sub> Load Jump Timer overflow flag is cleared.
LJTCNT	31:16	rh	<b>Load Jump Timer Value</b> This bit field reflects the current Load Jump timer value. LJTCNT value is cleared on timer overflow and on a taken Load Jump Request X us is the compare value. LSB = 1 us. Total range = 65.5 ms
0	3:2, 7:6, 11:9, 15:13	r	<b>Reserved</b> Read as 0; should be written with 0.

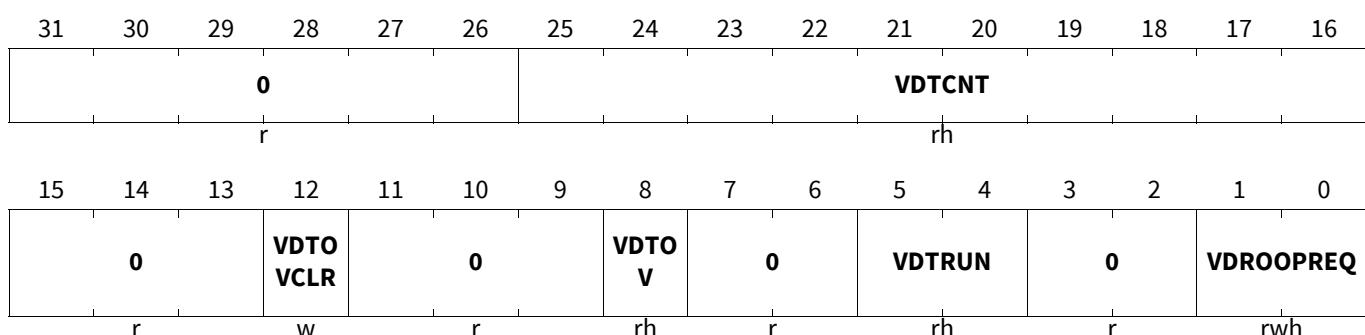

## Power Management Transition Control and Status Register 3

### PMTRCSR3

#### Power Management Transition Control and Status Register 3(01A4<sub>H</sub>)

Cold PowerOn Reset Value: 0000

0000<sub>H</sub>

## Power Management System for Low-End (PMSLE)

Field	Bits	Type	Description
<b>VDROOPREQ</b>	1:0	rwh	<p><b>Voltage Droop Request</b></p> <p>This bit requests a Voltage Droop consequently leading to Voltage Droop Timer start and VDTRUN bit being set if VDTEN=1. The request is not taken if VDTRUN bit is already in set state and VDT is currently running. The request is also not taken if (VDTOV bit is set AND VDTOVEN bit is enabled). The droop step is a positive offset if sd_droop_cntr_i = 01 and is a negative offset if sd_droop_cntr_i = 10 and no offset is applied if sd_droop_cntr_i = 00 and is applied immediately.</p> <ul style="list-style-type: none"> <li>00<sub>B</sub> Voltage Droop and Voltage Droop Timer inactive</li> <li>01<sub>B</sub> A Positive Voltage Droop Request made and taken. Voltage Droop Timer activated.</li> <li>10<sub>B</sub> A Negative Voltage Droop Request made and taken. Voltage Droop Timer activated.</li> <li>11<sub>B</sub> Voltage Droop and Voltage Droop Timer inactive</li> </ul>
<b>VDTRUN</b>	5:4	rh	<p><b>Voltage Droop Timer Run Status</b></p> <p>This status bit indicates that the Voltage Droop timer is currently running and a Voltage Droop is currently taking place. The VDTRUN bit is cleared on a compare overflow.</p> <p><i>Note:</i> All other bit combinations are reserved.</p> <ul style="list-style-type: none"> <li>00<sub>B</sub> Voltage Droop and Voltage Droop Timer inactive</li> <li>01<sub>B</sub> A SW triggered Voltage Droop active and Voltage Droop Timer active</li> <li>10<sub>B</sub> A HW triggered Voltage Droop active and Voltage Droop Timer active (reserved for future)</li> </ul>
<b>VDTOV</b>	8	rh	<p><b>Voltage Droop Timer Overflow Status</b></p> <p>This status bit indicates that the Voltage Droop timer compare match has happened. If VDTOVEN bit is enabled, then VDTOV can only be cleared by explicitly via VDTOVCLR bit. If VDTOVEN bit is disabled, VDTOV is cleared on a taken Voltage Droop Request (A new Voltage Droop request is taken only if both LJT &amp; VDT are not currently running and no active Voltage Droop request is being processed). VDTOV being set will lead to an interrupt if VDTOVIEN is enabled. Incase SDVOK is set by EVRC before VDT compare match, VDTOV bit is not set.</p> <ul style="list-style-type: none"> <li>0<sub>B</sub> Voltage Droop Timer compare overflow has not happened.</li> <li>1<sub>B</sub> Voltage Droop Timer compare overflow has happened.</li> </ul>
<b>VDTOVCLR</b>	12	w	<p><b>Voltage Droop Timer Overflow Status Clear</b></p> <p>This bit clears VDTOV status bit if VDTOVEN bit is enabled. If VDTOVEN bit is disabled, this bit has no effect. This bit always reads as 0.</p> <ul style="list-style-type: none"> <li>0<sub>B</sub> This clear bit has no effect on Voltage Droop Timer overflow flag.</li> <li>1<sub>B</sub> Voltage Droop Timer overflow flag is cleared.</li> </ul>
<b>VDTCNT</b>	25:16	rh	<p><b>Voltage Droop Timer Value</b></p> <p>This bit field reflects the current Voltage Droop timer value. VDTCNT value is cleared on timer overflow and on a taken Voltage Droop Request. X us is the compare value. LSB = 1 us. Total range = 65.5 ms</p>

### 12.4 IO Interfaces

The following table defines the signals connecting the PMSLE to other modules and the outside world.

Note that not all signals may be used in all members of the family. Consult the product specific appendix to see the available connections.

**Table 472 List of PMS Interface Signals**

Interface Signals	I/O	Description
HWCFG1IN	in	<b>HWCFG1 pin input</b> Hardware configuration 1 input for activation of EVR33 regulator.
HWCFG2IN	in	<b>HWCFG2 pin input</b> Hardware configuration 2 input for activation of EVRC regulator.
HWCFG4IN	in	<b>HWCFG4 pin input</b> Hardware configuration 4 input for test purposes.
HWCFG5IN	in	<b>HWCFG5 pin input</b> Hardware configuration 5 input for test purposes.
HWCFG6IN	in	<b>HWCFG6 pin input</b> Hardware configuration 6 input for activation of tri-state.
TESTMODEIN	in	<b>TESTMODE pin input</b> Test mode pin input to enable entry into test modes
PORSTIN	in	<b>PORST pin input</b> PORST pin input to trigger warm PORST
PORSTOUT	in	<b>PORST pin output</b> Cold PORST strong pull down control output to drive PORST pin low in case of primary monitor undervoltage events
PORSTWKPD	in	<b>PORST pad weak pull down control output</b> PORST weak pull down control to keep PORST weakly pulled low in case of bond wire breakage. The pull down is inactive to avoid additional current during STANDBY mode
ESR0PORST	out	<b>ESR0 control output during PORST activation</b> Warm PORST signal connected to ESR0 pad to ensure that ESR0 pad is asserted when PORST pin is asserted to propagate the reset
ESR0WKP	in	<b>ESR0 pin input</b> ESR0 pin input for wakeup from STANDBY mode
ESR1WKP	in	<b>ESR1 pin input</b> ESR1 pin input for wakeup from STANDBY mode

## Power Management System for Low-End (PMSLE)

**Table 472 List of PMS Interface Signals (cont'd)**

Interface Signals	I/O	Description
PINAWKP	in	<b>PINA ( P14.1) pin input</b> P14.1 pin input for wakeup from STANDBY mode
PINBWKP	in	<b>PINB (P33.12) pin input</b> P33.12 pin input for wakeup from STANDBY mode
VCAP0	out	<b>DCDC connection to flying capacitor (VCAP0N pin)</b>
VCAP1	out	<b>DCDC connection to flying capacitor (VCAP1P pin)</b>
DCDCSYNC	out	<b>DCDC (P32.4) synchronization output</b>
WUTUFLOW	out	<b>WUT counter underflow signal to CCU6/GTM</b> WUT Underflow output to support WUT calibration
DCDCSYNCGTM	in	<b>DCDC synchronization signal input from GTM</b> Synchronisation input from GTM module to EVRC SMPS regulator
DCDCSYNCCU	in	<b>DCDC synchronization signal input from CCU6</b> Synchronisation input from CCU6 (CCU60 COUT63) module to EVRC SMPS regulator
VDDMLVL	out	<b>VDDM monitor signal to Converter</b> Signal indicating whether VDDM is supplied with 5V or 3.3V. 0: VDDM = 5V 1: VDDM = 3.3V.

## Power Management System for Low-End (PMSLE)

### 12.5 Revision History

#### 12.5.1 Changes from AURIX TC33x PMS V1.0.1 Onwards

**Table 473 Revision History**

Reference	Change to Previous Version	Comment
<b>V1.0.2</b>		
<a href="#">Page 66</a>	Removed description related to external MOSFET complementary switch, since not related to the switched-capacitor DCDC.	
<a href="#">Page 84</a>	Removed VGATE reference from the EVRSTAT.SYNCLCK bit-field description.	
<a href="#">Page 157</a>	Removed the VGATE1P reference from the PMSWCR5.TRISTREQ bit-field description.	
<a href="#">Page 193</a>	Changed VGATE1P and VGATE1N to VCAP0/VCAP1 in the list of PMS interface signals.	
<a href="#">Page 17</a>	Enabled text description in <a href="#">Section 12.2.1.2.5</a> for the user manual.	
<a href="#">Page 22</a>	Aligned switching frequency values mentioned in <a href="#">Section 12.2.2.2</a> to 1.85 MHz (instead of e.g. 1.851 MHz).	
<a href="#">Page 25</a>	Specified register name for the SDFREQSPRD bit-field.	
<a href="#">Page 29</a>	Typo: corrected GPTM to GTM.	
<a href="#">Page 149</a>	Updated description of PMSWCR0.STBYRAMSEL bit-field: 100 <sub>B</sub> and 111 <sub>B</sub> values are reserved (no CPU1 dLMU available).	
<a href="#">Page 162</a>	Updated description of PMSWSTAT2.STBYRAM bit-field: 100 <sub>B</sub> and 111 <sub>B</sub> values are reserved (no CPU1 dLMU available).	
<a href="#">Page 187</a>	Updated the PMTRCSR0.LPSLPEN bit-field description, in the case of PMSLE it is reserved, since the SC-DCDC has no Low-Power Mode (LPM).	
<a href="#">Page 137</a>	Updated signal names in the description of the EVRSDCTRL9.SHHVEN and EVRSDCTRL9.SHLVEN bit-fields.	
<a href="#">Page 124</a>	Updated signal names in the description of the EVRSDCTRL1.TON and EVRSDCTRL1.TOFF bit-fields.	
<a href="#">Page 129</a>	Updated signal names in the description of the EVRSDCTRL4.SDVOKLVL and EVRSDCTRL4.SDLUT bit-fields.	
<a href="#">Page 130</a>	Updated signal name in the description of the EVRSDCTRL5.STCONLIMINC bit-field.	
<a href="#">Page 48</a>	In <a href="#">Table 390</a> , EVRCDCTRL is replaced with CONDUCTANCE.	
<a href="#">Page 172</a>	Corrected the OCDS trigger set in OTSC1.B0EC and OTSC1.B1EC for the 1 <sub>H</sub> value: replaced EVRCDPWM with CONDUCTANCE.	
<a href="#">Page 123</a>	Corrected the EVRSDCTRL0.UP reset value from 0x0 to 0x1.	
<a href="#">Page 128</a>	Corrected the EVRSDCTRL3.BYSEL reset value from 0x01 to 0x00.	
<a href="#">Page 129</a>	Corrected the EVRSDCTRL4.SDLUT reset value from 0x00 to 0x22.	
<a href="#">Page 129</a>	Corrected the EVRSDCTRL4.ZEROBIN reset value from 0x0 to 0x2.	
<a href="#">Page 130</a>	Corrected the EVRSDCTRL5.STCONDEC reset value from 0x1 to 0x3.	
<a href="#">Page 130</a>	Corrected the EVRSDCTRL5.R21 reset value from 0x1b to 0x00.	

## Power Management System for Low-End (PMSLE)

**Table 473 Revision History (cont'd)**

Reference	Change to Previous Version	Comment
<a href="#">Page 143</a>	Corrected the EVRSDCOEFF2.COEFF1 reset value from 0x343 to 0x3d9.	
<a href="#">Page 143</a>	Corrected the EVRSDCOEFF2.COEFF3V3 reset value from 0x2 to 0x4.	
<a href="#">Page 143</a>	Corrected the EVRSDCOEFF2.COEFF5V reset value from 0x4 to 0x2.	
<a href="#">Page 143</a>	Corrected the EVRSDCOEFF2.LINEPOSTHR reset value from 0x1 to 0x4.	
<a href="#">Page 143</a>	Corrected the EVRSDCOEFF2.LINENEGTHR reset value from 0x7 to 0x4.	
<a href="#">Page 145</a>	Corrected the EVRSDCOEFF3.BYPONTHR reset value from 0x00 to 0xa3.	
<a href="#">Page 145</a>	Corrected the EVRSDCOEFF3.SDDIGIN1 reset value from 0x1c to 0x00.	
<a href="#">Page 145</a>	Corrected the EVRSDCOEFF3.SDDIGIN2 reset value from 0x01 to 0x3c.	
<a href="#">Page 90</a>	Updated note on Reset Values of EVRRSTCON register: The Reset Value is updated by SSW only after cold power-on reset and not after warm resets.	
<a href="#">Page 95</a>	Updated note on Reset Values of EVRTRIM register: The Reset Value is updated by SSW only after cold power-on reset and not after warm resets.	
<a href="#">Page 100</a>	Updated note on Reset Values of EVRMONCTRL register: The Reset Value is updated by SSW only after cold power-on reset and not after warm resets.	
<a href="#">Page 105</a>	Updated note on Reset Values of EVRMONFILT register: The Reset Value is updated by SSW only after cold power-on reset and not after warm resets.	
<a href="#">Page 110</a>	Updated note on Reset Values of EVRUVMON register: The Reset Value is updated by SSW only after cold power-on reset and not after warm resets.	
<a href="#">Page 113</a>	Updated note on Reset Values of EVRUVMON2 register: The Reset Value is updated by SSW only after cold power-on reset and not after warm resets.	
<a href="#">Page 111</a>	Updated note on Reset Values of EVROVMON register: The Reset Value is updated by SSW only after cold power-on reset and not after warm resets.	
<a href="#">Page 114</a>	Updated note on Reset Values of EVROVMON2 register: The Reset Value is updated by SSW only after cold power-on reset and not after warm resets.	
<a href="#">Page 115</a>	Updated note on Reset Values of HSMUVMON register: The Reset Value is updated by SSW only after cold power-on reset and not after warm resets.	
<a href="#">Page 117</a>	Updated note on Reset Values of HSMOVMON register: The Reset Value is updated by SSW only after cold power-on reset and not after warm resets.	
<a href="#">Page 121</a>	Updated note on Reset Values of EVROSCCTRL register: The Reset Value is updated by SSW only after cold power-on reset and not after warm resets.	
<a href="#">Page 123</a>	Updated note on Reset Values of EVRSDCTRL0 register: The Reset Value is updated by SSW only after cold power-on reset and not after warm resets.	
<a href="#">Page 124</a>	Updated note on Reset Values of EVRSDCTRL1 register: The Reset Value is updated by SSW only after cold power-on reset and not after warm resets.	
<a href="#">Page 126</a>	Updated note on Reset Values of EVRSDCTRL2 register: The Reset Value is updated by SSW only after cold power-on reset and not after warm resets.	
<a href="#">Page 128</a>	Updated note on Reset Values of EVRSDCTRL3 register: The Reset Value is updated by SSW only after cold power-on reset and not after warm resets.	
<a href="#">Page 129</a>	Updated note on Reset Values of EVRSDCTRL4 register: The Reset Value is updated by SSW only after cold power-on reset and not after warm resets.	

## Power Management System for Low-End (PMSLE)

**Table 473 Revision History (cont'd)**

Reference	Change to Previous Version	Comment
<a href="#">Page 130</a>	Updated note on Reset Values of EVRSDCTRL5 register: The Reset Value is updated by SSW only after cold power-on reset and not after warm resets.	
<a href="#">Page 133</a>	Updated note on Reset Values of EVRSDCTRL6 register: The Reset Value is updated by SSW only after cold power-on reset and not after warm resets.	
<a href="#">Page 134</a>	Updated note on Reset Values of EVRSDCTRL7 register: The Reset Value is updated by SSW only after cold power-on reset and not after warm resets.	
<a href="#">Page 136</a>	Updated note on Reset Values of EVRSDCTRL8 register: The Reset Value is updated by SSW only after cold power-on reset and not after warm resets.	
<a href="#">Page 137</a>	Updated note on Reset Values of EVRSDCTRL9 register: The Reset Value is updated by SSW only after cold power-on reset and not after warm resets.	
<a href="#">Page 138</a>	Updated note on Reset Values of EVRSDCTRL10 register: The Reset Value is updated by SSW only after cold power-on reset and not after warm resets.	
<a href="#">Page 140</a>	Updated note on Reset Values of EVRSDCOEFF0 register: The Reset Value is updated by SSW only after cold power-on reset and not after warm resets.	
<a href="#">Page 141</a>	Updated note on Reset Values of EVRSDCOEFF1 register: The Reset Value is updated by SSW only after cold power-on reset and not after warm resets.	
<a href="#">Page 143</a>	Updated note on Reset Values of EVRSDCOEFF2 register: The Reset Value is updated by SSW only after cold power-on reset and not after warm resets.	
<a href="#">Page 145</a>	Updated note on Reset Values of EVRSDCOEFF3 register: The Reset Value is updated by SSW only after cold power-on reset and not after warm resets.	
<a href="#">Page 3</a>	Added a description of the pull-up and pull-down device resistance range for HWCFG[6] and HWCFG[1,2] in order to recognize the high respectively low state setting.	
<a href="#">Page 26</a>	Added a statement that toggling of the EVRSTAT.EVRCMOD lower bit is expected for load currents around the IMAXSC threshold.	
<a href="#">Page 66</a>	Corrected the name of the SMUEN register, from CTRL.SMUEN into CMD_STDBY.SMUEN.	
<a href="#">Page 69</a>	Corrected the name of the SMUEN register, from CTRL.SMUEN into CMD_STDBY.SMUEN.	
<a href="#">Page 28</a>	Removed VDD feedback indication from <a href="#">Figure 135</a> and added statement that no dedicated VDD feedback ball is available in BGA packages.	
<a href="#">Page 123</a>	Corrected reset value of the <b>EVRSDCTRL0.LCK</b> bit from 0 to 1.	
<a href="#">Page 124</a>	Corrected reset value of the <b>EVRSDCTRL1.LCK</b> bit from 0 to 1.	
<a href="#">Page 126</a>	Corrected reset value of the <b>EVRSDCTRL2.LCK</b> bit from 0 to 1.	
<a href="#">Page 128</a>	Corrected reset value of the <b>EVRSDCTRL3.LCK</b> bit from 0 to 1.

## Memory Test Unit (MTU)

### 13 Memory Test Unit (MTU)

The Memory Test Unit (MTU) controls and monitors the test, initialization and data integrity checking functions of the various internal memories in the device.

Each SRAM in this Platform has some digital logic surrounding it, known as SRAM Support Hardware (SSH). An SSH is a hardware block which controls the Error Detection & Correction, Memory Built-In-Self-Test(MBIST) of internal memories. Each SSH block provides an unified interface for controlling its various functionalities. There are multiple such SSH instances, each of which controls one or more of the different internal memories. The Memory Test Unit (MTU) in the AurixPlus Platform provides register interfaces to configure and control these various memory controllers.

#### 13.1 Feature List

The main features of the MTU are as follows:

- Unified interface to internal SSH instances
  - The MTU provides an unified register interface to control the operation and functionality of each internal SSH instance.
  - Various configurable test types for each of the SRAM blocks in the system can be controlled via the MTU.
- Data Initialization
  - Each SRAM block in the system can be hardware initialized via the MTU.
  - Security sensitive memories can be autoinitialized to prevent data read-out via the MTU.
- Memory Error Correction & Detection
  - Memory error detection/correction for the SRAM blocks in the system can be configured via the MTU.
  - Correctable and uncorrectable error detection.
  - Address Error detection
- Alarm notification to SMU: From each SRAM/SSH, 3 alarms are sent to the MTU, which are then forwarded to the SMU. These are the CE alarm, UCE alarm and ME alarm.

#### 13.2 Overview

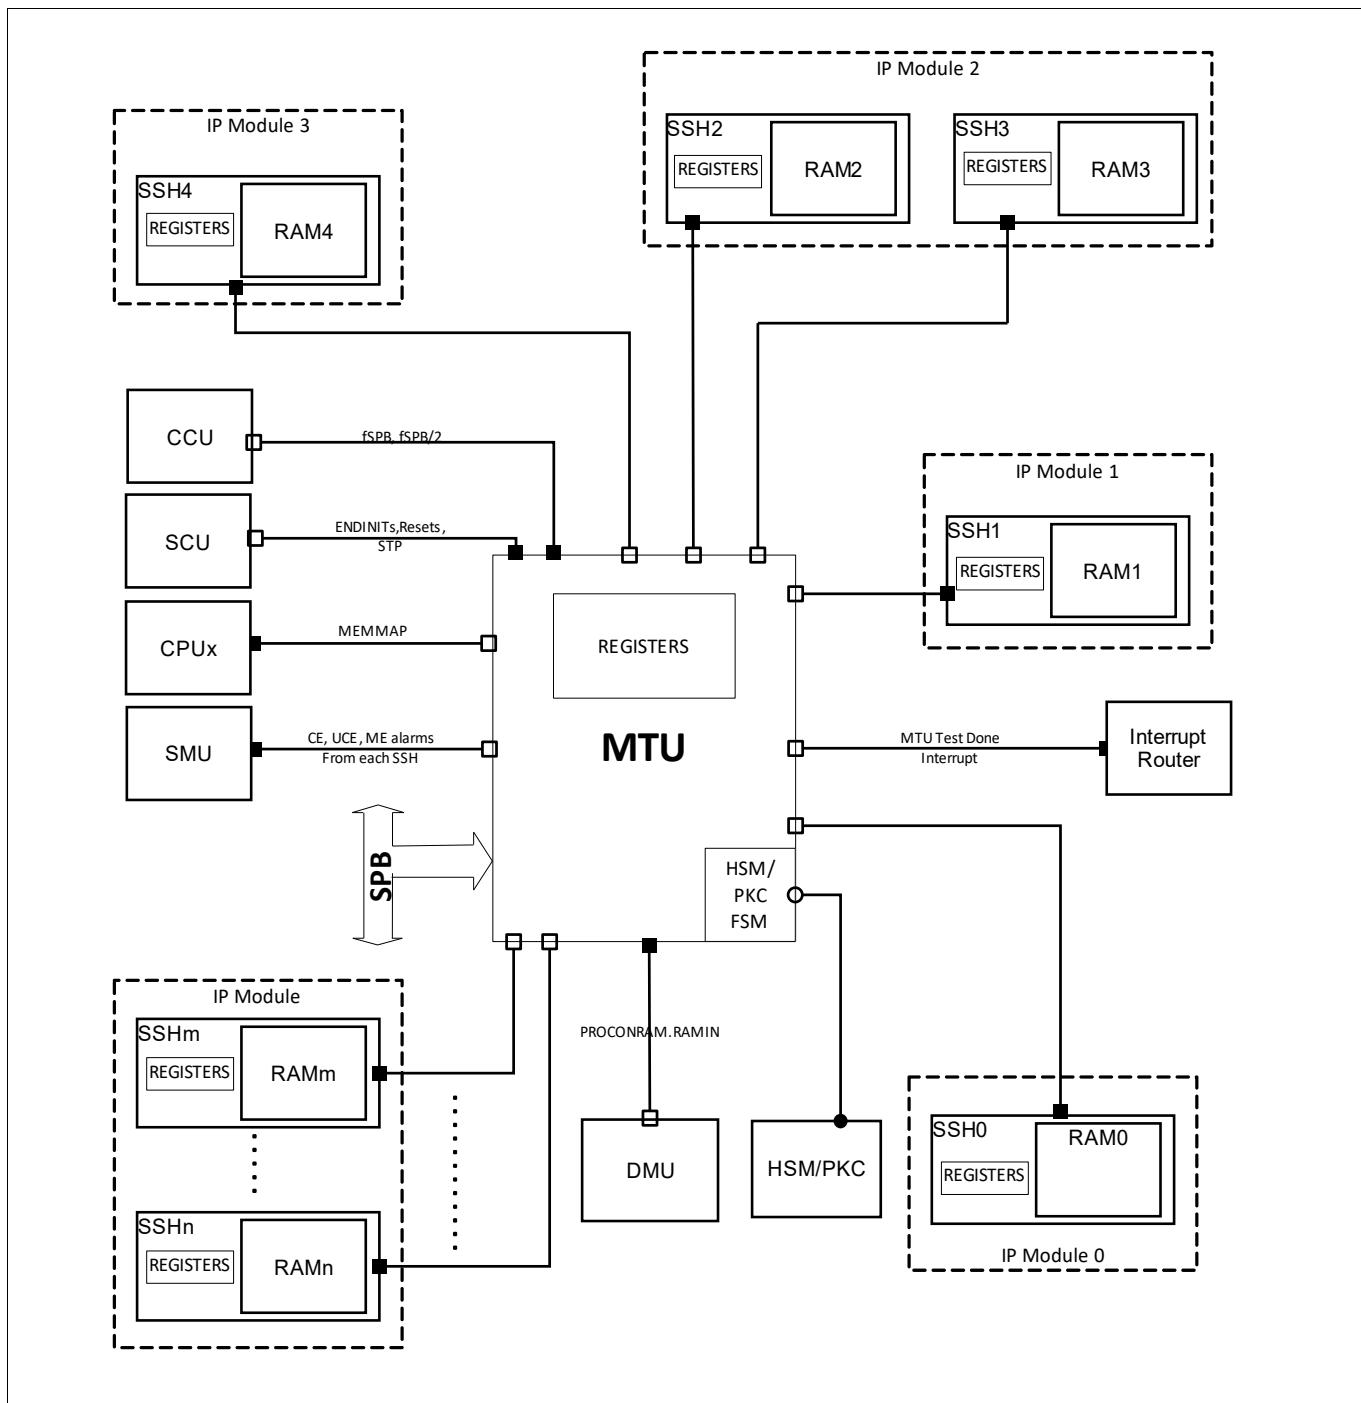

[Figure 153 “System View: MTU, SSHs and SRAMs in IPs” on Page 2](#) shows the system level view of the MTU, SRAM Support Hardware (SSH) Instances, and SRAMs in the system.

Different IP Modules in the system (E.g. CPU, LMU, CAN etc) may have one or more than one SRAM inside them. Surrounding every SRAM is its own SSH module, with its own registers ([SRAM Support Hardware \(SSH\) Registers](#)) and MBIST logic.

Each SSH is separately connected to the MTU via internal interfaces

The MTU itself is connected to the SPB bus, and each SSH's registers can be accessed via this SPB interface. Each SPB access is internally forwarded (and returned) to (and from) the corresponding SSH by the MTU.

## Memory Test Unit (MTU)

**Figure 153 System View: MTU, SSHs and SRAMs in IPs**

### 13.3 Functional Description

#### 13.3.1 Major Functional Changes from TC39xA-Step to TC39XB-Step / TC38XA-Step

There are several major functional changes compared to the TC39xA-step, which may have an impact on the software/application. Only the most important ones are highlighted here.

- The SRAM error notifications are now consolidated to 3 alarms from each SSH- CE alarm, UCE alarm and ME alarm.

## Memory Test Unit (MTU)

- Entering Test mode (i.e. setting MTU\_MEMTEST.MEMxEN = 1), or starting an MBIST test will trigger an UCE alarm.
- Similarly disabling any of the alarm sources or safety mechanisms will also trigger an SSH ME alarm.
- Software has to take care to handle these alarms generated while triggering these operations.
- The alarm status bits in the **MCI\_ECCD (i=0-95)** register are named CERR, UCERR and MERR. After any alarm, the software shall clear the corresponding bits after an alarm to get further alarms.
- New registers **MCI\_ALMSRCS (i=0-95)** and **MCI\_FAULTSTS (i=0-95)** have been added to enable and get the status of errors mapped to UCE and ME alarm.
- New bits PERMERRx have been added in the **MCI\_ECCD (i=0-95)**.
- It is made possible for the Non destructive test to be run with configurable march elements and directions.
- SRAM\_CLR is now defined to use ECC-correct zero data for the initialization (on the A-step, the actual data used for the initialization depended on the module).
- The reset domains of SSH are redefined.
- Alarm status bits in ETRRx, ERRINFOx and FAULTSTS registers are preserved until a power on reset. Similarly additional reset domains are defined within the SSH.

### 13.3.2 SRAM Support Hardware (SSH)

Each internal RAM (or multiple RAMs, depending on the configuration) in the AurixTC3XX Platform which is to be internally tested has some additional logic attached to it. This is the SRAM support hardware or SSH. All the SSH instances for the different memories in the device are connected to an internal bus via an unified MTU-SSH Interface. The SSH provides a direct access to the memories, without involving the CPU. Even small memories that are not directly accessible via the CPU can be tested via the SSH.

### 13.3.3 Control and Status Interfaces

The following section explains the hardware interface to access each individual SSH instance by the CPU via the peripheral bus.

#### 13.3.3.1 Interface to the CPU

The registers of an individual SSH can be accessed by the CPU via the MTU over the peripheral bus.

The registers of individual controllers are located in the SSH block. Logically they all have an MTU system address and can be accessed through normal 16 bit SPB bus accesses via the MTU, but since these have to go via the MTU->SSH interface, the accesses to individual SSH registers will be slower (maximum 20 SPB clock cycles for SSHs running synchronous to SPB clock) than normal SPB accesses to peripheral registers. Via the MTU, the SSH registers shall be accessed with 16 bits wide accesses (both Read and Write).

In general, if any SSH register is accessed while a test is on-going, then for writes: the values are not written to the register, and read access return the correct value. In both cases the access finishes cleanly on the SPB and there is no bus error. The **MCI\_MCONTROL (i=0-95)** register can be written to during a test to clear the start & resume bits. But in case other bits of MCONTROL are modified after a test has started (i.e. after MCONTROL.START has been set to 1) - then this may result in unpredictable behaviour.

It is forbidden to change any test parameter in the registers (i.e. CONFIG0, CONFIG1 and MCONTROL (except START & RESUME)) once a test has started. If the SSH registers are changed during a test (i.e. before the done is set) -> this may result in undefined and erroneous behaviour.

## Memory Test Unit (MTU)

### 13.3.4 Enabling the SRAM Support Hardware (SSH)

Each SSH in the AurixPlus Platform has an enable bit associated with it in the MTU\_MEMTEST $x$  ( $x = 0 - 2$ ) register.

Please refer to the **MEMTEST $i$  ( $i=0-2$ )** registers for the SSH enable bits implemented in the AurixPlus Platform.

The control registers of each SSH are accessible only when the SSH is enabled (MTU\_MEMTEST.MEM $x$ \_EN = 1).

The only exceptions to this are registers **MCI\_ECCS ( $i=0-95$ )**, **MCI\_ECCD ( $i=0-95$ )** and **MCI\_ETRR $x$  ( $i=0-95; x=0-4$ )**, **MCI\_ERRINFO $x$  ( $i=0-95; x=0-4$ )**, **MCI\_ALMSRCS ( $i=0-95$ )** and **MCIFAULTSTS ( $i=0-95$ )** (in each SSH instance) which are available at all times to permit easy runtime access to ECC features, i.e., these particular registers (i.e. ECCS, ECCD, ETRR $x$ , ERRINFO $x$ , ALMSRCS and FAULTSTS) can be read and written with the only pre-condition that the MTU clock is enabled via the MTU\_CLC register.

All other registers in the SSH can be accessed only when the SSH is enabled via the MEMTEST register, otherwise the MTU returns an SPB error.

For certain SSHs, enabling or disabling the SSH via the MEMTEST register may result in whole or part of the memory to be automatically initialized depending on the configuration (see "["Security-Sensitive Memories and AutoInitialization" on Page 4](#)"). This auto-initialization can take hundreds of clock cycles to complete. During this time, no SSH register is accessible (not even the registers which normally do not need the SSH to be enabled, to be accessed) - and any register access to the SSH running the auto-initialization will result in an SPB bus error.

Note that the clock input to the module containing the SRAM has to be enabled via the CCU registers, before any SSH registers can be accessed via the MTU. Other than this CCU clock configuration, there is no need to enable the module clock (e.g. using the CLC register) to access SSH registers.

**Note:**

2. When an SSH is enabled, functional access to the memory is temporarily unavailable. . When a memory is being tested, the software should prevent an attempted functional access to that memory (e.g. while testing a CPU's local memories, the CPU should be in an idle state, or executing from other memory).
3. Correct execution of an SSH operation (e.g. an MBIST test) requires that both the MTU and the module containing the memory-under-test are operational for the duration of the SSH operation(i.e. test). A reset of the module containing the memory-under-test, when an SSH is enabled can possibly result in unexpected behaviour. Software has to take care that events such as application reset, module resets, standby entry, clock frequency change etc. are not triggered when an SSH is enabled. For example - a module reset may result in the module trying to access the SRAM functionally after the reset, when the SSH is still enabled (and thus functional access is disabled)- such scenarios have to be avoided by software.
4. If communication is on-going (e.g. SSH register read or write) between the MTU and SSH when a module reset happens - the communication is aborted and a bus error triggered on the SPB immediately within a few cycles, without any timeout. Only the on-going read/write may be corrupted and future communication is not affected.
5. In case invalid SSH registers are accessed (e.g. registers not existing in an SSH instance, or a non existing SSH instance), this will result in a bus error on the SPB.

**NOTE:**

#### 13.3.4.1 Security-Sensitive Memories and AutoInitialization

In the AurixTC3XX Platform, certain internal memories are considered security sensitive. This means that during certain applications which are security sensitive, reading or modifying the contents of these memories via the SSH modules has to be prevented by the MTU. For these memories, enabling the corresponding SSH results in the memory being cleared, before the SSH is actually enabled. This operation can take hundreds of clock cycles.

This applies to the following memories (The corresponding enable bits in the MTU\_MEMTEST $x$  register have \_EN appended to the memory name):

## Memory Test Unit (MTU)

- CPUx\_DMEM(x = 0 - 5) - Only the cache part of the memory is considered security sensitive.
- CPUx\_DTAG(x = 0 - 5)
- CPUx\_PMEM(x = 0 - 5) - Only the cache part of the memory is considered security sensitive.
- CPUx\_PTAG(x = 0 - 5)

In the case of non-security applications (e.g. safety), it may be important that the modification of the memory contents is allowed via the SSH (e.g. for ECC error injection or run-time self-test).

It is possible to enable or disable this auto-data-init and partial-erase via PROCONRAM register in the DMU.

Please note that the auto-data-init and partial-erase are nominal functions, and it is not intended to guarantee that they satisfy the security requirements under all conditions - i.e. it may be possible to interrupt the initialization.

Note: The security of memory initialization during startup is not affected.

### 13.3.4.1.1 Security Applications

For security applications, the contents of the security sensitive memories can be autoinitialized to erase the existing contents. This is controlled by the PROCONRAM register in the DMU (please refer the DMU chapter).

If PROCONRAM.RAMIN = 00, 01 or 10 then automatic memory content initialization is enabled. PROCONRAM configures whether the initialization is triggered by cold resets, warm resets or both.

In these modes, an automatic initialization of security-sensitive memories is also triggered whenever the corresponding MTU\_MEMTEST.MEMx\_EN or MTU\_MEMMAP is changed (i.e. The corresponding SSH is enabled or disabled or if memory map mode is changed).

The **MEMSTAT*i*** (*i*=0-2) register bits indicate whether an automatic data initialization of Memory *x* has been triggered by a change of state of MEMTEST.MEMx\_EN or MTU\_MEMMAP and the initialization sequence has not yet completed. If a MEMx\_AIU bit in a MEMSTAT register is set, this means that Autoinitialization for that memory is still underway. The SSH is enabled only after, and disabled before the Auto-initialization starts. The software can wait for the Auto-initialization to be completed by polling this bit.

### 13.3.4.1.2 Non-Security Applications

If PROCONRAM.RAMIN=11 then no automatic initialization of RAM content is performed on a reset and no automatic initialization of RAM content is performed when SSH modules are enabled or disabled with MTU\_MEMTEST.MEMx\_EN or MTU\_MEMMAP register bits.

This permits the use of the SSH by an application (E.g. for error injection, data modification or runtime memory testing) without unwanted corruption of memory content.

### 13.3.4.2 Memory Map selection

The Memory Mapping Enable register (refer **MEMMAP**) has configurable control bits to map the CPU caches and tags to the system address space. For the address spaces from which the caches & tag memories can be accessed - kindly refer to the Memory Maps chapter.

The MBIST tests and other SSH operations work on the SRAM independent of the MEMMAP register settings.

### 13.3.5 SRAM Support Hardware (SSH) Operation

The operation and functionality of each internal SSH instance can be controlled via a set of registers. These registers are accessible via the MTU. As explained in the section "**Enabling the SRAM Support Hardware (SSH)" on Page 4**", an SSH instance has to be enabled first, before the memory can be tested.

The main functionalities provided by each SSH instance are explained in the following sections.

## Memory Test Unit (MTU)

### 13.3.5.1 Memory Testing and Initialization

The following section explains how to configure the SSH instances via the MTU, to perform various tests on the memory and obtain the results, or initialize the memories via the SSH.

**Note:** *The following operations can be performed only when the SSH instance under test has been enabled using the corresponding MEMx\_EN bit in the MTU\_MEMTESTx (x = 0-2) register.*

#### 13.3.5.1.1 Starting a Memory Test Sequence

Each memory test sequence is started by writing to the MCONTROL.START bit of the corresponding SRAM Support Hardware (Refer [MCi\\_MCONTROL \(i=0-95\)](#) register). When the test is complete, the MSTATUS.DONE is set by the hardware when the software has cleared the MCONTROL.START bit. Software can poll the [MEMDONEi \(i=0-2\)](#) registers in the MTU to get the status of test completion. These registers just reflect the DONE bit in the [MCi\\_MSTATUS \(i=0-95\)](#) register of each SSH.

Before the MCONTROL.START is set, the software should properly configure the Configuration registers, CONFIG0 and CONFIG1 registers. (Refer [MCi\\_CONFIG0 \(i=0-95\)](#), [MCi\\_CONFIG1 \(i=0-95\)](#)).

CONFIG0.ACCTYPE specifies the access type (Read or Write) to be performed on each single address in the current marching element, while CONFIG1.ACSPAT specifies the access pattern. CONFIG0.NUMACCS specifies the total number of accesses to a single address in the current marching element. The SSH supports some complex addressing schemes. The software can enable this using the CONFIG1.AG\_MOD bits.

Once the test is complete (MSTATUS.DONE=1), the MSTATUS.FAIL bit will be set in case of any failures.

When a Non-destructive test is configured using the CONFIG1.AG\_MOD bits, the MSTATUS.FAIL bit is not set - instead, the software has to check the ECCD, ETRR and ERRINFO registers for any errors detected during the test. Complex algorithm may require several march starts to get a full test.

#### 13.3.5.1.2 Memory Test Done Interrupt

The MTU provides an interrupt to the interrupt router (IR). The interrupt signifies the completion of all running tests. The reset value of this signal is high. When a test on any SRAM is started, this signal goes to low. On completion of all on-going tests, this signal again goes high, and this rising edge triggers the interrupt.

#### 13.3.5.1.3 Getting Detailed Memory Test Results

The MSTATUS.FAIL and MSTATUS.DONE (can be polled from the MTU itself via [MEMDONEi \(i=0-2\)](#) register) bits provide a general pass/fail information and test completion status.

If MCONTROL.FAILDMP = '1', the test stops after a failure and the fail information is immediately available for dump. MSTATUS.FDA (fail dump available) is set in this case. Any dump information has to be polled from registers RDBFL and ETRR(0). RDBFL contains the fail bit map and ETRR the failed address. Reading MSTATUS and the RDBFL(n-1) registers with MSTATUS.FDA = '1' will reset MSTATUS.FDA back to '0'. A consequent setting of MCONTROL.RESUME will resume the interrupted test sequence.

The RANGE register can be used to run consecutive tests on constantly shifted memory ranges so that in the end the complete memory has been analyzed.

Please note that if a test is stopped due to an intermediate failure, the MSTATUS.DONE is not set. MSTATUS.DONE is set only once the whole test sequence is completed and when MCONTROL.START has been cleared by software.

#### Error Injection During Memory Tests

It is possible to manually inject errors during memory tests (for example, to test the software).

For a non-destructive test, an error in the data can be introduced by programming a word with wrong ecc before the test, via the ECCMAP bits.

## Memory Test Unit (MTU)

During a destructive march test, it is possible to inject data errors via the RANGE.INJERR bit. When this bit is set (and RANGE.RAEN = 1), then the RANGE.ADDR field is taken as a pointer to a physical SRAM location, to which write accesses during the test are not executed. Software can then write a particular value (i.e. using single SRAM write access using the RDBFL register) before a march test, and then run the test with RANGE.INJERR and RAEN = 1.

The test then runs over the full memory, and on the address corresponding to RANGE.ADDR, writes are not executed. This results in mismatch of the expected data during the test, resulting in a FAIL.

With errors injected, all normal diagnostics and notifications can be tested- that is, alarms are triggered, errors are tracked in the ETRR/ERRINFO during a non-destructive test. And during a march test, FAIL bit is set, and when FAILDUMP = 1, the fail bitmap is obtained and FDA is set.

The fail bitmap is simply (Expected data pattern) XOR (Actual data pattern).

Address errors are triggered during the test by simply setting SFLE bit to 1. Note that this will trigger an address error from each address, and during a non-destructive test, result in the ETRR/ERRINFO getting filled with address errors.

### 13.3.5.1.4 Filling a Memory with Defined Contents

The SSH can be used to fill a memory range or a complete memory with a defined pattern very fast, i.e. one write access per cycle with the full memory data width, using the MCONTROL.DINIT bit. For this, it has to be ensured that MCONTROL.SRAM\_CLR = 0.

Before setting the MCONTROL.DINIT, the software should first fill the RDBFL register with the desired bit pattern (please refer to the [MCI\\_RDBFLy \(i=0-95;y=0-66\)](#)). It is not mandatory to have a valid ECC code in this pattern.

Next, the RANGE register needs to be set with the memory range into which the pattern needs to be filled.

Next, the MCONTROL.DINIT needs to be set, and then the MCONTROL.START bit should be set to start initializing the RAM. The software should then clear the MCONTROL.START. When MSTATUS.DONE bit is set by the hardware, the memory filling operation is complete.

This method of SRAM initialization using the DINIT bit is not supported for certain SRAMs. These exceptions are mentioned in the product specific appendix chapter.

### 13.3.5.1.5 Initializing SRAMs

Using the MCONTROL.SRAM\_CLR bit, it is possible to initialize the complete SRAM. This is supported for all SSHs and SRAMs.

For this operation, enable the SSH (MEMTESTx.MEMxEN = 1), and:

(Note that this will trigger an UCE alarm. Therefore, the alarm reaction may need to be disabled before. Software can set ALMSRCS.OPENE before)

1. Set the MCONTROL.SRAM\_CLR.
2. Start the initialization using MCONTROL.START.
3. Wait for MSTATUS.DONE (can be also polled in the MTU) to be reset and clear the MCONTROL.START.
4. Wait for the end of the initialization by polling the MSTATUS.DONE (can be polled via MTU\_MEMDONE register also) bit.
5. Clear the MCONTROL.SRAM\_CLR and leave the test mode (MEMTESTx.MEMxEN = 0).

With this initialization, the complete SRAM will be filled with ECC-correct zero value.

Clear the UCERR and OPERR flags set due to this operation. Re-enable ALMSRCS.OPENE if it was disabled before the test.

---

## Memory Test Unit (MTU)

Note that for SRAMs described in [Chapter 13.3.4.1](#), enabling or disabling the SSH via MEMTESTx register takes time, for the initialization to complete. Therefore software must wait for the corresponding MEMSTATx.AIUX bits to be cleared, to ensure that this operation is complete.

## Memory Test Unit (MTU)

### 13.3.5.1.6 Reading a Single Memory Location

The SSH can also be used to read the contents of a single word. The RDBFL register holds the contents of a complete memory word and thus it is possible to read all memory bits, including ECC or parity bits. The necessary steps are:

(Note that this will trigger an UCE alarm. Therefore, the alarm reaction may need to be disabled before)

1. Enter memory test mode
2. Initialize registers  
RANGE := RAEN = 0 (range disabled = single address) & address to be read  
CONFIG0 := 1001H (NUMACCS = 1<sub>H</sub>, ACCSTYPE = 01<sub>H</sub> (read))  
CONFIG1 := 0000H (linear mode, non inverted pattern)
3. MCONTROL := 4009H (FAILDMP = 0, direction up, start): Start read operation. MSTATUS.DONE will be cleared now.
4. MCONTROL := 4008H (clear START)
5. Wait for MSTATUS.DONE to be set again (Poll the corresponding bit in the **MEMDONE<sub>i</sub> (i=0-2)** register).
6. Read RDBFL register
7. Leave memory test mode
8. Clear the UCERR and OPERR flags set due to this operation.

### 13.3.5.1.7 Writing to a Single Memory Location

The SSH can also be used to write the contents of RDBFL register to a single memory location. RDBFL holds the contents of a complete memory word and thus it is possible to write to all memory bits, including ECC or parity bits. The necessary steps are:

(Note that this will trigger the UCE alarm. Therefore, the alarm reaction may need to be disabled before)

1. Enter memory test mode
2. Initialize registers  
RDBFL := write data  
RANGE := RAEN= 0 (range disabled = single address) & address to be written to  
CONFIG0 := 1000H (NUMACCS = 1<sub>H</sub>, ACCSTYPE = 00<sub>H</sub> (write))  
CONFIG1 := 0000H (linear mode, non inverted pattern)
3. MCONTROL := 4009H (FAILDMP = 0, direction up, start): Start write operation. MSTATUS.DONE will be cleared now.
4. MCONTROL := 4008H (clear START)
5. Wait for MSTATUS.DONE to be set again (Poll the corresponding bit in the **MEMDONE<sub>i</sub> (i=0-2)** register).
6. Leave memory test mode
7. Clear the UCERR and OPERR flags set due to this operation.

### 13.3.6 Resets and Clocks in the MTU, SSH & SRAM

Since the MTU is a central module and the different SRAMs (and surrounding SSHs) are embedded in different modules, multiple clocks and resets come into the picture.

#### 13.3.6.1 Clock Domains

The MTU runs on the SPB clock. The interface between the MTU and SSH runs on a clock which is always at a fixed divider of 1/2 times the SPB clock. The SRAM and the SSH logic (i.e. Registers, FSM etc) run at the module clock

## Memory Test Unit (MTU)

frequency (i.e. the module where the SRAM is embedded in). The SSH SFR accesses as well as alarm forwarding still work correctly even if system is running with lower clock divider in LPDIV mode.

**Attention:** Whenever accessing the SSH registers, the clock frequency of the corresponding module containing the SSH/SRAM should be equal to or greater than  $f_{SPB}/10$ . For example, with  $f_{SPB} = 100MHz$ , a module's clock frequency should be atleast 10MHz when reading or writing SSH registers in the module.

**Table 474 MTU, SSH and SRAMs Clock Domains**

	Clock
MTU	$f_{SPB}$ , Communication to SSH on $f_{SPB}/2$ clock
SSH	Communication to MTU on $f_{SPB}/2$ . Other SSH logic on Module Clock
SRAM	Module clock
Alarms	Propagated to SMU on $f_{SPB}/2$ clock

### 13.3.6.2 Reset Domains

There are different reset domains to be considered within the MTU, SSH and SRAMs.

**Table 475 MTU, SSH and SRAMs Reset Domains**

Module/Register/Function	Reset Domain
MTU & Alarm Path MTU<->SMU	Application Reset
MTU: Interface to SSH (and FFs in the interface path)	Application Reset
SSH: FSMs (MBIST FSM & Communication with MTU)	Application Reset
SSH: ECCS, ALMSRCS Registers- Notification Enable Bits	Application Reset
SSH: Alarm status Flags (ECCD.CERR, UCERR, MERR)	Application Reset
SSH: ETRR/ERRINFO, FAULTSTS Registers, ECCD.VAL, ECCD.PERMERR and ECCD.EOF bits	Warm PORST
SSH: Test Related Registers (MCONTROL, CONFIG0/1, MSTATUS, RDBFL, RANGE)	Application Reset
SRAM	Cold PORST

Exception for SCR FSI: The SSHs within the SCR are a special case since the SCR resides within the PMS subsystem and has separate reset domains (Asynchronous).

#### 13.3.6.2.1 Alarm Handling after Reset

When an alarm occurs, the system may perform a reset.

The Alarm status bits in the ECCD register (i.e. ECCD.CERR, UCERR and MERR) are cleared after an application reset.

However, the error status bits (i.e. ETRR, ERRINFO and FAULTSTS registers) are still available until a power-on reset for diagnosis purposes - they can only be cleared by software and are reset only with a warm PORST.

The alarm itself is also cleared with an application reset. This prevents a single alarm creating a reset loop.

## Memory Test Unit (MTU)

### 13.3.7 SRAM Addressing and Scrambling

When considering SRAM addressing, different levels of addressing need to be considered. At the highest level, all SRAMs which appear on the overall system memory map could be potentially accessed via a portion of the system address space. This is the logical address space to access the SRAM as far as the system is concerned.

However, from just the SSH point of view, this system level logical address cannot be seen, since the SSH is tightly coupled to the SRAM, and the system address translation or mapping occurs at a higher level before arriving at the SSH. Therefore, unless otherwise specifically mentioned, any “address” in this chapter does not correspond to any of the system address that is mentioned in the memory map chapter.

Within the SSH, the logical addresses increment linearly from 0x00 until a maximum address depending on the size of the SRAM. This maximum address can be inferred from the default (reset) value of the RANGE.ADDR field for each SSH.

During normal system operation , the incoming address is directly input to the SRAM. This address at the input to the SRAM is also stored in ETRR registers in case of any error.

In order to access the error address location stored in the ETRR during normal functional mode, the same address can be provided to the RANGE.ADDR, with RANGE.RAEN = 0 and MCONTROL.EN\_DESCR = 0.

### 13.3.8 MBIST Algorithms

In order to check the integrity of the SRAM and its contents, an MBIST may be run by configuring the SSH.

The test type and parameters are programmed via the SSH registers -CONFIG0 and CONFIG1, and certain parameters via the MCONTROL register.

Additional memory test algorithms are supported by the SSH, but used in production test modes only.

#### 13.3.8.1 Non-Destructive Test (NDT)

The Non-Destructive Test preserves the content of SRAMs exactly as it was before the test. It allows running memory test during application runtime, without destroying any application data in the memory. The following preconditions apply when running the NDT.

1) The SRAM has to be completely initialized with ECC correct data. This may be especially important when running the test after a cold power on reset, when the SRAM contents may not be defined.

For CPU and LMU memories, it may be possible to enable automatic initialization after a reset via firmware using the settings in the PROCOND register. To initialize SRAMs using the MTU, please refer to [Chapter 13.3.5.1.4](#) and [Chapter 13.3.5.1.5](#). In addition, it is also sufficient to initialize SRAMs by writing data to it from the CPU or DMA.

2) It is not possible to access the SRAM functionally when running a test (as long as the SSH is enabled via the MTU\_MEMTEST.MEMxEN bit). Any such access may stall and may result in some undefined state. Software has to take care that for example the CPU PMEM or DMEM SRAMs may be implicitly accessed if caches are enabled.

Therefore, for all CPU SRAMs and LMUs, before entering the test mode (MEMTESTx.MEMxEN = 1) - the program and data caches shall be disabled. It shall be ensured that other masters (e.g. another CPU, DMA or debugger) do not access the SRAM under the test. For peripherals SRAMs, it shall be ensured that the module does not access the SRAM under test.

#### NDT Algorithm

The NDT algorithm reads a word from the SRAM (DATA + ECC bits), inverts it and writes it back. If the ECC does not match the expected value when reading, an error is expected and notified.

## Memory Test Unit (MTU)

This is denoted by the sequence {r, w\*}. Here r denotes a read access, and w\* denotes a write access with inverted data compared to original SRAM contents.

A '\*' symbol in this notation always indicates that the data during that access is inverted with respect to the original content in the RAM.

A write access during the NDT test always inverts the previously read data, before writing it back to the SRAM. This means, to preserve the original contents of the SRAM, a sequence with an even number of writes is required.

A simple example of such a sequence is: {r, w\*, r\*, w}.

Steps (Apply all the steps one after the other on each word, and then move to the next word, until the complete address range is covered):

1. r: Read data word including check bits.
2. w\*: Write back all bits inverted.
3. r\*: Read data word including check bits (All bits are inverted compared to original SRAM contents).
4. w: Write back all bits inverted (The Data is now same as the original SRAM contents).

After this sequence, the user data is undisturbed and every bit would have seen '0' and '1'.

The NDT supports only a linear address sequence.

Note that if an NDT is programmed without a read as the very first access, then any previously read arbitrary data may be used for the write, resulting in data corruption.

## Programming the NDT

To run the Non-Destructive Test, the software has to program the CONFIG0, CONFIG1 and MCONTROL registers, as well as the RANGE register (address range of the RAM to be tested).

**Note:** *By default, after an application reset the RANGE register contains a value which corresponds to the complete memory range. Hence as long as this register is not changed by the software after an application reset, the complete memory is always tested by default (recommended).*

The end of the test is signalled by the DONE bit in the MSTATUS register. Error information can be obtained from the ECCD, ETRR and ERRINFO registers.

**Attention:** *The MSTATUS.FAIL bit (refer [Mci\\_MSTATUS \(i=0-95\)](#)) is set during an NDT only when an address error is detected.*

Similarly the FAILDUMP shall not be set during an NDT, and correspondingly the FDA bit is also irrelevant during an NDT.

The NDT algorithm is selected by programming CONFIG1.AG\_MOD = 0x5. (Refer [Mci\\_CONFIG1 \(i=0-95\)](#) register).

The number of accesses and each corresponding access type (read or write) shall be programmed in the CONFIG0.NUMACCS and ACCSTYPE fields respectively.

The CONFIG1.ACSPAT bits shall be programmed to 1 when the last programmed read access was with inverted data. Here "inverted" is always with respect to the original SRAM contents at the start of the test. Here the last march element is considered to "wrap around" to the first one - for example, consider programming a march sequence r-w\*-r\*-r\* - The ACSPAT shall be programmed as: 0b1001. Here ACSPAT[0] is 1 considering that the last element (corresponding to ACSPAT[3]) is an inverted read - and this "wraps around" to be the previous access of the first element, ACSPAT[0].

Here ACSPAT[0] corresponds to 'r' ; ACSPAT[1] corresponds to w\* and so on.

The address sequence is always linear, but can be incrementing or decrementing according to the setting of MCONTROL.DIR, and may be selected to change in bitline or wordline direction based on MCONTROL.RCADR.

## Memory Test Unit (MTU)

It is recommended that this test is run by setting MCONTROL.EN\_DESCR = 0 (i.e. over the system logical address space).

### Programming Sequences

Here a generic programming sequence on how to configure the NDT are described. It is assumed that the test is always run on the whole memory (i.e. the default value of RANGE is not changed).

Consider the sequence with 4 accesses (4N-NDT), {r, w\*, r\*, w}. For such a sequence, CONFIG0 and CONFIG1 have to be programmed to the following values:

CONFIG0 = 0x4005 (i.e. NUMACCS = 0x4; ACCSTYPE = 0b0101 -> Write-Read-Write-Read(1<sup>st</sup> access)).

CONFIG1 = 0x5008 (i.e. AG\_MOD = NDT; ACCSPAT = 0b1000 -> w (Previous Inverted Read) - r (Inverted Read) - w (Previous normal read) - r (normal read)).

Please note again that a 'w' access always writes the inverted value from the previous read access.

Test Programming Sequence:

1. Ensure that error detection is enabled, via the ALMSRCS and ECCS registers, and check for errors already present before the test (this is not required for the test, it is just a hint to software).  
Note that many steps here will trigger an UCE alarm & OPERR. In order to avoid any reaction from this expected error/alarm, the alarm reaction can be disabled before or ALMSRCS.OPENE can be set to 0 before starting the test.
2. Enter memory test mode (set the MTU\_MEMTEST.MEMxEN register).  
Note: This will trigger OPERR / UCE alarm. Additionally, for the security sensitive memories described in [Chapter 13.3.4.1](#) the test mode will be enabled only after the auto-initialization is complete. Therefore the software must wait for the MEMSTAT.AIUX bit to be cleared.
3. RANGE register assumed to have default reset value.
4. CONFIG0 = 0x4005
5. CONFIG1 = 0x5008  
Note: This will trigger OPERR / UCE alarm.
6. Set MCONTROL.DIR, RCADR and EN\_DESCR and start the test by writing a 1 to register bit MCONTROL.START. MCONTROL := 4009<sub>H</sub> (direction up, ROW first, EN\_DESCR = 0, START = 1). Note: This will trigger OPERR / UCE alarm if enabled.
7. Wait until MSTATUS.DONE is reset.
8. Clear MCONTROL.START  
MCONTROL := 4008<sub>H</sub> (direction up, ROW first, EN\_DESCR = 0, START = 0).
9. Wait for the end of the test - wait for MTU\_DONE interrupt to be triggered, or poll MSTATUS.DONE bit to be set, via MTU\_MEMDONE register.
10. Disable the memory test mode (clear the corresponding bit in the MTU\_MEMTEST register). For the security sensitive memories described in [Chapter 13.3.4.1](#) the test mode will be enabled only after the auto-initialization is complete. Therefore the software must wait for the MEMSTAT.AIUX bit to be cleared.
11. Check the result of the test  
- verify \*ERR bits in ECCD register
12. If the test failed check the error tracking registers ETRRx /ERRINFOx and the overflow bit (ECCD.EOF).
13. Clear the flags and the error tracking registers to enable further error tracking after the test.  
Clear the UCE alarm and OPERR flags set due to above operations, if they were enabled during the test.  
Otherwise, if UCE alarm reaction or ALMSRCS.OPENE were disabled before the test, re-enable them.

## Memory Test Unit (MTU)

To find failures during this test, software has to read the ECCD register for the CERR/UCERR and flags for any errors during the test. ETRR(0) will contain the first failed address, and the ERRINFO(0) register will contain the corresponding error type.

Consider a slightly more complicated sequence example, containing 8 access sequence in 3 programming steps:

$\{\{r, w^*\}, \{r^*, w, r, w^*\}, \{r^*, w\}\}$ . CONFIG0 and CONFIG1 for such a sequence shall be programmed as follows:

- $\{r, w^*\}$ : CONFIG0 = 0x2001 (i.e. NUMACCS = 2, ACCSTYPE = 0b01); CONFIG1 = 0x5000 (AG\_MOD = NDT, ACCSPAT = 0b00)
- $\{r^*, w, r, w^*\}$ : CONFIG0 = 0x4005 (i.e. NUMACCS = 4, ACCSTYPE = 0b0101); CONFIG1 = 0x5003 (AG\_MOD = NDT, ACCSPAT = 0b0110).
- $\{r^*, w\}$ : CONFIG0 = 0x2001 (i.e. NUMACCS = 2, ACCSTYPE = 0b01); CONFIG1 = 0x5003 (AG\_MOD = NDT, ACCSPAT = 0b10).

### Special Cases

For testing the complete CPU PMEM (i.e. PSPR + PCACHE area), the Non-Destructive test shall be run twice on the same memory, once with ECCS.TC\_TWR\_SEL = 0, and once with ECCS.TC\_TWR\_SEL = 1.

For EMEM SRAMs (except EMEM\_XTM), each read in the NDT is internally implemented by performing 2 reads. For example,  $\{r, w^*, r^*, w\}$  is actually performed as  $\{r, r, w^*, r^*, r^*, w\}$ . But this does not change the required programming of the registers (i.e. the CONFIG0 and CONFIG1 shall be programmed for  $\{r, w^*, r^*, w\}$  itself for example).

Special case of large DMEMs: In some devices of this family, certain CPUs have a large DMEM. Special handling is required in such a case. Please refer to the MTU chapter in the device specific appendix for a description.

### Usage of GANGs

The maximum current jump and total test time (for 4N-NDT) are specified in the datasheet of each device. In order to achieve these specified targets, the MBIST has to be run by grouping the SSHs into different gangs. Please refer to the appendix chapter of the device to find these Gangs.

Note: The total time for SRAM initialization (which is 1 access to each location, so a 1N operation) will be 1/4th of the time taken for the 4N test (this is specified in the datasheet of the device). However the maximum current is the same for 1N (e.g. SRAM intialization) or 4N (e.g. NDT) sequence.

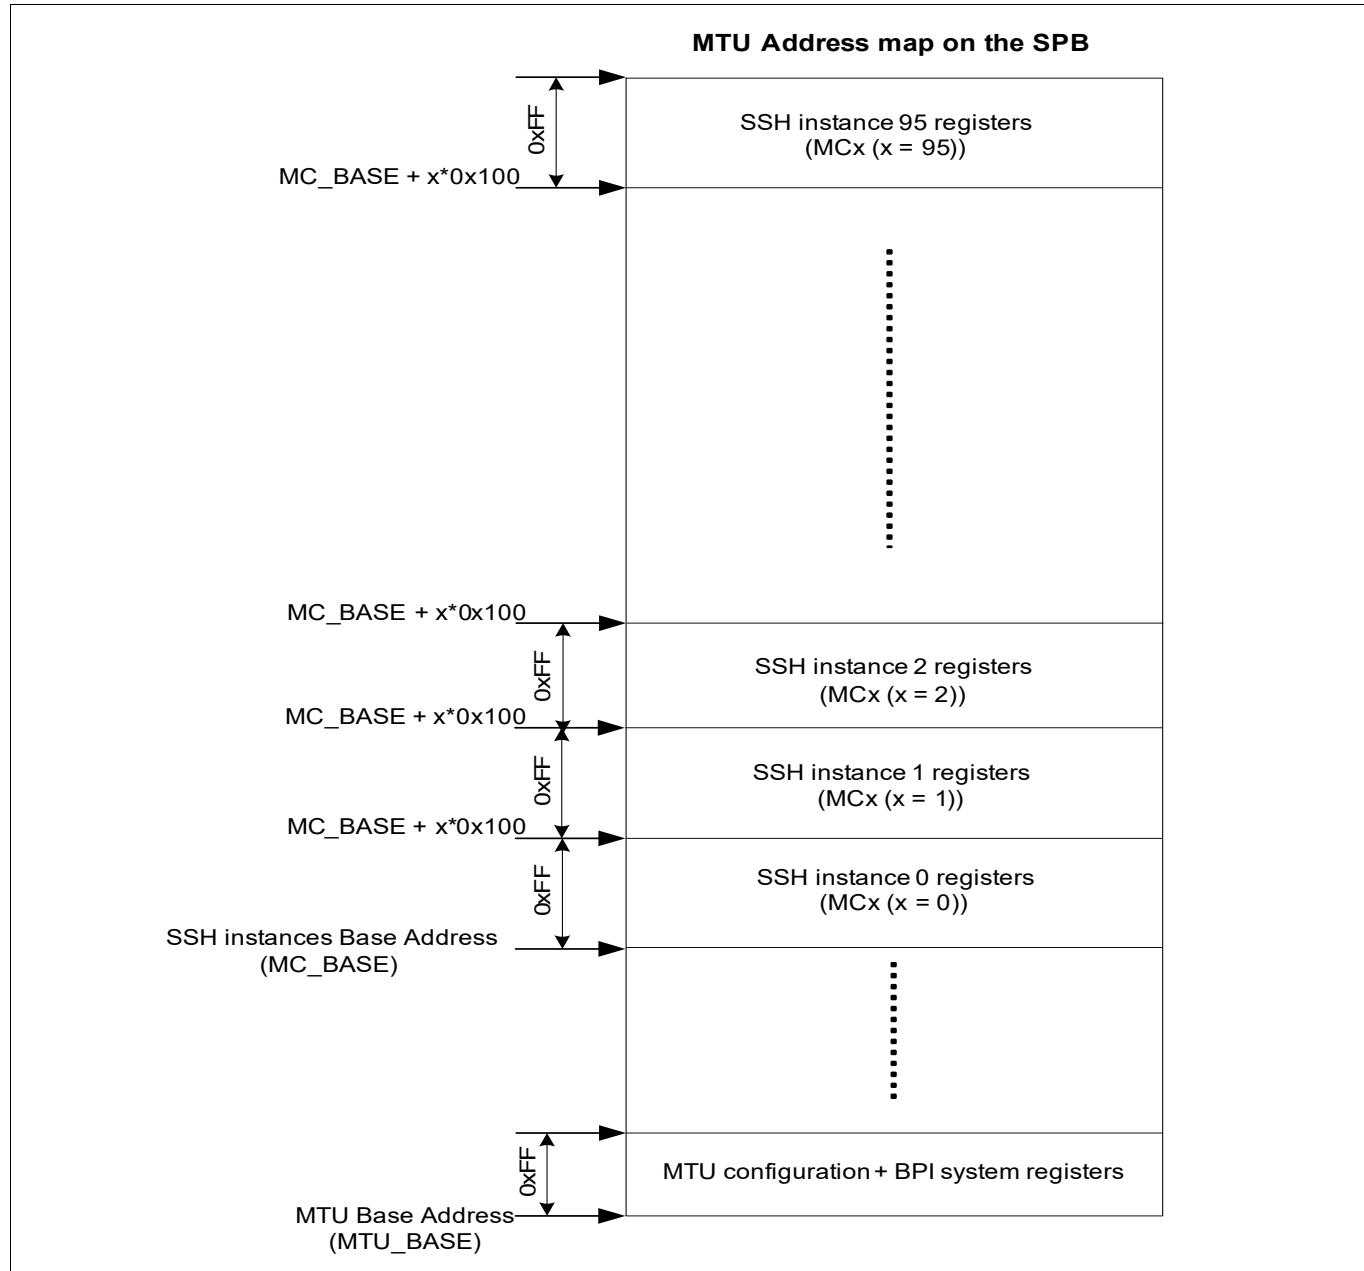

## 13.4 Registers

The overall address map of the various registers in the MTU is as shown in [Figure 154 “MTU Register Address Map” on Page 15](#). In addition to the standard system registers on the BPI, the registers in the MTU can be divided into two blocks:

- MTU Configuration registers - These registers provide the enable/disable functionality each individual memory controller.
- SRAM Support Hardware (SSH) Registers: These registers exist in each individual SSH in the device, and control the individual MBIST, ECC settings for the particular memory block.

*Note: Atomic bitwise operations are not supported on MTU/SSH registers.*

**Memory Test Unit (MTU)****13.4.2 Register Description**

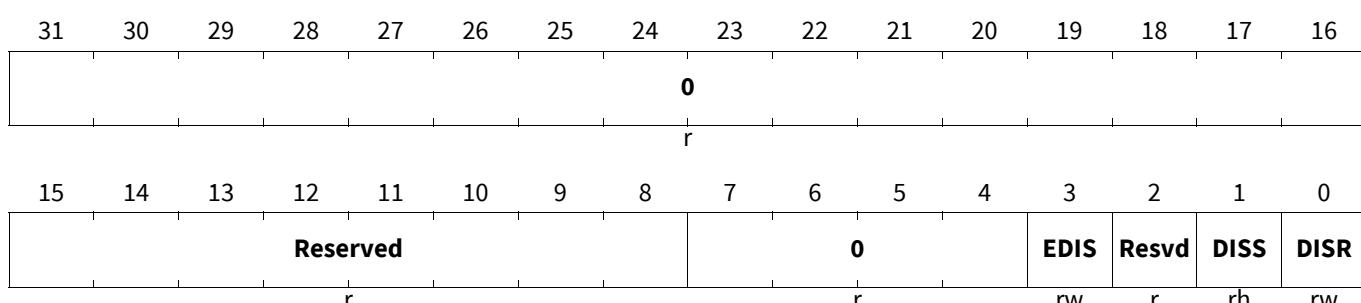

The following chapter describes the registers in the MTU. The MTU configuration registers described in [Page 20](#) control the enabling/disabling and autoinitialization functions of each memory controller. The memory controller registers described in [Page 24](#) are present for each memory controller in the device. They can be used to control and configure each memory controller separately.

**13.4.2.1 System Registers****Clock Control Register**

Whenever the clock to the MTU is disabled (either when CLC.DISR=1, or during sleep mode and CLC.EDIS=1,) then the alarms generated from the SSHs are not forwarded to the SMU. Therefore, if alarm notifications from the SSHs are required, the application should keep the MTU enabled. If the MTU is disabled, and an alarm occurs, the pending alarms are forwarded to the SMU when the MTU is re-enabled later.

**CLC**

**Clock Control Register** (0000<sub>H</sub>) Application Reset Value: 0000 0003<sub>H</sub>

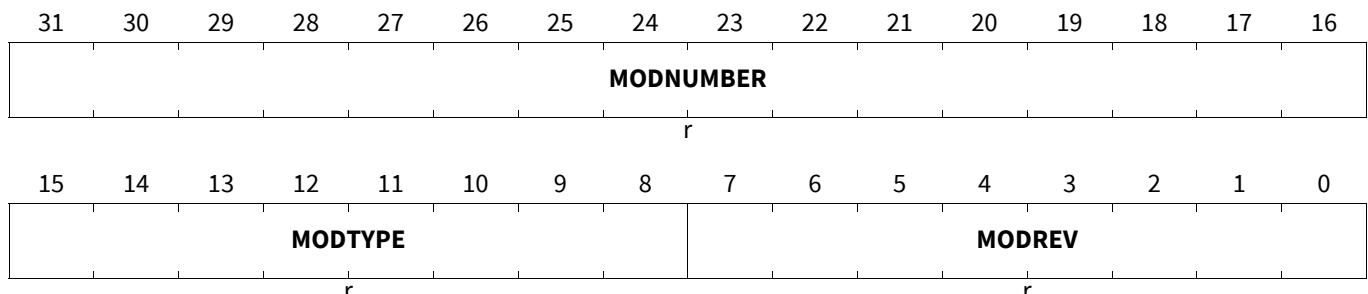

Field	Bits	Type	Description
<b>DISR</b>	0	rw	<b>Module Disable Request Bit</b> Used for enable/disable control of the module. 0 <sub>B</sub> Module disable is not requested 1 <sub>B</sub> Module disable is requested
<b>DISS</b>	1	rh	<b>Module Disable Status Bit</b> Bit indicates the current status of the module If the RMC field is implemented and if it is 0, DISS is set automatically. 0 <sub>B</sub> Module is enabled 1 <sub>B</sub> Module is disabled
<b>Resvd</b>	2	r	<b>Resvd</b> Read as 0. Must be written with 0 <sub>H</sub>
<b>EDIS</b>	3	rw	<b>Sleep Mode Enable Control</b> Used for module Sleep Mode control. 0 <sub>B</sub> Sleep Mode request is regarded. Module is enabled to go into Sleep Mode on a request. 1 <sub>B</sub> Sleep Mode request is disregarded: Sleep Mode cannot be entered on a request.
<b>Reserved</b>	15:8	r	<b>Reserved</b> Read as 0. Must be written with 0 <sub>H</sub>

## Memory Test Unit (MTU)

### 13.4.2.3 SRAM Support Hardware (SSH) Registers

There is one set of registers for each SSH instance corresponding to each SSH instance (please refer to the appendix chapter for the list of SSH instances). These registers are described below.

Some register field sizes or content depend upon the physical sizes of the memories. The default settings enable fill/test of the entire physical RAM and the register descriptions show the maximum bitfield sizes.

#### Configuration Registers

The bits in these registers can be used to control and program any march and hammer sequences. All bits concerning these test are concentrated here. All bits do not change during a test run. Setting MCONTROL.START will start the tests defined here. MSTATUS.DONE is reset at the beginning of a test and set after completion once MCONTROL.START is cleared by software. If no legal operation was defined in CONFIG1.AG\_MOD nothing will be done but the handshake of MCONTROL.START and MSTATUS.DONE is carried out.

The reset values of the CONFIG0/1 and MCONTROL registers will perform a {↑(w0,r0)} operation (direction up, write 0 to all cells and check for 0) which initializes the whole memory with 0 and checks the contents if MCONTROL.START is set. This is the start sequence of many tests.

#### MCi\_CONFIG0 (i=0-95)

##### Configuration Registers

(1000<sub>H</sub>+i\*100<sub>H</sub>)

Application Reset Value: 2002<sub>H</sub>

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
NUMACCS				R8				ACCSTYPE							
rw				r				rw							

Field	Bits	Type	Description
<b>ACCSTYPE</b>	7:0	rw	<b>Access type</b> This field specifies the type of access which is being performed to each single address in the current marching element. ACCSTYPE[n] specifies the n-th access of the marching element. 0 <sub>b</sub> write access 1 <sub>b</sub> read access
<b>R8</b>	11:8	r	<b>Reserved - Res</b> Reads return 0. Writes have no effect.

## Memory Test Unit (MTU)

Field	Bits	Type	Description
NUMACCS	15:12	rw	<p><b>Number of accesses per address</b></p> <p>This field specifies the total number of accesses which are being performed to each single address in the current marching element.</p> <p>Allowed values: 0-8 (Due to size limitation of CONFIG0.ACCTYPE and CONFIG1.ACSPAT fields).</p> <p>If NUMACCS=0 will not access a memory.</p> <p>If NUMACCS &gt; 8, 8 accesses will be performed.</p>

## Configuration Register 1

## MCi\_CONFIG1 (i=0-95)

## Configuration Register 1

(1002<sub>H</sub>+i\*100<sub>H</sub>)Application Reset Value: 0000<sub>H</sub>

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
AG_MOD				SELFASB				ACCSPAT							
rw				rw				rw							

Field	Bits	Type	Description
ACCSPAT	7:0	rw	<p><b>Access pattern</b></p> <p>When AG_MOD is selected for any test other than the Non-Destructive test, this field specifies directly the bit pattern (i.e. '0' or '1') which is being used for an access to each single address in the current marching element.</p> <p>ACCSPAT[n] specifies the n-th access of the marching element. These patterns are toggled according to MCONTROL.BITTOG and MCONTROL.ROWTOG.</p> <p>When AG_MOD selects the Non-Destructive test: For corresponding ACCSTYPE as READ or WRITE access:</p> <p>Program 0 when the previous read access was with normal data; and 1 when the previous read was with inverted data.</p> <p>Note: When considering the previous read access, consider that the last access is a previous access to the first, as a "wrap around".</p> <p>Please refer to section on Non-Destructive test for more details on how to program these bits.</p>
SELFASB	11:8	rw	<p><b>Select Fast Bit</b></p> <p>This field defines during a <math>2^i</math> test the address bit position that has the Hamming distance of 1, i. e. changes fastest. Bit 0 of either column or row address is swapped with the indicated bit of either column or row according to MCONTROL.RCADR.</p> <p>MCONTROL.RCADR=0 -&gt; column MCONTROL.RCADR=1 -&gt; row</p> <p><math>0_H</math> normal addressing sequence, bit 0 in its normal position. <b>others</b>, bit 0 swapped with the indicated position.</p>

## Memory Test Unit (MTU)

Field	Bits	Type	Description
<b>AG_MOD</b>	15:12	rw	<p><b>Address Generator Mode</b></p> <p>These bits enable the special hardware for performing the more complex addressing schemes.</p> <p>In case RANGE.RAEN (range enable) is set to 0 (single access) linear address mode has to be selected and NUMACCS set to 1.</p> <ul style="list-style-type: none"> <li><math>0_H</math> run the test with linear address generation</li> <li><math>1_H</math> run the right half select test</li> <li><math>2_H</math> run the test with GALPAT9 algorithm</li> <li><math>3_H</math> run the left half select test</li> <li><math>4_H</math> run the test with the GALPAT5 algorithm</li> <li><math>5_H</math> run the non-destructive test. The march elements, direction and backgrounds are defined by other settings in CONFIG0/1 and MCONTROL. For this test, the SRAM has to be pre-initialized with valid content (i.e. with ECC correct data). Unlike a normal MBIST march test, this test uses the ECC itself to find errors in the data. The result of the test is not reflected via MSTATUS.FAIL - instead, the detected ECC errors are tracked in the ETRR &amp; ERRINFO registers, and additionally ECCD:*ERR bits if the alarm notifications are enabled. registers</li> <li><math>8_H</math> run the write mask test</li> <li><math>A_H</math> run the test with <math>2^i</math> address generation</li> <li><b>others</b>, Nothing is done but the handshake of START and DONE is carried out.</li> </ul>

### MBIST Control Register

The bits in these registers can be used to control and program any march and hammer sequences. All bits concerning these test are concentrated here. All bits do not change during a test run. Setting MCONTROL.START will start the tests defined here. MSTATUS.DONE is reset at the beginning of a test and set after completion once MCONTROL.START is cleared by software. If no legal operation was defined in CONFIG1.AG\_MOD nothing will be done but the handshake of MCONTROL.START and MSTATUS.DONE is carried out.

The reset values of the CONFIG0/1 and MCONTROL registers will perform a  $\{\uparrow(w0,r0)\}$  operation (direction up, write 0 to all cells and check for 0) which initializes the whole memory with 0 and checks the contents if MCONTROL.START is set. This is the start sequence of many tests.

#### MCi\_MCONTROL (i=0-95)

#### MBIST Control Register

( $1004_H + i * 100_H$ )

**Memory Test Unit (MTU)**

Field	Bits	Type	Description
<b>START</b>	0	rw	<p><b>START</b></p> <p>If this bit is written to '1' by software the memory test will start. If it is reset by software, and the test has finished, MSTATUS.DONE will be set to 1.</p> <p>If MCONTROL.FAILDMP is set, a fail will stop the current execution. RESUME will continue a suspended test.</p> <p>0<sub>B</sub> No test started, finished or waiting for test end 1<sub>B</sub> Start memory test</p>
<b>RESUME</b>	1	rwh	<p><b>Resume failed test</b></p> <p>This bit allows a test with fail that got suspended to be resumed after the dump of the fail bit map. A restart is possible only if MSTATUS.FDA was reset by hardware. It will be reset by hardware once the test is resumed.</p> <p>0<sub>B</sub> Do not resume 1<sub>B</sub> Resume suspended MBIST run</p>
<b>ESTF</b>	2	rw	<p><b>Enable Sticky Fail Bit</b></p> <p>This bit enables the sticky fail bit MSTATUS.SFAIL. If set any fails will be collected in MSTATUS.SFAIL. Resetting this bit to 0 will also reset MSTATUS.SFAIL.</p> <p>0<sub>B</sub> Do not collect fail events 1<sub>B</sub> Collect fail events</p>
<b>DIR</b>	3	rw	<p><b>Direction Select</b></p> <p>This field specifies the direction of a memory test operation.</p> <p>0<sub>B</sub> DOWN: Address direction is highest to lowest. 1<sub>B</sub> UP: Address direction is lowest to highest.</p>
<b>DINIT</b>	4	rw	<p><b>Data Initialization Enable</b></p> <p>This bit enables a write of the RDBFL data to all locations defined by the range register. RDBFL can contain data that will produce an ECC error. Execution is started with MCONTROL.START. For this predefined action any information contained in CONFIG0/1 registers and the bits BITTOG, ROWTOG and DIR are ignored.</p> <p>0<sub>B</sub> Disabled 1<sub>B</sub> Enabled</p>
<b>RCADR</b>	5	rw	<p><b>Fast Row / Fast Column Addressing Scheme Select</b></p> <p>This bit selects between fast row and fast column addressing. "Fast Row" moves along the word-lines first and then in bit-line direction, "Fast Column" along the bit-lines first.</p> <p>0<sub>B</sub> Fast row 1<sub>B</sub> Fast column</p>
<b>ROWTOG</b>	6	rw	<p><b>Row toggling</b></p> <p>This field specifies whether to toggle the used bit pattern (non inverted/inverted) with each physical memory row. This is required when writing a checkerboard pattern or a row stripe pattern.</p> <p>0<sub>B</sub> Do not toggle 1<sub>B</sub> Do toggle with each row</p>

## Memory Test Unit (MTU)

Field	Bits	Type	Description
<b>BITTOG</b>	7	rw	<p><b>Bit toggling</b></p> <p>This field specifies whether to toggle the used bit pattern (non inverted/inverted) with each physical memory column. This is required when writing a checkerboard pattern or a column stripe pattern.</p> <p>0<sub>B</sub> Do not toggle 1<sub>B</sub> Do toggle with each column</p>
<b>R8</b>	8	rw	<p><b>Reserved</b></p> <p>This bit shall always be written with 0.</p>
<b>FAILDMP</b>	9	rw	<p><b>Fail bitmap dump</b></p> <p>This field enables a dump of the failing address and a fail bit map after a fault has been detected. The memory test is suspended afterwards and resumed by MCONTROL.RESUME. MSTATUS.FDA shows that a fail dump is available.</p> <p>This functionality can be used only if bit MCONTROL.LDRED = 1. In case a fail dump is available, RDBFL will contain the fail bit map and ETRR the failing address.</p> <p>0<sub>B</sub> Do not dump 1<sub>B</sub> Dump each fault</p>
<b>EN_DESCR</b>	10	rw	<p><b>Enable Descrambling</b></p> <p>This bit has an effect only when the SSH itself is enabled. If this bit is set, the internal address de-scrambler in the SSH will be enabled. The reset value is 0, hence the de-scrambler is not enabled by default .</p> <p>0<sub>B</sub> Descrambler is not enabled in the address generation path within the SSH 1<sub>B</sub> Descrambler is enabled in the address generation path within the SSH</p>
<b>R11</b>	11	r	<p><b>Reserved</b></p> <p>Reads return 0</p>
<b>R12</b>	12	rw	<p><b>Reserved</b></p> <p>This bit shall always be written with 0.</p>
<b>R13</b>	13	rw	<p><b>Reserved</b></p> <p>This bit shall always be written with 0.</p>
<b>R14</b>	14	rw	<p><b>Reserved</b></p> <p>This bit shall always be written with 1.</p>
<b>SRAM_CLR</b>	15	rw	<p><b>Clear the SRAM</b></p> <p>This bit initializes the complete SRAM with ECC correct "All-0" data. Execution is started with MCONTROL.START. For this predefined action any information contained in CONFIG0/1, RANGE registers and the bits BITTOG, ROWTOG and DIR are ignored. This bit shall not be set together with other initialization or test configurations. After the SRAM clearing is complete, the software has to reset this bit back to '0' before disabling the SSH.</p> <p>0<sub>B</sub> Do not clear the entire SRAM. 1<sub>B</sub> Clear the entire SRAM. The SRAM is fully filled with zeroes, and is also ECC correct.</p>

## Memory Test Unit (MTU)

### Status Register

The bits in the status register show the status of the currently running and last test respectively.

#### MCI\_MSTATUS (i=0-95)

##### Status Register

( $1006_H + i * 100_H$ )

Application Reset Value:  $0001_H$

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R4										rh	Res4	SFAIL	FDA	FAIL	DONE

Field	Bits	Type	Description
<b>DONE</b>	0	rh	<b>DONE</b> This bit is reset at the start of a test and set when a test is completed and MCONTROL.START was reset by software. It is not set when a test is interrupted for fail dump.
<b>FAIL</b>	1	rh	<b>FAIL</b> This bit will be reset when a test is being started. It will be set to '1' by hardware under the following conditions: 0 <sub>B</sub> no error occurred 1 <sub>B</sub> detailed description see above
<b>FDA</b>	2	rh	<b>Fail Dump Available</b> This bit shows that a fail has occurred if MCONTROL.FAILDMP is set. The test is suspended and fail dump information is available. The fail bit map is in RDBFL and the associated address is in ETRR(0). As long as no fail has occurred RDBFL contains the last read information and ETRR has no valid data. This bit will be set by hardware. It will be reset when MSTATUS was read with MSTATUS.FDA = 1 and the dump information was read from ETRR and RDBFL. Only the last read from the last word of RDBFL is checked by the hardware and taken as an indication for a complete read. A suspended test will be resumed by MCONTROL.RESUME if FDA was reset. This forms some sort of handshake to insure that a suspended test can only be resumed (by a broadcasted) MCONTROL.RESUME if the last fail information was actually collected. 0 <sub>B</sub> No fail dump data available. A suspended MBIST run can be resumed. 1 <sub>B</sub> Fail dump data is available and waiting for read.
<b>SFAIL</b>	3	rh	<b>Sticky Fail Bit</b> This bit is set to 1 together with MSTATUS.FAIL provided MCONTROL.ESTF is set. In contrast to FAIL it will not be reset when a new test is started. Therefore it will collect fail information over more than one MBIST run. It will be reset when MCONTROL.ESTF is reset, or MBIST mode is switched off. 0 <sub>B</sub> No fail collected. 1 <sub>B</sub> A fail occurred during one of the test runs since MCONTROL.ESTF was set to 1.

## Memory Test Unit (MTU)

Field	Bits	Type	Description
Res4	4	rh	<b>Reserved - Res</b> Shall be written with zero.
R4	15:5	r	<b>Reserved - Res</b> Reads return 0

### Range Register, single address mode

The Range Register can be used to run a test only on a dedicated part of the RAM.

The range can be set in 64 word increments.

The range register can also be used to write to one specific address or read from it. In this case the range is disabled and the remaining part of the register is used as the address field. The addresses generated via the RANGE register (single or range) can be physical or logical depending on the MCONTROL.EN\_DESCR bit.

#### MCi\_RANGE (i=0-95)

		(1008 <sub>H</sub> +i*100 <sub>H</sub> )										Application Reset Value: XXXX <sub>H</sub>						
		15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	
RAEN	INJERR	ADDR																
rw	rw									rw								

Field	Bits	Type	Description
ADDR	13:0	rw	<b>Address</b> When RAEN = 0, This field specifies the address of a single memory location. Reads and writes to this location are possible. When RAEN=1, this field is interpreted as 2 different fields. ADDR[13:7] is interpreted as Upper Range Limit. ADDR[6:0] is interpreted as Lower Range Limit. For smaller SRAMs which require lesser number of address bits, the MSB bits are reserved. Writes to these bits are ignored, and reads return '0'.
INJERR	14	rw	<b>Inject Error</b> Enables Error-Injection during march tests. This is supported only for linear march tests. 0 <sub>B</sub> Do not mask any writes during march tests. RANGE.ADDR and RAEN used normally. 1 <sub>B</sub> Use RANGE.ADDR as a pointer to a physical SRAM address to which write accesses during a march test will not be executed. This bit helps in error injection during a march test over the whole SRAM. This bit has an effect only when RAEN is also set. With INJERR and RAEN = '1', the test is by default run over the entire SRAM.

## Memory Test Unit (MTU)

Field	Bits	Type	Description
RAEN	15	rw	<p><b>Range Enable</b></p> <p>0 Disabled, single address mode. In this case a single word can be addressed for read or write. Config registers have to be set as follows      CONFIG.NUMACCS:= “0001” (single access)      CONFIG.AG_MOD := “0000” (linear)      MCONTROL.DIR :=1 (up)</p> <p>For read just the value in this location will be delivered. No check against expected values is made; i.e. MSTATUS.FAIL will not be set.</p> <p>1 Enabled. ADDR[13:7] is interpreted as Upper Range Limit. ADDR[6:0] is interpreted as Lower Range Limit.</p>

### Setting Address Ranges

If the RAEN field is set to ‘1’ then range mode is enabled. In this case, the ADDR field of the RANGE register is interpreted as two separate fields:

ADDR[13:7] is interpreted as the Upper Range Limit.

This field specifies the upper logical block address limit in 64 word increments.Upper end of the address range is UPLIMIT & 111111B

ADDR[6:0] is interpreted as the Lower Range Limit

This field specifies the lowerlogical block address limit in 64 word increments.Lower end of the address range is LOLIMIT & 000000B.

Note that the default reset value of the ADDR field will be set to the maximum range of the physical memory. The default behaviour is therefore that an initialization or test will operate over the whole memory.

Also note that for smaller memories which require less than 13 bits of addressing, the relevant MSB bits of the address field are reserved.

### Usage of MCi\_RANGE register

Usage of MCi\_RANGE register in order to perform initialization or MBIST over any partial SRAM address ranges is not recommended. The recommendation is to always perform initialization and MBIST over the complete address range of any SRAM. Therefore the user is recommended not to change the reset value of this register, and always use this register with its reset value while performing any tests or initialization.

### Revision ID Register

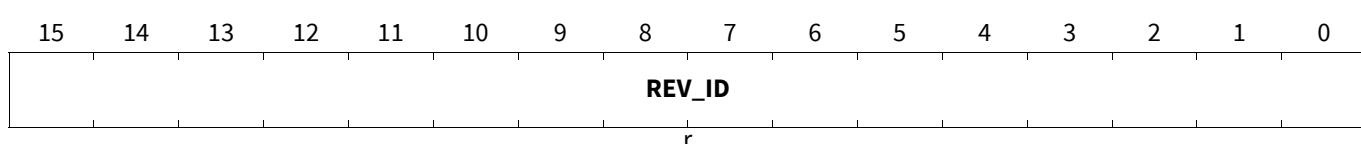

The revision ID register contains a hard coded read only constant which describes the current status of the MBIST/ECC IP.

#### MCi\_REVID (i=0-95)

#### Revision ID Register

(100C<sub>H</sub>+i\*100<sub>H</sub>)

Application Reset Value: 0610<sub>H</sub>

## Memory Test Unit (MTU)

Field	Bits	Type	Description
<b>REV_ID</b>	15:0	r	<b>Revision Identifier</b> This field defines the currently implemented release, version and functionality of the used MBIST/ECC controller to track the MBIST/ECC version for easier handling at the tester.

### ECC Safety Register

This register controls the various error detection and notification modes. This register can be accessed even if the corresponding SSH is not enabled using the MEMTEST.MEMx\_EN bit.

Writing to this register is only permitted when safety endinit is cleared.

The hardware features that implement fault tolerance mechanisms for the SRAMs (e.g. single bit correction) shall be enabled per default after any reset. This is ensured by the reset value of the ECC safety register where ECCS.ECE = 1 after a reset.

#### MCI\_ECCS (i=0-95)

<b>ECC Safety Register</b>												<b>(100E<sub>H</sub>+i*100<sub>H</sub>)</b>				<b>Application Reset Value: 001F<sub>H</sub></b>

Field	Bits	Type	Description
<b>SERR</b>	0	rwh	<b>Error Detected</b> Write of '0' clears the sticky status. Write of '1' has no effect. In the case of a write of '0' simultaneously with an error detection, the setting of the bit by hardware will take priority. This bit is reset with an Application Reset. Read as: 0 <sub>B</sub> No error detected. 1 <sub>B</sub> An error was detected and alarm forwarded: CERR, UCERR or MERR.
<b>CERR</b>	1	rwh	<b>CE alarm occurred</b> Write of '0' clears the bit, and enables further alarms to be forwarded to SMU. Write of '1' has no effect. When the bit is set, software can perform additional diagnostics from the information in the ETRR/ERRINFO registers. Please refer to the safety section for more details. This bit is reset with an Application Reset. Read as: 0 <sub>B</sub> No CE alarm event occurred. 1 <sub>B</sub> CE alarm event occurred.
<b>UCERR</b>	2	rwh	<b>Uncorrectable Error Alarm Occured</b> Write of '0' clears the bit, and enables further alarms to be forwarded to SMU. When the bit is set, software can perform additional diagnostics from the information in the ETRR/ERRINFO registers. Please refer to the safety section for more details. Write of '1' has no effect. This bit is cleared on an application reset. Read as: 0 <sub>B</sub> No UCE alarm event occurred. 1 <sub>B</sub> UCE alarm event occurred
<b>MERR</b>	3	rwh	<b>Miscellaneous Error Alarm Occured</b> Write of '0' clears the bit, and enables further alarms to be forwarded to SMU. When the bit is set, software can perform additional diagnostics from the information in the ETRR/ERRINFO and ALMSRCS registers. Please refer to the safety section for more details. Write of '1' has no effect. This bit is reset with an application reset. Read as: 0 <sub>B</sub> No ME Alarm Event occurred. 1 <sub>B</sub> ME Alarm Event occurred.

## Memory Test Unit (MTU)

Field	Bits	Type	Description
TRC	4	w	<p><b>Tracking Clear</b></p> <p>Writing this bit with '1' clears the EOV, VAL bits plus the ETRR and ERRINFO registers, depending on the PERMERR settings.</p> <p>This bit will always read 0.</p> <p><math>0_B</math> No effect.</p> <p><math>1_B</math> Clear the ETRR, ERRINFO and ECCD.VAL &amp; EOV bits. If a PERMERR bit is set, then the corresponding entries are not cleared. Note: If PERMERR and TRC are written at the same time, the clearing due to TRC takes place with the previous PERMERR settings, and the new settings take effect only after.</p>
VAL	9:5	rh	<p><b>Valid Bits</b></p> <p>Every tracking register (ETRRx) has a valid bit associated. Reset by ECCD.TRC. 5 error tracking registers are available and 5 valid bits. These bits are preserved until a PORST.</p>
PERMERR	14:10	rw	<p><b>Permanent Error in ETRR Entry</b></p> <p>Denotes an ETRR entry that shall not be cleared by setting the TRC or moved up when a new error occurs. With this bit set, the corresponding ETRR+ERRINFO entry remain as they are until a PORST.</p> <p><math>00_H</math> The corresponding entry in ETRR can be cleared by setting TRC.</p> <p><math>01_H</math> The corresponding entry in ETRR shall not be cleared by setting TRC.</p>
EOV	15	rh	<p><b>Error Overflow</b></p> <p>The Error Tracking registers have an overflow condition.</p> <p>This bit is preserved until a warm PORST.</p> <p><math>0_B</math> All errors detected since last clear were tracked.</p> <p><math>1_B</math> More errors were detected since last clear than error tracking registers are available. Also, this bit is set if more than one memory block was in error at the same time. See ETRR.MBI for details. The setting of this bit and the forwarding of the overflow error via the UCE alarm is enabled by ECCS.TRE = 1 and ALMSRCS.OVFE = 1. This bit is reset by ECCD.TRC.</p>

Table 478 Reset Values of MCI\_ECCD (i=0-95)

Application Reset	-----0 $0000_B$	Application Reset

## Error Tracking Register x

These registers contain the address of errors detected. 5 registers are implemented per SSH instance. ETRR(0) contains the last error detected. Successive errors will push previous errors up. Correctable, uncorrectable and address errors are stored here in the same manner.

The error type (Single Bit Error (SBERR), Double-bit error (DBERR) or Address error (ADDRERR)) at each address entered is stored in the corresponding entry of the **MCI\_ERRINFOx** register. If a new error occurs with different error types (ERRINFO contents will not match) at an address which is already stored, then this address will again be stored for second time in the ETRR registers, this time with the new error types in the corresponding ERRINFO

## Memory Test Unit (MTU)

register. However, a new error at an already stored address, where the ERRINFO contents will match, is not stored again as a separate entry.

Only one new entry can be tracked at one time. If more than one error occurs at the same time in different memory blocks (SRAM towers) ECCD.EOF will be set, no matter how many ETRR registers are still available, and the lowest memory index in which an error occurs is stored in the ETRR.MBI bits. Note that if more than one error occurs at the same time in different sub-towers of same memory block, the ECCD.EOF is not set, and if the error types in the sub-towers are different, all of them are stored in the corresponding same ERRINFO register.

The CERR, and UCERR and the SERR bits in the ECCD register are also set appropriately if enabled.

The address tracked is physical i.e. the address is directly equivalent to the SRAM address input signals.

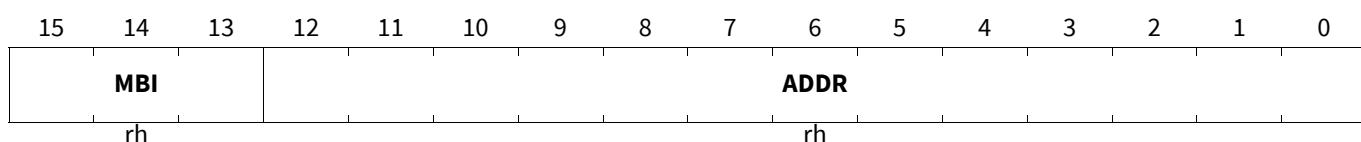

The associated valid bit(s) is/are contained in the register ECCD.VAL. ECCD.TRC clears the associated valid bits and all contents of ETRR and ERRINFO will also be cleared.

It/they contain(s) the faulty address(es) of both the correctable, uncorrectable case and address errors.

Once all registers are used up ECCD.EOF is set.

### **MCi\_ETRRx (i=0-95;x=0-4)**

**Error Tracking Register x**      **( $1012_H + i * 100_H + x * 2$ )**      **PowerOn Reset Value: 0000\_H**

Field	Bits	Type	Description
<b>ADDR</b>	12:0	rh	<b>Address of Error(i)</b> Address of the error detected since last clear operation. If some MSB bits are not required for addressing smaller memories, they are reserved and read as '0'.
<b>MBI</b>	15:13	rh	<b>Memory Block Index of Error(i)</b> If more than one memory is implemented in parallel, these three bits contain the index of the memory block in error to identify the memory in error and the tracked address belongs to this memory. Otherwise these bits always are set to 0.

### **Usage of MCi\_ETRRx registers**

The MCi\_ETRRx registers store the physical addresses -i.e. address at the input of the SRAMs. This address is not the same as system address (shown in MEMMAP chapter). The user should rely on the MCi index (i) to find out in which SSH the error occurred. However it is not recommended to translate the address in MCi\_ETRRx register back to system address.

### **Read Data and Bit Flip Register y**

This register is used for several purposes whenever a register with the size of the memory width is needed.

Normally when test mode is enabled this register contains the data which are directly read back from the RAM (without any data scrambling) during the last read access.

During test mode, it contains the bit flip information. If ECCS.BFLE is set, this information is used to flip bits written to the SRAM.

## Memory Test Unit (MTU)

After a failed test it contains the failed bit map if MCONTROL.FAILDMP is set. The corresponding failure address is contained in the error tracking register.

When MCONTROL.DINIT is set, the content of RDBFL is written to all locations within range.

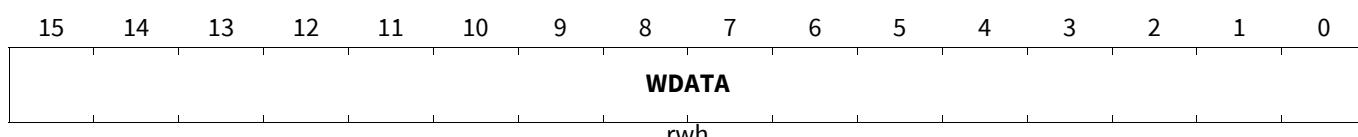

Writes to this register are not permitted while a test is underway.

### MCi\_RDBFLy (i=0-95;y=0-66)

SSH/SRAM errors as a source to the ME alarm.</p> <p>1<sub>B</sub> Enable the detection and forwarding of misc. SSH/SRAM errors as a source to the ME alarm</p>
<b>R6</b>	15:6	r	<p><b>Reserved - Res</b></p> <p>Reads return 0</p>

**SSH Safety Faults Status Register**

This register shows the status of the errors detected in the SRAM, which are forwarded as part of the UCE and ME alarms.

After power-up and before initialization by the SSW the safety flip-flops in the SSH can indicate a fault since some internal registers are not initialized. As a consequence MCI\_FAULTSTS.MISCERR[2] could be set and result in an alarm. LBIST does initialize the internal registers and clears the error. Alarms resulting from MCI\_FAULTSTS.MISCERR[2] should be ignored during start-up and cleared right after execution of the SSW in case LBIST was not run.

### Error Information Register x

The **MCI\_ETRRx** register(s) contain(s) the address of the error(s) detected. The type of error at the memory location corresponding to each ETRR address entry can be found using the Error Information Registers (ERRINFO). One ERRINFO register is implemented corresponding to each ETRR entry. An ERRINFO register is valid only when the corresponding ETRR entry is valid (ECCD.VAL = 1), and is cleared by ECCD.TRC.

#### MCI\_ERRINFOx (i=0-95;x=0-4)

Field	Bits	Type	Description
<b>SBERR</b>	0	rh	<b>Single Bit Error Detected</b> Read as: 0 <sub>B</sub> No Single Bit error detected at the memory address in the corresponding ETRRx register. 1 <sub>B</sub> Single Bit detected at the memory address in the corresponding ETRRx register.
<b>DBERR</b>	1	rh	<b>Double Bit Error Detected</b> Read as: 0 <sub>B</sub> No Double-Bit error detected at the memory address in the corresponding ETRRx register. 1 <sub>B</sub> Double Bit error detected at the memory address in the corresponding ETRRx register. Note that for SRAMs with Address-ECC (refer to the Appendix chapter for the list of such SRAMs in the device), this bit is also set if an error in the Address bits are detected.
<b>ADDRERR</b>	2	rh	<b>Address Fault Detected</b> Read as: 0 <sub>B</sub> No address error detected at the memory address in the corresponding ETRRx register. 1 <sub>B</sub> Address error detected at the memory address in the corresponding ETRRx register. Note that for SRAMs with Address-ECC, this bit is not used. For such SRAMs, errors in both Address and Data bits are notified by the DBERR bits.
<b>R3</b>	15:3	r	<b>Reserved - Res</b> Reads return 0

## Memory Test Unit (MTU)

### 13.5 Safety Measures

Please refer to the safety manual as the final reference regarding safety mechanisms and reactions. The following chapter only aims to provide a generic description.

There are a number of safety features that help to detect random hardware faults in the SRAM cells as well as periphery.

Random hardware faults in the data (data path as well as SRAM cell), address logic within the SRAM and control logic within the SRAM are protected by safety mechanisms.

Safety notifications (alarms) are provided to the SMU.

This section provides a short summary of these safety mechanisms and safety notifications. Additionally, some of these features may be explained in more detail in other sections.

#### 13.5.1 Safety Features

The safety features implemented in the SRAMs, SSH instances and the MTU are the following:

- Error Detection and Correction Codes / Logic
- Address Error Monitor
- SRAM Mux Factor
- Error Tracking Registers
- Safety Flip-Flop implementation for critical register bits.

##### 13.5.1.1 SRAM Error Detection & Correction (EDC/ECC)

All SRAMs are implemented with Error Detection or Correction Codes (ECC) for the stored Data. Except for certain SRAMs described in the appendix chapter, the ECC is computed over the data alone.

During a WRITE operation, checksum bits (ECC bits) for the input data word are generated using an ECC encoder. These bits are stored in the SRAM along with and additionally to the data word itself.

During a READ operation, an ECC decoder compares the read Data word + ECC bits to the expected ECC value. If due to any random hardware failure, soft error etc., the data word stored in the SRAM was corrupted, then there will be a mismatch compared to the expected ECC value. This is notified as an error and alarm.

Two different kinds of ECC codes are used in the system for different SRAMs - SECDED codes or DED codes.

SECDED codes can detect upto a double bit error (DBE), as well as correct a single bit error (SBE). That is, the Hamming distance of these codes = 4.

DED codes can detect upto a double bit error, but cannot correct any error.

The column "ECC Type" in the SSH instances table shows which type of ECC code is used for each SRAM.

There are two error notifications sent to the SMU from the ECC decoder via the CE and UCE alarms. For SRAMs with SECDED ECC- correctable error event (ie SBE corrected or detected) alarm and Un-correctable error detected (ie DBE detected) alarm. For SRAMs with DED ECC, there is only one error notification and this is notified by the DBE error and UCE alarm.

SBE notification (Depending on ECCS.ECE, forwarded as a source in CE alarm or UCE alarm) as well as tracking in the ETRR/ERRINFO is enabled by setting ALMSRCS.SBE = 1.

DBE notification (Forwarded as a source in UCE alarm) as well as tracking in the ETRR/ERRINFO is enabled by setting ALMSRCS.DB = 1.

Please note that the ECCS.CENE, UCENE and TRE bits act as a further global enable and have to be set for the ECC alarm notifications to be sent to SMU as well as to enable error tracking in the ETRR/ERRINFO.

The number of ECC words in an SRAM tower is defined by the ECC granularity, described in the SSH instances table in the appendix chapter.

## Memory Test Unit (MTU)

For example: An ECC granularity of 2 implies that there are 2 ECC words per physical SRAM block.

### 13.5.1.2 Address Error Monitor

Similar to how the ECC helps to monitor errors in the data, the Address Error Monitoring mechanism helps to detect failures in the address generation logic within the SRAMs.

An error in the address generation within the SRAM can lead to:

- A valid input address selecting no wordline/bitline
- A valid input address selecting multiple wordlines/bitlines
- A valid input address selecting a wrong wordline/bitline
- A valid input address selecting a non-existing (eg. out of range) wordline/bitline

All the above SRAM failure modes are detected by the address error monitor.

Whenever an error is detected by the address error monitor, an alarm is sent to the SMU.

The address error detection, tracking and notification is enabled by setting ALMSRCS.ADDRE, and the alarm is forwarded as one of the sources to the UCE alarm.

If an address error is enabled (ALMSRCS.ADDRE = 1) and an error is detected, then it is tracked in the ETRR and ERRINFO registers (ERRINFO.ADDRERR is set). Please note that the ECCS.UCENE and TRE bits act as a further global enable and have to be set for the address error alarm notifications to be sent to SMU as well as to enable error tracking in the ETRR/ERRINFO.

**NOTE:** In devices with EMEM, EMEM SRAM does not have address signatures. Instead, the ECC is computed out of both address and data. These SRAMs are described in the appendix chapter. Hence in these SRAMs, the Address Error detection is enabled via ALMSRCS.DBE itself, and the status notified in ERRINFOx.DBERR. The ALMSRCS.ADDRE bit has no effect in this case.

### 13.5.1.3 SRAM Mux Factor

In order to reduce the probability of a single random hardware fault (e.g. an alpha particle strike or contact fail) causing more than a single-bit error, the bits in each logical data word are interleaved by a certain factor (4, 8 or 16). This means, two consecutive bits in a logical data word are actually physically 4, 8 or 16 bits apart. The mux factor used in each SRAM is mentioned in the SSH instances table.

### 13.5.1.4 Error Tracking Registers

The error tracking registers store the addresses (ETRR) and the corresponding type (ERRINFO) of errors in the SRAM. When a threshold of errors is reached (i.e. when the ETRR registers are fully filled) - then an overflow alarm is raised to the SMU. The system can react appropriately to such an overflow.

Error Tracking is globally enabled by setting ECCS.TRE. Tracking of individual error types (SBE, DBE, ADDRE) can be enabled or disabled via the corresponding bits in the ALMSRCS register.

Additionally, ALMSRCS.OVFE enables the forwarding of overflow error notification via the UCE alarm to the SMU.

#### Error Tracking

It is possible for the software to track the error type and the address in which it occurred. The ECCS.TRE enables the tracking of the address and type of a detected error.

Whenever address tracking is enabled, the 5 ETRRx(x = 0-4) (Refer [MCI\\_ETRRx \(i=0-95;x=0-4\)](#)) registers contain the physical address of the detected error. ETRR0 contains the last error detected. The ECCD.VAL is a 5 bit field corresponding to the 5 ETRR registers. When any of the ETRRx registers contain a valid error address, the corresponding ECCD.VAL bit is also set. The [MCI\\_ERRINFOx \(i=0-95;x=0-4\)](#) registers contain the error type (Correctable, Uncorrectable or Address Error) at the address in the corresponding ETRRx register entry.

## **Memory Test Unit (MTU)**

Software can clear the ECCD.EOF, ECCD.VAL and the ETRRx(x=0-4) and ERRINFOx(x=0-4) registers by setting the tracking clear bit, ECCD.TRC. The errors are always tracked since the last clear.

### **Soft Error Handling**

The ECCD.PERMERR bits are useful to separate permanent and soft errors, if required. When an error occurs, software may probe the location to ascertain if it is a hard error or not.

When PERMERR[x] is set by software, then the corresponding ETRR/ERRINFO entry is denoted to be a permanent error, and are hence no longer considered part of the error tracking buffers. Even setting ECCS.TRC has no effect in clearing such entries. In such a case, even the overflow is generated when all the entries with PERMERR = 0 are filled.

If all entries are marked with PERMERR[x] = 1, then any new error automatically triggers the overflow.

The PERMERR bits shall be set by software only if the corresponding VALID bits are already set. The PERMERR bits shall not be set when the corresponding VALID bits are 0.

### **13.5.1.5 Safety Flip-Flops**

Certain critical registers have to be protected against soft errors changing their values. These registers protected by safety FF are:

In the MTU:

- MTU\_MEMMAP (SFF Detection Only)

In each SSH:

- ECCS: MENE, ECCMAP, SFLE & BFLE bits protected by DED ECC SFFs - UE Error notifications OR-ed and sent via UCE alarm & OPERR[2].
- ALMSRCS: MISCE bit protected by ECC DED SFF - Error notification via UCE alarm & OPERR[2].

The safety FFs in the MTU report errors directly to the SMU. The safety FFs in the SSH report errors via the UCE alarm and the status via OPERR[2].

### **13.5.2 Safety Notifications**

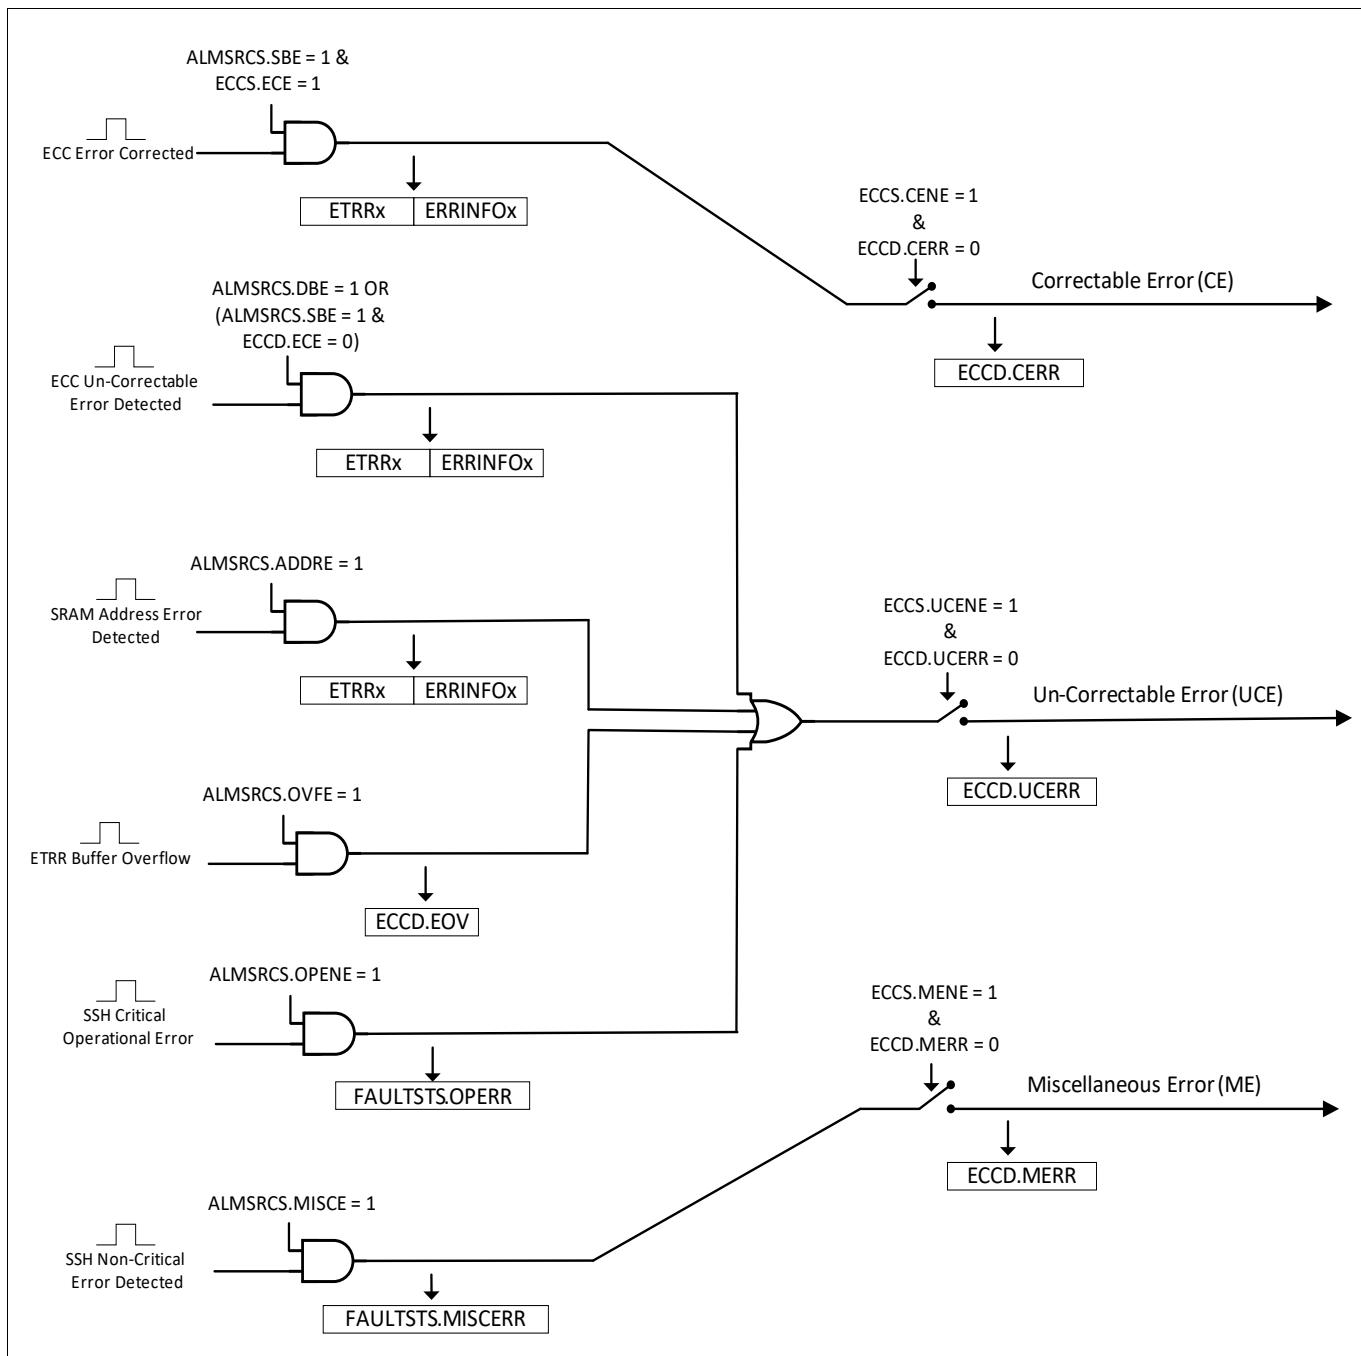

The error notifications from all SRAMs/SSHS in the system can be reported to the Safety Management Unit (SMU). The SMU may be programmed to initiate appropriate action.

Each SSH provides the following alarms to the MTU which are then forwarded to the SMU:

- SRAM ECC Correction Event Occurred Alarm (CE alarm)- Status via ECCD.CERR bit.
- SSH Un-Correctable Event Critical for Operation Alarm (UCE alarm)- Status via ECCD.UCERR bit.
- SSH Miscellaneous Error Events Alarm (ME alarm) - Status via ECCD.MERR bit.

These alarms are forwarded from each SSH to the MTU. The MTU consolidates the alarms from all the SSHs and forwards this further to the SMU.

## Memory Test Unit (MTU)

**Figure 155 Alarms and Error Detection enabling (ECCS.TRE assumed to be set).**

When an alarm occurs, the corresponding \*ERR bit in the ECCD register is set. No new alarms of the same type are forwarded as long as this bit remains set. Hence, once an alarm occurs, the software shall clear the corresponding \*ERR bit in order to enable forwarding of further alarms of the same type again.

Normally, there may be a time window of multiple clock cycles from when an alarm event occurs (ie ECCD.\*ERR is set) to until the software reacts and clears the flag to enable forwarding further alarms. During this time window, further new errors corresponding to the same alarm type may occur. For any such new event, although no new alarm is generated, the errors are still tracked - i.e. - the information about new errors are stored in the ETRR, ERRINFO, and FAULTSTS registers. Thus software may retrieve the information regarding new errors during this window from these status registers.

## Memory Test Unit (MTU)

Even if the new hardware event happens exactly at the same cycle as the software clear event takes effect - the ECCD bits are cleared and a new alarm is not generated. Hence software has to always rely on the ETRR, ERRINFO and FAULTSTS registers for new errors occurring during the time window of clearing.

NOTE: As long as an alarm notification is enabled, and the corresponding \*ERR bit is not set, it shall be ensured that no alarm is blocked, lost or cleared.

**Table 479 SSH Safety Notifications Summary**

Alarm	Errors or Events Mapped	Enable	Software Handling / Clearing
CE	- ECC Correction Event Occurred	ECCS.CENE = 1 and ECCS.ECE = 1 and ALMSRCS.SBE = 1	ECCD.CERR has to be cleared to forward further CE alarms. The error is always tracked in the ETRR & ERRINFO registers independent of the value of CERR. If ECE is '0', All enabled ECC errors are notified to the UCE alarm.
UCE	- ECC Uncorrectable Event Detected - Address Error Detected - ETRR Overflow Occurred - Error Critical for SSH Operation Detected (Incl. Critical Safety-FF Errors)	- ECCS.UCENE = 1 and - ALMSRCS.ADDRE = 1, or - ALMSRCS.DBE = 1 or - ECCS.TRE = 1, ALMSRCS.OVFE = 1 and event to set EOF, or - ECCS.ECE = 0 and ALMSRCS.SBE = 1, or - ALMSRCS.OPENE = 1	ECCD.UCERR has to be cleared to forward further UCE alarms. The errors and status are always tracked in the ETRR & ERRINFO & ALMSRCS registers independent of the value of UCERR.
ME	- Less Critical Safety-FF Errors (Enable Bits in ECCS, ALMSRCS) - Disabling of alarm notifications. - Disabling of safety mechanisms.	ECCS.MENE = 1 and - ALMSRCS.MISCE = 1	ECCD.MERR has to be cleared to forward further ME alarms.

### 13.5.2.1 Alarm Handling

As shown in **Table 479**, there are 3 alarms from each SSH, and different events / errors are mapped to each alarm. Each alarm is enabled by the corresponding enable bit in the ECCS register (i.e. ECCS.CENE, UCENE and MENE). When an alarm occurs, the corresponding status flag in the ECCD register is set (i.e. ECCD.CERR; UCERR and MERR).

For the events mapped to each alarm type, there are separate enable bits in the ALMSRCS register (all enabled by default).

For ECC SBE or DBE error event and Address Faults (ADDRE) - the status of the error can be obtained from the ETRR and ERRINFO registers (and ECCD.VALID bits).

Similarly, Error tracking overflow is enabled by setting ALMSRC.OVFE, and an overflow occurs, then the ECCD.EOF bit is set. Of course, the tracking itself happens only if ECCS.TRE = 1 (by default).

For safety reasons, some operational faults are detected which affect the normal operation or access to the SRAM (e.g. SSH gets accidentally enabled, Auto-data-init gets triggered etc). These are also notified via the UCE alarm, and can be enabled via the ALMSRCS register OPENE bit (Operational Error Notification Enable). Please refer to

## Memory Test Unit (MTU)

**“Mapping of Errors to FAULTSTS.OPERR and UCE alarm” on Page 47 and “Mapping of Errors to FAULTSTS.MISCERR and ME alarm” on Page 48** for the error mapping.

**Attention:** *The MTU clock has to be enabled via the MTU\_CLC register to forward any SSH alarm.*

Certain faults do not directly impact the usage of the SRAM, but if left latent, could potentially have a serious effect- for example, the ECC or Address Error notification enable bits or the Alarm enable bits get flipped due to a soft error. Such errors are enabled by the ALMSRCS.MISCE bit.

### 13.5.2.1.1 Alarms after startup

The System Firmware of the AURIX™ TC3xx platform performs certain operations on the SSH, such as configured SRAM initialization (via PROCONRAM register) and timing and redundancy installation. Since these operations involve enabling SSHs and writing to the SRAM, they can trigger SSH alarms, specifically the UCE alarm via the FAULTSTS.OPERR[0] and OPERR[3]. The corresponding alarm status bits are left uncleared as an indication of correct System Firmware execution.

- After any System Reset: For each and every SSH in the system, the UCE alarm status in the SMU, the ECCD.UCERR (Consequently also SERR) and the FAULTSTS.OPERR[0] will be set.
- For SRAMs enabled for initialization via firmware (via PROCONRAM) - additionally the FAULTSTS.OPERR[3] flag will be set after the reset (Warm or Cold Porst) on which SRAM initialization is enabled.
- If the above flags are set, then clear these flags and continue with normal application startup and starup safety checks. It may be assumed that the boot was safely completed with regards to SRAM handling and initialization.
- If any of the flags are not set, it shall be assumed that the System Firmware boot did not safely complete with regards to SRAM handling and initialization. To proceed from such a situation, the application shall follow the recommendations in the safety manual.

**Attention:** *In case of an application reset, there are no SSH alarms or status bits triggered by the system firmware. Hence any alarm or error status after an application reset serves as an indication of a real error.*

**Note:** *The above sequence also applies to the standby controller SRAMs (SCR XRAM & IRAM) - but needs to be taken into account only after a cold-power-on reset and SCR was not enabled; instead of a system reset.*

**Note:** *Special case of EMEM: In case of an emulation device, due to the PROLOG code handling by the System Firmware, the FAULTSTS.MISCERR[1] and [2] will be additionally set in the case of a cold PORST and Warm PORST*

### 13.5.2.1.2 Diagnostics

When an alarm from an SSH occurs, the software has to check multiple registers to diagnose the causes of the fault.

ECCD.CERR, UCERR and MERR bits give the overall status of which alarm occurred.

ETRR/ERRINFO registers store the address and the fault type of a fault in the SRAM (i.e. SBE, DBE or ADDR error).

FAULTSTS register bits store the status of other faults in the SSH itself which are mapped to UCE or ME alarm.

All the error status bits (ETRR, ERRINFO, FAULTSTS, ECCD.VAL, PERMERR & EOV) are preserved until a power-on reset. The alarm status (ECCD.CERR, UCERR, MERR and SERR) are cleared on an application reset.

Software can clear the bits by writing to them (when specified) or by setting the TRC bit as appropriate.

Please refer to **Table 480** and **Table 481** for hints towards runtime error diagnosis and application recovery.

## Memory Test Unit (MTU)

### 13.5.2.1.3 Error Mapping

Both the UCE and the ME alarms have multiple events mapped to them. These events are tapped in such a way that the logic cone that can potentially cause the fault is covered as much as possible.

The OPERR bit in the FAULTSTS register stores the status of various errors critical to SSH or SRAM operation.

**Table 480 Mapping of Errors to FAULTSTS.OPERR and UCE alarm**

Error Status Bit	Error Description during normal application run	Hints for software reaction for recovery
FAULTSTS.OPERR[0]	SSH enabled. Functional access to SRAM is disabled.	Perform an application reset <sup>1)</sup> .
FAULTSTS.OPERR[1]	Auto-data-init or Partial erase (caches) was triggered, resulting in overwriting of SRAM data.	Perform an application reset <sup>2)</sup> .
FAULTSTS.OPERR[2]	Safety Flip-Flop error detected in one of the registers. (After a self test triggered by SFFD, this error has to be taken into account together with MISCERR[0]).	Perform a system reset. - Initialize the SRAM & SSH registers - Trigger a safety flip-flop self test via ECCS.SFFD. - Check that the test does not report a fail (MISCERR[0]).  If the error still persists and cannot be cleared, a warm PORST has to be issued before performing the initialization and safety flip-flop self test.
FAULTSTS.OPERR[3]	MBIST FSM got triggered, test muxes got enabled in the data path, or some other random hardware failure triggered caused data in the SRAM to be overwritten or corrupted by a part of SSH logic. Set when CONFIG1.AG_MOD is switched to non-zero value or MCONTROL.START is set to trigger a test.	Perform an application reset <sup>1)</sup> .

1) For FSI, perform a system reset. For SCR RAMs, a cold PORST is required.

2) For FSI, a system reset is required.

The MISCERR bit in the FAULTSTS register stores the status of various errors which may not be directly critical for SSH or SRAM operation, but if left latent, may result in a critical failure in the future.

## Memory Test Unit (MTU)

**Table 481 Mapping of Errors to FAULTSTS.MISCERR and ME alarm**

Error Status Bit	Error Description during normal application run	Hints for software reaction for recovery
FAULTSTS.MISCERR[0]	This bit can be set only after the software has triggered a Safety Flip-Flop self test via the ECCS.SFFD bit. If the test detected an error and the test failed, this bit is set. (The ME alarm is not triggered in this case).	<p>Perform a system reset.</p> <ul style="list-style-type: none"> <li>- Initialize the SRAM &amp; SSH registers</li> <li>- Trigger a safety flip-flop self test via ECCS.SFFD.</li> <li>- Check that the test does not report a fail (MISCERR[0]).</li> </ul> <p>If the error still persists and cannot be cleared, a warm PORST has to be issued before performing the initialization and safety flip-flop self test.</p>
FAULTSTS.MISCERR[1]	Any of the alarm notifications of UCENE or CENE got disabled (i.e. one or more of the bits CENE or UCENE in the ECCS register went from 1 to 0). Note: ECCS.MENE is protected by Safety Flip Flop.	Re-initialize SSH registers (ECCS).
FAULTSTS.MISCERR[2]	Any of the safety mechanisms got disabled (i.e. ECE, TRE, SBE, DBE, ADDRE, OVFE, OPENE) was set from 1 to 0. Note: ALMSRCS.MISCE is protected by a Safety Flip Flop.	Re-initialize SSH registers (ECCD, ALMSRCS).

**13.5.2.1.4 Error Injection and Alarm Triggering**

To ensure proper behaviour of safety related software, it may be required to inject errors and trigger different safety notifications.

In order to trigger ECC errors (status denoted by ERRINFO.SBERR and DBERR), the ECCMAP bits may be used. When ECCMAP is not equal to 0, then either data or ECC bits alone can be accessed. Using this feature, single or double bit soft errors may be introduced in the SRAM.

Note that ECCMAP is intended for error injection before a test, and shall not be set to non-zero during a test itself.

The Address errors (status denoted by ERRINFO.ADDRERR) may be triggered by setting the SFLE bit, which can force an error into the address by flipping one address bit.

The CE and UCE alarms may be triggered by injecting an ECC or address error.

In order to trigger an ME alarm for test purpose, any of the safety notifications can be simply disabled. This will trigger an ME alarm.

## General Purpose I/O Ports and Peripheral I/O Lines (Ports)

### 14 General Purpose I/O Ports and Peripheral I/O Lines (Ports)

Each Port module “Port slice” controls a set of assigned General Purpose Input/Output (GPIO) port lines which are connected to pads connected to device pins/balls.

#### 14.1 Feature List

Depending on its configuration a Port module can have the following features:

- Controls up to 16 port lines.
- Enables SW to control the output of each port line.
- Output modification registers ease clearing, setting and toggling of single port lines and nibbles of port lines without affecting the state of other port lines.
- Enables SW to read the input value of each port line.
- Multiplexes up to 7 alternate functions to each output.
- Supports direct I/O control by a peripheral on a per line granularity.
- Controls pad characteristics of the assigned pads like drive strength, slew rate, pull-up/down, push/pull or open-drain operation, selection of TTL or CMOS/automotive input levels.
- The emergency stop feature allows to switch off the output driver of configurable port lines by SMU or special port pins.
- For pad pairs with LVDS functionality it controls LVDS characteristics and allows switching between LVDS and CMOS modes.
- In packages with reduced pin count the Port module can disable selected pins.

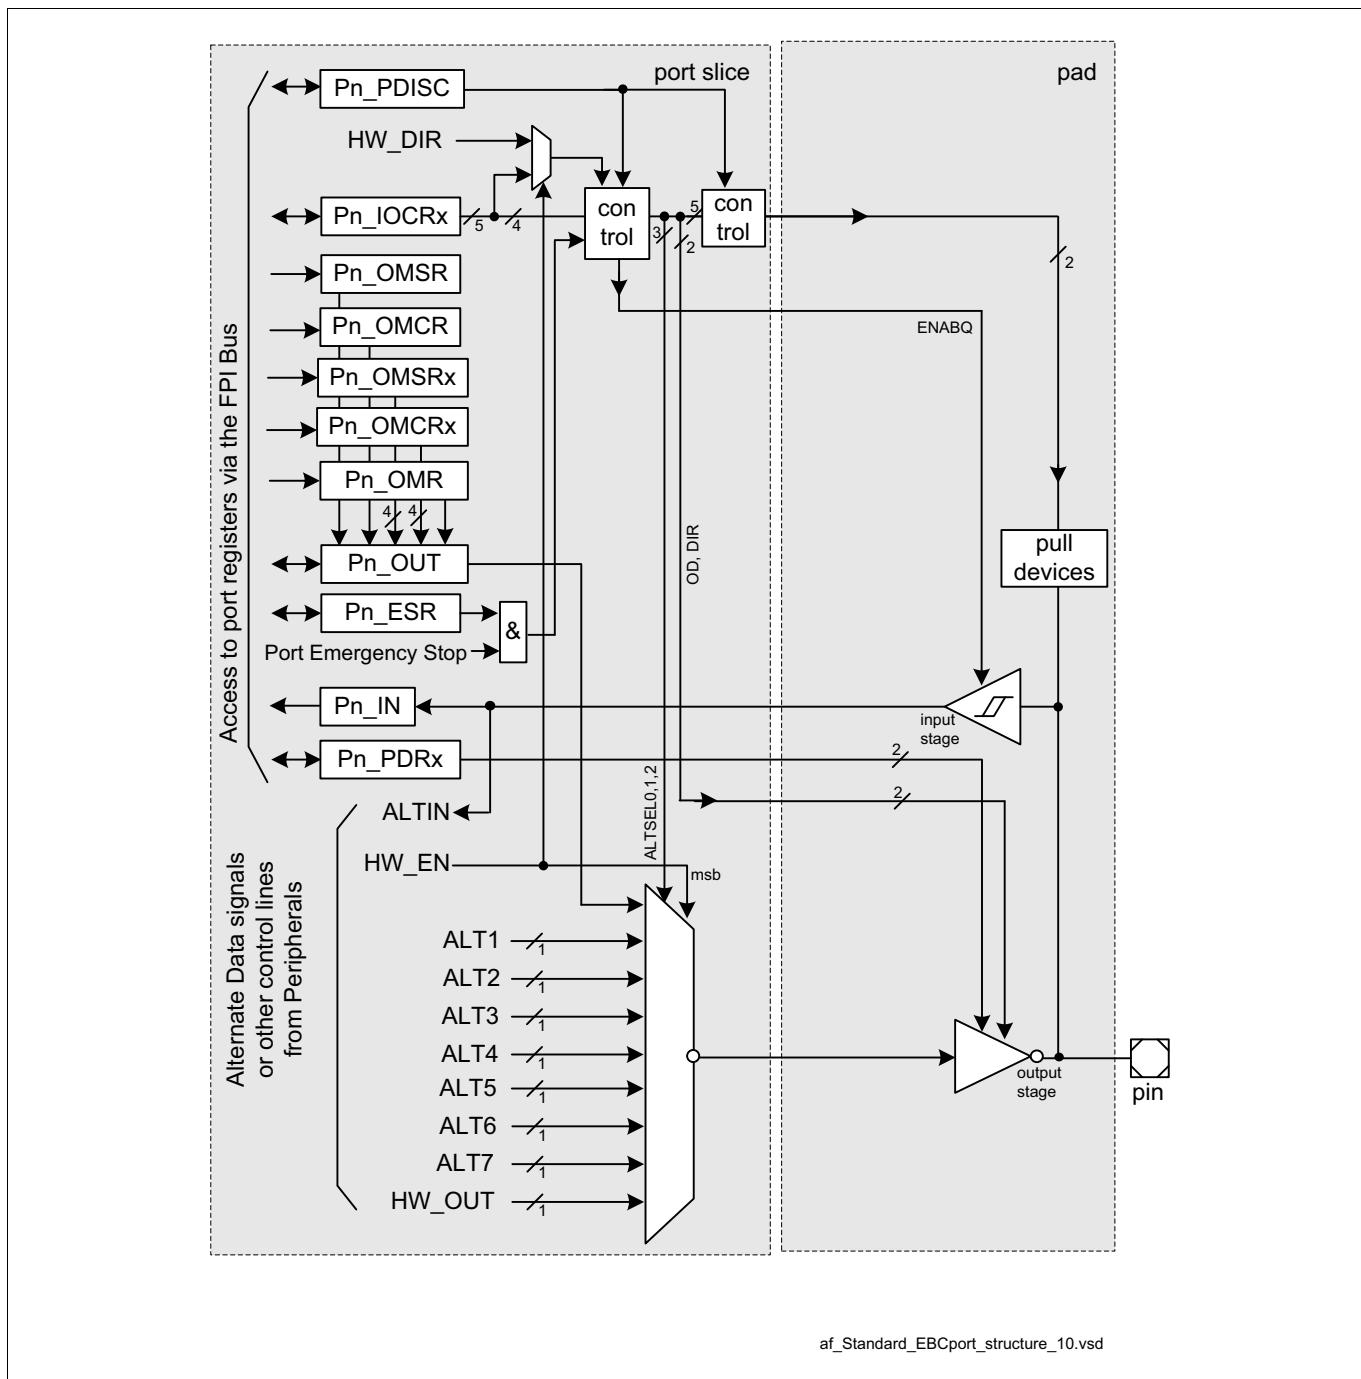

#### Device Dependent Implementation of Ports

The implementation of the Ports is dependent on the device. The configuration is partly done during startup by the Firmware, e.g. to disable pins not available in a certain package. The device specific addendum of this specification describes the configuration.

#### 14.2 Overview

[Figure 156](#) is a general block diagram of a GPIO port slice not showing LVDS functionality.

## General Purpose I/O Ports and Peripheral I/O Lines (Ports)

**Figure 156 General Structure of a Port Pin**

Each port line has a number of control and data bits, enabling very flexible usage of the line. Each port pad can be configured for input or output operation. In input mode (default after reset), the output driver is switched off (high-impedance). The actual voltage level present at the port pin is translated into a logical 0 or 1 via a Schmitt-Trigger device and can be read via the read-only register Pn\_IN. Input signals are connected directly to the various inputs of the peripheral units. The function of the input line from the pin to the input register Pn\_IN and to the peripheral is independent of whether the port pin operates as input or output. This means that when the port is in output mode, the level of the pin can be read by software via Pn\_IN or a peripheral can use the pin level as an input.

In output mode, the output driver is activated and drives the value supplied through the multiplexer to the port pin. Switching between input and output mode is accomplished through the Pn\_IOCR register, which enables or

## General Purpose I/O Ports and Peripheral I/O Lines (Ports)

disables the output driver. If a peripheral unit uses a GPIO port line as a bi-directional I/O line, register Pn\_IOCR has to be written for input or output selection. The Pn\_IOCR register further controls the driver type of the output driver, and determines whether an internal weak pull-up, pull-down, or without input pull device is alternatively connected to the pin when used as an input. This offers additional advantages in an application.

The output multiplexer in front of the output driver selects the signal source for the GPIO line when used as output. If the pin is used as general-purpose output, the multiplexer is switched by software (Pn\_IOCR register) to the Output Data Register Pn\_OUT. Software can set or clear the bit in Pn\_OUT through separate Pn\_OMSR or Pn\_OMCR registers. The set or clear operations for the bits in Pn\_OUT can also be done for up to four bits per register in Pn\_OMSRx and Pn\_OMCRx ( $x=0,4,8,12$ ). Alternatively, the set, clear or toggle function can be achieved through Pn\_OMR, where adjacent pins within the same port can be set, cleared or toggled within one write operation. The manipulation of the control bits in these registers can directly influence the state of the port pin. If the on-chip peripheral units use the pin for output signals, the alternate output lines ALT1 to ALT7 can be switched via the multiplexer to the output driver. The data written into the output register Pn\_OUT by software can be used as input data to an on-chip peripheral. This enables, for example, peripheral tests via software without external circuitry.

When selected as general-purpose output line, the logic state of each port pin can be changed individually by programming the pin-related bits in the Output Modification Set Register Pn\_OMSR, Output Modification Set Register x Pn\_OMSRx ( $x=0,4,8,12$ ), Output Modification Clear Register Pn\_OMCR, Output Modification Clear Register x Pn\_OMCRx ( $x=0,4,8,12$ ) or Output Modification Register, OMR. The bits in Pn\_OMSR/Pn\_OMSRx and Pn\_OMCR/Pn\_OMCRx make it possible to set and clear the bits in the Pn\_OUT register. While the bits in Pn\_OMR allows the bits in Pn\_OUT to be set, cleared, toggled or remain unchanged.

When selected as general-purpose output line, the actual logic level at the pin can be examined through reading Pn\_IN and compared against the applied output level (either applied through software via the output register Pn\_OUT, or via an alternate output function of a peripheral unit). This can be used to detect some electrical failures at the pin caused through external circuitry. In addition, software-supported arbitration schemes can be implemented in this way using the open-drain configuration and an external wired-And circuitry. Collisions on the external communication lines can be detected when a high level (1) is output, but a low level (0) is seen when reading the pin value via the input register Pn\_IN.

Most of the digital GPIO lines have an emergency stop logic<sup>1)</sup>. This logic makes it possible to individually disconnect outputs and put them onto a well defined logic state in an emergency case. In an emergency case, the pin is switched to input function with internal pull-up device connected or tri-state (depending on global configuration). The Emergency Stop Register Pn\_ESR determines whether an output is enabled or disabled in an emergency case.

### LVDS Port Operation

The LVDS pads offer LVDS RX or TX functionality for a pair of pins (see Pinning). Additionally they contain — if not specified differently — a bidirectional CMOS pad for each of the pins. The CMOS functionality is controlled by above described set of standard registers. The LVDS functionality is controlled by additional Pn\_LPCR registers ([Chapter 14.4.4](#)).

## 14.3 Functional Description

The following description add further details to [Chapter 14.2](#).

### 14.3.1 System Connectivity of Ports

The connectivity of the Ports is described in the pinning tables. These are contained in the Data Sheet.

1) This feature is not available for all port lines, for details see Data Sheet.

## General Purpose I/O Ports and Peripheral I/O Lines (Ports)

**Table 483 Example Port Table**

Pin	Symbol	Ctrl.	Buffer Type	Function	
10	Pxx.y	I	FAST / PU1 / VEXT	<b>General-purpose input</b>	
	TIMm_n			<b>GTM_TIN</b>	
	Pxx.y	O0		<b>General-purpose output</b>	
	TOMa_b	O1		<b>GTM_TOUT</b>	
	TOMc_d			<b>GTM_TOUT</b>	
	IOM_REFv_w	O2		<b>IOM reference input</b>	
	ASCLINz RTS			<b>ASCLIN0 output</b>	
	...	...		...	
	ETH0_MDIO	O		<b>Ethernet output</b>	

The symbols in the **Ctrl.** column indicate the multiplexer connectivity:

I = Input (for GPIO port lines with IOCR bit field Selection  $PCx = 0XXX_B$ )

AI = Analog input

O = Output (the assigned function is active when a peripheral takes control of the port line)

O0 = Output with IOCR bit field selection  $PCx = 1X000_B$  (Pxx.y)

O1 = Output with IOCR bit field selection  $PCx = 1X001_B$  (ALT1)

O2 = Output with IOCR bit field selection  $PCx = 1X010_B$  (ALT2)

O3 = Output with IOCR bit field selection  $PCx = 1X011_B$  (ALT3)

O4 = Output with IOCR bit field selection  $PCx = 1X100_B$  (ALT4)

O5 = Output with IOCR bit field selection  $PCx = 1X101_B$  (ALT5)

O6 = Output with IOCR bit field selection  $PCx = 1X110_B$  (ALT6)

O7 = Output with IOCR bit field selection  $PCx = 1X111_B$  (ALT7)

To each input several functions can be connected. The peripherals' configuration defines if this input is used.

The port module decides which of the 8 output signals O0 to O7 drives the pad.

Some Ox rows list more than one function, e.g. several TOM outputs and IOM reference inputs. The GTM module (see corresponding chapter) has its own sub-multiplexer structure that defines which of the GTM sub-units drives this signal. Additionally the IOM modules "listens" on these output signals (see IOM chapter).

### Pins without Port module

The pinning of some devices shows Px.y pins without assigned Port module "Px". This is the case for RIF module pins (P50.y and P51.y) for which the RIF module itself contains the necessary control registers.

### Control of Port Line by Peripheral (HW\_DIR/HW\_EN/HW\_OUT)

By using the HW\_DIR/HW\_EN/HW\_OUT interface (see [Figure 156](#)) a peripheral can take over control of the output path of a port line. When the peripheral activates HW\_EN its data line connected to HW\_OUT is driven to the output driver. With HW\_DIR the peripheral can control the output driver activation. The data line connected to HW\_OUT is shown in the "O" rows in the pinning tables.

When a peripheral activates HW\_DIR and HW\_EN the output driver operates in push/pull mode.

**Note:** *The SMU uses for FSP1 this interface therefore FSP1 operates in push/pull mode. For FSP0 the SMU takes direct control of the output pad by copying the configuration of this pad from the Port module. Therefore FSP0 can operate also in open-drain mode. For details of this cooperation see SMU chapter.*

## General Purpose I/O Ports and Peripheral I/O Lines (Ports)

### 14.4 Registers

The following describes the register set of a generic fully featured Port module.

**Note:** *Destructive read is not implemented in any of the registers.*

**Note:** *Parallel requests from on chip bus masters to the ports module are executed sequentially via the on chip bus system. Read-modify-write feature provides an atomic read/write sequence where no other master can access the ports module in between the operations*

#### Implementation

The implemented port modules are derived from this generic module. Registers for unavailable functionality are usually not implemented. **Table 484** describes general rules for realization of registers with unavailable Port lines. The exact description of each register can be found in the device specific appendix.

**Table 484 Register Behavior of Unavailable Port Lines**

Register	Behavior
Pn_OUT, Pn_ESR, Pn_PDR0, Pn_PDR1, Pn_IOCRx (x=0-3), Pn_PDISC	The unused control fields within the same nibble pin group as available pins are "rw", returns value that was last written and must be written with reset value. Otherwise, these unused control fields are 'r', read as 0 and should be written with reset value.
Pn_OMR, Pn_OMSR, Pn_OMSRx, Pn_OMCR, Pn_OMCRx, (x=0-3)	The unused control fields within the same nibble pin group as available pins are able to control Pn_OUT. Otherwise, these unused control fields do not have an influence on Pn_OUT.
Pn_LPCRx	These registers are only implemented for pad pairs with LVDS functionality.
Pn_PCSR	These register are always implemented but mostly reserved. They configure Tricore/SCR control, Ethernet fast RGMII/RMII/MII mode, VADC PDD/MDD feature.

### 14.4.1 Module Identification Register

#### Port n Identification Register

The module Identification Register ID contains read-only information about the module version.

Field	Bits	Type	Description
<b>MODREV</b>	7:0	r	<b>Module Revision Number</b> This bit field indicates the revision number of the AURIX™ TC3xx Platform module (01 <sub>H</sub> = first revision).
<b>MODTYPE</b>	15:8	r	<b>Module Type</b> This bit field is C0 <sub>H</sub> . It defines a 32-bit module
<b>MODNUMBER</b>	31:16	r	<b>Module Number</b> This bit field defines the module identification number. The value for the Ports module is 00C8 <sub>H</sub>

## General Purpose I/O Ports and Peripheral I/O Lines (Ports)

### 14.4.2 Port Input/Output Control Registers

#### Port n Input/Output Control Register 0

The port input/output control registers select the digital output and input driver functionality and characteristics of a GPIO port pin. Port direction (input or output), pull-up, pull-down, or no pull devices for inputs, and push-pull or open-drain functionality for outputs can be selected by the corresponding bit fields PCx (x = 0-15). Each 32-bit wide port input/output control register controls four GPIO port lines:

Register Pn\_IOCRO controls the Pn.[3:0] port lines

Register Pn\_IOCRA controls the Pn.[7:4] port lines

Register Pn\_IOCRA8 controls the Pn.[11:8] port lines

Register Pn\_IOCRA12 controls the Pn.[15:12] port lines

The structure with one control bit field for each port pin located in different register bytes offers the possibility to configure the port pin functionality of a single pin with byte-oriented accesses without accessing the other PCx bit fields.

The reset values of  $1010\ 1010_H$  and  $0000\ 0000_H$  for Pn\_IOCRAx registers represents input pull-up and no input pull device (tri-state mode) being activated, respectively. The switching of the intended mode of the device is controlled by HWCFG6. When a cold reset is activated and HWCFG6=1, the port pins except P33.8, P40 and P41 are set to input pull-up mode, P33.8, P40 and P41 are in tri-state mode as long as PORST is activated. If HWCFG6=0, the pins have the default state of tri-state mode. The pad state can also be configured by software through PMSWCR5.TRISTREQ bit. In the event of a warm reset or wake-up from standby mode, PMSWCR5.TRISTREQ is not affected by reset, hence Pn\_IOCRAx registers have the reset values configured as per the last state of the TRISTREQ bit.

**Note:** *In LVDS (RX and TX) operation the IOCRA register of both pins of the LVDS pair must be configured as output, i.e.  $1xxxx_B$ . This ensures that the pull devices are disconnected and don't interfere with LVDS operation.*

Register Pn\_IOCRO controls the Pn.[3:0] port lines

#### IOCRO

#### Port n Input/Output Control Register 0 (010<sub>H</sub>) Reset Value: [Table 487](#)

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

### Output Characteristics

The pad structure of the GPIO lines offers the possibility to select the output driver strength and the slew rate. These two parameters are controlled by the PDX bit fields in the pad driver mode registers Pn\_PDR0/1 for output modes. The available modes depend on the respective pad type.

**Table 497 Pad Driver Mode Selection for RFast Pads**

PDX.1	PDX.0	Speed Grade	Driver Setting
0	0	1	Strong driver, sharp edge ("ss")
0	1	2	Strong driver, medium edge ("sm")
1	0	3	Medium driver ("m")
1	1	4	RGMII driver.

**Table 498 Pad Driver Mode Selection for Fast Pads**

PDX.1	PDX.0	Speed Grade	Driver Setting
0	0	1	Strong driver, sharp edge ("ss")
0	1	2	Strong driver, medium edge ("sm")
1	0	3	Medium driver ("m")
1	1	4	TC39x A-Step: Medium driver ("m") Else: Reserved when operating as output. When operating as input see below "Pad Level Selection for Input Function".

**Table 499 Pad Driver Mode Selection for Slow Pads**

PDX.1	PDX.0	Speed Grade	Driver Setting
X	0	1	Medium driver, sharp edge ("sm") <sup>1)</sup>
X	1	2	Medium driver ("m")

1) This setting is marked "sm" as the electrical characteristics are identical to the strong driver medium edge setting. The Data Sheet contains also only common "sm" tables.

**Note:** The Data Sheet describes the DC characteristics of all pad classes.

## General Purpose I/O Ports and Peripheral I/O Lines (Ports)

### TTL/Automotive Input Selection

The input function can operate with different VIH and VIL levels depending on the pad supply voltage, the pad type and the selection done by the PLx bits of the Pn\_PDRx as of [Table 500](#). PLx.1 changes additionally the pull-up and pull-down resistors.

**Table 500 Pad Level Selection for Input Function**

PLx.1	PLx.0	Input Levels
0	X	Automotive level “AL”.
1	0	TTL level for 5V pad supply. Degraded TTL level used for CIF when pad supply is 3.3V
1	1	TTL level for 3.3V pad supply.
X	X	Only for pads with RGMII input buffer (marked “RGMII_Input” in the pinning table): <ul style="list-style-type: none"> <li>when PDx.1=1 and PDx.0=1 the input level RGMII is selected.</li> <li>for other PDx values the input level is determined by PLx as for all other pads (first three rows of this table).</li> </ul>

### LVDS

The default CMOS mode can be switched to LVDS mode in LVDS pads through the LPCRx register.

### Pad Driver Mode Registers

This is the general description of the PDR registers. Each port contains its own specific PDR registers, described additionally at each port, that can contain between one and eight PDx fields for PDR0 and PDR1 registers, respectively. Each PDx field controls 1 pin. For coding of PDx, see [Table 497](#), [Table 498](#) and [Table 499](#). Similarly, each PLx bit controls 1 pin. For coding of PLx, see [Table 500](#).

The boot software configures the reset value of Pn\_PDR0 and Pn\_PDR1 registers from 0000 0000<sub>H</sub> to 2222 2222<sub>H</sub> except for analog ports and if the package doesn't make any of the related pins available. The resulting value depends on the implemented port width. The documented value is valid for the largest package.

#### **14.4.4 LVDS Pad Control Register**

## **Port n LVDS Pad Control Register x**

The LVDS Pad Control Register controls the RX or TX functions of the LVDS pads. For usage of RX pad, bit field [7:0] are applicable. If used for TX pad, bit field [15:7] apply.

The sleep functionality of the LVDS pads is not controllable via this register. This is exclusively controlled by the HSCT module when this is connected.

The register  $x$  controls in general the pad pair  $2^*x$  and  $2^*x+1$  of the port  $n$ .

Exceptionally when available the pad pair P14.9 and P14.10 is controlled by P14\_LPCR5.

**Attention:** The bit field P21\_LPCR2.PS configures the pad supply for the LVDS bias distributor for all (not-RIF) LVDS pads and for the oscillator. Therefore even if no LVDS pad is used, this field has to be configured to the correct pad supply level.

LPCR<sub>x</sub> (x=0-7)

## **Port n LVDS Pad Control Register x**

$$(0A0_H + x^*4)$$

## General Purpose I/O Ports and Peripheral I/O Lines (Ports)

### 14.4.5 Pin Function Decision Control Register

#### Port n Pin Function Decision Control Register

The pad structure of the GPIO lines offers the possibility to disable/enable port pad, select digital input or analog ADC input functionalities. Note that Class S pads have different characteristics than other digital input pads. For analog inputs, setting PDISx to 1 disables the Schmitt trigger input buffer, which would otherwise reduce analog input accuracy. For the ADC diagnostic features “PDD” and “MD” however the corresponding PDISx needs to be 0 to allow activation of their pull resistors. This feature can be controlled by individual bits in the Pn\_PDISC register, independently from input/output and pull-up/pull-down control functionality as programmed in the Pn\_IOCR register. One Pn\_PDISC register is assigned to each port.

**Note:** After reset, all Px\_PDISC registers have the reset value of  $0000\ 0000_H$ . The startup software enables only the pads with digital input/output functionality which are available in that package. P40\_PDISC and P41\_PDISC are configured by the SSW for analog input function (kept disabled). The documented reset value shows the value in the largest package.

### 14.4.6 Pin Controller Select Register

#### Port n Pin Controller Select Register

This register has different functionality in each port:

- In Ports shared with the standby controller (SCR) it selects if the SCR or the Tricore system control data and control functions of these port lines.
- In Ports with analog inputs to the EVADC it enables control of pull by the EVADC for the Pull Down Diagnostics (PDD) / Multiplexer Diagnostics (MD) feature.
- In Ports with Ethernet output it selects between alternate output and fast RGMII/RMII/MII mode.
- In Ports with SMU FSP pin (P33.8) the PCSR.SEL bit enables the SMU to override pad configuration signals. Therefore this bit has the reset value 1<sub>B</sub> and shall be kept 1<sub>B</sub> by the application. The SMU override is documented in the SMU chapter (see SMU\_PCTL.PCFG and Figure “SMU/PAD Control Interface to the PADs”).

### 14.4.7 Port Output Register

#### Port n Output Register

The port output register determines the value of a GPIO pin when it is selected by Pn\_IOCRx as output. Writing a 0 to a Pn\_OUT.Px (x = 0-15) bit position delivers a low level at the corresponding output pin. A high level is output when the corresponding bit is written with a 1. Note that the bits of Pn\_OUT.Px can be individually set or cleared by writing appropriate values into the port output modification set register Pn\_OMSR or port output modification clear register Pn\_OMCR, respectively. The Pn\_OUT.Px bits can also be set, cleared or toggled with register Pn\_OMR within the same write operation.

Field	Bits	Type	Description
ENx (x=0-15)	x	rw	<b>Emergency Stop Enable for Pin x</b> This bit enables the emergency stop function for all GPIO lines. If the emergency stop condition is met and enabled, the output selection is automatically switched from alternate output function to GPIO input function. 0 <sub>B</sub> Emergency stop function for Pn.x is disabled. 1 <sub>B</sub> Emergency stop function for Pn.x is enabled.
0	31:16	r	<b>Reserved</b> Read as 0; should be written with 0.

**Table 521 Access Mode Restrictions of ESR sorted by descending priority**

Mode Name	Access Mode		Description
Master enabled in ACCEN and Supervisor Mode and ENDINIT	rw	ENx (x=0-15)	write access for enabled masters
Otherwise (default)	r	ENx (x=0-15)	

Most GPIO lines have an emergency stop logic implemented (see Figure “General Structure of a Port Pin” in the Family chapter).

Each of these GPIO lines has its own emergency stop enable bit ENx that is located in the emergency stop register Pn\_ESR of Port n. If the emergency stop signal becomes active, one of two states can be selected:

- Emergency stop function disabled (ENx = 0):  
The output line remains connected (alternate function).
- Emergency stop function enabled (ENx = 1):  
The mapped output function is disconnected and the safe state is entered by switching to input function with internal pull-up connected or tri-state, depending on the configured reset value of the corresponding Pn\_IOCR register through PMSWCR5.TRISTREQ or setting of HWCFG[6].(the content of the corresponding PCx bit fields in register Pn\_IOCR will not be considered).

## General Purpose I/O Ports and Peripheral I/O Lines (Ports)

### Exceptions for Emergency Stop Implementation

The Emergency Stop function is available for all GPIO Ports with the following exceptions:

- Not available for P20.2 (General Purpose Input/GPI only, overlayed with Testmode)
- Not available for P40.x and P41.x (analog input ANx overlayed with GPI)
- Not available for P32.0 and P32.1 when using EVRC regulator.
- Not available for P21.2 (used as EMGSTOPB pin).
- Not available for P33.8 (used as EMGSTOPA pin).
- Not available for dedicated I/O without General Purpose Output function (e.g ESRx, TMS, TCK)

The Emergency Stop function can be overruled on the following GPIO Ports:

- P00.x: Emergency Stop can be overruled by the VADC. Overruling can be disabled via the control register P00\_PCSR.
- P14.0 and P14.1: Emergency Stop can be overruled in the DXCPL (DAP over CAN physical layer) mode. No Overruling in the DXCM (Debug over can message) mode
- P21.6: Emergency Stop can be overruled in JTAG mode if this pin is used as TDI
- P21.7: Emergency Stop can be overruled in JTAG or Three Pin DAP mode.
- P33.0-7, P33.9-15 and P34.1: Emergency Stop can be overruled by the 8-Bit Standby Controller (SCR), if implemented. Overruling can be disabled via the control register P33\_PCSR and P34\_PCSR.

On pins with LVDS TX pads the Emergency Stop affects only the CMOS driver not the LVDS driver. Thus only when LPCRx.TX\_EN selects CMOS mode the output is switched off. When TX\_EN selects LVDS mode the output is not switched off.

### 14.4.14 Port Input Register

#### Port n Input Register

The logic level of a GPIO pin can be read via the read-only port input register Pn\_IN. Reading the Pn\_IN register always returns the current logical value at the GPIO pin independently whether the pin is selected as input or output.

IN															
Port n Input Register (024 <sub>H</sub> ) Application Reset Value: 0000 XXXX <sub>H</sub>

Field	Bits	Type	Description
0	31:16	r	<b>Reserved</b> Read as 0.

#### **14.4.15 Access Protection Registers**

## **Port n Access Enable Register 0**

Each port has its own dedicated ACCEN0 and ACCEN1 registers.

The Access Enable Register 0 controls write<sup>1)</sup> access for transactions with the on chip bus master TAG ID 000000B to 011111B (see On Chip Bus chapter for the products TAG ID <-> master peripheral mapping). The BPI\_FPI is prepared for a 6-bit TAG ID. The registers ACCEN0 and ACCEN1 are providing one enable bit for each possible 6-bit TAG ID encoding.

Mapping of TAG IDs to ACCENO.ENx: EN0 -> TAG ID 000000B, EN1 -> TAG ID 000001B , ... , EN31 -> TAG ID 011111B.

ACCENO

## **Port n Access Enable Register 0**

(OFC<sub>H</sub>)

## **Application Reset Value: FFFF FFFF**

Field	Bits	Type	Description
<b>ENx (x=0-31)</b>	x	rw	<p><b>Access Enable for Master TAG ID x</b></p> <p>This bit enables write access to the module kernel addresses for transactions with the Master TAG ID n</p> <p>0<sub>B</sub> Write access will not be executed</p> <p>1<sub>B</sub> Write access will be executed</p>

## General Purpose I/O Ports and Peripheral I/O Lines (Ports)

### 14.5 Revision History

**Table 524 Revision History from V1.8.19 to the latest revision**

Reference	Changes to Previous Version	Comment
<b>V1.8.20</b>		
<a href="#">Page 34</a>	Revision History entries up to V1.8.19 removed.	
<a href="#">Page 8</a>	Removed confusing phrase “, only input selection apply.” from register IOCRx from bitfield description of PC.	
-	Only cosmetic change: register documentation generator merges more reserved bit fields (e.g. “0” or “1” bit fields).	
<b>V1.8.21</b>		
<a href="#">Page 1</a>	Removed “hysteresis” in Feature List from bullet point “Controls pad characteristics of the assigned pads like drive strength, slew rate, pull-up/down, hysteresis, ...”	

---

**Safety Management Unit (SMU)****15      Safety Management Unit (SMU)**

## Safety Management Unit (SMU)

### 15.1 Feature List

The SMU implements the following features:

- Collects every alarm signal generated from safety mechanisms
- Alarm flags are stored in a diagnosis register that is only reset by the Power-on reset, to enable fault diagnosis and possible recovery.
- An alarm emulation facility is provided to enable software-based diagnostics to post an alarm condition with the same properties as the hardware alarms.
- Implements the access protection and Safety ENDINIT modes to protect configuration registers.
- Implements a Fault Signaling Protocol (FSP) reporting internal faults to the external environment. The FSP can be configured using the following modes:
  - Bi-stable single pin output, also called ErrorPin (push-pull active low configuration using SMU\_FSP0)
  - Timed dual rail coding using two inverted values on the ErrorPins (SMU\_FSP0 and SMU\_FSP1)
  - Single-bit timed protocol using the ErrorPin
- The FSP value driven by the microcontroller can be observed via the FSP Status Register.
  - Additionally a monitor is available to check the timing and state properties of the FSP protocol when a fault is reported.
- After power-on reset the FSP is disabled. Software needs to connect the FSP to port using the Port Control Register
- Each individual alarm can be configured to activate the fault signaling protocol.
- Two SMU instance: one located in the core domain called SMU\_core and another in the stand-by domain called SMU\_stby
- Alarms processed in SMU\_core can be configured to activate one of the following internal actions:
  - generate an interrupt request to any of the CPUs, concurrent interrupts to several CPUs can be configured
  - generate a NMI request to the System Control Unit
  - generate a reset request to the System Control Unit
  - activate the Port Emergency Stop signal controlling the safe state of output pads
  - generate a CPU reset request
- All power and temperature related alarms are processed in a diverse way by both the SMU\_core and SMU\_stby.
- Implements an SMU Alive alarm which signals if the SMU\_core is not triggering the configured reaction when an alarm is raised.
- After reset every alarm reaction, except for watchdog time-out alarm, is disabled.
- A lock mechanism is available to protect the SMU configuration
- Implements internal watchdog(s) time-out pre-warning function.
- Implements an internal watchdog called recovery timer to monitor the execution of critical software error handlers. The watchdog is started automatically by hardware according to configurable alarm events.

### 15.2 Overview

The SMU is a central component of the safety architecture providing a generic interface to manage the behavior of the microcontroller under the presence of faults. The SMU centralizes all the alarm signals related to the different hardware and software-based safety mechanisms. Each alarm can be individually configured to trigger internal actions and/or notify externally the presence of faults via a fault signaling protocol. The severity of each alarm shall be configured according to the needs of the safety application(s): per default every alarm reaction is

## Safety Management Unit (SMU)

disabled with the exception of the watchdog time-out alarms. For debug and diagnosis purposes the alarm signals set a sticky bit, which is resilient to application or system resets. The SMU also implements some housekeeping functions related to the management and test of dedicated safety mechanisms. A special test mode is available to test the SMU itself enabling to detect latent faults. In addition to the register access protection, the SMU implements a configuration locking mechanism. Moreover, in order to mitigate the potential common cause faults, the SMU is partitioned in two parts:

- SMU\_core: located in the core domain
- SMU\_stby: located in the stand-by domain

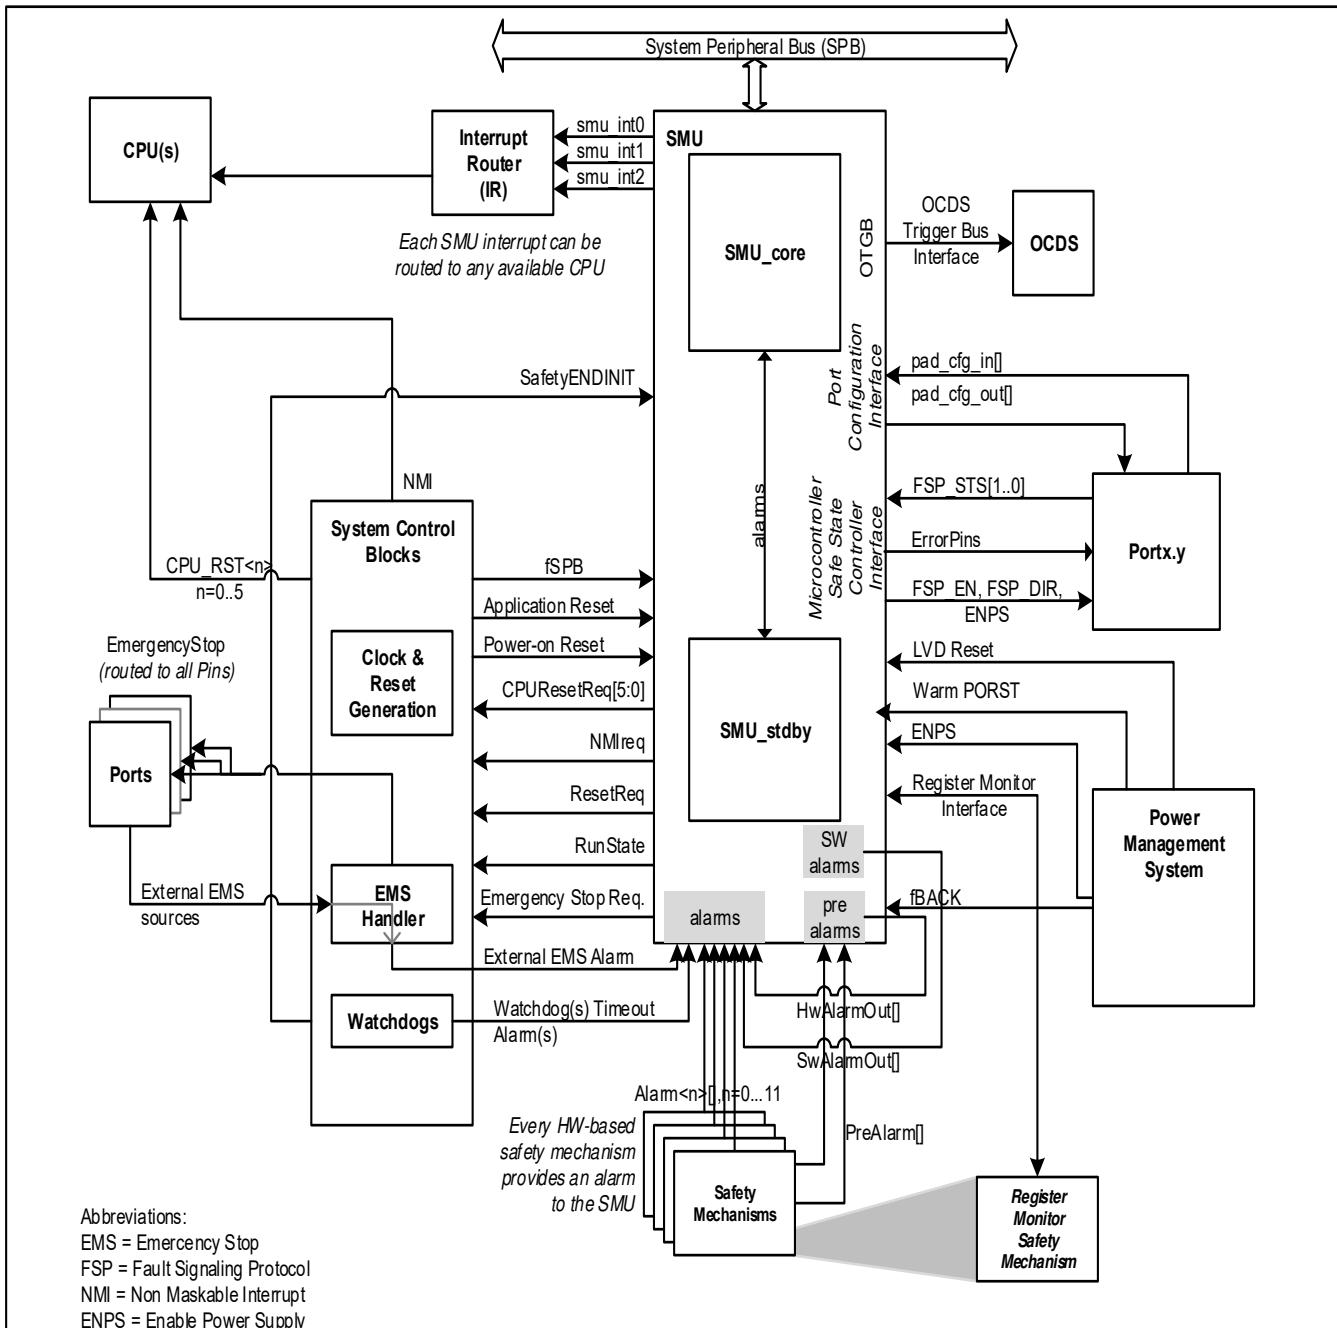

The SMU\_core and SMU\_stby are diverse in the way they are designed and in their timing. There is a physical isolation between the two parts of the SMU. They are located in different clock and power domains. This allows the SMU to process any incoming alarm regardless of the frequency of the clock used to generate this alarm. Also, alarm events generated on fSPB (or derivatives) will be processed by the SMU\_core and alarm events generated on fBACK by the SMU\_stby. This way, all Clock Alive Monitor alarms are processed in the same clock domain as they are generated. Moreover, power and temperature related alarms are processed in a diverse way since they are processed by both SMU\_core and SMU\_stby. One or more reactions to these alarms could be configured in the SMU\_core or the SMU\_stby.

Also, in order to detect errors in the SMU\_core an alarm, **smu\_core\_alive**, is sent from the SMU\_core to the SMU\_stby. The reaction to these alarms is configurable in both domains. However, for the SMU\_stby, only no reaction or setting the ErrorPins in high impedance state can be configured as an alarm reaction.

The SMU in combination with the embedded safety mechanisms enable to detect and report more than 99% of the critical failure modes of the microcontroller within the fault tolerance time interval. The timing characteristics of the fault tolerance time interval can be configured in the SMU.

**Figure 157** gives an overview of the SMU interfaces.

## Safety Management Unit (SMU)

**Figure 157 SMU Interfaces**

### 15.2.1 Architecture

Figure 158 gives an overview of the SMU architecture.

## Safety Management Unit (SMU)

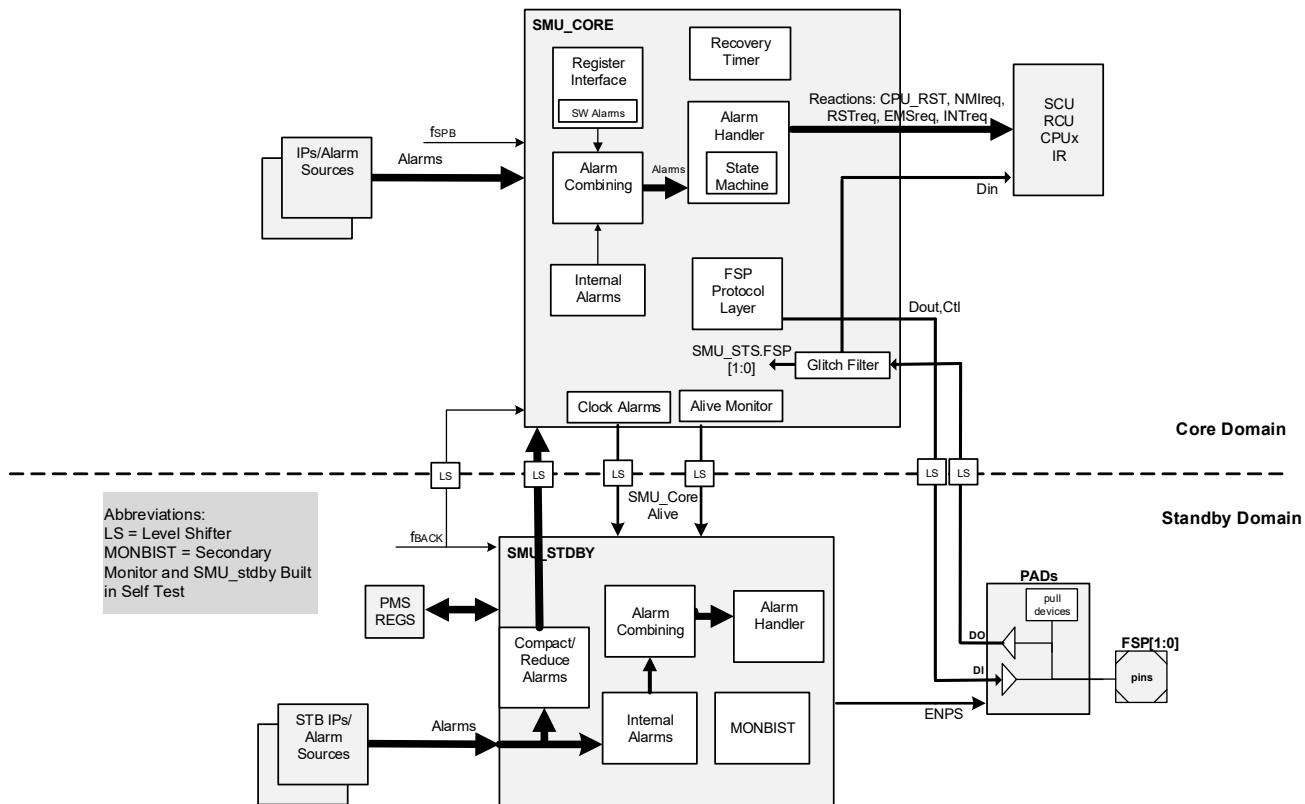

Figure 158 SMU Architecture

### 15.2.2 SMU\_core

The core domain SMU, also called SMU\_core, collects the majority of the alarms signals from the hardware monitors, safety mechanisms, defined by the safety concept. The section **Alarm Mapping** specifies the alarm interface and classifies them into alarm groups. The alarm groups define a logical mapping used to map alarm signals to internal status registers. The section **Alarm Handling** describes the configuration options. The configuration options specify the behavior of the SMU\_core when an alarm event is detected. The alarm event can trigger an internal action and/or the activation of the ErrorPin(s) that indicates the presence of a fault to the external environment. The section **SMU\_core Control Interface** specifies how the SMU\_core can be controlled by software and the dependencies with the hardware operation. The section **Fault Signaling Protocol (FSP)** describes the properties of the external fault signaling protocol defining the timing and logical properties of the ErrorPin(s).

### 15.2.3 SMU\_stdby

The stand-by domain SMU, also called SMU\_stdby, collects alarms from modules which detect clock (no clock), power (under/over voltage) and temperature failures (under/over temperature). The SMU\_stdby also collects the SMU\_alive alarm signal which notifies when the SMU\_core is not triggering a reaction after an alarm is raised. Moreover, the SMU\_stdby implements a **Built-In Self Test** feature which allows users to test the SMU\_stdby reaction to alarm signals and the complete alarm path from the Secondary Voltage Monitor to the SMU\_stdby. Please refer to the Power Management System chapter for more details on the Secondary Monitor and SMU\_stdby Built in Self Test.

The section **Alarm Mapping** specifies the alarm interface and classifies them into two alarm groups. The section **Alarm Handling** describes the configuration options that can be specified. The configuration options specify the behavior of the SMU\_stdby when an alarm event is detected. The alarm event can trigger the activation of the ErrorPins that indicates the presence of a fault to the external environment.

## Safety Management Unit (SMU)

### 15.3 Functional Description

This section describes the SMU\_core, the SMU\_stby and the interdependencies between them.

#### 15.3.1 SMU\_core

##### 15.3.1.1 Reset Types

The SMU\_core requires multiple reset types. The reset types are fully specified in the System Control Units. The reset types that are required by the SMU\_core are:

- Power-on Reset
- System Reset
- Debug Reset
- Application Reset

**Table 525** specifies the scope of each reset type to the SMU\_core control configuration and logic.

**Table 525 Effect of Reset Types to SMU functionality**

SMU Function	Application Reset	Debug Reset	System Reset	Power-on Reset
SMU_core FSP Function <a href="#">Chapter 15.3.1.8</a>	Not Affected	Not Affected	Not Affected	Reset
SMU_core State Machine Function <a href="#">Chapter 15.3.1.7</a>	Not Affected	Not Affected	Not Affected	Reset
SMU_core Debug Function <a href="#">Chapter 15.3.1.9</a>	Not Affected	Reset	Not Affected	Reset

SMU_core SPB BPI	Reset	Not Affected	Reset	Reset
SMU_core Other Functions	Reset	Not Affected	Reset	Reset

#### 15.3.1.2 Interfaces Overview

This section describes the interface signals between the SMU\_core and other modules.

##### 15.3.1.2.1 Interfaces to SCU

Internal actions resulting from an alarm event that interface to the System Control Unit. The interface signals are:

- Emergency Stop Request
- Reset Request
- NMI Request

## Safety Management Unit (SMU)

- CPU Reset Request

### 15.3.1.2.2 Interfaces to the Interrupt Router

Internal actions resulting from an alarm event that interface to the Interrupt Router. The interface signals are:

- SMU Interrupt Service Request 0
- SMU Interrupt Service Request 1
- SMU Interrupt Service Request 2

The mapping of SMU Interrupt Service Requests to the Interrupt Router (IR) interrupt nodes can be found in the Interrupt Router chapter (SRC\_SMUy, y=0..2).

The **AGC.IGCSx**, x={0,1,2} register fields provide the software interface to control how the SMU triggers interrupt requests to the interrupt router.

Each **AGC.IGCSx** is a 3-bits bit-field:

- **AGC.IGCSx[0]** shall be set to ‘1’ to trigger SMU Interrupt Service Request 0
- **AGC.IGCSx[1]** shall be set to ‘1’ to trigger SMU Interrupt Service Request 1
- **AGC.IGCSx[2]** shall be set to ‘1’ to trigger SMU Interrupt Service Request 2

The usage of the three **AGC.IGCSx** bit-fields is defined in [Alarm Configuration](#);

### 15.3.1.2.3 Interface to the Ports (ErrorPin)

The generic port structure is presented in presented in [Figure 159](#).

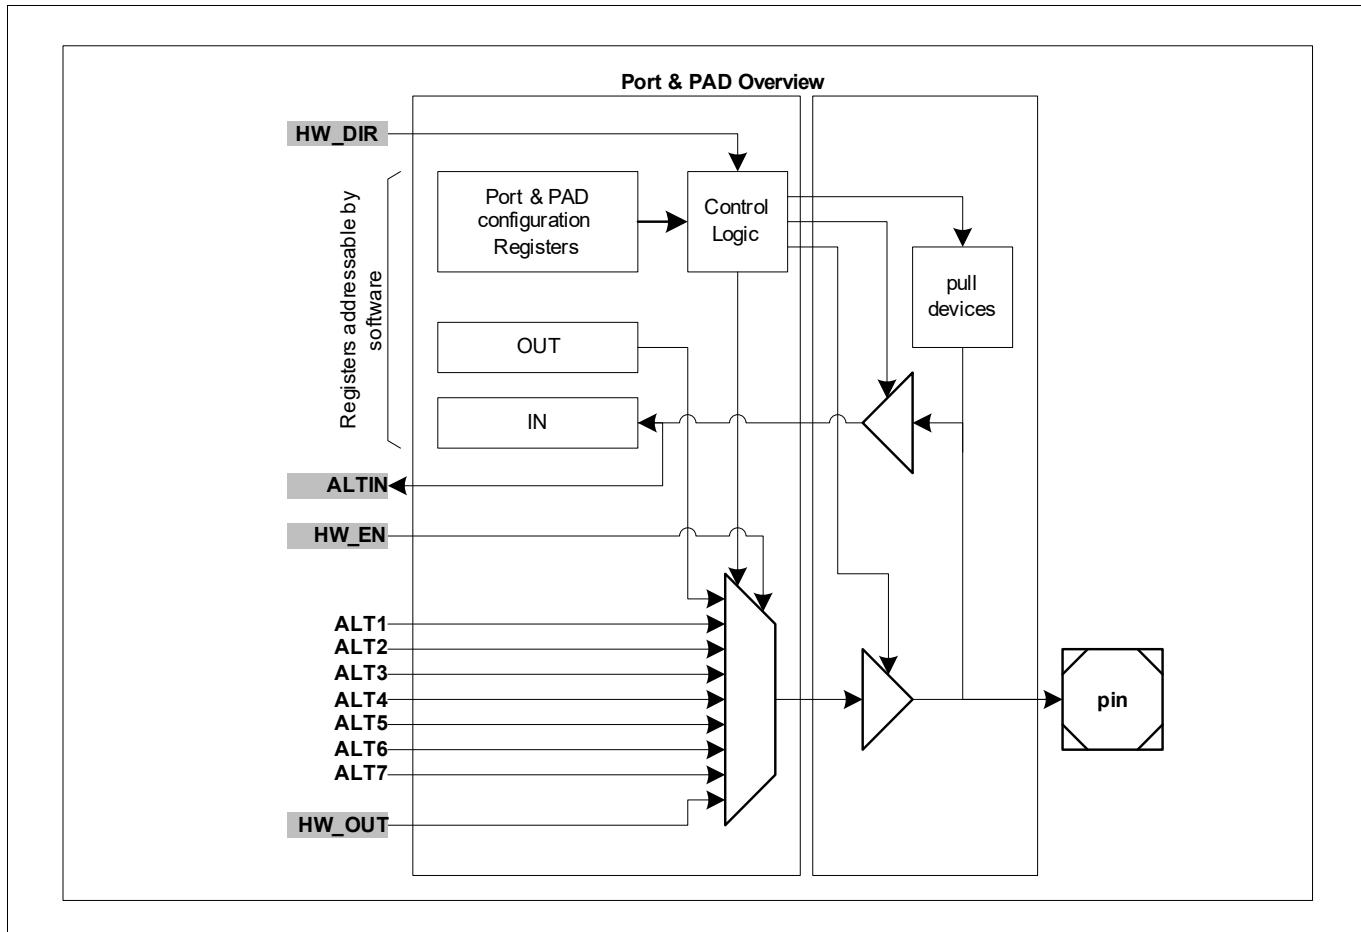

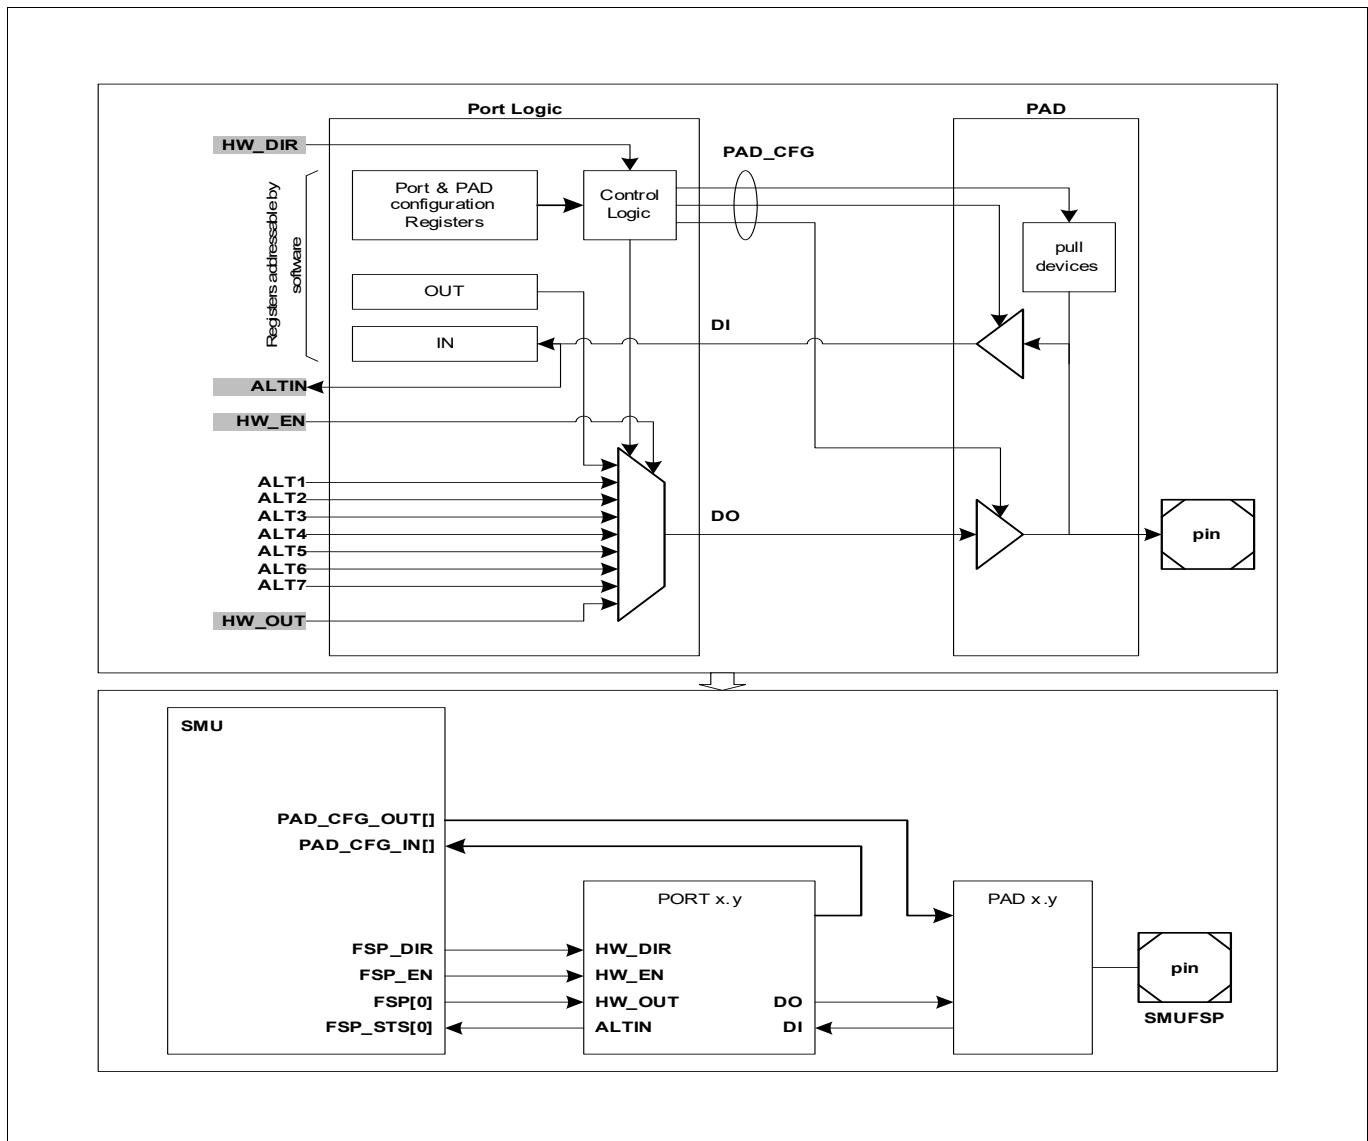

Figure 159 Generic Port Structure

## Safety Management Unit (SMU)

The port pin can be connected to peripheral via the ALTx output lines. This is the default state of the port after power-on reset (see Ports chapter for more details). The SMU\_core connects to the port using the HW\_DIR, ALTIN, HW\_EN, HW\_OUT signals. When the HW\_EN port input is driven active by the SMU\_core, SMU\_core gets full control over the port, bypassing any other software configuration related to the usage of the ALTx inputs.

**Figure 160** provides a more detailed overview of the port structure and highlights the signals involved in the SMU\_core connectivity.

**Figure 160** SMU/PAD Control Interface to the PADs

SMU\_FSP0 (FSP[0] in **Figure 160**) is controlled by hardware. FSP\_DIR and FSP\_EN are controlled by software as follows:

- FSP\_DIR output is directly driven by the **PCTL.HWDIR**
- FSP\_EN output is directly driven by the **PCTL.HWEN**

This also applies for SMU\_FSP1 when used.

**PCTL** provides a field PCS that, in combination with the P33\_PCSR.SEL bitfield, enables software to change the PAD control of FSP[0]. With P33\_PCSR.SEL, **PCTL** HWDIR, HWEN and PCS fields, software can control the FSP[0] PAD ownership transition from GPIO to full SMU hardware control.

## Safety Management Unit (SMU)

SMU\_FSP1 PAD is not under the control of the SMU\_core. **PCTL** PCS field does not enable software to change the PAD control of SMU\_FSP1. However, the **PCTL** HWDIR and HWEN fields can be used to overrule the PAD configuration.

The contents of the **PCTL** register are locked by the **KEYS** register and are only reset by a power-on reset, therefore the PAD configuration remains preserved even in the presence of an application or system reset. Furthermore the **PCTL** register is implemented using safety flip-flops safety mechanism that detects, during run-time, any bit change caused by a random hardware fault.

Refer to [SMU\\_core Integration Guidelines](#) for the SMU and PORT configuration steps that are required to use the ErrorPin.

### Glitch Filter (not available in TC39x A-Step)

In systems which are using the ErrorPin in Open Drain mode, glitches up to 1.2 µs can be suppressed by a glitch filter. There are two relevant paths from the ErrorPin in case of Open Drain mode usage:

- ErrorPin to **STS.FSP[0]**
  - For this path the filter can be switched on/off in **PCTL.GFSTS\_EN**
- ErrorPin to SCU for Port Emergency Stop usage
  - For this path the filter can be switched on/off in **PCTL.GFSCU\_EN**

## Safety Management Unit (SMU)

### 15.3.1.2.4 Interface to the Register Monitor

#### Safety Flip-flop Self-Test Protocol

The interface between the Register Monitor Control (**RMCTL**), Register Monitor Error Flag (**RMEF**) and Register Monitor Self Test Status registers (**RMSTS**) is specified as follows:

- **RMCTL.TE[31:0]**
  - Setting **RMCTL.TE[i]** to 1 starts a self-test on the safety flip-flop protected registers of a given module (see **Table 526**)
  - These bits have to be set back to 0 at the end of the self-test
- **RMEF.EF[31:0]**
  - **RMEF.EF[i]** is set to 1 whenever a fault is detected in a safety flip-flop protected register of a given module, regardless of the state of the **RMCTL.TE[i]** (see **Table 527**)
- **RMSTS.STS[31:0]**
  - **RMSTS.STS[i]** is set to 1 at the end of a safety flip-flop self-test sequence (see **Table 528**)

The mapping of the Register Monitor registers is specified as follows:

**Table 526 Register Monitor Self-Test Enable**

SMU_RMCTL	Module
SMU_RMCTL[0]	MTU
SMU_RMCTL[1]	IOM
SMU_RMCTL[2]	IR
SMU_RMCTL[3]	EMEM

SMU_RMSTS[8]	CERBERUS
SMU_RMSTS[9]	SYS_PLL/PER_PLL
SMU_RMSTS[10]	CCU
SMU_RMSTS[31..11]	Reserved

### Safety Flip-flop Self-Test Conditions

In order prevent unexpected behaviors during the self-test, the following conditions shall to be fulfilled:

- The clock of the module to be tested must be enabled
- The clocks and clock ratios of the modules involved in the self-test shall not be modified during the self-test
- The clock ratio of the modules involved in the self-test sequence shall be set in a specific way. For more detail please refer to the safety flip-flop related chapter
- The microcontroller shall not be set in reset, sleep or debug state whilst a self-test is being executed

### 15.3.1.2.5 Interface to SMU\_stdby

In case of a malfunction the SMU\_core generates a signal, smu\_core\_alive, to the SMU\_stdby.

The smu\_core\_alive signal will be generated if one of the following conditions is meet:

- An alarm event occurs while the SMU\_core is in RUN or FAULT state and the SMU\_core Alive Monitor, SCAM, detects that a reaction has not been generated by the SMU\_core.
- A watchdog or recovery timer alarm event occurs while the SMU\_core is in START state and the SCAM detects that a reaction has not been generated by the SMU\_core.
- SMU\_ActivateFSP or SMU\_ActivatePES command is sent but the appropriate reaction is not generated by the SMU\_core
- An alarm's configuration is changed while this alarm is being processed

---

## Safety Management Unit (SMU)

The smu\_core\_alive signal can be tested by sending the SMU\_AliveTest command.

Indeed, sending the SMU\_AliveTest command will trigger the SCAM to inject a fault and to forward the smu\_core\_alive alarm to the SMU\_stdby. The smu\_core\_alive alarm flag can be read in the [AG2i\\_STDBY \(i=1\)](#) whether or not the SMU\_stdby is enabled (see [Interdependency Between SMU\\_core and SMU\\_stdby](#)). The SCAM error injection can be disabled by sending the SMU\_AliveTest command with a different argument (see [Table 534](#)). However, the SMU\_AliveTest command cannot clear the smu\_core\_alive alarm when this one is generated by a real fault. An application reset (at least) is needed to clear the smu\_core\_alive alarm.

For the TC39xB and the TC38x, when the SMU\_core is in START state, a fault in the processing of the Recovery Timer 1 timeout alarm will not generate the smu\_core\_alive alarm.

## Safety Management Unit (SMU)

### 15.3.1.3 SMU\_core Integration Guidelines

This chapter extends the [Interfaces Overview](#) section by providing additional information for the usage of the ErrorPin (**Fault Signaling Protocol (FSP)**) in combination with other input/output (GPIO) functions of the microcontroller and the configuration of the **Fault Signaling Protocol (FSP)**.

**Note:** *The PAD properties (push-pull, open-drain, drive strength,...) are configured in the registers of the PORT to which the SMU connects to. These registers are described in the Ports chapter.*

- During power-on-reset, the ErrorPin is in high impedance: the pull devices are disabled.
- After power-on-reset the default mode of the PORT to which the ErrorPin is connected is GPIO.
- Before changing the ownership of the PAD to SMU, software shall configure the PORT registers including the following:
  - Disable the pull devices if GPIO is not used
  - Program the GPIO registers of the ErrorPin to strong driver output constant low
  - Set P33\_PCSR.SEL8 to 1
  - Set P33\_PCSR.SEL10 to 0
- To enable SMU to control the ErrorPin PAD, software shall activate the PAD configuration safeguarding process (see [Interface to the Ports \(ErrorPin\)](#)).
  - The safeguarding process requires a software action that consists in writing a 1 into the **PCTL.PCS** field.  
**Only the first transition from 0 to 1 leads to the safeguarding process. A new PORT configuration followed by a new transition from 0 to 1 of the PCTL.PCS has no effect on the hardware.**

Also, the following steps need to be followed to reconfiguring the **Fault Signaling Protocol (FSP)** settings:

- While in Fault Free State and the Time Switching or Dual Rail protocol is in use:
  - Disable Time Switching or Dual Rail protocol by setting FSP in Bi-stable protocol mode (FSP.MODE = 00B)
  - Wait until Bi-stable protocol mode is active (read back register FSP twice)
  - Write desired value to PRE1, PRE2 or TFSP\_HIGH
  - Switch FSP.MODE to the desired protocol (if required)
- While in Fault Free State and the Bi-stable protocol is in use:
  - Write desired value to PRE1, PRE2 or TFSP\_HIGH
  - Switch FSP.MODE to the desired protocol (if required)

---

## Safety Management Unit (SMU)

### 15.3.1.4 Alarm Mapping

Please refer to the appendix document for device specific alarm tables

#### 15.3.1.4.1 SMU\_core Internal Alarms

The following tables describe the alarms generated by the SMU\_core

##### SMU\_CORE Alarm Table

**Table 529 SMU\_CORE Alarm Table**

Description	SMU Targets
SMU.SMU_CORE - SMU_core Alive Alarm	ALM21[16]
SMU_core - Safety flip-flop uncorrectable error	ALM6[7]
SMU_core - Safety flip-flop uncorrectable error	ALM10[21]
SMU.SMU_core - Recovery Timer 0 Time-out alarm	ALM10[16]
SMU.SMU_core - Recovery Timer 1 Time-out alarm	ALM10[17]

##### FSP Alarm Table

**Table 530 FSP Alarm Table**

Description	SMU Targets
SMU.SMU_core - ErroPin Fault State Activation alarm	ALM10[18]

## Safety Management Unit (SMU)

### 15.3.1.5 Alarm Handling

This section specifies the hardware and software alarm processes.

#### 15.3.1.5.1 Alarm protocol

Each safety mechanism shall interface with the SMU\_core using a pre-defined protocol. The protocol enables to cross clock domains in a reliable manner. The operation of the protocol has no influence to the software layers.

#### 15.3.1.5.2 Alarm Configuration

Upon reception of an alarm event the SMU\_core decodes the actions to be performed. The action can be classified into an internal behavior and an external behavior. Both the internal and external behavior can be configured for every alarm.

The external behavior is related to the Fault Signaling Protocol (see [Fault Signaling Protocol \(FSP\)](#)). The external behavior is configured via the following registers:

- [AGiFSP \(i=0-11\)](#)

The internal behavior of the SMU under the presence of an alarm is controlled via the following registers:

- [AGiCFj \(i=0-11;j=0-2\)](#)

The internal behavior is specified by a 3-bit code as follows:

- Code = SMU\_AG<n>CF2. SMU\_AG<n>CF1. SMU\_AG<n>CF0, n=0...11

**Table 531 SMU Alarm Configuration**

Code	Name	Behavior
0x0	SMU_NA	No Action. Reset value. Alarm disabled.
0x1	SMU_RSVD	Reserved. No Action. Alarm disabled.
0x2	SMU_IGCS0	Sends an interrupt request to the interrupt system according to the Interrupt Generation Configuration Set 0 from the <a href="#">AGC</a> register.
0x3	SMU_IGCS1	Sends an interrupt request to the interrupt system according to the Interrupt Generation Configuration Set 1 from the <a href="#">AGC</a> register.
0x4	SMU_IGCS2	Sends an interrupt request to the interrupt system according to the Interrupt Generation Configuration Set 2 from the <a href="#">AGC</a> register.
0x5	SMU_NMI	Sends an NMI request to the SCU
0x6	SMU_RESET	Sends a reset request to the SCU. The SCU shall be configured to generate an application or system reset.
0x7	SMU_CPU_RST	Triggers a CPU reset request using CPU Reset Configuration Set from the <a href="#">AGC</a> register

#### 15.3.1.5.3 Alarm operation

Whenever an input alarm event is detected and the SMU\_core state machine is in the RUN or FAULT state, the SMU checks for the corresponding actions to be done for the internal action and for the FSP in a concurrent way. If an input alarm event is detected and no action is specified for the alarm, the corresponding status bit shall be set to 1 as well but no action takes place.

The processing of the incoming alarm events is performed as follows:

- All alarm groups and every alarm are scanned at the same time.

## Safety Management Unit (SMU)

- The execution of pending alarms is done concurrently.
- The processing of an alarm within an alarm group may take several fSPB cycles.
- If a fault handling is done, the corresponding bit in SMU\_AEX register is set. As long as a bit is set, the corresponding fault handling is blocked. This bit needs to be reset by SW after fault handling is done.
  - If the alarm execution bit in SMU\_AEX register related to a pending alarm is already set, then the alarm event is ignored but the status bit and also the corresponding alarm missed event bit are set.
  - If the status flag related to an alarm event is already set to 1, the alarm event is ignored.
  - Whenever an alarm event is processed, the corresponding status bit is set to 1 by hardware in the AG<x> register. If an internal SMU\_core action is configured and executed, the action counter (ACNT) in the **AFCNT** register increments.

## Safety Management Unit (SMU)

### 15.3.1.5.4 Alarm Status Registers

**Table 532** specifies the possible software actions on the AG<x> alarm group status registers depending on the SMU\_core State machine state.

**Table 532 Handling of Alarm Status**

SMU State Machine	SW Action	Effect on AG<x>
START	SMU_ASCE(0) command Write Data at AG<x> Address	If (Data[i] == 1 && (ALARM[i] == 0    (ALARM[i] != WDTx_ALARM && ALARM[i] != RTx_ALARM <sup>1)</sup> ))) AG<x>[i] = 0 else “no effect”
START	Write Data at AG<x> Address	If (Data[i] == 1) AG<x>[i] = 1 else “no effect”
RUN or FAULT	SMU_ASCE(0) command Write Data at AG<x> Address	If (Data[i] == 1 && ALARM[i] == 0) AG<x>[i] = 0 else “no effect”
RUN or FAULT	Write Data at AG<x> Address	No Effect

- 1) Recovery timer alarms are not clearable in START state only if when they have their default alarm configuration. See [Chapter 15.3.1.5.7](#) for more detail about recovery timers default configuration.

In the START state software has the possibility to “emulate” the occurrence of input alarm events by writing at an AG<x> address. Software shall read back the AG<x> register to ensure the completion of the operation if necessary. Also, after clearing an alarm, software shall re-check the alarm status bit (for alarms occurring during the time window of the clearing).

To clear individual alarm flags, use only 32bit writes.

### 15.3.1.5.5 Alarm Diagnosis Registers

The alarm diagnosis registers enable the application to improve the diagnosis of the root cause that lead to a malfunction. In that context they may help to implement recovery strategies, if allowed by the application. The SMU\_Ad<sub>x</sub> diagnosis registers shall make a snapshot of the SMU\_AG<sub>x</sub> registers when:

- the action to be executed by the SMU is a reset when the SMU is in the RUN or in the FAULT state
- a condition which switches SMU\_core state machine (SSMSSM) to the FAULT state (RUN -> FAULT, FAULT -> FAULT) takes place, either controlled by the SMU hardware or a software command

The SMU\_Ad<sub>x</sub> registers shall only be cleared by a power-on reset.

**Note:** After every condition which triggers the SMU to make a snapshot of the SMU\_AG<sub>x</sub> registers the SMU\_Ad<sub>x</sub> diagnosis registers are overwritten with the current SMU\_AG<sub>x</sub> register values. This is also valid if the SMU is already in FAULT state and the FSP is activated again.

### 15.3.1.5.6 Port Emergency Stop

The port emergency stop feature enables forcing a pad into General Purpose Input Mode. The port emergency stop request to the SCU can be activated by any of the following situations:

- a SMU\_ActivatePES() software command
- an alarm event with SMU\_AG<x>FSP enabled and **FSP.PES** enabled
- an alarm event with an internal action configured in SMU\_AG<x>CFx registers and SMU\_AGC.PES enabled for that action.

## Safety Management Unit (SMU)

### 15.3.1.5.7 Recovery Timer

A recovery timer (RT) is available to enable the monitoring of the duration or internal error handlers activated by an alarm, NMI or Interrupt action. In the current SMU\_core implementation two independent instances (RT0 and RT1) are available. The recovery timer duration (identical for all instances) is configured in the register **RTC**. It is possible to enable or disable each instance, however both instances are enabled by default as it is required for the operation of the CPU watchdogs (see also [Watchdog Alarms](#)). In addition to **RTC** additional configuration registers (**RTAC00**, **RTAC01**, **RTAC10** and **RTAC11**) are available per recovery timer instance to configure the alarm mapping.

The alarm mapping consists of a pair of parameters {GIDI, ALIDI} (with i = 0..3), where GIDI is a group identifier and ALIDI is the alarm identifier belonging to the group. Four {GIDI, ALIDI} pairs can be configured per recovery timer instance. It is possible to configure the same group identifier several times. If less than four alarms need to be mapped to a recovery timer, the same {GIDI, ALIDI} shall be configured several times.

*Note:* *The use of the recovery timer only makes sense if the internal action is an interrupt or NMI. However no hardware check is done, it is up to software to configure the SMU\_core in the appropriate way.*

If a recovery timer is enabled and for any of the {GIDI, ALIDI} pairs an alarm event occurs and if an internal action is configured leading to an internal action (the alarm status shall be cleared), the recovery timer is automatically started by hardware. Such situation is called a recovery timer event. An alarm without internal action shall not start a recovery timer.

Once a recovery timer event has occurred, the recovery timer starts and counts until software stops it with the `SMU_RTStop()`. If the timer expires, an internal SMU alarm (Recovery Timer Timeout) is issued. During the time the recovery timer is running, any other action that requests the recovery timer is ignored. If such event happens, the bit RTME (Recovery Timer Missed Event) is set to '1' by hardware in the **STS** register. The bit RTME can only be cleared by software. The bit RTS (Recovery Timer Status) is set to '1' by hardware in the **STS** register during the time the recovery timer is running: from the timer activation until a `SMU_RTStop()` is received or the timer expires. The bit RTS is cleared by hardware upon reception of `SMU_RTStop()` or the timer expires.

If a `SMU_RTStop()` command is received when the recovery timer is not active, the command returns an error response.

*Note:* *If RTC.RTD shall be written, make sure no recovery timer is running (recovery timer state is indicated by bits RTS0 and RTS1 in the STS register).*

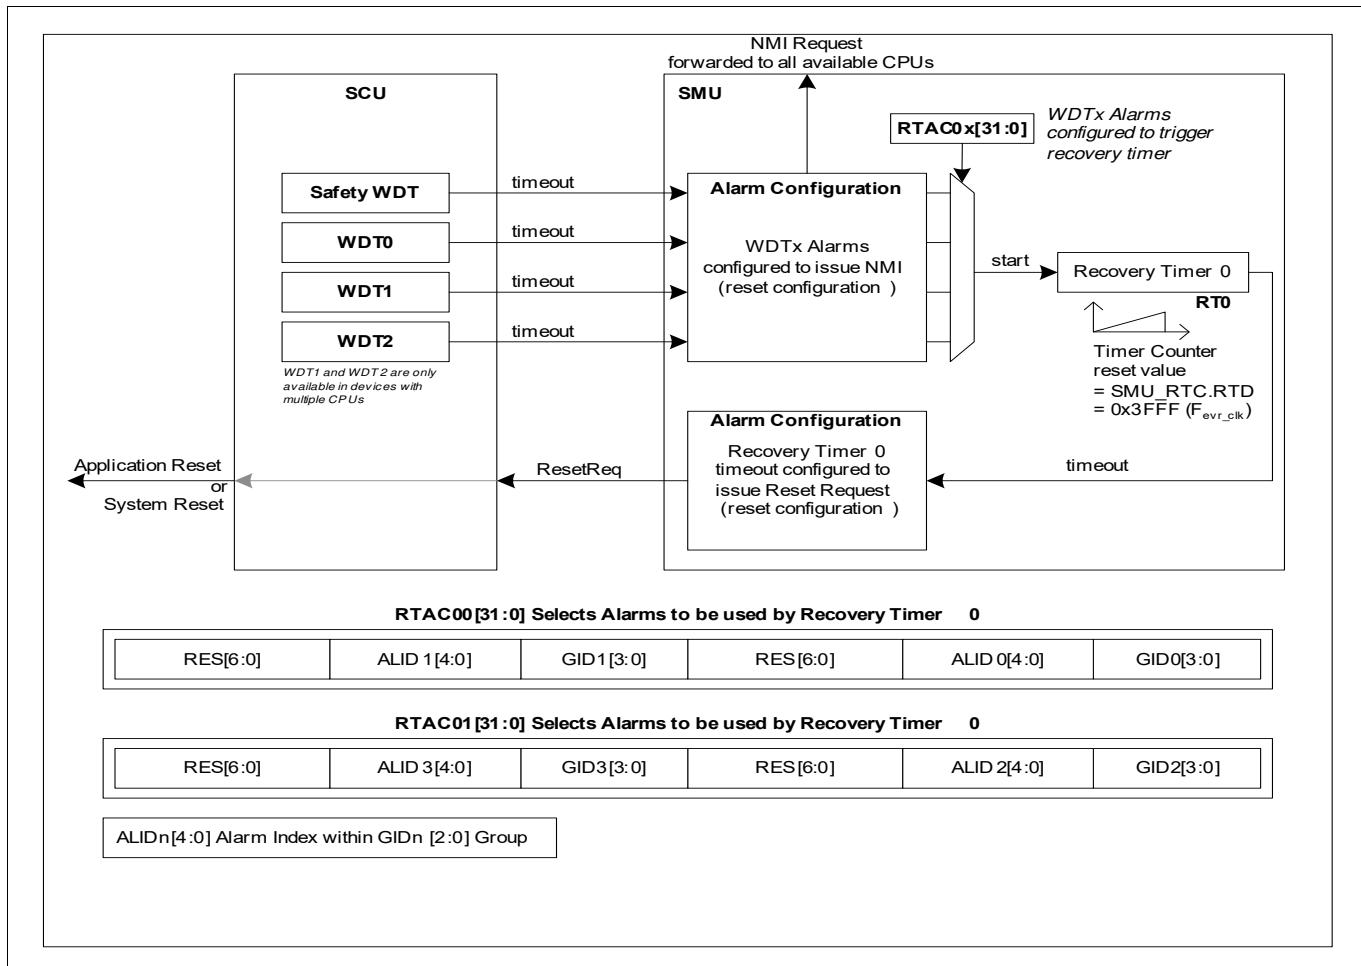

### 15.3.1.5.8 Watchdog Alarms

The watchdogs (WDT) timeout alarms require a special processing in order to ensure a correct microcontroller behavior if the watchdogs are not serviced by software or firmware. It shall be ensured that the microcontroller is reset after a pre-warning phase, where software can still perform some critical actions.

- Every timeout alarm shall activate an NMI
- Recovery Timer 0 shall be configured to service WDT timeout alarms for Safety WDT, CPU0 WDT, CPU1 WDT and CPU2 WDT
- Recovery Timer 1 shall be configured to service WDT timeout alarms for CPU3 WDT, CPU4 WDT and CPU5 WDT
- Recovery Timer 0 and Recovery Timer 1 timeout alarms shall be configured to issue a reset request and activate the Fault Signaling Protocol.

The aforementioned properties are implemented as reset values for the watchdog(s) timeout alarm(s) and for the recovery timer 0 and 1.

## Safety Management Unit (SMU)

**Figure 161 Watchdog timeout alarm configuration (RTAC 0)**

The figure shows only the example for RTAC 0 and the related four WDT. In the same way the RTAC 1 with the related WDT3, WDT4 and WDT5 is set up.

Because the watchdog timeout detection is also required from the very first instruction executed by a CPU, the SMU shall process any watchdog timeout alarm during the START state.

**Note:** If the same behavior is expected for all WDT alarms, it is recommended to use the global WDT timeout alarm that implements a logical OR among all WDT timeout alarms, thus freeing some {GIDI<sub>i</sub>, ALIDI<sub>i</sub>} configuration pairs in **RTAC00**, **RTAC01**, **RTAC10**, and **RTAC11**, for other purposes.

### 15.3.1.6 SMU\_core Control Interface

The core functionality of the SMU\_core is introduced through its control interface. The control interface defines how the SMU\_core can be controlled by software, as summarized in **Table 533**. The control interface is directly linked to the SMU\_core state machine (SSM) operation described in **SMU\_core State Machine** and to the Fault Signaling Protocol (FSP) described in **Fault Signaling Protocol (FSP)**. The control interface is implemented by the **CMD** register using the **CMD** and **ARG** fields. The command completion status is available via the **STS** register.

## Safety Management Unit (SMU)

**Table 533 SMU\_core Commands**

Command	Description	Code
SMU_Start(ARG)	Forces the SSM to go to the RUN state from the START state. Argument ARG shall be set to 0.	0x0
SMU_ActivateFSP(ARG)	Activates the Fault Signaling Protocol. This action is possible in any state of the SSM. Argument ARG shall be set to 0.	0x1
SMU_ReleaseFSP(ARG)	Turns the FSP into the inactive fault free state. In the START state, SMU_ActivateFSP() and SMU_ReleaseFSP() can be called as many times as necessary to perform self tests of every alarm source. Argument ARG shall be set to 0.	0x2
SMU_ActivatePES(ARG)	Triggers the activation of the Port Emergency Stop (PES). The PES is also directly controlled by the SMU_core when entering the FAULT state. Argument ARG shall be set to 0.	0x3
SMU_RTStop(ARG)	Stop the recovery Timer. Argument ARG shall be set to the recovery timer instance available in the product.	0x4
SMU_ASCE(ARG)	Alarm Status Clear Enable Command. Software shall execute this command prior to clear a AG<n> alarm status bit. This command sets the ASCE bit in the <b>STS</b> register. Argument ARG shall be set to 0.	0x5
SMU_Alarm(ARG)	Triggers a software based alarm. ARG specifies the alarm index according to the mapping defined in <b>Alarm Mapping</b> . A software alarm has the same properties as an hardware alarm.	0x6
SMU_AliveTest(ARG)	Enables the testing of the smu_core_alive signal. Sending this command will forward the smu_core_alive alarm to the SMU_stby. Argument ARG shall be set to 0x5 to start the test and to 0xA to end the test.	0x7

Note: *If the argument does not comply with the specification of the command the command is ignored and returns an error code.*

The next table provides the legal conditions for the execution of the commands. The conditions depend on the SMU\_core state machine (SSM) states (see **SMU\_core State Machine**). Any situation not specified leads to an error code.

**Table 534 SMU\_core commands and valid conditions**

Command	SSM state	Other conditions
SMU_Start(ARG)	START	ARG == 0
SMU_AliveTest(ARG)	START	ARG == 0x5 to start the test and 0xA to end the test
SMU_ActivateFSP(ARG)	Any	ARG == 0
SMU_ReleaseFSP(ARG)	START	ARG == 0
SMU_ReleaseFSP(ARG)	FAULT	ARG == 0 & <b>AGC.EFRST == 1<sup>1)</sup></b>
SMU_ActivatePES(ARG)	Any	ARG == 0

## Safety Management Unit (SMU)

**Table 534 SMU\_core commands and valid conditions (cont'd)**

Command	SSM state	Other conditions
SMU_RTStop(ARG)	Any	ARG >= 0 and ARG <= Number of Recovery Timer Instances and Recovery Timer Enabled
SMU_ASCE(ARG)	Any	ARG == 0
SMU_Alarm(ARG)	RUN, FAULT <sup>2)</sup>	ARG >= 0

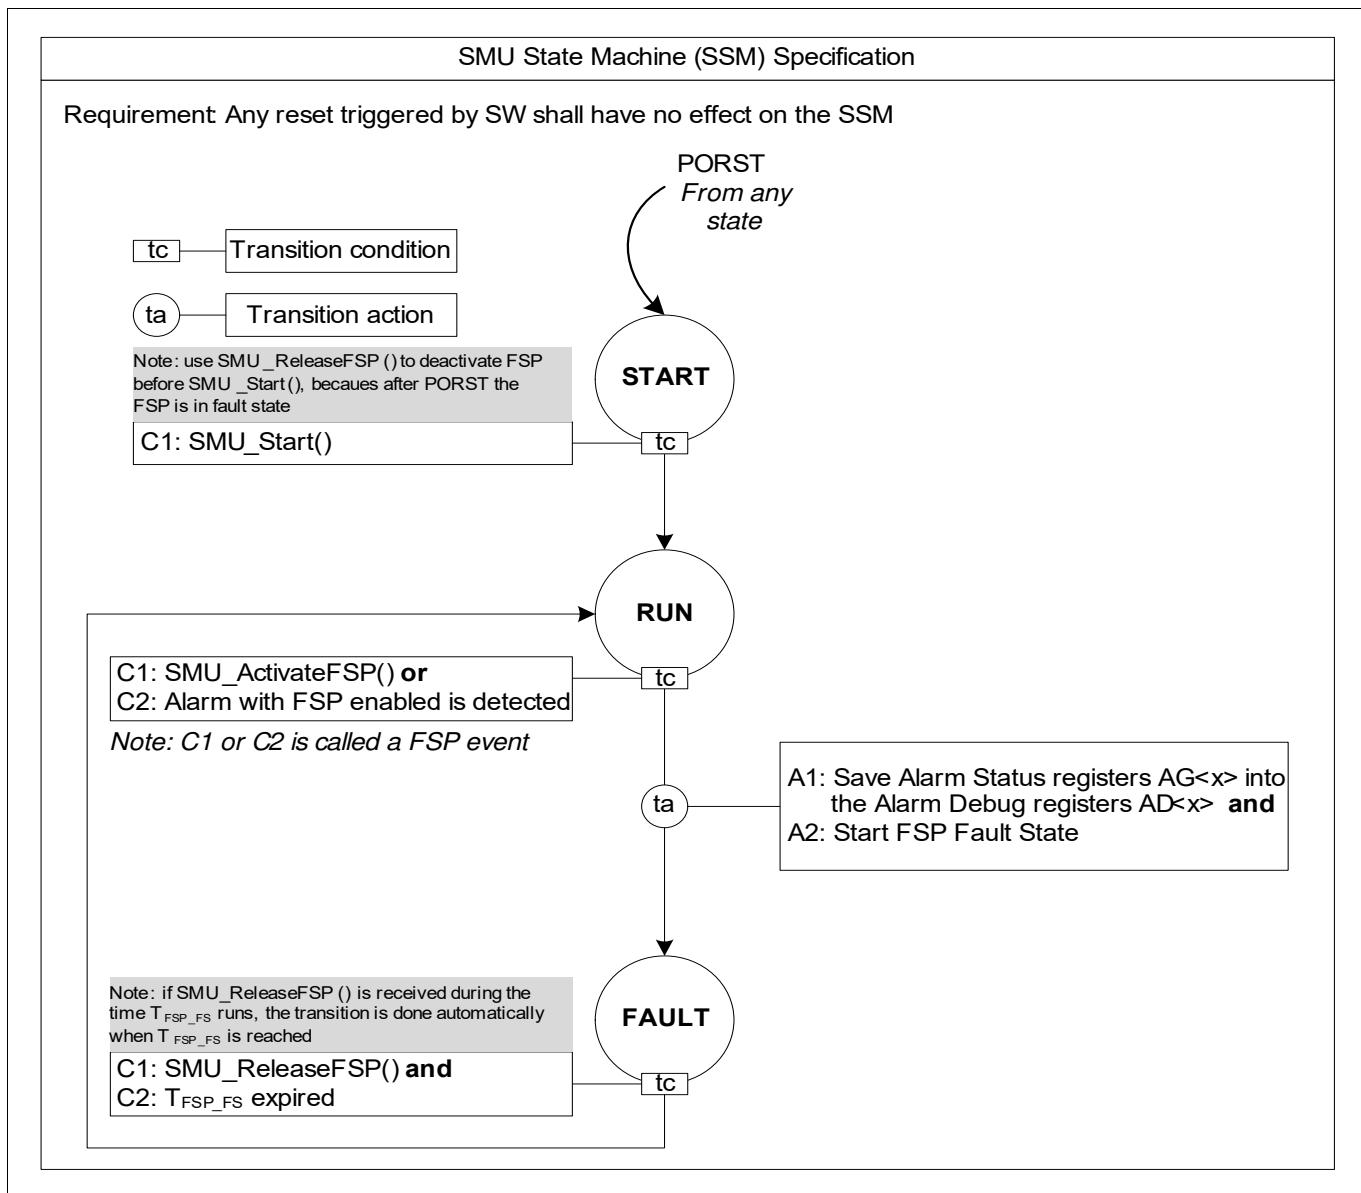

1) See also [Fault Signaling Protocol \(FSP\)](#).

2) In the START state of the SMU\_core input alarms are not processed, therefore software triggered alarms will have no effect.

## Safety Management Unit (SMU)

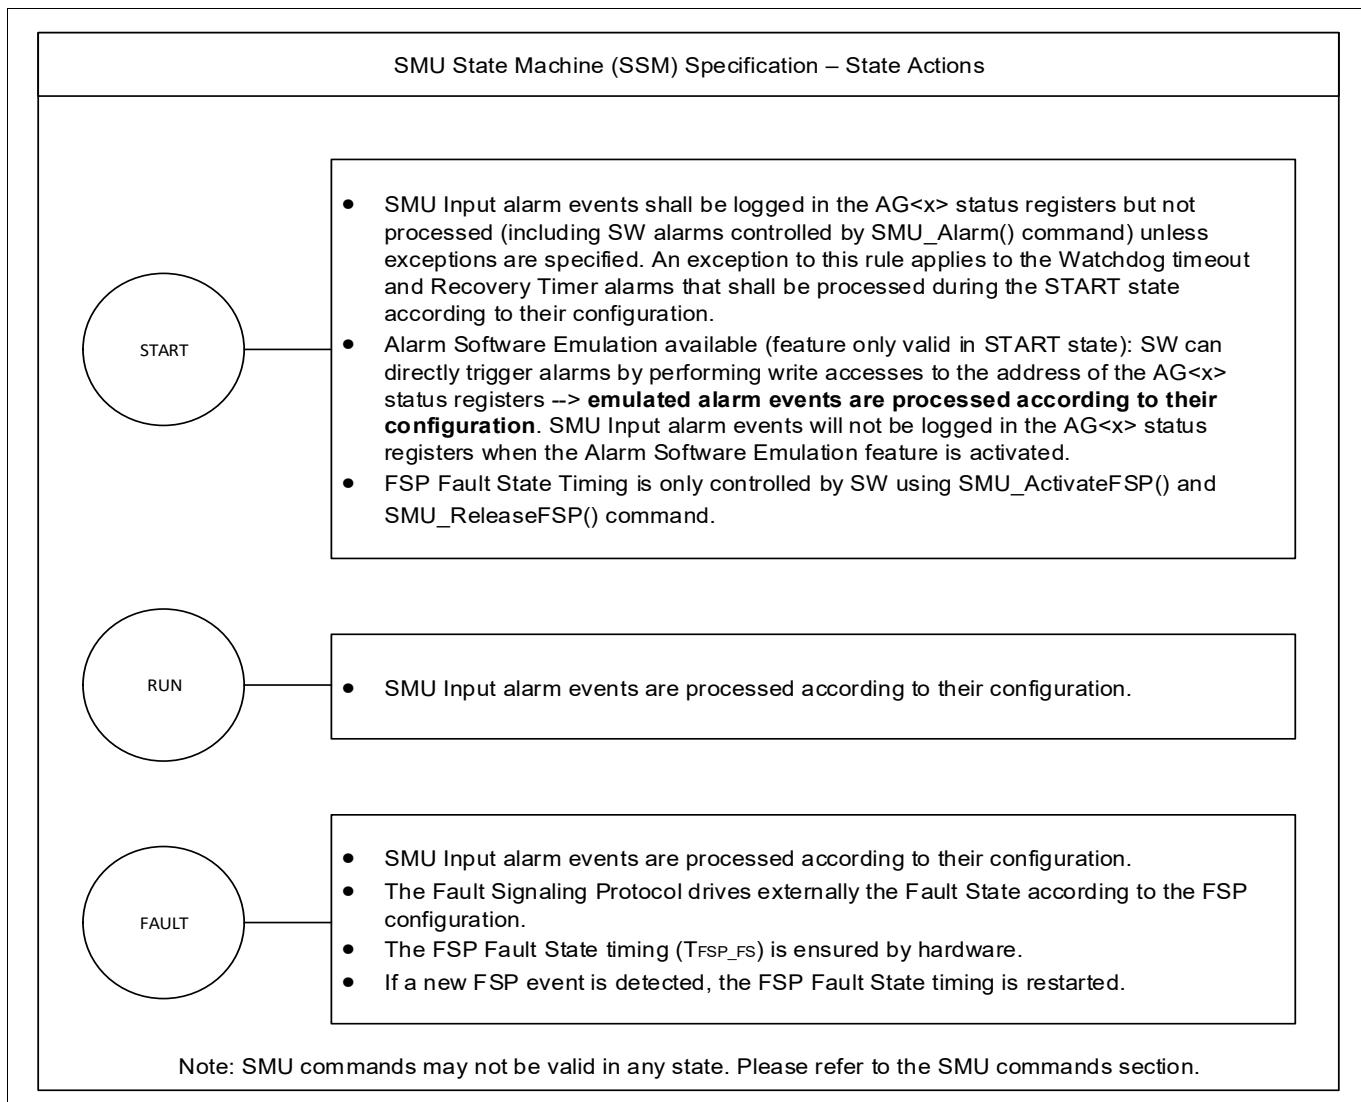

### 15.3.1.7 SMU\_core State Machine

**Figure 162** and **Figure 163** describe the behavior of the SMU\_core state machine (SSM).

**Figure 162 SMU\_core state machine (SSM): transition conditions and actions**

## Safety Management Unit (SMU)

**Figure 163 SMU\_core state machine: state actions**

### Fault Counter

The SMU implements a Fault Counter (**AFCNT**) that counts the number of transitions from the RUN state to the FAULT state. The Fault Counter register is only reset by a warm power-on-reset.

## Safety Management Unit (SMU)

### 15.3.1.8 Fault Signaling Protocol (FSP)

The Fault Signaling Protocol enables the microcontroller to report a critical situation to an external safety controller device in order to control the safe state of the safety system.

#### 15.3.1.8.1 Introduction

The fault signaling protocol is configured via the **FSP** command register. The FSP status is indicated by the FSP flag in the **STS** register. The FSP has three states:

- The power-on reset state. After warm power-on reset the SMU is disconnected from the ports (see **SMU\_core Integration Guidelines**). After warm power-on reset the SMU FSP output shall be the Fault State.
- The Fault-free State. Whenever the fault-free state is controlled by a timing, the timing will be called TFSP\_FFS and is controlled by the **FSP** register.
- The Fault State. The timing of the fault state is controlled by the **FSP** register. The minimum active fault state time is called TFSP\_FS.

The Fault-free and fault state behavior can be configured with the following protocols:

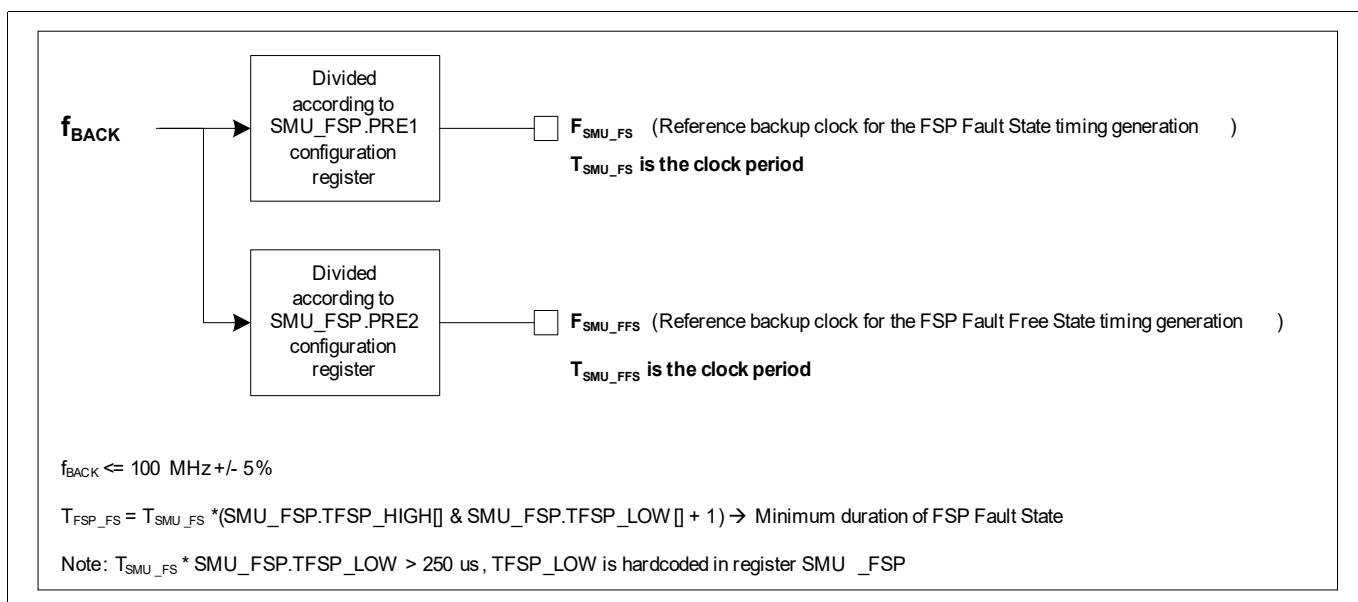

- Bi-stable protocol (default)
- Dynamic dual-rail protocol
- Time-switching protocol

The FSP can be controlled by:

- Software using the **SMU\_ActivateFSP()** and **SMU\_ReleaseFSP()** commands using the **CMD** register
- Hardware based on the **AGiFSP (i=0-11)** configuration registers.

To avoid unexpected alarms, perform the configuration of the PRE1, PRE2 or TFSP\_HIGH fields only when the SMU is not in the Fault State and FSP is in Bi-stable protocol mode (FSP.MODE = 00B). Mode switching and configuration shall not be done with the same write access to register FSP. If field FSP.PRE1 shall be written, make sure no recovery timer is running (state of recovery timer is indicated by bits RTS0 and RTS1 in the STS register).

**Figure 164** specifies the intermediate clocks to generate the TFSP\_FFS and TFSP\_FS timings.

**Figure 164 Reference clocks for FSP timings**

## Safety Management Unit (SMU)

### 15.3.1.8.2 Bi-stable fault signaling protocol

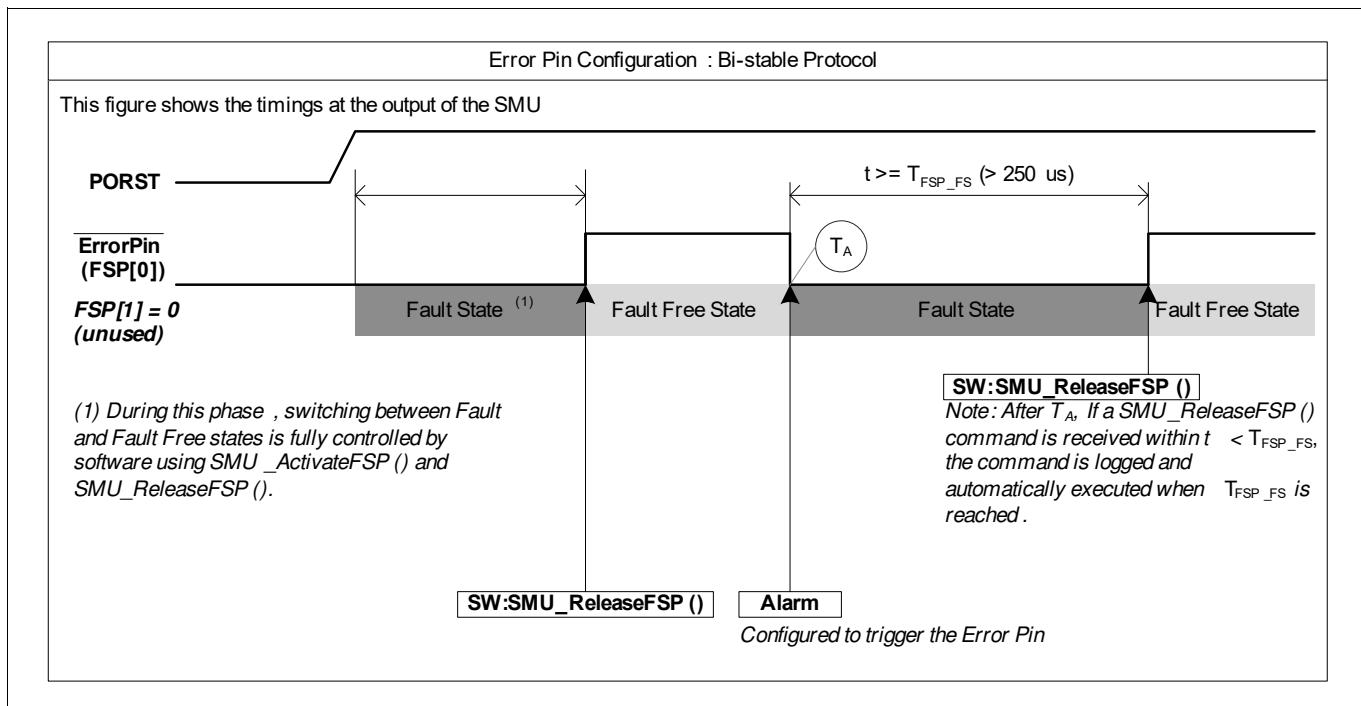

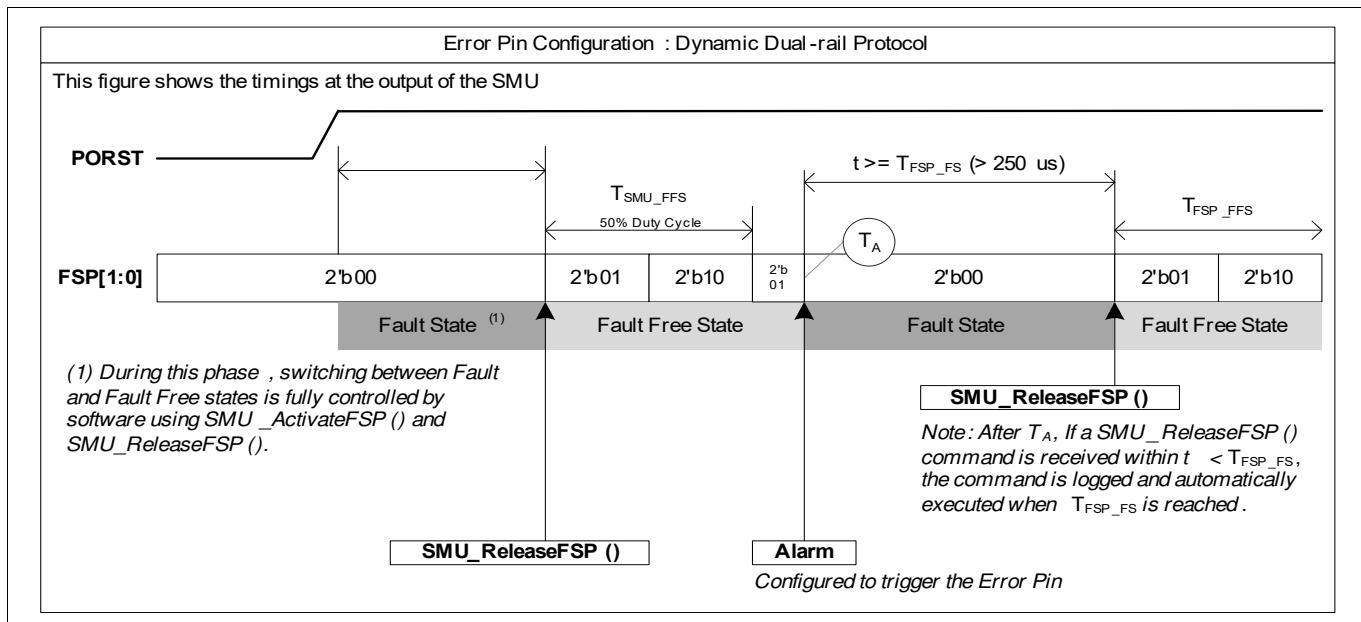

Figure 165 Bi-stable fault signaling protocol

#### Operation

- During power-on-reset  $FSP[0] = 0$  (fault state).
- After power-on reset  $FSP[0]$  stays in the fault state.
- $FSP[0]$  must be set to the fault free state per software ( $SMU\_ReleaseFSP()$ ).
- Upon detection of an alarm event configured to activate the FSP,  $FSP[0]$  goes to the fault state and remains in this state until a  $SMU\_ReleaseFSP()$  command is received and  $TFSP\_FS$  is satisfied or a Power-on Reset takes place.
- While in the Fault State, if a new alarm event configured to activate the FSP is received and the  $TFSP\_FS$  has not yet been reached, the  $TFSP\_FS$  timing shall be restarted.
- While in the Fault State, if a new alarm event configured to activate the FSP is received and the  $TFSP\_FS$  has already been reached, the  $TFSP\_FS$  timing shall be started.

## Safety Management Unit (SMU)

### 15.3.1.8.3 Timed dual rail

**Figure 166 Dynamic dual-rail fault signaling protocol**

#### Operation

Dual-rail encoding is an alternate method for encoding bits. Dual-rail codes use two signals to define a logical state.

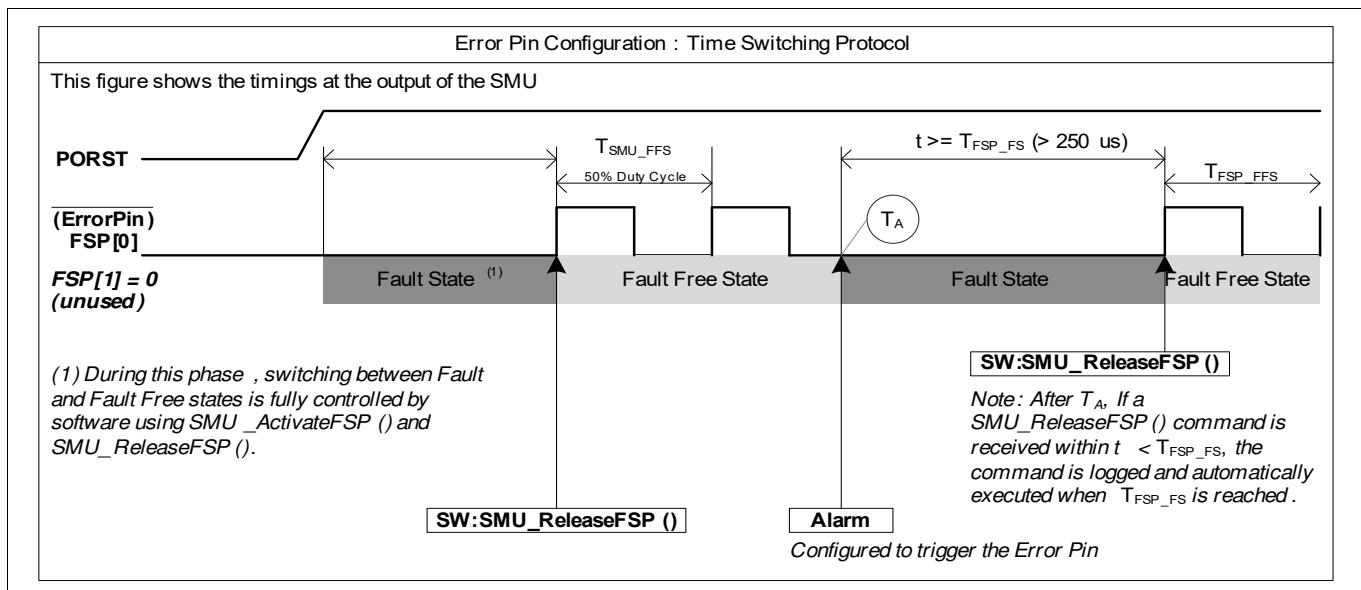

- During power-on-reset FSP[1:0] = 2'b00 (fault state)
- After power-on-reset FSP[1:0] stays in the fault state.
- FSP[1:0] must be set to the fault free state per software(SMU\_ReleaseFSP()).
- The fault free state is defined by FSP[1:0] oscillating between 2'b01 and 2'b10 with a defined frequency configured via the **FSP** register and with a duty cycle of 50% (see **Figure 166**).
- Upon detection of an alarm event configured to activate the FSP, FSP[1:0] goes immediately to the fault state and remains in this state until a SMU\_ReleaseFSP() command is received and TFSP\_FS is satisfied or a Power-on Reset takes place.

**Table 535 Dual rail coding**

Code	Description
{0,1}	Fault free state
{1,0}	Fault free state
{0,0}	Fault state
{1,1}	Fault state (encoding not used)

### 15.3.1.8.4 Time switching protocol

## Safety Management Unit (SMU)

**Figure 167 Time switching protocol**

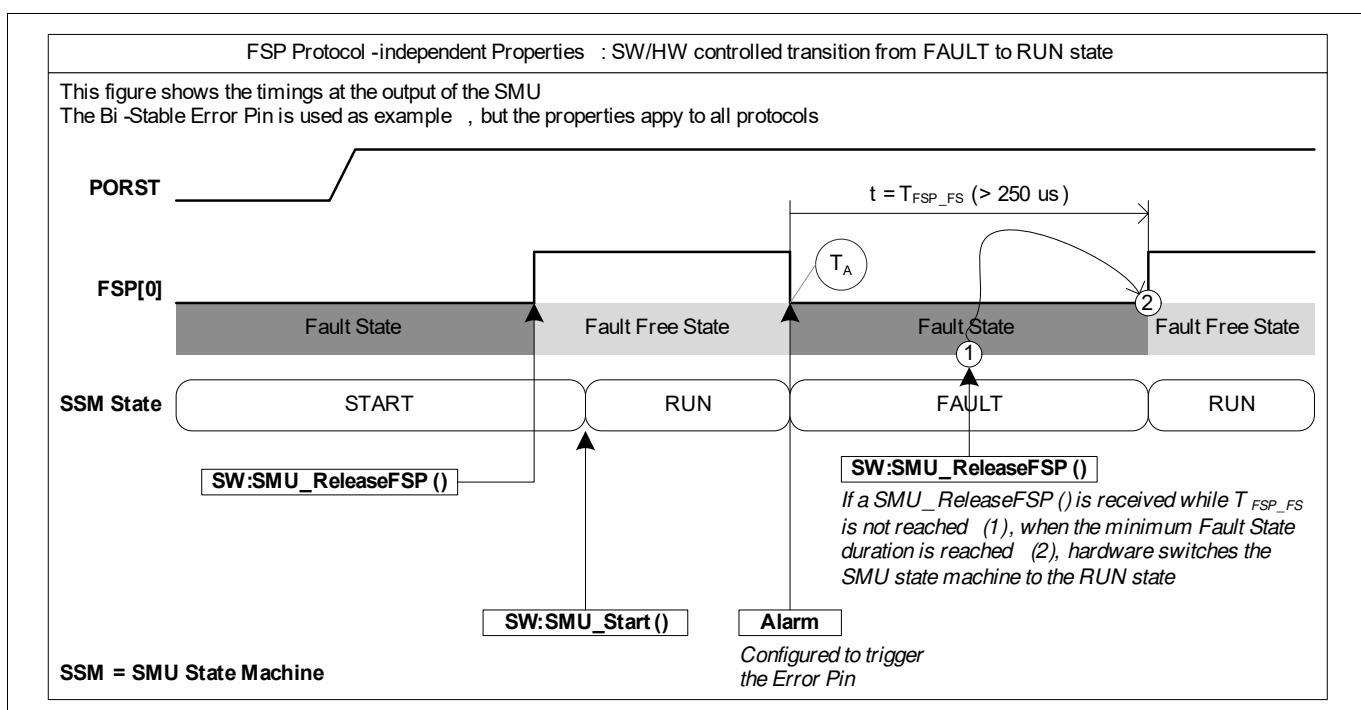

FSP[0] is toggled between logic level 0 and logic level 1 with a defined frequency. This frequency modulation protocol is violated when the SMU\_core enters the FAULT state.

- During power-on-reset FSP[0] = 0 (fault state).
- After power-on-reset FSP[0] stays in the fault state.
- FSP[0] must be set to the fault free state per software (SMU\_ReleaseFSP()).
- In the fault free state, FSP[0] oscillates between logic level 0 and logic level 1 with the frequency configured via the **FSP** register (see [Figure 167](#)).
- Upon detection of an alarm event configured to activate the FSP, FSP[0] goes immediately to the fault state and remains in this state until a SMU\_ReleaseFSP() command is received and TFSP\_FS is satisfied or a Power-on Reset takes place.

## Safety Management Unit (SMU)

### 15.3.1.8.5 FSP Fault State

When an alarm configured to activate the FSP, the SMU\_core automatically switches to the FAULT state. During this time it is also possible for the safety-related software to try to analyze the root cause (when the microcontroller is still operational) and decide about the severity of the error. As the FSP is active for at least  $T_{FSP\_FS}$ , it is ensured that the safe state of the system is entered through external mechanisms independent from the microcontroller (besides FSP itself). During the time  $T_{FSP\_FS}$  FSP is in the Fault State, software may have concluded the fault is uncritical and decides to issue a `SMU_ReleaseFSP()` command, notifying the SMU\_core that it can return to the RUN state (the run-time of the software error handler is not directly correlated with the  $T_{FSP\_FS}$  duration and in practice shall be much shorter).

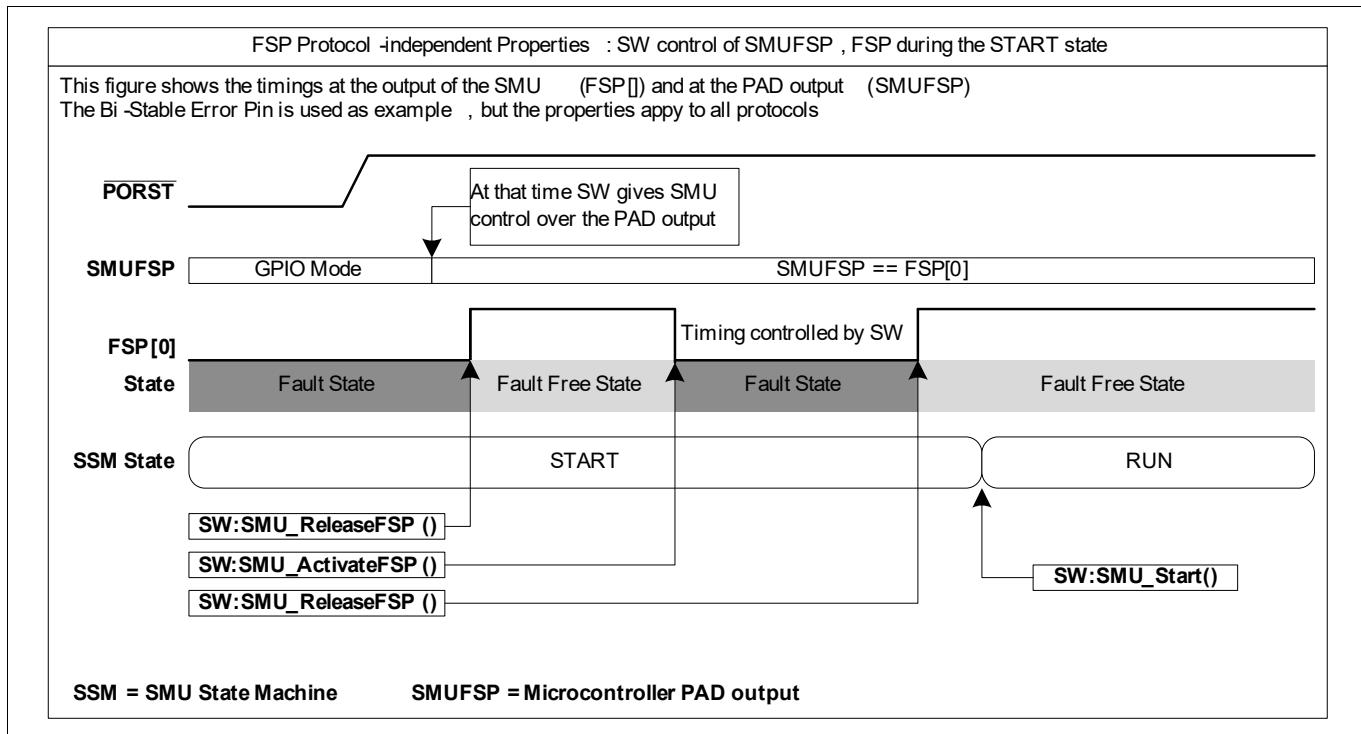

**Figure 168 FSP: Fault State to Fault Free State Transition**

This feature shall be used with caution, a microcontroller reset is highly recommended to restart the operation of the safety function when a fault reported by the SMU is assessed to be uncritical. Therefore this feature is per default disabled and shall be configured with the EFRST (Enable Fault to Run State Transition) field in the **AGC** register.

## Safety Management Unit (SMU)

### 15.3.1.8.6 FSP and SMU\_core START State

**Figure 169** shows a typical use case where the FSP transitions between the Fault State and Fault Free State are controlled by software using the SMU\_ReleaseFSP() and SMU\_ActivateFSP() commands.

**Figure 169 Software Control of FSP during SMU\_core START State**

#### Conditions of Use

- Software shall ensure that the FSP is in the Fault Free State before entering the RUN state with the SMU\_Start() command.

## Safety Management Unit (SMU)

### 15.3.1.9 OCDS Trigger Bus (OTGB) Interface

The SMU\_core concentrates all failure indicator signals (alarms) of the device. By using them as MCDS trace information (failure type) and trace control (stop trace recording), the analysis of a failure's root cause is supported. This is even the case, when the alarm handling within the system includes a PORST, since the content of the trace memory will be still valid after the PORST.

The alarms handled in the SMU\_core are very rare and sporadic. So it's acceptable that they are visible on the Trigger Bus with a small delay and not all in parallel with a cycle accurate timing resolution. The SMU Trigger Set is shown in **Table 536**. It is output on OTGB0 or OTGB1 controlled by the **OCS** register.

**Table 536 TS16\_SMU Trigger Set SMU**

Bits	Name	Description
0	AA	Any ALM bit active
1		Reserved
[3:2]	ABI	ALM Byte Index, selecting the byte within the ALM group
[7:4]	AGI	ALM Group Index
[15:8]	ALM	Selected byte of the ALM group

If no alarm is active, TS16\_SMU will be all zero. If alarms are only active within one ALM Byte, TS16\_SMU will show statically this byte. If alarms are active in two or more ALM Bytes, TS16\_SMU will change between these bytes.

Note that due to the implementation, that all the ALM Bytes are being scanned one per clock cycle, the TS16\_SMU ALM Byte information on OTGB0/1 can be delayed by up to 51 clock cycles for the second alarm. TS16\_SMU.AA will however become active (and inactive) immediately. The implementation will make sure, that the ALM Byte with the first causing alarm will be traced with MCDS before a reset as safety action clears this information.

**Note:** *In some cases, it might be possible to clear an alarm faster than it is captured on the OTGB. Therefore software needs to take care that the time from an incoming alarm until it is cleared is longer than 48 SPB clock cycles to ensure that the alarm is captured on the OTGB.*

## Safety Management Unit (SMU)

### 15.3.1.10 Register Properties

#### 15.3.1.10.1 Register Write Protection

The SMU\_core registers are write protected against illegal master accesses by the master protection mechanism implemented in the System Peripheral Bus interface logic. The registers controlling the master access protection are described in the section [System Registers description](#). In addition the SMU\_core registers can only be written if the Safety ENDINIT is enabled. Read accesses have no restriction as there is no side effect specified when reading registers. The Safety ENDINIT has the same properties as the system ENDINIT but it is generated by the safety watchdog. In order to access a SMU\_core register the software must first activate the safety watchdog via a signature protected sequence. The safety watchdog is configured to enable only safety-related software to activate the Safety ENDINIT.

In addition to the aforementioned standard features, additional mechanisms are implemented to control and protect the SMU\_core configuration. In order to configure and lock the SMU\_core configuration the following steps shall be followed:

- The SMU\_core configuration is only possible if the CFGLCK field of the **KEYS** register is set to 0xBC.
- If the PERLCK field of the **KEYS** register is set to 0xFF no further SMU configuration is possible, including the **KEYS** register itself. No SMU configuration is possible anymore until the PERLCK field of the **KEYS** register is reset to 0x00 by an application reset.

The SMU configuration registers controlled by the **KEYS** register properties are:

- **FSP**
- **AGC**
- **RTC**
- **RTAC00**
- **RTAC01**
- **RTAC10**
- **RTAC11**
- **AGiCF<sub>j</sub> (i=0-11;j=0-2)**
- **AGiFSP (i=0-11)**
- **PCTL**
- **RMCTL**

The **CMD** register is not locked as it is used for run-time hardware/software interaction, it is not a configuration register.

The SMU\_AGx registers are not locked as it is possible during run-time to clear the alarm by software.

The **OCS**, **ACCEN0** and **ACCEN1** do not belong to the SMU\_core kernel but to the standard bus interface module, therefore they can't be controlled by the **KEYS** register.

The read only registers do not need to be protected.

#### 15.3.1.10.2 Safety Flip-flops

Safety flip-flops are special flip-flops that implement an hardware mechanism capable to detect single event effects that may lead to single event upsets (bit flip). The SMU\_core configuration and control registers that shall be implemented with safety flip-flops are:

- **FSP**
- **CMD**

## Safety Management Unit (SMU)

- AGC
- RTC
- KEYS
- PCTL
- RTAC00
- RTAC01
- RTAC10
- RTAC11
- AEX
- AGiCF<sub>j</sub> (i=0-11;j=0-2)
- AGiFSP (i=0-11)

Additionally the following SMU\_core functions shall also be implemented with safety flip-flops:

- SMU\_core state machine registers
- Registers implementing the FSP function

### 15.3.2 SMU\_stby

#### 15.3.2.1 Reset Types

The SMU\_stby requires multiple reset types for its operation. The reset types are fully specified in the Power Management System. The reset types that are required by the SMU\_stby are:

- Warm Power-on Reset.
- LVD Reset.

**Table 537** specifies the scope of each reset type to the SMU\_stby functions (a function includes the control and configuration registers and the related logic).

**Table 537 Effect of Reset Types to SMU\_stby functionality**

SMU Function	Warm Power-on Reset	LVD Reset
SMU_stby Alarm Status Registers <b>Chapter 15.4.2.3</b>	Not Affected	Reset
SMU_stby Alarm Configuration Functionalities	Reset	Reset
SMU_stby BIST functionality	Reset	Reset
SMU_stby other functions	Reset	Reset

#### 15.3.2.2 Interfaces Overview

This section describes the main interface signals between the SMU\_stby and the other modules.

##### 15.3.2.2.1 Interface to the Pads (ErrorPin)

The SMU\_stby has the ability to signal an error to the external world via the FSP ErrorPin.

**Figure 170** fully specifies the data path connectivity of the SMU\_stby with the FSP ErrorPins.

## Safety Management Unit (SMU)

The ErrorPin is connected to the SMU\_stdby via two enable signals, FSP0EN and FSP1EN, and the ENPS signal. FSP0EN and FSP1EN are controlled by the bitfields **CMD\_STDBY**.FSP0EN, **CMD\_STDBY**.FSP1EN. They enable the SMU\_stdby to use the ErrorPins.

When **CMD\_STDBY**.FSP0EN and **CMD\_STDBY**.FSP1EN are set, the ENPS signal can be driven active by the SMU\_stdby which would set FSP[1..0] in high impedance state regardless of the port configuration and of SMU\_core actions.

In this case, an external pull-down device might be needed to make the high impedance state correspond to the FSP Fault State.

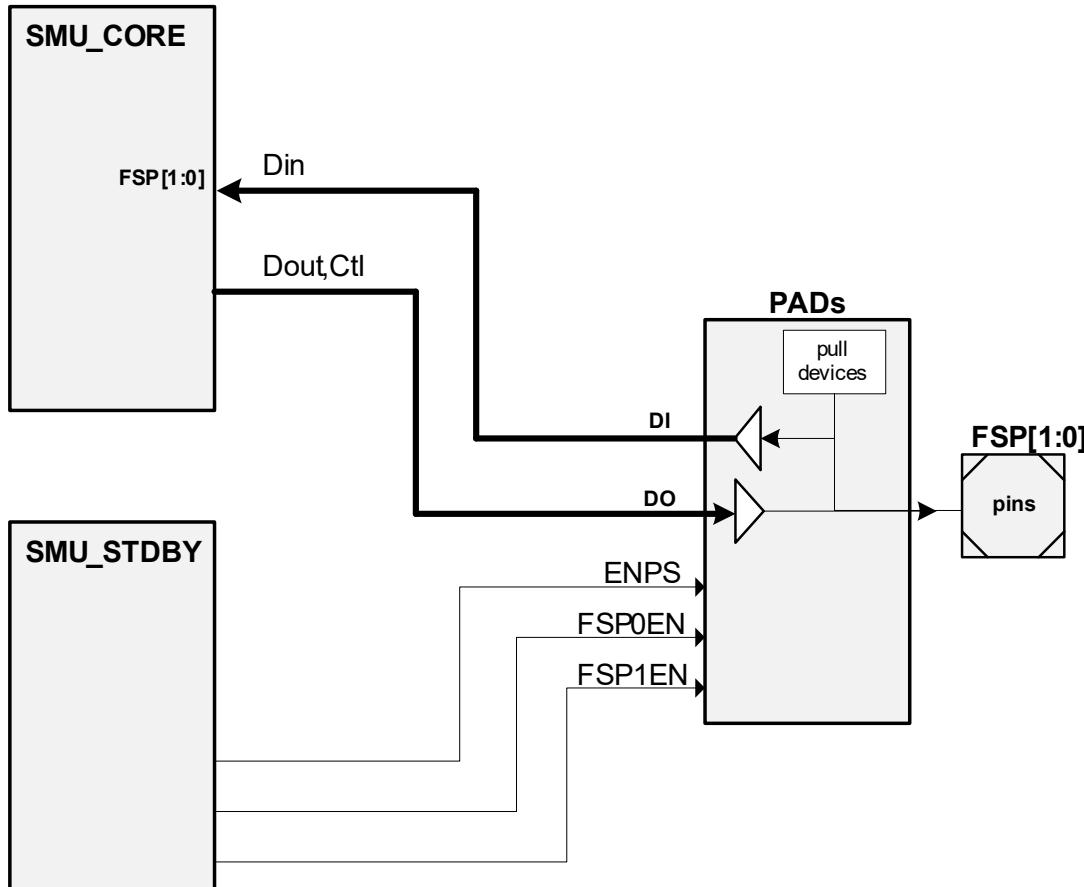

Figure 170 SMU\_stdby Data Path Interfaces with the ErrorPins

Description	SMU Targets
SMU.SMU_stby - Safety flip-flop Uncorrectable error	ALM21[7]

---

## Safety Management Unit (SMU)

### 15.3.2.4 Alarm Handling

This section specifies the hardware and software alarm processes.

#### 15.3.2.4.1 Alarm protocol

Each safety mechanism shall interface with the SMU\_stdby using a pre-defined protocol. The protocol enables to cross clock domains in a reliable manner. The operation of the protocol has no influence to the software layers.

#### 15.3.2.4.2 Alarm Configuration

Upon reception of an alarm event the SMU\_stdby decodes the actions to be performed. The action can either be not to generate any reaction or to set FSP[1..0] in high impedance state. Both behaviors can be configured for every alarm.

The external behavior (setting of FSP[1..0] in high impedance state) is configured via the following registers:

- **AG2iFSP\_STDBY (i=0)**
- **AG2iFSP\_STDBY (i=1)**

*Note:* *In order to recognize the high impedance state of the ErrorPins as the fault state, an external pull-down device might be necessary.*

**Attention:** *When the SMU\_stdby, as a reaction to an alarm, sets the FSP[0] or/and FSP[1] in high impedance state, the STS.FSP[0] or/and STS.FSP[1] will be set to 1 if no external pull-down device is connected to the respective ErrorPin.*

## Safety Management Unit (SMU)

### 15.3.2.5 Register Properties

#### 15.3.2.5.1 Register Write Protection

The SMU\_stdby registers are write protected against illegal master accesses by the master protection mechanism implemented in the System Peripheral Bus interface logic. In addition the SMU\_stdby registers can only be written if the Safety ENDINIT is enabled. Read accesses have no restriction as there is no side effect specified when reading registers. The Safety ENDINIT has the same properties as the system ENDINIT but it is generated by the safety watchdog. In order to access a SMU\_stdby register the software must first activate the safety watchdog via a signature protected sequence. The safety watchdog is configured to enable only safety-related software to activate the Safety ENDINIT.

The read only registers do not need to be protected.

#### 15.3.2.5.2 Safety Flip-flops

Safety flip-flops are special flip-flops that implement an hardware mechanism capable to detect single event effects that may lead to single event upsets (bit flip). The SMU\_stdby configuration and control registers that shall be implemented with safety flip-flops are:

- [AG2iFSP\\_STDBY \(i=0\)](#), [AG2iFSP\\_STDBY \(i=1\)](#)
- [MONBISTCTRL](#)
- [CMD\\_STDBY](#)

#### 15.3.2.6 SMU\_stdby Built-In Self Test

The SMU\_stdby contains a built-in mechanism that enables users to test all alarm paths, alarm configurations, and alarm reactions. The [MONBISTCTRL](#) register enables the user to start the BIST of the SMU\_stdby. Results of the BIST are available in the [MONBISTSTAT](#) register. Please refer to the Power Management Unit Chapter for more details about the SMU\_stdby BIST operations.

### 15.3.3 Interdependency Between SMU\_core and SMU\_stdby

The SMU\_core and SMU\_stdby are designed to function together. The SMU\_stdby monitors the SMU\_core and can, via the ErrorPins, notify an external device of a fault in the SMU\_core.

All alarms (except for PLLx/fSPB and SMU\_core alive alarms) that are processed by the SMU\_stdby are also forwarded to the SMU\_core and processed whether or not the SMU\_stdby is enabled. Also, the SMU\_stdby alarm status registers are accessible even when the SMU\_stdby is disabled. SMU\_core Alive alarm can be monitored when SMU\_stdby is disabled. Thus, a user could decide to run an application with both SMU\_core and SMU\_stdby enabled or with the SMU\_core enabled and the SMU\_stdby disabled.

However, the Fault Signaling Protocol is generated by the SMU\_core. As a consequence, if the SMU\_core is not enabled and in run state, the FSP ErrorPins are in their default state, which is the FSP fault state. In such a configuration, the reaction of the SMU\_stdby to any alarm (setting the ErrorPins in fault state) will not be noticeable.

Thus, the SMU\_stdby cannot be used to react to alarms when the SMU\_core is not enabled and in run state.

PMS Alarms occurring during warm PORST will not be latched neither in the SMU\_core nor in the SMU\_stdby Alarm Status Registers.

## 15.4 Registers

This section describes the SMU\_core module and SMU\_stdby module registers.

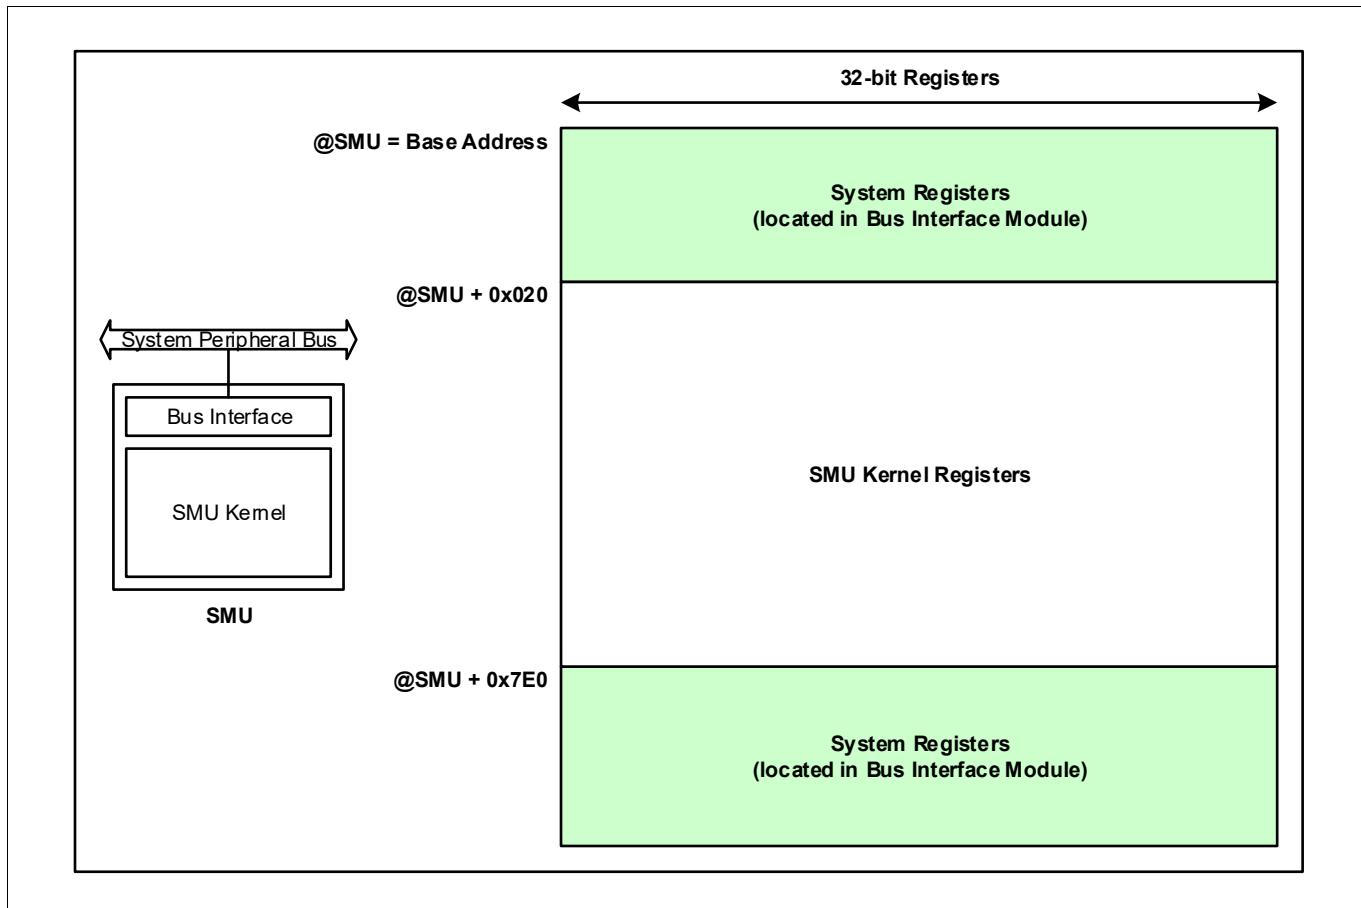

## Safety Management Unit (SMU)

### 15.4.1 SMU\_core Module Registers

**Figure 171** shows the SMU\_core module register map.

**Table 539** shows the SMU\_core Address Space

**Table 540** lists all registers implemented in the SMU\_core.

#### **15.4.1.1 System Registers description**

## Clock Control Register

The Clock Control Register allows the programmer to adapt the functionality and power consumption of the module to the requirements of the application. The SMU\_core shall be enabled per default.

**Note:** The other features controlled by the CLC register are not supported by the SMU\_core.

**CLC**  
**Clock Control Register** (000<sub>H</sub>) Application Reset Value: 0000 0000<sub>H</sub>

## Safety Management Unit (SMU)

### Module Identification Register

ID

Field	Bits	Type	Description
<b>MOD_REV</b>	7:0	r	<b>Module Revision Number</b> This bit field defines the module revision number. The value of a module revision starts with 01H (first revision).
<b>MOD_TYPE</b>	15:8	r	<b>Module Type</b> The bit field is set to C0H which defines the module as a 32-bit module.
<b>MOD_NUMBE R</b>	31:16	r	<b>Module Number Value</b> This bit field defines a module identification number. The value for the SMU module is 0089H.

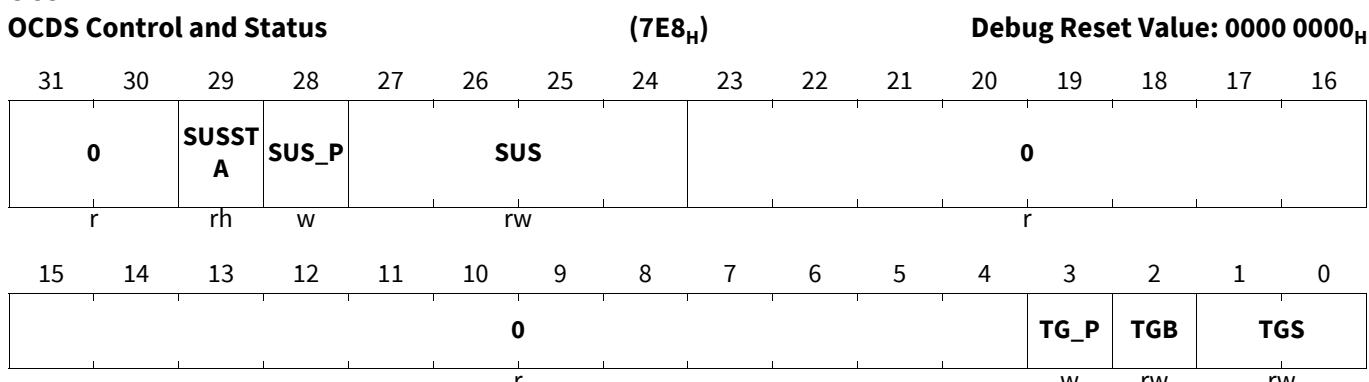

### OCDS Control and Status

SMU OCDS Control Register. This register is implemented in the BPI.

The OCDS Control and Status (OCS) register is reset by Debug Reset. The OCS register includes the module related control bits for the OCDS Trigger Bus(OTGB).

The register can only be written and the OCS control register bits are only effective while the OCDS is enabled (OCDS enable = '1'). While OCDS is not enabled, OCS reset values/modes are effective.

OCS

**Safety Management Unit (SMU)**

Field	Bits	Type	Description
<b>TGS</b>	1:0	rw	<b>Trigger Set for OTGB0/1</b> 00 <sub>B</sub> No Trigger Set output 01 <sub>B</sub> TS16_SMU <b>others</b> , reserved
<b>TGB</b>	2	rw	<b>OTGB0/1 Bus Select</b> 0 <sub>B</sub> Trigger Set is output on OTGB0 1 <sub>B</sub> Trigger Set is output on OTGB1
<b>TG_P</b>	3	w	<b>TGS, TGB Write Protection</b> TGS and TGB are only written when TG_P is 1, otherwise unchanged. Read as 0.
<b>SUS</b>	27:24	rw	<b>OCDS Suspend Control</b> Controls the sensitivity to the suspend signal coming from the OCDS Trigger Switch (OTGS) 0 <sub>H</sub> Will not suspend 1 <sub>H</sub> Hard suspend. Clock is switched off immediately. 2 <sub>H</sub> Soft suspend. <b>others</b> , reserved
<b>SUS_P</b>	28	w	<b>SUS Write Protection</b> SUS is only written when SUS_P is 1, otherwise unchanged. Read as 0.
<b>SUSSTA</b>	29	rh	<b>Suspend State</b> Read as 0; must be written with 0.
<b>0</b>	23:4, 31:30	r	<b>Reserved</b> Read as 0; must be written with 0.

**SMU\_core Access Enable Register 0**

The Access Enable Register 0 controls write access for transactions with the on chip bus master TAG ID 000000B to 011111B (see On Chip Bus chapter for the products TAG ID <-> master peripheral mapping). The BPI\_FPI is prepared for a 6-bit TAG ID. The registers ACCEN0 / ACCEN1 are providing one enable bit for each possible 6-bit TAG ID encoding.

**Note:** The mapping with the on-chip master-capable modules is described in the bus chapters of the microcontroller.

**ACCEN0****SMU\_core Access Enable Register 0**      (7FC<sub>H</sub>)      Application Reset Value: FFFF FFFF<sub>H</sub>

## Safety Management Unit (SMU)

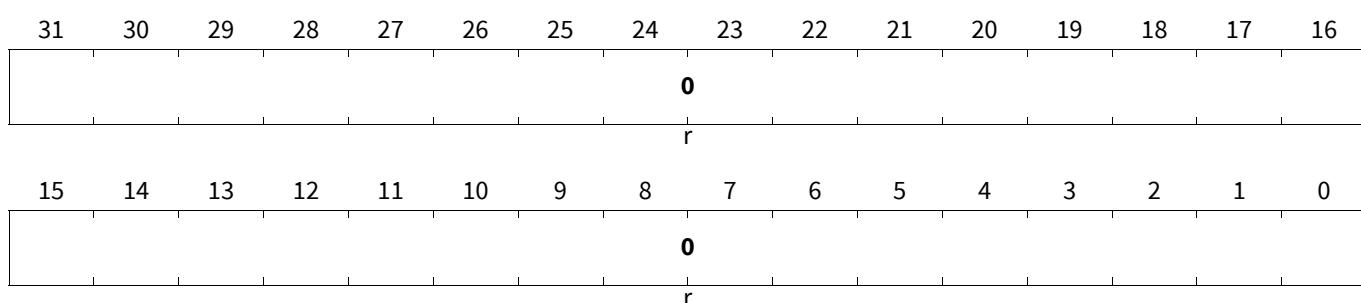

Field	Bits	Type	Description
<b>ENy (y=0-31)</b>	y	rw	<b>Access Enable for Master TAG ID y</b> This bit enables write access to the module kernel addresses for transactions with the Master TAG ID y 0 <sub>B</sub> Write access will not be executed 1 <sub>B</sub> Write access will be executed

### SMU\_core Access Enable Register 1

The Access Enable Register 1 controls write access for transactions with the on chip bus master TAG ID 100000B to 111111B (see On Chip Bus chapter for the products TAG ID <>> master peripheral mapping). The BPI\_FPI is prepared for a 6-bit TAG ID. ACCEN1 is not implemented with register bits as the related TAG IDs are not used in the AURIX devices.

#### ACCEN1

**SMU\_core Access Enable Register 1** **Application Reset Value: 0000 0000<sub>H</sub>**

Field	Bits	Type	Description
<b>0</b>	31:0	r	<b>Reserved</b> Read as 0; should be written with 0.

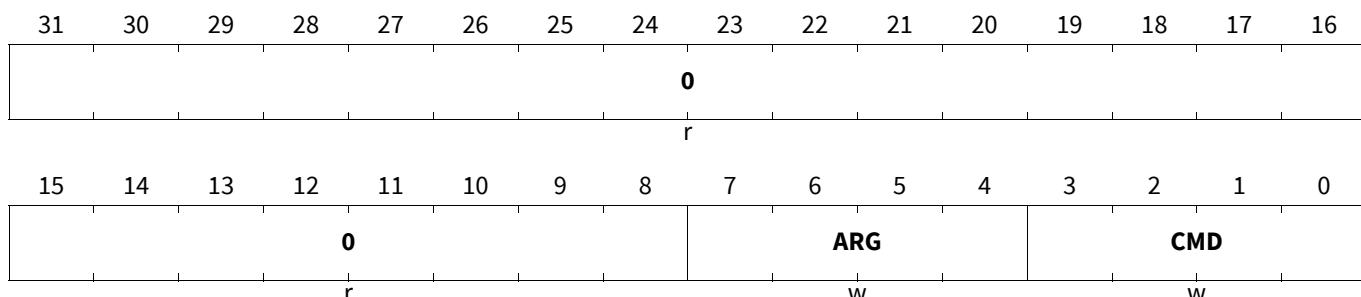

## Safety Management Unit (SMU)

### 15.4.1.2 SMU\_core Configuration Registers

#### Command Register

CMD

#### Command Register

(020<sub>H</sub>)Application Reset Value: 0000 0000<sub>H</sub>

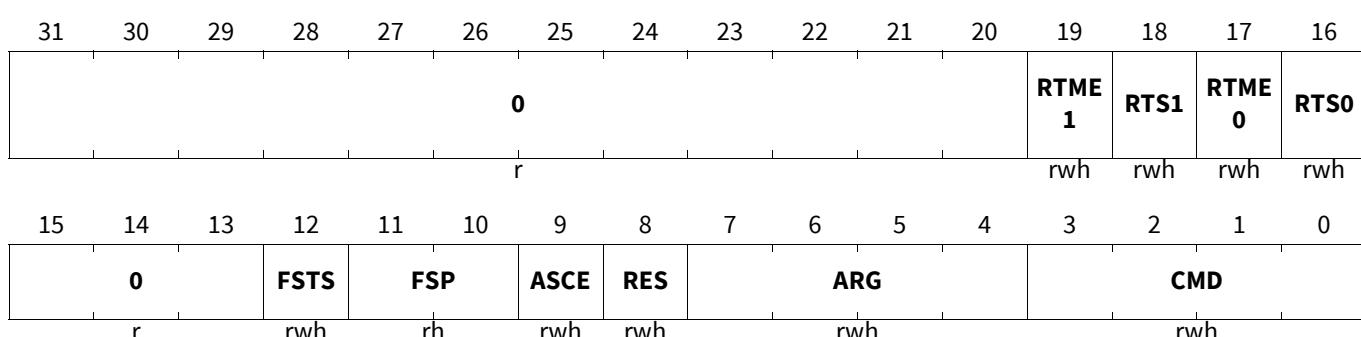

Field	Bits	Type	Description
CMD	3:0	w	<b>Implements the SMU_core Command Interface.</b> See <a href="#">Table 533 “SMU_core Commands” on Page 20</a> for the command encoding. Read as 0.
ARG	7:4	w	<b>Implements the SMU_core Command Interface.</b> Argument to be used with the command. See <a href="#">Table 533 “SMU_core Commands” on Page 20</a> for the argument encoding. Read as 0.
0	31:8	r	<b>Reserved</b> Read as 0; should be written with 0

#### Status Register

Note: A write to this register (regardless of the data written) clears all the fields with the rwh type. If on the same cycle a software write event and hardware event is detected, the hardware action wins.

STS

#### Status Register

(024<sub>H</sub>)Application Reset Value: 0000 0X00<sub>H</sub>

**Safety Management Unit (SMU)**

Field	Bits	Type	Description
<b>CMD</b>	3:0	rwh	<b>Last command received</b> Same encoding as CMD field of <a href="#">CMD register</a>
<b>ARG</b>	7:4	rwh	<b>Last command argument received</b> Same encoding as ARG field of <a href="#">CMD register</a>
<b>RES</b>	8	rwh	<b>Result of last received command</b> $0_B$ Command was successful $1_B$ Command failed
<b>ASCE</b>	9	rwh	<b>Alarm Status Clear Enable</b> This bit controls if a status flag set in an AG<x> register upon detection of an alarm event can be cleared by software or not. When ASCE is enabled software shall write a 1 to the bit position in AG<x> to clear the bit (W1C). When a W1C action takes place the ASCE bit is automatically cleared to 0 by hardware and software shall set the ASCE bit again by using the SMU_ASCE() command. $0_B$ Alarm status bits AG<x> can not be cleared $1_B$ Alarm status bits AG<x> can be cleared.
<b>FSP</b>	11:10	rh	<b>Fault Signaling Protocol status</b> FSP[0] = FSP_STS[0] input signal FSP[1] = FSP_STS[1] input signal This field is updated by hardware every clock cycle, therefore a software clear on write is not meaningful for this field.  Note: When the FSP[0] and/or FSP[1] is set in fault state by the SMU_stdby this bitfield does not reflect the actual state of the ErrorPins. Indeed, the SMU_stdby sets the ErrorPins in high impedance state to indicate the presence of a fault.
<b>FSTS</b>	12	rwh	<b>Fault State Timing Status</b> This bit indicates if the minimum timing duration of the FSP fault state has been reached or not. The bit is cleared by hardware when the fault state is entered. $0_B$ Minimum timing duration not reached $1_B$ Minimum timing duration reached
<b>RTS0</b>	16	rwh	<b>Recovery Timer 0 Status</b> See " <a href="#">Recovery Timer" on Page 18</a> for the usage of this field. $0_B$ Recovery Timer not running $1_B$ Recovery Timer running
<b>RTMEO</b>	17	rwh	<b>Recovery Timer 0 Missed Event</b> See " <a href="#">Recovery Timer" on Page 18</a> for the usage of this field. $0_B$ Recovery Timer event not detected $1_B$ Recovery Timer event detected
<b>RTS1</b>	18	rwh	<b>Recovery Timer 1 Status</b> See " <a href="#">Recovery Timer" on Page 18</a> for the usage of this field. $0_B$ Recovery Timer not running $1_B$ Recovery Timer running

## Safety Management Unit (SMU)

Field	Bits	Type	Description
<b>RTME1</b>	19	rwh	<b>Recovery Timer 1 Missed Event</b> See “ <b>Recovery Timer</b> ” on Page 18 for the usage of this field. $0_B$ Recovery Timer event not detected $1_B$ Recovery Timer event detected
<b>0</b>	15:13, 31:20	r	<b>Reserved</b> Read as 0; should be written with 0.

### Fault Signaling Protocol

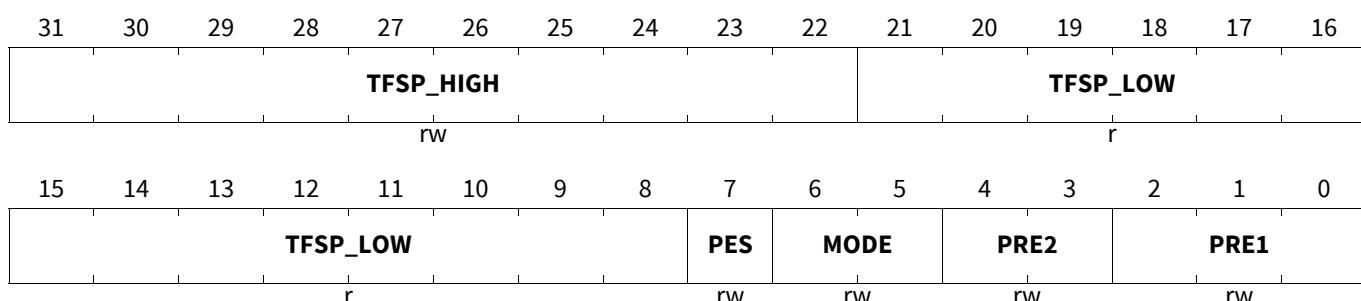

This register controls the timing of the fault signaling protocol.

#### FSP

#### Fault Signaling Protocol

(028<sub>H</sub>)

PowerOn Reset Value: 003F FF00<sub>H</sub>

Field	Bits	Type	Description
<b>PRE1</b>	2:0	rw	<b>Prescaler1</b> Dividing factor to apply to the reference clock fBACK. It is assumed that the maximal value for fBACK is 100 MHz with a precision of 5%. The divided clock is used as reference to generate the timing of the fault signaling protocol fault state.  <i>Note:</i> <i>It is only allowed to write PRE1 when the SMU is not in the Fault State and FSP is in Bi-stable protocol mode. Also, it is not allowed to write to the PRE1 when at least one recovery timer is running.</i>  The frequency of the divided clock (called FSMU_FS) is defined as follows: $000_B$ reference clock frequency divided by 2 $001_B$ reference clock frequency divided by 4 $010_B$ reference clock frequency divided by 8 $011_B$ reference clock frequency divided by 16 $100_B$ reference clock frequency divided by 32 $101_B$ reference clock frequency divided by 64 $110_B$ reference clock frequency divided by 128 $111_B$ reference clock frequency divided by 256

## Safety Management Unit (SMU)

Field	Bits	Type	Description
<b>PRE2</b>	4:3	rw	<p><b>Prescaler2</b></p> <p>Dividing factor to apply to the reference clock fBACK in order to generate the timing of the fault free state for the dynamic dual rail and time switching modes of the fault signaling protocol.</p> <p><i>Note:</i> <i>It is only allowed to write PPRE2 when the SMU is not in the Fault State and FSP is in Bi-stable protocol mode.</i></p> <p>The frequency of the divided clock (called FSMU_FFS) is defined as follows:</p> <ul style="list-style-type: none"> <li><math>00_B</math> reference clock frequency divided by 512</li> <li><math>01_B</math> reference clock frequency divided by 1024</li> <li><math>10_B</math> reference clock frequency divided by 2048</li> <li><math>11_B</math> reference clock frequency divided by 4096</li> </ul>
<b>MODE</b>	6:5	rw	<p><b>Fault Signaling Protocol configuration</b></p> <ul style="list-style-type: none"> <li><math>00_B</math> Bi-stable protocol</li> <li><math>01_B</math> Dual Rail protocol</li> <li><math>10_B</math> Time switching protocol</li> <li><math>11_B</math> Reserved</li> </ul>
<b>PES</b>	7	rw	<p><b>Port Emergency Stop (PES)</b></p> <p>When this bit is set a Port Emergency Stop is automatically requested when an alarm event configured to start the Fault Signaling Protocol is detected.</p> <ul style="list-style-type: none"> <li><math>0_B</math> Port Emergency Stop disabled</li> <li><math>1_B</math> Port Emergency Stop enabled</li> </ul>
<b>TFSP_LOW</b>	21:8	r	<p><b>Specifies the FSP fault state duration</b></p> <p>TFSP_FS= TFSP_HIGH &amp; TPSP_LOW. TFSP_LOW shall be specified as a number of FSMU_FS ticks. TFSP_LOW is defined so that the minimum duration is greater than 250 us. It can not be changed by software.</p>
<b>TFSP_HIGH</b>	31:22	rw	<p><b>Specifies the FSP fault state duration</b></p> <p>TFSP_FS= TFSP_HIGH &amp; TPSP_LOW. TFSP_HIGH shall be specified as a number of FSMU_FS ticks. TFSP_HIGH and PRE1 shall enable to configure a fault state duration of 500 ms.</p> <p><i>Note:</i> <i>It is only allowed to write TFSP_HIGH when the SMU is not in the Fault State and FSP is in Bi-stable protocol mode.</i></p>

### Alarm Global Configuration

This register controls some properties related to the behavior of the SMU\_core to alarm.

## Safety Management Unit (SMU)

### AGC

#### Alarm Global Configuration

(02C<sub>H</sub>)Application Reset Value: 0000 0000<sub>H</sub>

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
0	EFRST		PES				0			RCS					
r	rw		rw				r			rw					

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
		0			IGCS2		0		IGCS1		0		IGCS0		
		r			rw		r		rw		r		rw		

Field	Bits	Type	Description
IGCS0	2:0	rw	<b>Interrupt Generation Configuration Set 0</b> Defines the output value of the interrupt request vector when the alarm configuration flag selects the interrupt configuration set 0. Enables to issue an interrupt request to several CPUs: see “ <a href="#">Interfaces to the Interrupt Router” on Page 7.</a>
IGCS1	6:4	rw	<b>Interrupt Generation Configuration Set 1</b> Defines the output value of the interrupt request vector when the alarm configuration flag selects the interrupt configuration set 1. Enables to issue an interrupt request to several CPUs: see “ <a href="#">Interfaces to the Interrupt Router” on Page 7.</a>
IGCS2	10:8	rw	<b>Interrupt Generation Configuration Set 2</b> Defines the output value of the interrupt request vector when the alarm configuration flag selects the interrupt configuration set 2. Enables to issue an interrupt request to several CPUs: see “ <a href="#">Interfaces to the Interrupt Router” on Page 7.</a>
RCS	21:16	rw	<b>CPU Reset Configuration Set</b> Defines the output value of the CPU reset request vector when the alarm configuration flag selects the CPU Reset Configuration Set. Enables to issue an reset request to several CPUs if required. More complex reset scenarios can be handled by using software interrupts. Setting the bit n to 1 enables issuing a reset request to CPUn.
PES	28:24	rw	<b>Port Emergency Stop</b> This field enables control of the Port Emergency Stop (PES) feature independently for each internal action. When an action is triggered and if the corresponding bit (as defined below) is set, the hardware triggers automatically a port emergency stop request. Each bit of PES is allocated to an action as follows: 01 <sub>H</sub> SMU_IGCS0 activates PES 02 <sub>H</sub> SMU_IGCS1 activates PES 04 <sub>H</sub> SMU_IGCS2 activates PES 08 <sub>H</sub> SMU_NMI activates PES 10 <sub>H</sub> SMU_CPU_RESET activates PES

## Safety Management Unit (SMU)

Field	Bits	Type	Description
<b>EFRST</b>	29	rw	<b>Enable FAULT to RUN State Transition</b> See “ <b>FSP Fault State</b> ” on Page 28 chapter for the usage of this field. 0 <sub>B</sub> FAULT to RUN State Transition disabled 1 <sub>B</sub> FAULT to RUN State Transition enabled
0	3, 7, 15:11, 23:22, 31:30	r	<b>Reserved</b> Read as 0; should be written with 0

### Recovery Timer Configuration

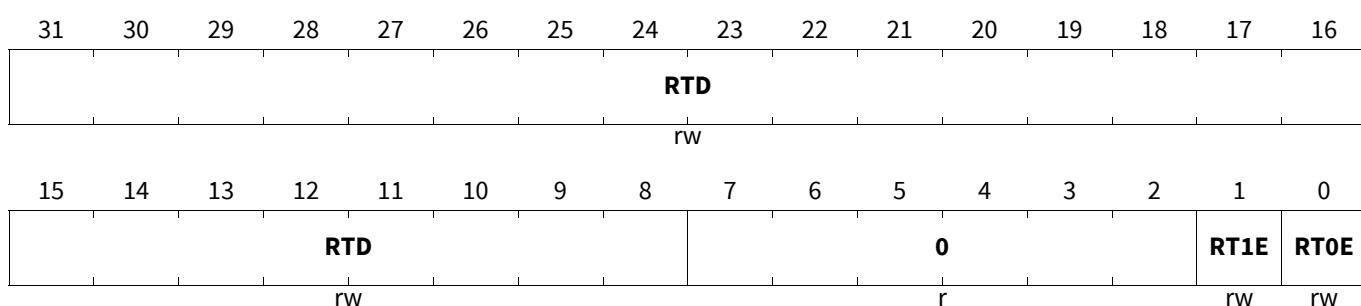

This register controls the timing duration of the recovery timer.

#### RTC

#### Recovery Timer Configuration

(030<sub>H</sub>)

Application Reset Value: 003F FF03<sub>H</sub>

Field	Bits	Type	Description
<b>RT0E</b>	0	rw	<b>RT0 Enable Bit</b> 0 <sub>B</sub> Recovery Timer 0 is disabled 1 <sub>B</sub> Recovery Timer 0 is enabled
<b>RT1E</b>	1	rw	<b>RT1 Enable Bit</b> 0 <sub>B</sub> Recovery Timer 1 is disabled 1 <sub>B</sub> Recovery Timer 1 is enabled
<b>RTD</b>	31:8	rw	<b>Recovery Timer Duration</b> This field specifies the maximum duration of the recovery timer. When the timer counter reaches the programmed value, the internal alarm rt_timeout is issued. The timer is stopped by a SMU_RTStop() command before the recovery timer. RTD shall be specified as a number of the FSMU_FS clock ticks. <i>Note:</i> It is not allowed to write to the RTD when at least one recovery timer is running.
0	7:2	r	<b>Reserved</b> Read as 0; should be written with 0

## Safety Management Unit (SMU)

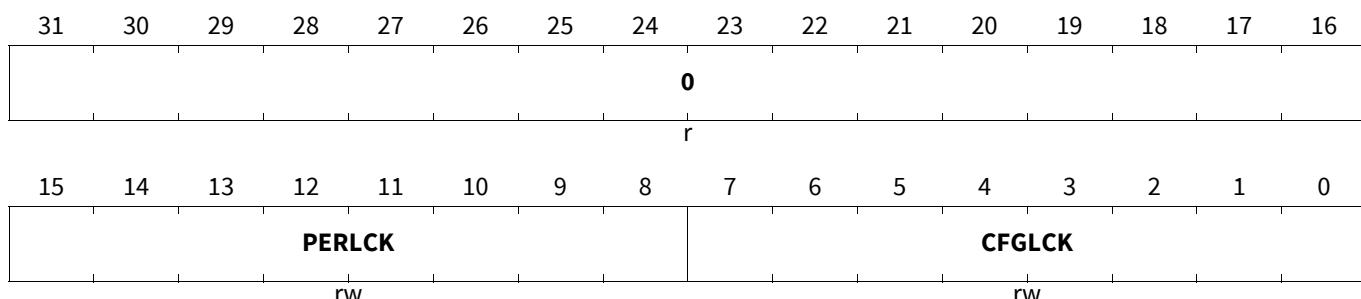

### Key Register

#### KEYS

##### Key Register

(034<sub>H</sub>)

Application Reset Value: 0000 0000<sub>H</sub>

Field	Bits	Type	Description
CFGLOCK	7:0	rw	<b>Configuration Lock</b> The SMU_core configuration is only possible if this field is set to 0xBC. Refer to “ <a href="#">Register Properties</a> on Page 31” for the list of registers controlled by this field.
PERLCK	15:8	rw	<b>Permanent Lock</b> If this field is set to 0xFF, no further configuration of the SMU_core is possible. Refer to “ <a href="#">Register Properties</a> on Page 31” for the list of registers controlled by this field.
0	31:16	r	<b>Reserved</b> Read as 0; shall be written with 0

### Debug Register

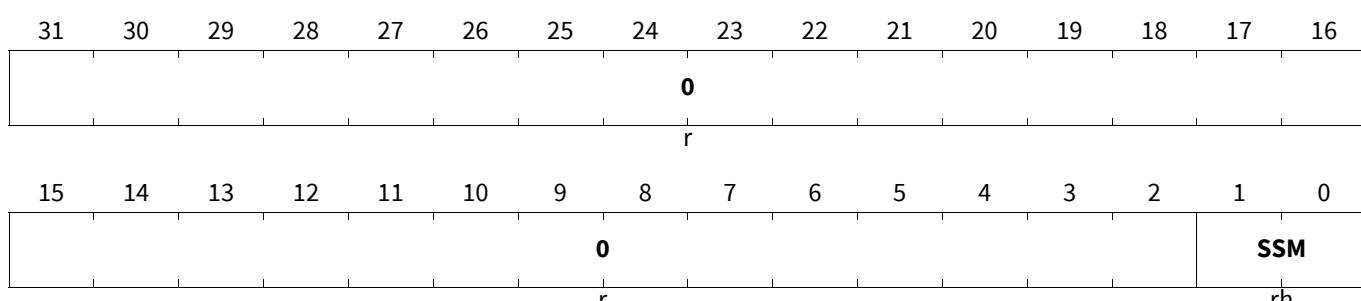

This register enables to observe some internal states of the SMU\_core hardware. Definition will be completed based on design information.

#### DBG

##### Debug Register

(038<sub>H</sub>)

PowerOn Reset Value: 0000 0000<sub>H</sub>

Field	Bits	Type	Description

## Interrupt Router (IR)

# 16 Interrupt Router (IR)

The chapter describes the Interrupt Router module that schedules interrupts (here called service requests) from external resources, internal resources and SW to the CPU and the DMA modules (here called Service Provider).

### Scope of this Document

This document is valid for the TC3xx and covers the topics:

- Interrupt system architecture
- Interrupt system configuration
- Interrupt Router operations

### 16.1 Feature List

The following list shows the main features of the interrupt router module:

- Interrupt System with support of up to 1024 service requests
- Support of up to 255 service request priority levels per ICU<sup>1)</sup> / Service Provider
- Support of up to 8 ICUs / Service Providers
- A dedicated ICU for each implemented CPU / DMA module (Service Provider)
- Low latency arbitration - three / four clocks<sup>2)</sup> from receipt of an service request to sending it to the service provider
- Each peripheral interrupt with a dedicated Service Request Node (SRN)
- Each SRN with a programmable 8-bit priority vector<sup>1)</sup>
- Each SRN can be mapped to one of the implemented ICUs / Service Providers
- SRNs are cleared automatically by hardware on interrupt acknowledge by the configured service provider
- Interrupt System with Integrity support
- 8 General Purpose Service Requests (GPSR) per CPU that can be used as Software Interrupts (not assigned to peripherals or external interrupts)
- Service Request Broadcast Registers (SRB) to signal General Purpose Service Requests (Software Interrupts) simultaneously to multiple Service Providers
- Priority dependent masking of service requests (for CPUs, related control registers included in the CPUs)
- External Interrupts with filter modes and trigger modes (to e.g. falling edge, rising edge, high or low level). Modes can be configured during runtime<sup>3)</sup>
- CPU wake up support (service request to CPUx is signalled to SCU to wake up CPUx in case CPUx is in IDLE state)

### 16.2 Delta to TC2xx

The following functional changes where introduced from Aurix to TC3xx:

- General Purpose Service Request Group: Number of Service Request Nodes per group changed from 4 to 8 SRNs (see “[General Purpose Service Requests, Service Request Broadcast](#)” on Page 19)

1) Max. 255 of the implemented service requests can be mapped to one CPU

2) Depends on the complexity and the clock frequency of the Interrupt Router. Details for the implementation are described in the chapter Module Implementation

3) External Interrupt logic and related control registers are described in the System Control Unit (SCU) chapter, External Request Unit (ERU)

## Interrupt Router (IR)

- Broadcast Register: Broadcast register bit map was adapted to new GPSR SRN number (see “[General Purpose Service Requests, Service Request Broadcast” on Page 19](#))
- Broadcast Register: Each Broadcast register now with a dedicated ACCEN register (see “[Access protection of SRBx registers \(ACCEN\\_SRBy\)](#)” on Page 20)
- SRCx: Access protection of SRCx[31:0] was introduced (one ACCEN register per implemented TOS encoding/ICU, see “[Protection of the SRC Registers” on Page 7](#) )
- SRC.ECC: Size of ECC bit field was changed from 6 to 5 bit (see “[General Service Request Control Register Format](#)” on Page 4)
- SRC.TOS: Size of TOS bit field was changed to 3 bit (see “[General Service Request Control Register Format](#)” on Page 4)
- SRC offset and Index numbering scheme changed: SRCs are mapped to a 1024 \* 32 bit range. The Index Number (0-1023) is equal to the 32 bit offset of the SRC (see “[General Service Request Control Register Format](#)” on Page 4)
- On detection of a service request signaled to a Reserved TOS, an alarm is signaled to the SMU
- Mapping of SRC registers to the IR address map was re-worked

### 16.3 Overview

An interrupt request can be serviced either by the CPUs or by a DMA module. Interrupt requests are called “service requests” rather than “interrupt requests” in this document because they can be serviced by either one of the service providers.

The interrupt system is realized in the Interrupt Router module which includes the Service Request Nodes (SRNs), the Interrupt Control Units (ICUs) and additional functionality for SW development support.

As shown in [Figure 172](#), each module that can generate service requests is connected to one or more Service Request Nodes (SRNs) in the central Interrupt Router module. The Interrupt Router module includes also several general purpose Service Request Nodes (SRNs) that can be used for software (SW) triggered service requests.

Each SRN contains a Service Request Control Register (SRC) to configure the service request regarding e.g. priority, mapping to one of the available service providers.

Each SRN is connected to all ICUs in the interrupt router module where the SRNs control register setting defines the target service provider and the priority of the service request.

Each ICU handles the interrupt arbitration among competing service requests from SRNs that are mapped to the ICU.

Each ICU is connected to one service provider (CPU or DMA module) where the ICU offers the valid winning service request/SRN of an arbitration round and the service provider signals back to the ICU when and which service request it is processing.

## Interrupt Router (IR)

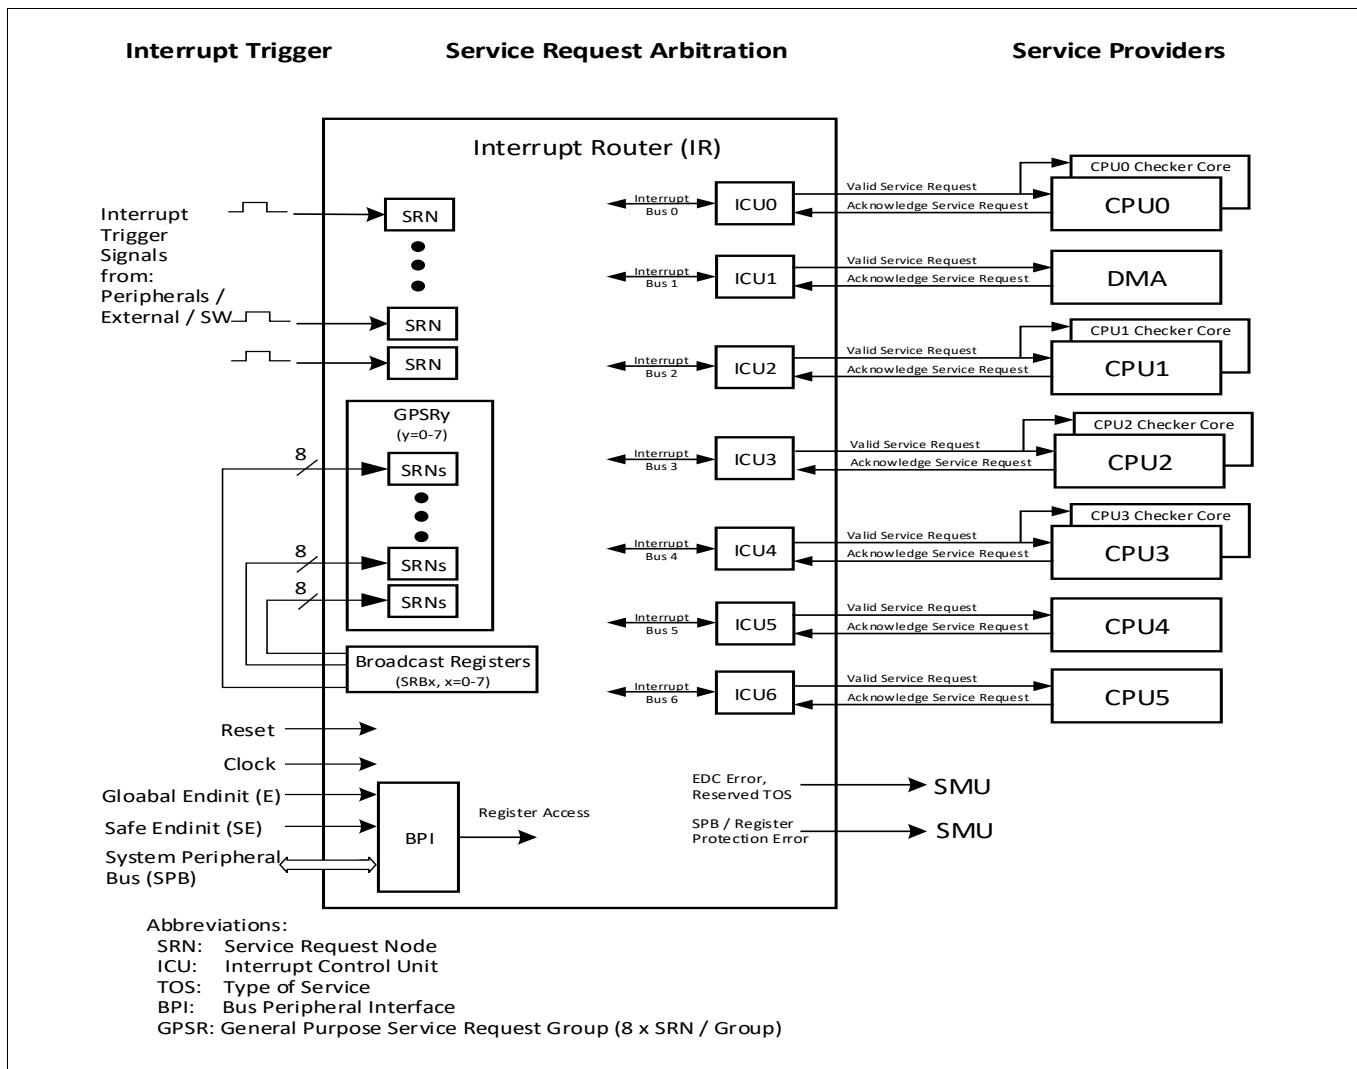

Figure 172 Block Diagram of the Interrupt System

## 16.4 Service Request Nodes (SRN)

Each Service Request node (SRN) inside the Interrupt Router module contains a Service Request Control (SRC) Register and interface logic that connects it to the triggering unit outside the Interrupt Router module and to the interrupt arbitration buses inside the Interrupt Router (see also: [Figure 172](#)).

### 16.4.1 Service Request Control Registers

All Service Request Control Registers in the Interrupt Router module have the same format. In general, these registers contain:

- Enable/disable information (SRE, [Page 9](#))
- Service Request Set bit and Service Request Clear bit (SETR, CLRR, [Page 9](#))
- Software Sticky Bit (SWS) as indication of an Software initiated Service Request (SWS, [Page 12](#))
- Service Request Priority Level vector (SRPN, [Page 10](#))
- Service Request destination / Service Provider (TOS, [Page 9](#))
- Service request status bit (SRR, [Page 9](#))
- Integrity errors signalled to the Safety Management Unit (SMU) ([Page 11](#))
- Interrupt Overflow bits (IOV, [Page 11](#))

**Interrupt Router (IR)**

Besides being activated by the associated triggering unit through hardware, each SRN can also be set or reset by software via two software-initiated service request control bits.

**16.4.1.1 General Service Request Control Register Format****16.4.1.1.1 Service Request Control Register (SRC)**

The description given in this chapter characterizes the Service Request Control registers (SRC).

Pls. note: several modules have additional interrupt related control registers on module level (e.g. interrupt status, set clear or enable register). These module registers are described in the corresponding sections of the module chapters.

**Service Request Control Register i****SRCi (i=0-1023)**

## Interrupt Router (IR)

### 16.4.1.2 Changing the SRN configuration

All Service Request Nodes are disabled per default. To use a Service Request Node, it has to be configured and enabled by setting the SRC.SRE bit=‘1’.

The Service Request Nodes can be configured regarding the interrupt service provider target (SRC.TOS) and regarding the service request priority number (SRC.SRPN).

Once an SRN is enabled, the TOS and/or SRPN bit fields can be changed by using the following sequence:

- Disable the SRN (set SRC.SRE=‘0’)
- Check that the SRN is disabled (read back SRC.SRE and check for SRE=‘0’)
- Check the register LWSRx (Last Winning Service Request, read/poll LWSRx, see note below):
  - If LWSRx.STAT=‘0’ or LWSRx.SRPN or LWSRx.ECC are not equal to the old SRC values anymore go on with the next step (change SRC value)
  - If LWSRx.STAT=‘1’ and LWSRx.SRPN and LWSRx.ECC are equal to the (old) SRC value check LWSRx again
- Change the SRC.TOS and/or SRC.SRPN bit field
- Enable the SRN (SRC.SRE=‘1’) (write to SRC.SRE)

If the service request that has to be re-configured was just pending when it was disabled, it can be that the service request was already arbitrated and provided to the Interrupt Service Provider (CPU or DMA). In this situation the enable of the re-configured SRN should be delayed until the LWSRx poll algorithm above is fulfilled to ensure that the configuration of the just disabled SRN is not present anymore in the interrupt system. The time of the read/poll sequence is not deterministic if the disabled Service Request Node is mapped to TriCore. If the ISP is the DMA module, enter and acknowledge are signalled in the same cycle. The ‘x’ in LWSRx means that the LWSR register related to the TOS setting has to be checked (TOS=0 -> LWSR0, TOS=1 -> LWSR1, ...).

### 16.4.1.3 Protection of the SRC Registers

The SRC register is write protected via an On Chip Bus Master TAG-ID protection (see [Chapter 16.8.1](#)). This protection is controlled via the Interrupt Router control registers ACCEN\_CONFIG and ACCEN\_TOSx.

#### Access protection of SRC[31:16]

- SRC[31:16] is write protected by ACCEN\_TOSx (x = SRC.TOS)
- SRC[15:0] is write protected by ACCEN\_CONFIG

The split of the SRC write protection into different write protection registers for SRC[31:16] and SRC[15:0] allows to define a different protection configuration for the configuration of all the Service Request Nodes (that is normally static during runtime) and the Service Request Nodes control registers that might be used during runtime by the related SW task as part of normal application (e.g. software interrupt).

#### Write access to SRC[31:16] with access protection violation

When an SRC register is written with a 32 bit data access, only the SRC register parts without ACCEN protection violation will be updated:

- Violation for SRC[31:16] (ACCEN\_TOSx) and SRC[15:0] (ACCEN\_CONFIG)
- no update of the SRC registers, Alarm send to SMU
- Violation for SRC[31:16] (ACCEN\_TOSx)
- no update of SRC[31:16], updated of SRC[15:0], Alarm send to SMU
- Violation for SRC[15:0] (ACCEN\_CONFIG)
- update of SRC[31:16], no updated of SRC[15:0], Alarm send to SMU

## Interrupt Router (IR)

### Access protection of the SRC configuration (SRC[15:0])

The lower half of all SRC registers SRCx[15:0] is write protected via the ACCEN\_CONFIG register.

This means that the configuration of the ACCEN\_CONFIG defines which TAG ID is allowed to write to the lower half of all implemented SRC registers. Please note that a modification of SRC.TOS, SRC.SRE, SRC.SRPN (all mapped in SRC[15:0]) will indirectly also modify the SRC.ECC bit field.

### Background / Use Case (SRC[15:0] protected by ACCEN\_CONFIG)

SRCx[15:0] includes the configuration bits / bit fields of the Service Request Nodes that are normally:

- configured during startup
- static during runtime
- shall not be modified by non safe SW tasks

ACCEN\_CONFIG allows a configuration where only specific TAG IDs are enabled to re-configure the SRC configurations, for example a CPUx.DMI Safe TAG ID.

### Access protection of the SRC control bits (SRC[31:16])

The upper half of a SRC register SRC[31:16] is write protected via one of the ACCEN\_SRC\_TOSx registers.

The ACCEN\_SRC\_TOSx register that protects a SRN is selected by the SRC.TOS configuration of the SRN:

- SRCx.TOS = 0 -> SRC register is write protected by ACCEN\_SRC\_TOS0
- SRCx.TOS = 1 -> SRC register is write protected by ACCEN\_SRC\_TOS1
- SRCx.TOS = 2 -> SRC register is write protected by ACCEN\_SRC\_TOS2
- ...

**Note:** *For 'Reserved' TOS encodings no ACCEN\_SRC\_TOSx register is implemented. This means for an SRCy that is configured with a Reserved TOS encoding, SRCy can be always written. A service request to a not implemented ISP (SRC.TOS=Reserved) will be signalled as alarm to the SMU.*

### Background / Use Case (SRC[31:16] protected by ACCEN\_SRC\_TOSx)

SRCx[31:16] includes the control bits / bit fields of a Service Request Node that can be used during runtime to:

- Set a Service Request (SW interrupt)
- Clear a service Request
- Clear the Interrupt Overflow or Sticky bit
- Inject an ECC error via the SRC.ECC bit field

Without this mechanism, any CPU task and any on chip bus IP with master functionality could e.g. generate SW interrupts to any CPU and/or clear any interrupt.

The implemented mechanism enables the system to encapsulate SW tasks on a 'per CPU' granularity and to restrict the side effects of incorrect SW to the CPU where this SW is executed.

Example: all SRNs that are mapped to CPU0 (TOS=0) are write protected by ACCEN\_SRC\_TOS0. Means that via the ACCEN\_SRC\_TOS0 configuration it is defined which TAG ID is allowed to set or clear service requests to CPU0.

SW. ACCEN\_SRC\_TOS0 could be for example configured that only CPU0 tasks are allowed to set SW interrupts to CPU0. This ensures that a corrupted SW an any other CPU or DMA channel can not influence CPU0 by permanent Software Interrupts.

**Note:** *In this case an access protection error the write is silently ignored, an error is signaled to the SMU. Beside this signaling to the SMU, no other error, interrupt or trap is generated.*

## Interrupt Router (IR)

### 16.4.1.4 Request Set and Clear Bits (SETR, CLRR)

The SETR and CLRR bits allow software to set or clear the service request bit SRR.

- Writing a 1 to SETR causes bit SRR to be set to 1
- Writing a 1 to CLRR causes bit SRR to be cleared to 0
- Writing a 1 to SETR and CLRR at the same time, SRR is not changed
- The value written to SETR or CLRR is not stored
- Writing a 0 to these bits has no effect
- These bits always return 0 when read

### 16.4.1.5 Enable Bit (SRE)

The SRE bit enables an interrupt to take part in the arbitration for the selected service provider. It does not enable or disable the setting of the request flag SRR; the request flag can be set by hardware or by software (via SETR) independent of the state of the SRE bit. This allows service requests to be handled automatically by hardware or through software polling.

#### SRE = 1:

If SRE = 1, pending service requests are passed on to the designated service provider for interrupt arbitration. The SRR bit is automatically set to 0 by hardware when the service request is acknowledged by the Interrupt Service Provider. It is recommended that in this case, software should not modify the SRR bit to avoid unexpected behavior due to the hardware controlling this bit.

#### SRE = 0:

If SRE = 0, pending service requests are not passed on to service providers. Software can poll the SRR bit to check whether a service request is pending. To acknowledge the service request, the SRR bit must then be reset by software by writing a 1 to CLRR.

**Note:** *In this document, ‘active source’ means an SRN whose Service Request Control Register has its request enable bit SRE set to 1 to allow its service requests to participate in interrupt arbitration.*

### 16.4.1.6 Service Request Flag (SRR)

When set, the SRR flag indicates that a service request is pending. It can be set or reset directly by hardware or indirectly through software using the SETR and CLRR bits. Writing directly to this bit via software has no effect.

SRR can be set or cleared either by hardware or by software regardless of the state of the enable bit SRE. However, the request is only forwarded for service if the enable bit is set. If SRE = 1, a pending service request takes part in the interrupt arbitration of the service provider selected by the device’s TOS bit field. If SRE = 0, a pending service request is excluded from interrupt arbitrations.

SRR is automatically reset by hardware when the service request is acknowledged and serviced. Software can poll SRR to check for a pending service request. SRR must be reset by software in this case by writing a 1 to CLRR.

**Note:** *Clearing a pending service request flag SRR and enabling the corresponding service request node (SRN) should be done in two steps / two writes: first clear the SRR flag (SRC.CLRR), than enable the (SRC.SRE).*

### 16.4.1.7 Type-Of-Service Control (TOS)

Each TriCore CPU and each system DMA instance can act as an interrupt service provider (ISP).

## Interrupt Router (IR)

A Service Request Node can be mapped via the TOS bit field to exactly one ISP.

The TOS configuration maps a service request to

- an Interrupt Service Provider (CPUx, DMA)
- the Interrupt Router internal Interrupt Control Unit related to the ISP (ICUx, TOS=0 -> ICU0, TOS=1 -> ICU1, ....)
- an ACCEN\_SRC\_TOSx write protection register (TOS=0 -> ACCEN\_SRC\_TOS0, ...)

*Note:* If a SRN is enabled and configured with a Reserved TOS encoding, a trigger of this SRN by HW or SW is signalled via Alarm to the SMU, no further action.

*Note:* If a SRN is enabled and configured with a Reserved TOS encoding, a trigger of this SRN by HW or SW is signalled via Alarm to the SMU, no further action.

### 16.4.1.8 Service Request Priority Number (SRPN)

The Service Request Priority Number (SRPN) defines the priority of a service request with respect to other sources requesting service from the same service provider, and with respect to the priority of the service provider itself.

Each active SRN mapped to the same service provider (same TOS configuration):

- Can have a unique SRPN value
- Can have a non unique SRPN to give a group of Service Requests the same priority
- For a group of Service Requests with the same SRPN, the sequence of execution can not be defined
- If an SRN is not active – meaning its SRE bit is 0 – no restrictions are applied to the SRPN configuration

#### Service Provider is a CPU

Service requests are associated with Service Request Priority Numbers by an Interrupt Vector Table located in each CPU. This means that the CPU Interrupt Vector Table is ordered by priority number. This is unlike traditional interrupt CPU architectures in which their interrupt vector tables are ordered by the source of the interrupt. The CPU Interrupt Vector Tables allow a single peripheral to have multiple priorities for different purposes.

#### Notes

1. For a CPU, the SRPN value of  $0000_H$  is a special value. A Service Request with the SRPN  $0000_H$  ignored by a CPU. The CPU will not acknowledge it, the related Service Request Node will therefore not be cleared. But because priority 0 is the lowest service request priority, it will not block the Interrupt Router arbitration.
2. TriCore CPUs are providing a flexible interrupt table alignment with a configurable vector spacing of 8 byte or 32 byte. Pls. see also CPU chapter.

#### Service Provider is a DMA

Service Requests are associated with Service Request Priority Numbers to DMA channel numbers:

- SRPN=x will trigger DMA channel x, if DMA channel x implemented

Only the SRPN numbers 0 ... max\_channel\_number will result in a trigger of the related DMA channel.

SRPN numbers > max\_channel number will be handled as any other pending service request to the DMA but will not result in a DMA channel trigger inside the DMA module nor any other signalling.

#### Examples

- In case of an 16 channel DMA module the SRPN number 00H will trigger the channel 0, 07H will trigger the channel 7. All SRPN > 0FH will be handled as any other service request but will not result in a channel trigger.

## Interrupt Router (IR)

- In case of an 64 channel DMA module the SRPN number 00H will trigger the channel 0, 17H will trigger the channel 23 and 3FH. will trigger channel 64. All SRPN > 3FH will not be executed as any other service request but will not result in a channel trigger.
- A corrupted SRC configuration that is triggering a non existing DMA (due to the corruption of TOS, SRPN or SRE) will be detected by the ICU EDC check ([Chapter 16.4.1.9](#)) and signalled to the ICU as soon the service request with the corrupted configuration is acknowledged by the Interrupt Service Provider (here: DMA).

### 16.4.1.9 ECC Encoding (ECC)

The SRC.ECC bit field will be updated by the SRN under the following conditions:

- Write or Read-Modify-Write to SRC[31:0]
- Write to SRC[15:0] (16-bit write)
- Write to SRC[15:8] or write to SRC[7:0] (byte write)

In case of a 32-bit write or a Read-Modify-Write to the SRC, the ECC bit field will be updated with the calculated ECC, the data written to ECC bit field will be ignored.

ECC encoding covers the new values of SRC.SRPN, SRC.TOS, SRC.SRE and the internal 10 bit index number of the written SRN.

There is no permanent ECC check. ECC check will be checked whenever the SRN with an pending service request was accepted by the selected (TOS) service provider as next service request to be processed.

For a check of the error detection mechanisms ECC errors can be inserted (ECC bit field modified) by:

- Writing to SRC[23:16] (byte write)
- Writing to SRC[31:16] (16-bit write)

*Note: In the current implementation the ECC code is only used for error detection. Detected errors are reported to the SMU but not corrected.*

#### ECC Code

The ECC code used for the Interrupt Router Error Detection mechanism is a Hsiao 22\_5 code with DED (double error detection) capability:

```

GEN_ENC22_5 : if (word_width_g/(nb_mems_g*ecc_granularity_g)) = 22 and
(nb_check_bits_g = 5) generate cmr22_5: for i in 0 to nb_check_bits_g - 1 generate
CODE_MATRIX_ROWS(i)      <= code_rows_22_5(i);      end generate; end generate;

type rows_22_5_t is array (4 downto 0) of std_ulogic_vector(21 downto 0); constant
code_rows_22_5 : rows_22_5_t := ("0001001011001011011011",
"00100101010101101",                      "0100100110100110110110",
"1000111000111000111111",                  "11110000001111100011"
);

```

### 16.4.1.10 Interrupt Trigger Overflow Bit (IOV)

The IOV bit is set by HW if both conditions are true:

- Service request is pending
- A new service request is triggered via interrupt trigger or SETR bit

## Interrupt Router (IR)

### 16.4.1.11 Interrupt Trigger Overflow Clear Bit (IOVCLR)

The Interrupt Trigger Overflow Clear Bit can be used to clear the IOV bit. The IOV bit is cleared by writing a '1' to the IOVCLR bit.

### 16.4.1.12 SW Sticky Bit (SWS)

The Software Sticky Bit is set when the SETR (Request Set Bit) is written with 1.

### 16.4.1.13 SW Sticky Clear Bit (SWSCLR)

The Software Sticky Clear Bit can be used to clear the SWS bit. The SWS bit is cleared by writing a '1' to the SWSCLR bit.

## 16.5 Mapping of Module Interrupt Request Triggers to SRNs

All module interrupt requests are mapped to Service Request Nodes (SRN) in the Interrupt Router.

There is one dedicated Service Request Node (SRN) for each module interrupt request.

Each SRN has one unique SRN Index Number within the Interrupt Router module. The index numbers are not required for the functionality of the interrupt router module itself. The index numbers can be used to select a Service Request Nodes for observation via the OTGM feature.

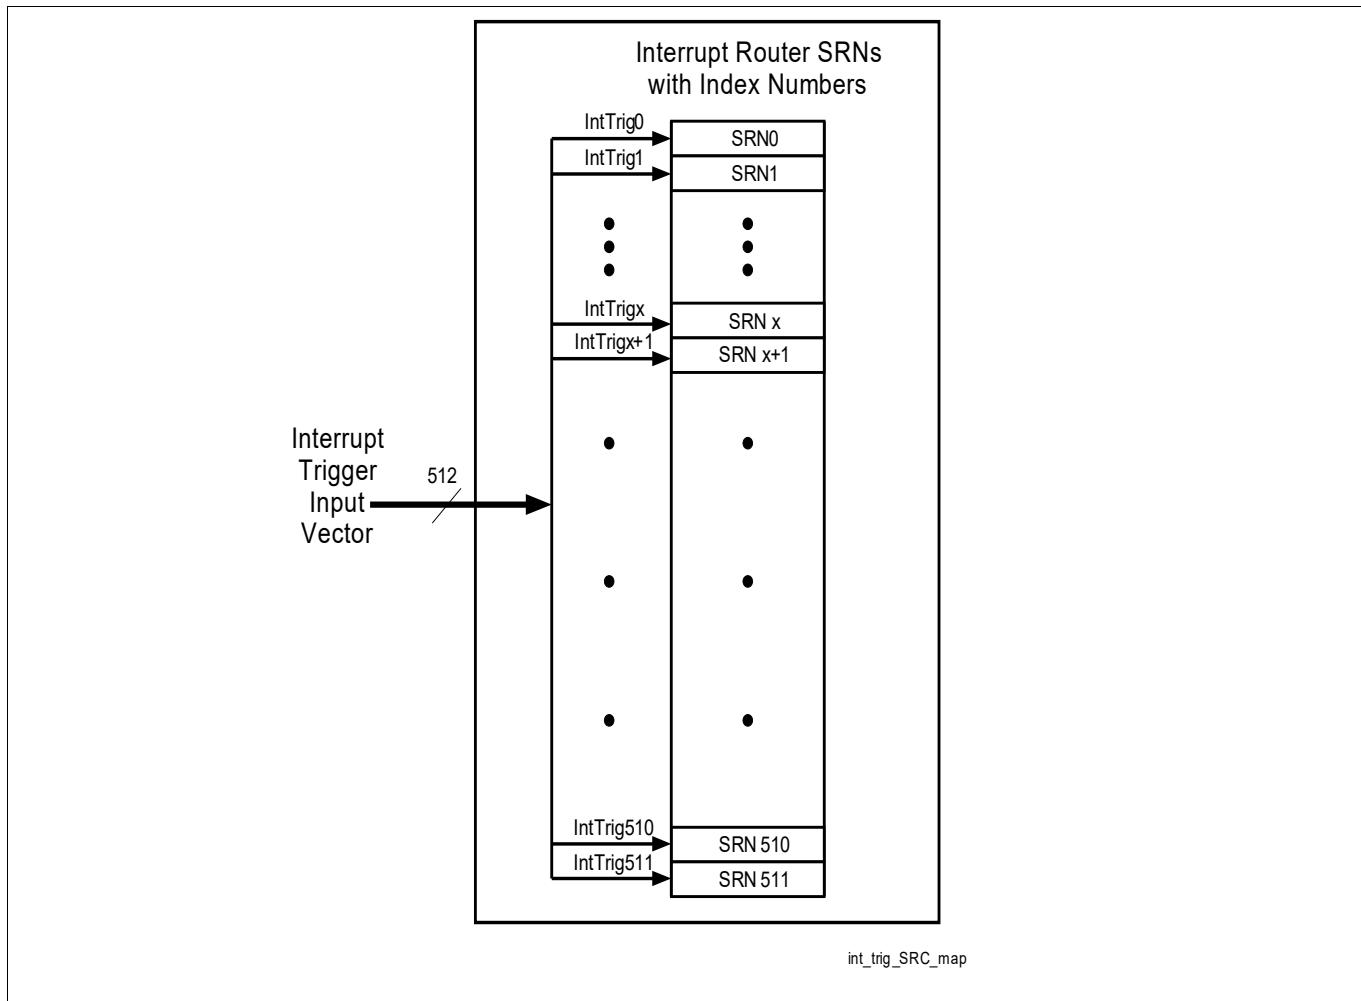

The index number of an Service Request Control (SRC) register can be directly calculated out if its address offset in the SRC address range, see also [Chapter 16.5.1](#).

The Interrupt Router module has one 1024 interrupt trigger input vector. Each interrupt trigger input vector bit [x] is related to one SRN with the SRN Index Number x<sup>1)</sup>. This means that a trigger pulse on interrupt trigger input vector bit [x] will trigger the SRN [x].

*Note:* A positive edge on a interrupt trigger signal is interpreted as interrupt trigger. See also: [Chapter 16.5.3](#).

1) The Interrupt Router register overview table shows for all module service requests the SRC registers with its address offset and the related SRN Index number

## Interrupt Router (IR)

**Figure 173 Mapping of Module Interrupt Trigger to SRN (Index Numbers)**

### 16.5.1 SRC Index Number

Each Service Request Node can be configured and controlled via its dedicated Service Request Control register (SRC). The implemented SRC registers are described in the chapter [Page 28](#).

The address of SRC registers related to one module instance is identical over the whole Aurix family (e.g. interrupts of QSPI0).

Each SRC has a unique index number inside the interrupt router module.

The index number of a Service Request Control (SRC) can be directly calculated out if its address offset in the SRC address range:

- $\text{Index}(\text{SRC}) = \langle \text{SRC Address Offset} \rangle / 4$

Example:

- SRC\_BCU\_SPB offset is 20Hex (see [Chapter 16.13](#))
- $\text{Index}(\text{SRC\_BCU\_SPB}) = 20\text{Hex} / 4 = 8$

### 16.5.2 Interrupts related to the Debug Reset

For software debug purposes the AURIX devices require some service request nodes related only to the Debug Reset. These SRNs keep its SRC register contents and the pending service request status in case of a non Debug

## Interrupt Router (IR)

Reset (e.g. an Application Reset). In combination with other debug reset related debug logic (e.g. breakpoint logic) this allows customer SW to debug situations that result in an application reset and after an application reset.

### 16.5.3 Timing characteristics of Service Request Trigger Signals

The Interrupt Router is clocked with the System Peripheral Bus (SPB) clock Rules for the module interrupt / Service Request trigger signals to the Interrupt Router:

- Trigger signals must be synchronous to SPB clock
- Interrupt Router trigger inputs are edge sensitive (positive clock edge)
- Trigger signal pulse with min. high length of one SPB clock cycle, high pulse length can be > 1 SPB clock cycle
- Debug related trigger signal pulse should be kept high by the related module until the trigger was processed

## Interrupt Router (IR)

### 16.6 Interrupt Control Unit (ICU)

The Interrupt Router module includes one ICU per service provider (CPUs and DMA modules) where each ICU is related to one service provider. SRNs can be mapped to one of the ICUs via the SRNs SRCx.TOS register bit field (see also: [Figure 172](#)).

The Interrupt Control Units (ICU):

- Manages the arbitration among competing service requests from SRNs that are mapped to the ICU
- Provides the winner of the arbitration round to the service provider
- Receives the information from the service provider which service request was accepted
- Checks the accepted service request information (ECC check)
- Signals integrity errors to the Safety Management Unit (SMU)
- Manages the clearing of acknowledged service requests in the related SRNs

**Note:** *In the current implementation the ECC code is only used for error detection. Detected errors are reported to the SMU but not corrected.*

#### 16.6.1 ICU Interface to ISP

The interface in between the ICU and the connected ISP is covered by the IR EDC protection. In order to add robustness to this interface, ICU and ISP outputs are set to default values while no service request is signalled to the ISP and/or while the ISP does not acknowledge a service request to the ICU.

On a stuck-at-one error of the VALID signal, a CPU will ignore the default information (SRPN=8 'h 00), a DMA will trigger Channel and acknowledge the default information to the ICU where it is detected by the EDC protection and an Alarm is send to the SMU.

On a stuck-at-one error of the ACKNOWLEDGE signal, the ICU will take the default values and detect an EDC error.

As long the ICU does not send a service request to the connected ISP (VALID = '0'), the ICU output signals are set to the following default values:

- IDX = 10 'h 000
- PIPN/SRPN = 8 'h 00
- ECC = 5 'h 00

As long the ISP does not acknowledge a service request to the related ICU (ACKNOWLEDGE = '0'), the ICU output signals are set to the following default values:

- IDX = 10 'h 000
- PIPN/SRPN = 8 'h 00
- ECC = 5 'h 00

**Interrupt Router (IR)****16.6.2 ICU Control Registers**

This section describes the Interrupt Control Unit (ICU) registers. Each ICU includes two control registers:

- Latest Winning Service Request register ([Page 16](#)) provides information about the winner of the last service request arbitration round
- Last Acknowledged Service Request register ([Page 17](#)) provides information about the last service request that was accepted by the service provider
- Error Capture register ([Page 17](#)) captures the Last Acknowledged Service Request ([Page 17](#)) register contents when an ECC error was detected by the ICU

**16.6.2.1 Latest Winning Service Request Register (LWSR)****Latest Winning Service Request Register x, related to ICUx**

The Latest Winning Service Request register provides informations about the winner of the last arbitration round. The register bit fields are representing what is provided by the ICU to the Interrupt Service Provider.

**LWSRx (x=0-7)**

**Latest Winning Service Request Register x, related to ICUx(0200<sub>H</sub>+x\*10<sub>H</sub>) Application Reset Value: 0000 0000<sub>H</sub>**

ST															0			ECC			0									PN	

Field	Bits	Type	Description
PN	7:0	r	<b>Latest Winner Priority Number</b> This bit field shows the Priority Number of a pending service request that won the last arbitration round. This bit field is only valid if STAT is set to 1
ECC	14:10	r	<b>Latest Winner ECC</b> This bit field shows the ECC field (SRN.ECC) that was transferred from the last winning SRN to the ICU. This bit field is only valid if STAT is set to 1.  Note: <i>In the current implementation the ECC code is only used for error detection. Detected errors are reported to the SMU but not corrected.</i>
ID	25:16	r	<b>Latest Winner Index Number</b> This bit field shows the ID number of the last winning SRN. This bit field is only valid if STAT is set to 1
STAT	31	r	<b>LWSR Register Status</b> The STAT register indicates if the PN, ECC and ID bit fields are still valid. They are still valid if the interrupt from the SRN identified by ID is still pending. If the ICU does not have an winner because no interrupt is pending or not yet arbitrated then it clears the STAT bit. 0 <sub>B</sub> LWSR bit fields are not valid 1 <sub>B</sub> LWSR bit fields are valid

## Interrupt Router (IR)

Field	Bits	Type	Description
<b>0</b>	9:8, 15, 30:26	r	<b>Reserved</b> Read as 0; should be written with 0.

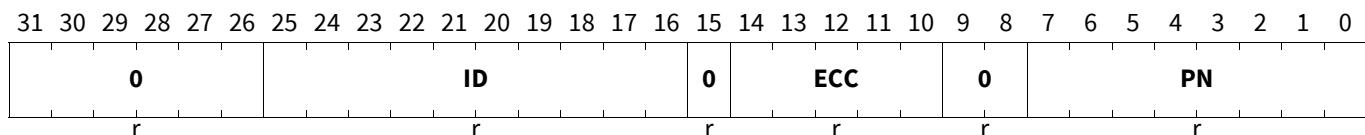

### 16.6.2.2 Last Acknowledged Service Request Register (LASR)

#### Last Acknowledged Service Request Register x, related to ICUx

The Last Acknowledged Service Request register is representing the informations about the last service request that was acknowledged by the Interrupt Service Provider. The register bit fields show what was sent by the Interrupt Service Provider together with the latest acknowledge.

#### LASRx (x=0-7)

**Last Acknowledged Service Request Register x, related to ICUx(0204<sub>H</sub>+x\*10<sub>H</sub>) Application Reset Value: 0000 0000<sub>H</sub>**

Field	Bits	Type	Description
<b>PN</b>	7:0	r	<b>Last Acknowledged Service Request Priority Number</b> This bit field shows the Priority Number of the last acknowledged service request
<b>ECC</b>	14:10	r	<b>Last Acknowledged Interrupt ECC</b> This bit field shows the ECC value of the last acknowledged service request, as send by the service provider with acknowledge  Note: <i>In the current implementation the ECC code is only used for error detection. Detected errors are reported to the SMU but not corrected.</i>
<b>ID</b>	25:16	r	<b>Last Acknowledged Interrupt SRN ID</b> This bit field shows the ID number of the last acknowledged service request, as sent by the service provider with acknowledge
<b>0</b>	9:8, 15, 31:26	r	<b>Reserved</b> Read as 0; should be written with 0.

### 16.6.2.3 Error Capture Register (ECR)

#### Error Capture Register x, related to ICUx

On detection of an ECC error, the Error Capture register (**ECRx**) captures the related Service Request information. This is done by updating the ECR with the content of the Last Acknowledged Service Request (**LASRx**) register on detection of the ECC error. The ECR shows always the last ECR contents where an ECC error was detected. Software can clear the ECR bitfields PN, ECC, ID by writing to the **ECRx**. Error Status (STAT) and Error Overflow (EOV) bits can be used as error handling mechanism and indication that error information were lost.

**Interrupt Router (IR)**

If ECR.EOF is cleared by SW, ECR.EOF must be cleared together with ECR.STAT. If a new error is detected in parallel to the ECR.EOF clear than ECR.EOF is set again by hardware while ECR.STAT is cleared.

**Note:** *In the current implementation the ECC code is only used for error detection. Detected errors are reported to the SMU but not corrected.*

**ECRx (x=0-7)****Error Capture Register x, related to ICUx (0208<sub>H</sub>+x\*10<sub>H</sub>)****Application Reset Value: 0000 0000<sub>H</sub>**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
<b>ST AT</b>	<b>EO V</b>	<b>ST AT</b>	<b>EO VC</b>	<b>0</b>																			<b>ECC</b>	<b>0</b>				<b>PN</b>			

Field	Bits	Type	Description
<b>PN</b>	7:0	rwh	<b>Service Request Priority Number</b> This bit field shows the priority number of the last service request where an error was detected. Bit field can be modified by writing to it.
<b>ECC</b>	14:10	rwh	<b>Service Request ECC</b> This bit field shows the ECC of the last service request where an error was detected. Bit field can be modified by writing to it. This bit field can be modified by: <ul style="list-style-type: none"><li>• Writing to SRC[23:16] (byte write)</li><li>• Writing to SRC[31:16] (16-bit write)</li></ul>
<b>ID</b>	25:16	rwh	<b>Service Request Node ID</b> This bit field shows the ID of the last service request where an error was detected. Bit field can be modified by writing to it
<b>EOVCLR</b>	28	w	<b>Error Overflow Bit</b> The EOVCLR bit is used to clear the EOF bit. The EOF bit must be cleared together with the STAT bit. $0_B$ No action $1_B$ Clear EOF bit; bit value is not stored; read always returns 0; no action if EOF bit is set in parallel.
<b>STATCLR</b>	29	w	<b>Error Status Bit</b> The STATCLR bit is used to clear the STAT bit. $0_B$ No action $1_B$ Clear STAT bit; bit value is not stored; read always returns 0; no action if STAT bit is set in parallel.
<b>EOF</b>	30	rh	<b>Error Overflow Bit</b> The bit is set if an ECC error was detected by the ICU while ECR.STAT='1' (Error Overflow situation). $0_B$ No Error Overflow situation detected $1_B$ Error Overflow situation detected

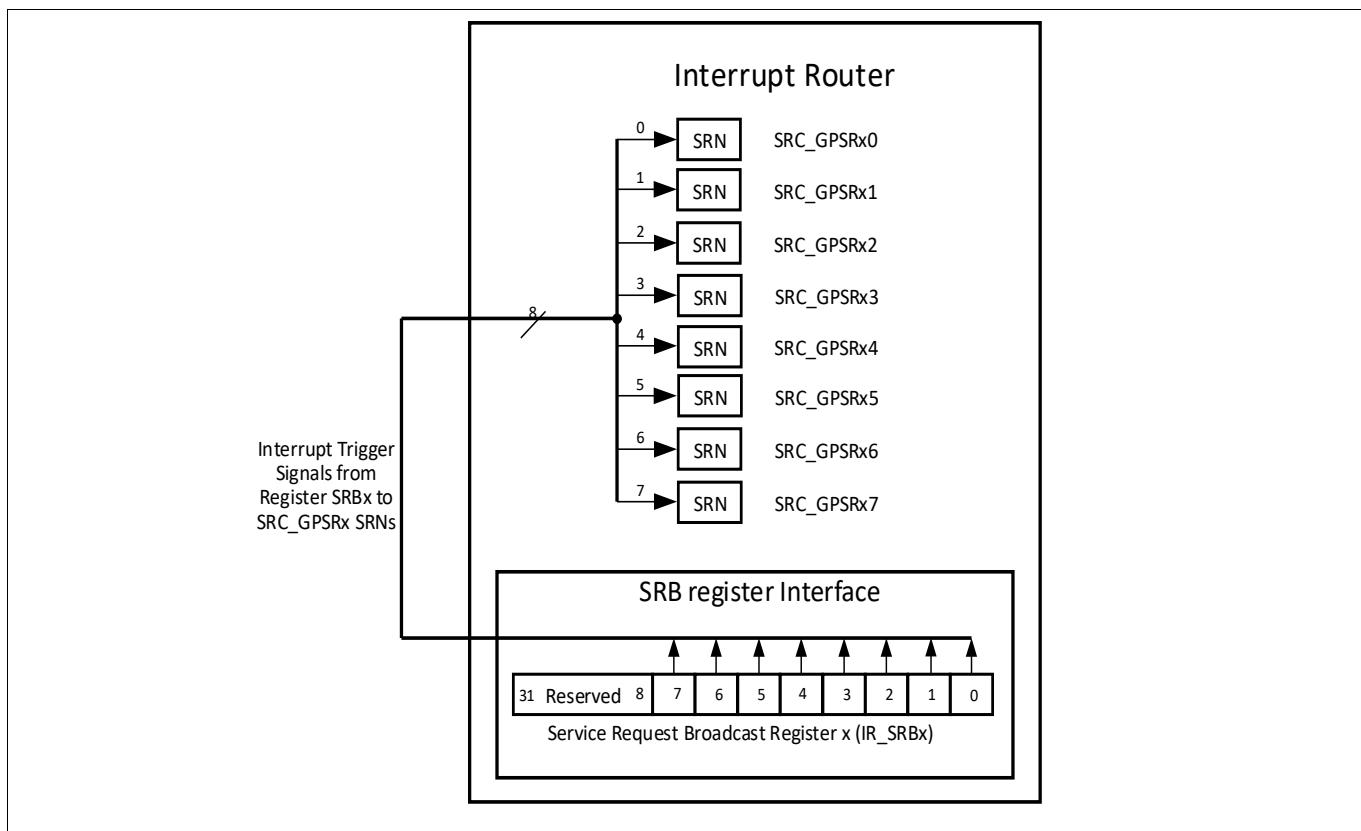

## Interrupt Router (IR)

Field	Bits	Type	Description
<b>STAT</b>	31	rh	<b>Error Status Bit</b> The Error Status Bit is set whenever an ECC was detected by the ICU. $0_B$ No ECC error detected $1_B$ ECC error detected
<b>0</b>	9:8, 15, 27:26	r	<b>Reserved</b> Read as 0; should be written with 0.

## 16.7 General Purpose Service Requests, Service Request Broadcast

The INT module provides multiple groups of General Purpose Service Requests (GPSR) and a mechanism to trigger multiple Service Requests of a GPSR group in parallel, by software ([Chapter 16.7.2](#)).

General Purpose Service Requests are intended for Software Interrupts because they are not mapped to a hardware interrupt trigger events.

**Figure 174 Structure of a General Purpose Service Request Group and the related Broadcast register (Example for SRC\_GPSR0x, SRBx).**

### 16.7.1 General Purpose Service Requests (GPSRxy)

The INT module provides multiple groups of General Purpose Service Requests:

- Each General Purpose Service Request Group consists of eight Service Request Nodes.
- The General Purpose Service Requests are named SRC\_GPSRxy<sup>1)</sup>
- The GPSR are intended for SW interrupts (not mapped to hardware service request triggers)

1) SRC\_GPSRxy: x = group number; y= number of interrupt within the group, y=0:7

## Interrupt Router (IR)

- A GPSR can only be triggered by writing '1' to the related SRC\_GPSRxy.SETR<sup>1)</sup> bit or by writing a '1' to the related Service Request Broadcast register bit in SRBx[y])

### 16.7.2 Service Request Broadcast Registers (SRBx)

Service Broadcast registers (SRBx) can be used to set service requests to multiple Service Providers (CPU or DMA) in parallel.

There is one Service Request Broadcast register (SRBx) implemented for each General Purpose Service Request Group (GPSRxy<sup>1</sup>).

A Service Request Broadcast register (SRBx) can be used to trigger multiple Service Requests within the SRC\_GPSR<sup>1</sup> group in parallel (see [Figure 174](#)).

- A Service Request Broadcast Register is always read as 0
- Writing '1' to SRBx[y] triggers the service request GPXRxy<sup>1)</sup>
- Writing '1' to SRBx[31:6] has no effect.

### 16.7.3 Access protection of SRBx registers (ACCEN\_SRBx)

Each SRBx register is write protected via a dedicated ACCEN\_SR<sub>x</sub>0 / ACCEN\_SR<sub>Bx</sub>1 register set:

- Each SRBx register has a related ACCEN\_SRBx register (x = same number)
- The configuration of the ACCEN\_SRBx defines which TAG ID is allowed to write to the related SRBx register
- In the case of an access protection violation the write is silently ignored, an error is signaled to the SMU. Beside this signaling to the SMU, no other error, interrupt or trap is generated.

Use case: ACCEN\_SRBx defines which TAG ID is allowed to write to SRBx in order to trigger multiple Service Request Nodes of the General Purpose Service Request Group x.

## 16.8 System Registers

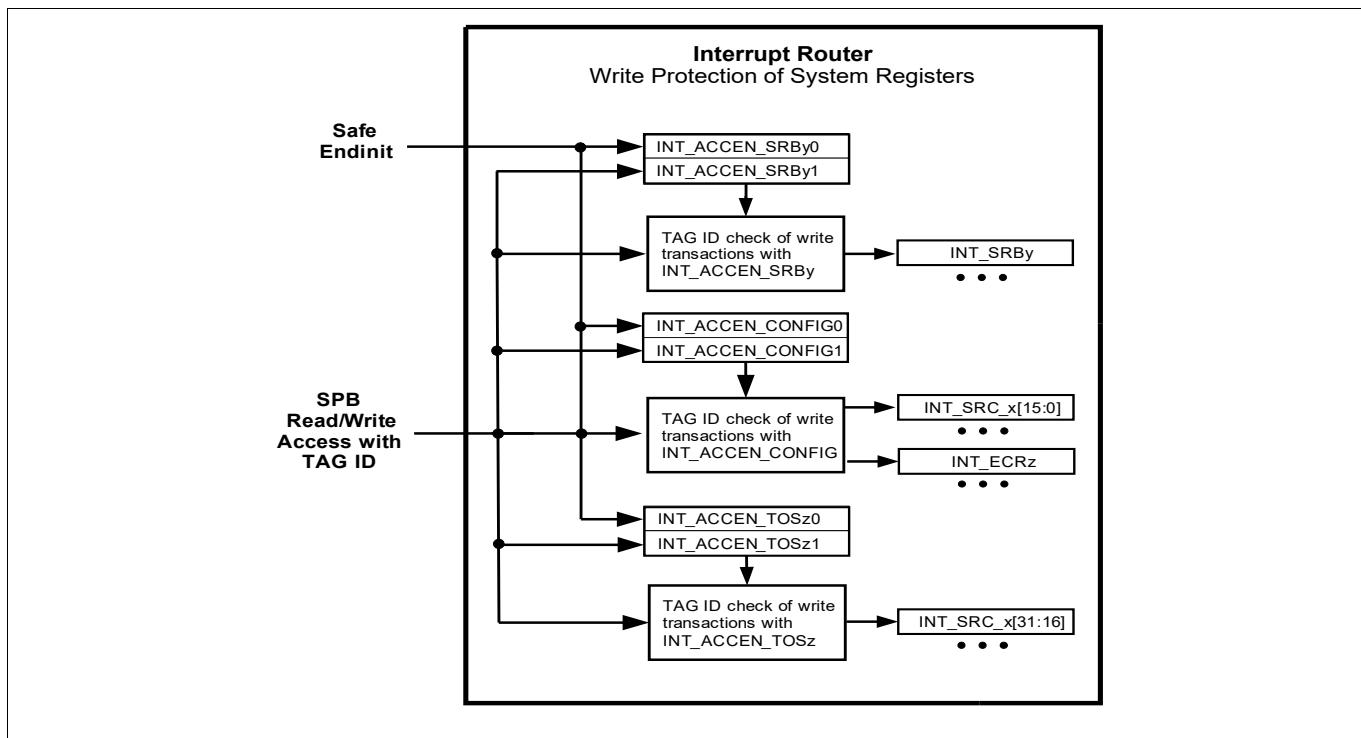

The Interrupt Router module does not support the CLC, the OCS and the KRSTx registers. The interrupt router supports multiple sets of access enable (ACCEN) registers:

- INT\_ACCENx: Register access protection is implemented with the standard ACCEN register but with the registers ACCEN\_CONFIG0/1, ACCEN\_SR<sub>Bx</sub>0/1 and the ACCEN\_SRC\_TOS<sub>x</sub>0/1
- INT\_CLC: the Interrupt Router module does not support this Clock Control (CLC) feature
- INT\_KRSTx: the Interrupt Router module does not support the Module Kernel Reset feature
- OCS: the interrupt router does not support the OCDS Control and Status Register

### 16.8.1 Write Protection of Interrupt Router registers

The Interrupt Router module provides a master TAG ID based write access protection as part of the AURIX safety concept. Each on chip resource with direct or indirect bus master capability has a unique master TAG ID that can be used to identify the master of an on chip bus transaction (see also chapter On Chip Bus Systems).

## Interrupt Router (IR)

**Figure 175 Write Protection of Interrupt Router Registers**

The Interrupt Router module provides write protection to the control registers via three Access Enable Registers / Register Sets (see [Figure 175](#)):

### Access protection of the Service Request Broadcast Registers (ACCEN\_SRBy0/1)

The interrupt router module provides one or more groups of General Purpose Service Request groups, GPSSxy:

- x is the number of the General Purpose Service Request Group (GPSRx)
- y is the number of the Service Request Node within the Group (y=5:0, one group has 6 SRNs)

For each GPSRx group a dedicated Service Request Broadcast Register (SRBy) is implemented that can be used to set multiple Service Request Nodes of the group in parallel.

For more details pls. see [Chapter 16.7.3](#)

### Access protection of the static control registers (ACCEN\_CONFIG0/1)

The ACCEN\_CONFIG provides write access protection for the following registers:

- SRCx[15:0], lower 15 bit of all SRC registers. This includes the SRC bit fields Type of Service (TOS), Service Request Enable (SRE) and Service Request Priority Number (SRPN) (For more details pls. see [Chapter 16.4.1.3](#))
- ECRx, all ICU Error Capture Registers (ECR).

### Access protection of the SRC control registers (ACCEN\_SRC\_TOSy)

The ACCEN\_SRC\_TOSy provides write access protection for the following registers:

- SRCx[31:16]

For more details pls. see [Chapter 16.4.1.3](#)

## Interrupt Router (IR)

### 16.8.2 Kernel Reset Registers (KRST1/0, KRSTCLR)

The INT module does not include the kernel reset registers (KRST1, KRST0, KRSTCLR).

**Note:** *The Interrupt Router module does not support a module kernel reset.*

### 16.8.3 Clock Control Register (CLC)

The INT module does not include the module clock control (CLC).

**Note:** *The Interrupt Router module does not support the Clock Control register functionality which means that the Interrupt Router module clock can not be disabled by the CLC register.*

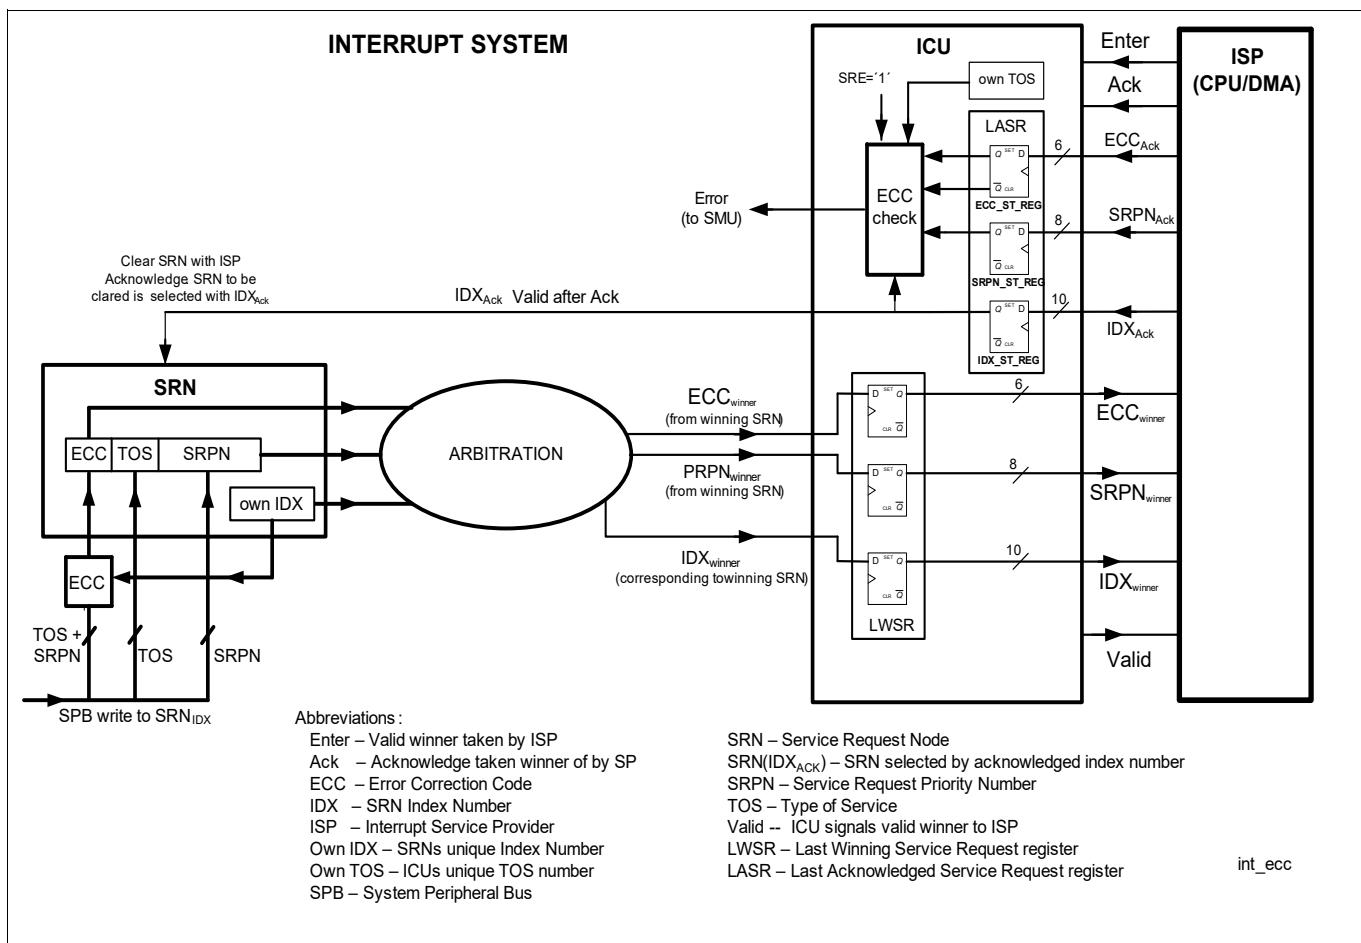

### 16.8.4 OCDS Control and Status Register (OCS)

The INT module does not include OCDS Control and Status (OCS) register.

**Note:** *The Interrupt Router module does not support the OCS register functionality.*

## 16.9 Arbitration Process

Each ICU in the interrupt module has its own interrupt bus. Each Service Request Node (SRN) can be directed to one service provider by mapping it via the SRC.TOS bit field setting to the related ICU / Interrupt Bus.

**Figure 176 Interrupt System Arbitration Scheme Overview**

## Interrupt Router (IR)

With a first pending service request, the related interrupt bus is starting a first arbitration process. The related Interrupt Control Unit provides the service request that won the last arbitration process.

The arbitration process uses 3-4 system peripheral bus clock cycles to determine the pending service request with the highest priority number, SRPN. The exact number of the implementation is described in the Module Implementation chapter.

In an arbitration process, the interrupt bus compares the SRC.SRPN bit fields of all pending Service Request Nodes, mapped to this interrupt bus via SRC.TOS setting. During the arbitration process, the pending service request with the highest priority number is identified as winner and the related SRN Service Request Control register bit field values SRPN, ECC and the Index of the SRN are provided to the ICU. The ICU provides these (SRPN, ECC, SRN Index) to the service provider. The ICU does an ECC check when it gets these information back from the service provider with an acknowledge. The ECC check is done with the received values: ECC, SRPN, SRN Index Number, SRE bit assumed to be '1' (SRN enabled) and the TOS number of the ICU.

The Interrupt Router module signals detected errors to the Safety Management Unit (one bit in the SMU, covers errors from all SRN and ICUs).

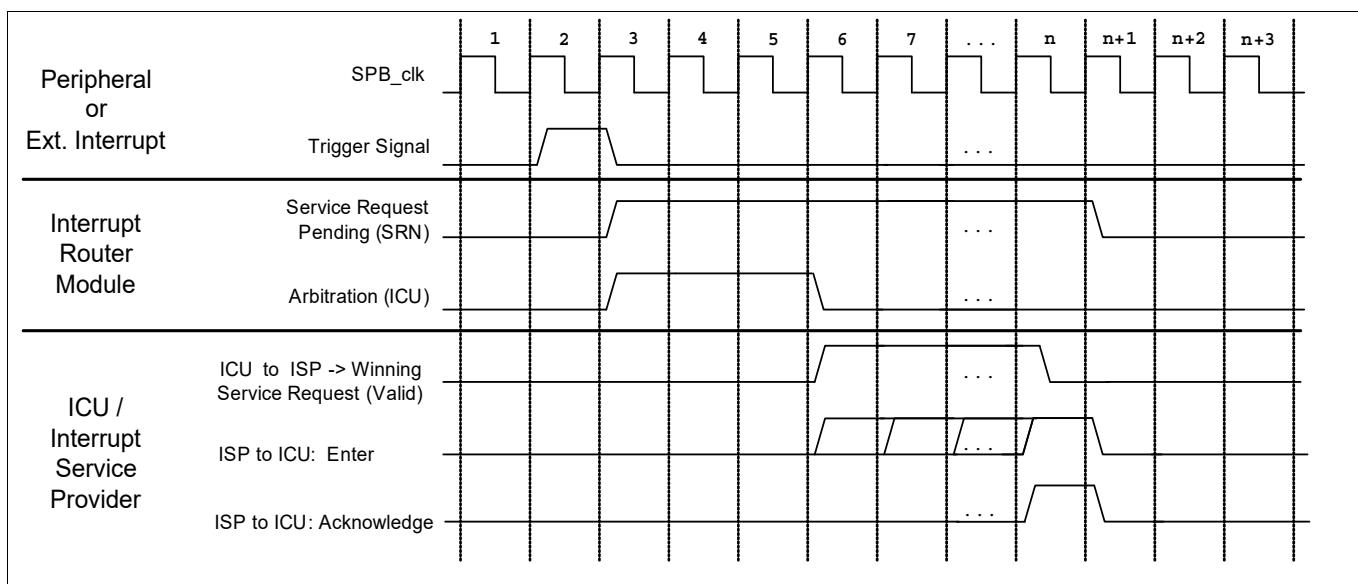

**Note:** *In the current implementation the ECC code is only used for error detection. Detected errors are reported to the SMU but not corrected.*

### 16.9.1 Number of Clock Cycles per Arbitration Process

The Interrupt Router implementation can be configured regarding the number of:

- Supported service requests (Service Request Nodes, SRN, up to 1024)
- SRPN bit size (8-bit)
- Supported service providers (Interrupt Control Units, ICUs)
- Clock cycles per service request arbitration (3-4 SPB clock cycles)

The characteristics of the Interrupt Router module implemented in an AURIX product is described in the Module Implementation sub-chapter.

**Figure 177 Interrupt System Timing (Schematic Overview, 3 Cycle Arbitration)**

**Figure 177** shows the interrupt timing of an Interrupt Router implementation with 3 cycle arbitration.

Cycle 1: No service request for the ICU is pending (therefore no arbitration round)

## Interrupt Router (IR)

Cycle 2: One module is triggering a service request by sending a pulse to the related SRN in the Interrupt Router module.

Cycle 3-5: Arbitration among all pending service requests to the ICU

Cycle 6: ICU provides winning service request to the service provider (SRPN, ECC, SRN Index)

Cycle 7 - n-1: ICU re-arbitrates whenever a new service request from another SRN is pending, provides new winning service request to ICU if there is a new pending one with a higher SRPN number (higher priority)

Cycle 6- n-1: Interrupt Service Provider takes the information of the latest winning SRN (Enter)

Cycle n: Service provider acknowledges service request (provides SRPN, ECC, SRN Index informations of the acknowledged service request). ICU changes signals to ICU to 'no valid service request available' in the same clock cycle.

Cycle n+1: ICU does an ECC check of the acknowledge information (SRPN, ECC, SRN Index, SRE='1', TOS number of the ICU). If mismatch -> Integrity Error signalled to SMU/ SRPN, ECC and Index are captured in the ECR). The SRN with the acknowledged Index Number is cleared by hardware.

Cycle n+2: If at least one service request to the ICU is pending: new arbitration among all pending service request to the ICU

### 16.9.2 Service Request Valid

The ICU signals the ISP the information of the pending Service Request that won the arbitration round by asserting the Valid signal. Re-arbitration will be done until the ISP asserts the Enter signal.

### 16.9.3 Service Request Enter

The Interrupt Service Provider signals to the ICU that it took over the Valid information of a Service Request and starts now to prepare itself for the execution of the related Interrupt Service Routine. The Enter signal can re-set by the ISP either with Acknowledge (the Interrupt Service Routine has started, ICU will clear the related SRN) or without Acknowledge (e.g. CPU got a trap or exception before it was able to start the ISR, ICU will not clear the related SRN).

### 16.9.4 Service Request Acknowledge

When a Service Provider starts with the execution of a service request that was provided by the ICU, the Service Provider sends an acknowledge to the ICU. In parallel to the acknowledge, the Service Provider sends the informations about the executed service request back to the ICU (SRPN, ECC, SRN Index Number).

In the same clock cycle, the Service Provider sends an acknowledge, the ICU changes to 'no service request available': the ICU does not provide an arbitration winner to the service provider. This behavior of the ICU ensures that a just acknowledged service request is not provided again before the SRN was re-set (see [Figure 177](#)).

### 16.9.5 Handling of detected ECC Errors

The ICU does an Error Detection check of the informations it receives with the acknowledge from the Service Provider and the TOS number of the ICU itself. Assumption for the SRE bit is '1' (SRN was enabled). ECC in the SRN is covering the SRC bit field values: SRC.SRPN, SRC.SRN Index, SRC.SRE and SRC.TOS. (see [Figure 177](#))

Whenever the ICU receives an Acknowledge from the Interrupt Service Provider it does an Error Detection check. The check is done on the informations received with the acknowledge from the Service Provider (TOS, SRPN, Index and ECC), the TOS number of the ICUX itself and an SRE bit assumed as '1' (SRN was enabled). The ECC in the SRN is covering the SRC bit field values: SRC.SRPN, SRC.SRN Index, SRC.SRE and SRC.TOS. (see [Figure 177](#))

## Interrupt Router (IR)

**Note:** *In the current implementation the ECC code is only used for error detection. Detected errors are reported to the SMU but not corrected.*

If the ICUs detect an ECC error:

- ICUs captures the ECC, SRPN and the Index that showed an ECC error in the Error capture registers (ECRx), sets the ECRx.STAT bit and the ECRx.EOF bit if the STAT bit is still set.
- ICU signals the error via the Interrupt Router error signal to the AURIX™ TC3xx Platform Safety Management Unit (SMU). The SMU forwards this information to a CPU (if enabled).
- ICUs clears the service request in the SRN (selected by the Index)
- The CPU that received the ‘ECC error detected in Interrupt Router’ information via SMU can identify the ICU via the Error Status bits (ECRx.STAT=‘1’), read out the related service request information and clear the ECRx.STAT bit by writing with ‘1’. The CPU can also identify if one or multiple ECC errors where detected by this ICU via the Error Overflow bit (ECRx.EOF=‘1’).

## 16.10 Usage of the Interrupt System

The following sections provide a short description of the Service Provider interfaces to the Interrupt Router ICUs.

**Note:** *All ICU sub-modules in the Interrupt Router have the same functionality.*

### 16.10.1 CPU to ICU Interface

The interrupt router module has a dedicated Interrupt Control Unit (ICU) for each CPU and DMA module. The CPU ICU interface consists of a register set where the CPU takes over the informations of a service request provided by the ICU (SRPN, SRN Index, ECC). The informations will be send back to the ICU when the CPU acknowledges the provided service request (see also [Chapter 16.4.1.8](#)).

The CPU ICU interface contains an Interrupt Control Register (ICR) that holds the current CPU priority number (CCPN), the global interrupt enable/disable bit (IE) and the pending interrupt priority number (PIPN). Further details of the CPU ICU interface and the CPU handling of interrupts can be found in the CPU chapter.

### 16.10.2 DMA to ICU Interface

The interrupt router module has dedicated Interrupt Control Unit (ICU) for each DMA module.

The DMA takes over the service request informations from the ICU, triggers the related DMA channel and acknowledge it immediately to the ICU where the related SRN is cleared.

The DMA to ICU interface consists of a register set where it takes over the information of a service request provided by the ICU (SRPN, SRN Index, ECC). The DMA sends them back to the ICU in the next clock cycle with an acknowledge (see also [Chapter 16.4.1.8](#)).

The DMA channel priority scheme is identical to the SRPN priority scheme:

- Lowest priority within the DMA: channel 0
- Lowest priority within the Interrupt Router: SRPN = 0

### 16.10.3 Software-Initiated Interrupts

Any Service Request Node can be used Software interrupt. Software can set the service request bit (SRR) in any SRN by writing to its Service Request Control Register. Thus, software can initiate service requests that are handled by the same mechanism as hardware initiated service requests.

## Interrupt Router (IR)

After the SRR bit is set in an SRN, there is no way to distinguish between a software initiated service request and a hardware initiated service request. For this reason, software should only use SRNs and interrupt priority numbers that are not being used for hardware initiated service requests.

The device contains groups of General Purpose Service Request SRNs per CPU that support software-initiated interrupts. One group per implemented TriCore CPU, each group including 8 SRNs. These SRNs are not connected to internal or external hardware trigger signals and can only be used as software interrupts / software initiated service requests. These SRNs are called General Purpose Service Requests Nodes (SRC\_GPSR $xy$ ,  $x$ =group number,  $y$ =0-7).

Additionally, any otherwise unused SRN can be employed to generate software interrupts.

### 16.10.4 External Interrupts

Eight SRNs (Int\_SCUSRC[7:0]) are reserved to handle external interrupts. The setup for external GPIO port input signals (edge/level triggering, gating etc.) that are able to generate an interrupt request is controlled in the External Request Unit (ERU). The ERU functionality is described in detail in the SCU chapter.

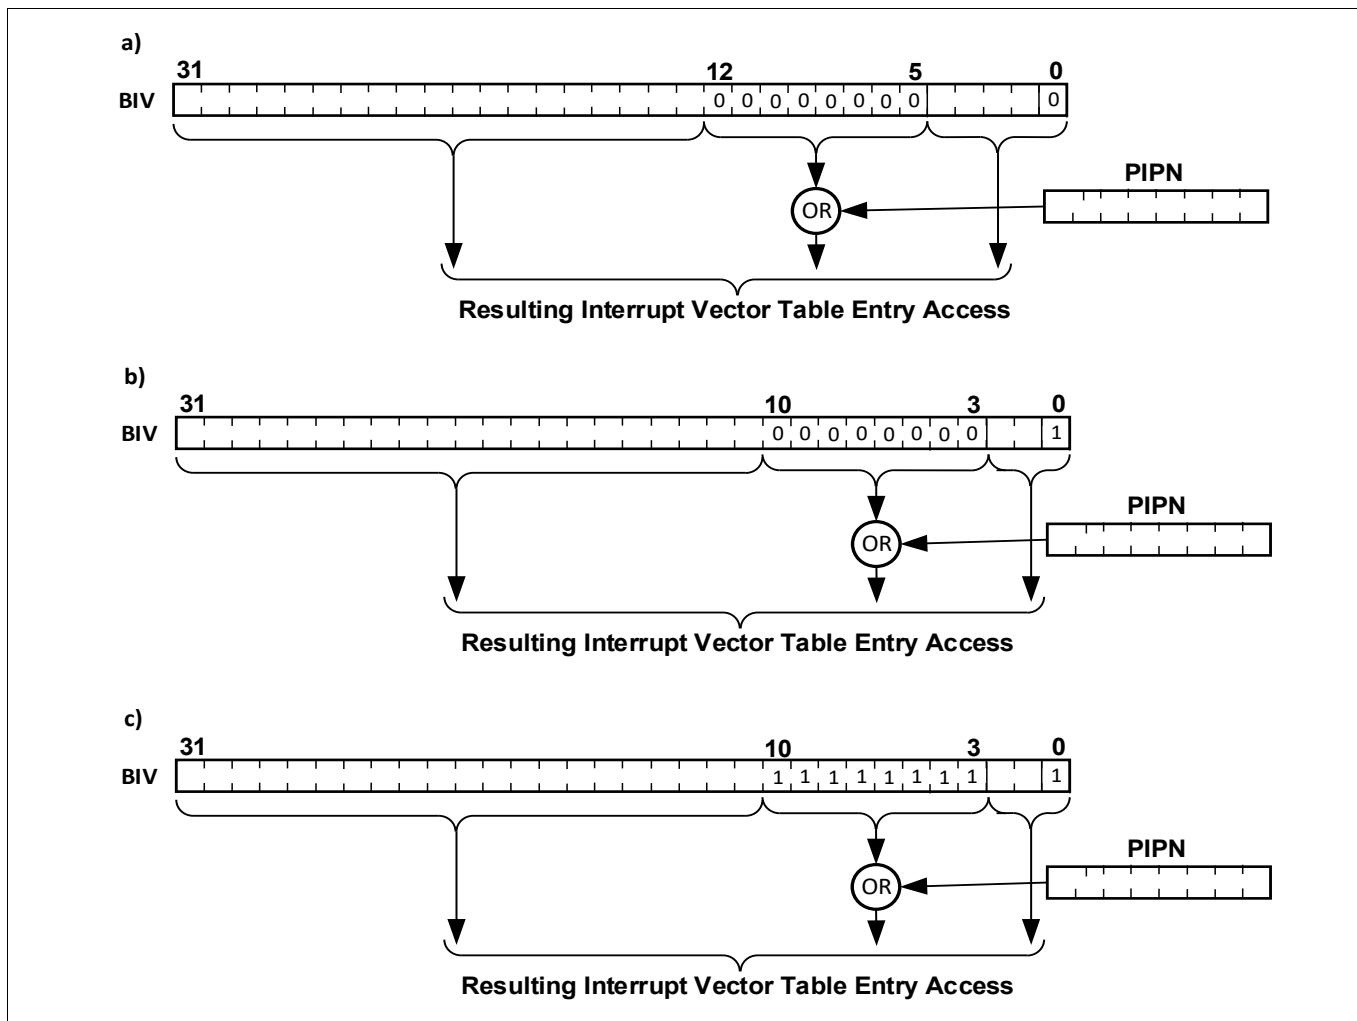

## 16.11 Use Case Examples

This section shows a use case for the interrupt system and a use case for the OTGS.

### 16.11.1 Use Case Example Interrupt Handler

This section explains how to organize the TriCore interrupt vector table. When an interrupt is accepted by the TriCore, the entry address into the interrupt vector table is calculated by the base interrupt vector table pointer TriCore register BIV and the priority number of that interrupt (PIPN). The TriCore TC1.6P and TC1.6E architecture offers the possibility to configure the vector spacing per entry to either 32 Byte (see Figure below a ([Figure 178](#)) or 8 Byte (see Figure below b ([Figure 178](#))). As a third option the vector table can be reduced to a single entry by masking the PIPN (see Figure below c ([Figure 178](#))).

## Interrupt Router (IR)

**Figure 178 Interrupt Vector Table Address Calculation for a) 32 Byte b) 8 Byte vector entry or c) single entry**

By using the 32 Byte configuration small interrupt routines can be implemented directly into the vector table. They can even span multiple vector entries (see also TriCore Architecture Manual). This type of fast interrupt handling is useful, if the vector table can be located into the TriCore program side memory. The 8 Byte configuration reduces the vector table size. Each vector entry contains only a jump instruction or a call and return as 16-bit op-code instruction. The TriCore compiler supports this kind of interrupt vector table generation by keywords or functions. A minimum vector table can be configured if the BIV mask the PIPN so that any interrupt address calculation results in the same address. E.g.

```
_mtcr(BIV,0x80000001 | 0xFF<<3); // move to core register BIV
```

This configures the BIV register to use a common, single entry where a function interruptHandler is located to branch to the specific interrupt routine by using an array of function pointers. If a pointer to the array is used the array could be switched quickly.

### Step description to initialize and install interrupts

- (Line 1) define ISR pointer array. Max. 255 interrupts possible.
- (Line 2) define pointer which points to the start of the isr\_pointer\_array.
- (Line 3) start of function interruptHandlerInstall. This function installs the interrupts in the array. Necessary information are the interrupt priority and ISR entry address.
- (Line 4) This line stores the ISR entry address in the array.

## Interrupt Router (IR)

(Line 5 and 6) This function branches to the specific interrupt routine and gets called immediately after an interrupt occurs.

(Line 7) This line gives the return command, after the ISR has been processed.

### C Code Example to initialize and install interrupts

```
(1) void (*isr_pointer_array[256])(void); (2) void (**isr)(void) = isr_pointer_array;
(3) void interruptHandlerInstall(long int SRprio, long int addr){ (4)
*isr_pointer_array[SRprio]=addr; } (5) void interruptHandler(void){ (6) isr[__mfcr(ICR)
& 0xFF](); (7) asm (" rfe"); // return from event }
```

The interrupt entry addresses are stored in a data array instead of encoding the values into the instructions. The function interruptHandlerInstall organizes the installation of the interrupts in that array (see the application of this interrupt handler in a module e.g. use case example in STM chapter). This kind of vector table generation offers sometimes more flexibility than the 8 Byte configuration and does not require any specific compiler support for interrupts.

**Note:** Before an interrupt is able to occur, the interrupt system has to be globally enabled. The Interrupt Control Register (ICR) holds the global interrupt enable bit (ICR.IE) which enables the CPU service request system. Most compiler support the attribute (or similar):  
`_enable();`  
 to set this bit. (See also Architecture Manual for more details)

## 16.12 Module Implementation

### 16.12.1 Characteristics of the Interrupt Router Module

**Table 556** shows the Interrupt Router configuration as implemented in the different TC3xx devices.

Shared arbitration is implemented per ICUx pair, starting with ICU0 (ICU0/ICU1, ICU2/ICU3, ....)

**Table 556 Mapping of Interrupt Service Provider to ICUs and implemented SRNs**

	CPU0	DMA	CPU1	CPU2	CPU3	CPU4	CPU5
TC39x	ICU0	ICU1	ICU2	ICU3	ICU4	ICU5	ICU6
TC38x	ICU0	ICU1	ICU2	ICU3	ICU4	-	-
TC37x ED / PD	ICU0	ICU1	ICU2	ICU3	-	-	-
TC36x	ICU0	ICU1	ICU2	-	-	-	-
TC33x ED	ICU0	ICU1	ICU2	-	-	-	-
TC33x PD	ICU0	ICU1	-	-	-	-	-
TC35x	ICU0	ICU1	ICU2	ICU3	-	-	-

## 16.13 Interrupt Router System and Module Registers

**Figure 179** shows all registers associated with the Interrupt Router module in the device. The Interrupt Router allocates two address ranges:

- 2 \* 256 byte address range covering the Interrupt Router system registers, ICU control registers and OTGM registers
- 8 KByte address range covering the Service Request Control registers

## Interrupt Router (IR)

**Table 557 Register Address Space - INT**

Module	Base Address	End Address	Note
INT	F0037000 <sub>H</sub>	F0037FFF <sub>H</sub>	IR Status and Control Registers

**Table 558 Register Address Space - SRC**

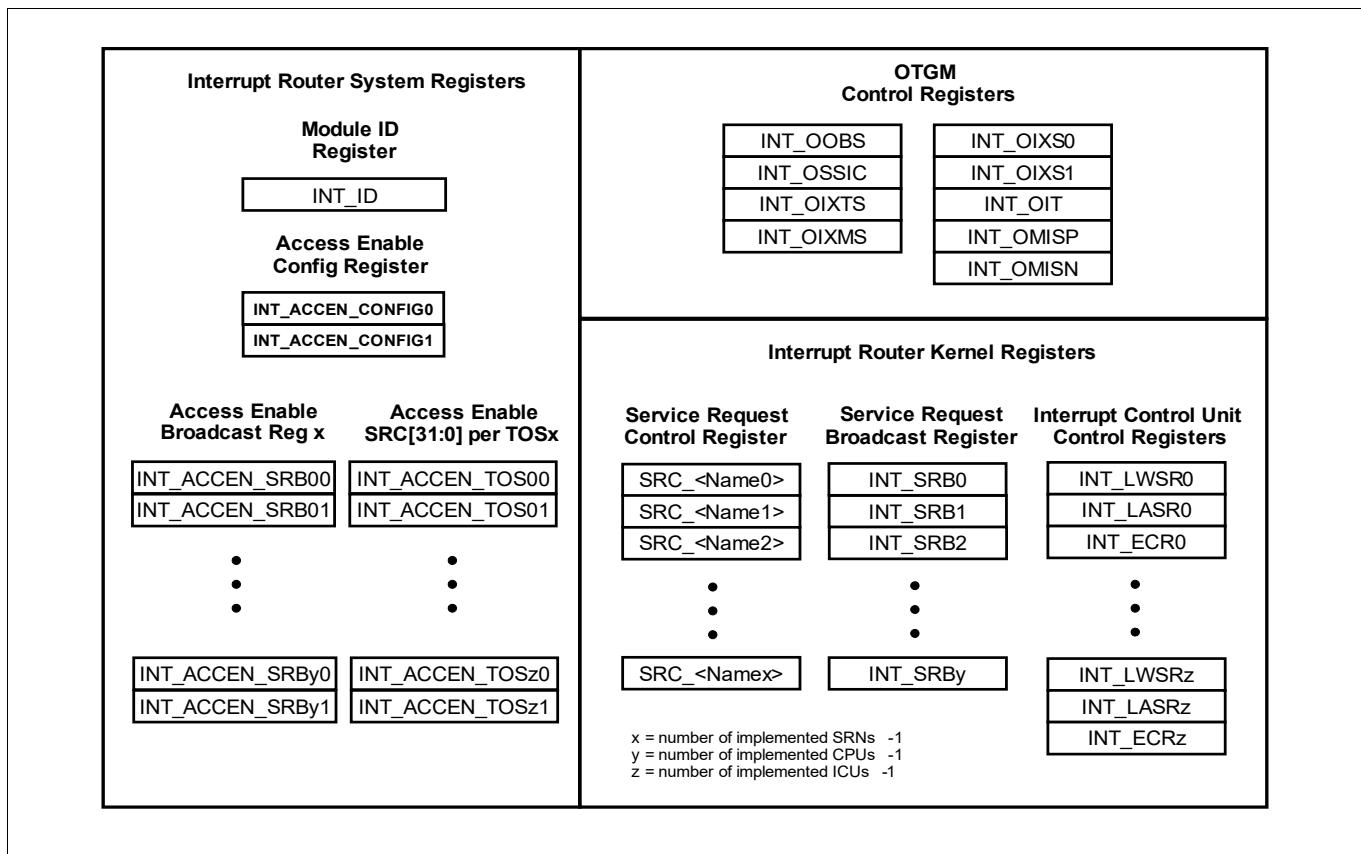

Module	Base Address	End Address	Note
SRC	F0038000 <sub>H</sub>	F0039FFF <sub>H</sub>	IR Service Request Control Registers (SRC)

### List of used Access Protection Register abbreviations

- P0 -> ACCEN\_SRBy, write protection of the related SRBy register. Number of Service Request Broadcast registers (SRB) and the related ACCEN\_SRBy registers is equal to the number of implemented TriCore CPUs.
- P1 -> ACCEN\_CONFIG, write protection of all SRCx[15:0] and ICUx Error Capture registers (ECRx)
- P2 -> ACCEN\_SRC\_TOSx, write protects bits [31:16] of all SRCs that are mapped to TOSx (SCR.TOS=x). For each implemented Interrupt Control Unit, one ACCEN\_SRC\_TOSx register is implemented.

**Note:** A violation of the access protection will not be executed (e.g. a write to a 'Px'/ACCEN protected register by an SPB access with a disabled Master TAG-ID). In this case an access protection error is signaled to the SMU. Beside this signaling to the SMU, no other error, interrupt or trap is generated.

## Interrupt Router Module Registers

**Figure 179 Interrupt Router module registers**

**Interrupt Router (IR)****Table 559 Register Overview - INT (sorted by Name)**

<b>Short Name</b>	<b>Long Name</b>	<b>Offset Address</b>	<b>Page Number</b>

## Flexible CRC Engine (FCE)

### 17 Flexible CRC Engine (FCE)

The FCE provides a parallel implementation of Cyclic Redundancy Code (CRC) algorithms. The current FCE version for the AURIX™ TC3xx Platform implements the IEEE 802.3 ethernet CRC32, the Autosar CRC32P4, the CCITT CRC16 and the SAE J1850 CRC8 polynomials. The primary target of FCE is to be used as an hardware acceleration engine for software applications or operating systems services that use CRC signatures.

The FCE operates as a standard peripheral bus slave. The FCE supports multiple parallel channels of CRC context. Each of these channels can be configured to use any one of the CRC algorithms at a time. Thus, using these channels, multiple software tasks can use even the same CRC algorithm concurrently.

**Note:** The FCE register names described in “[Registers](#) on Page 15” are referenced in a product User’s Manual by the module name prefix “FCE<sub>x</sub>”, x: 0 - (Number of FCE instances - 1)

#### Input documents

CFG	Configuration

#### 17.1 Feature List

The FCE provides the following features:

- The FCE implements the following CRC polynomials:
  - CRC kernel 0: IEEE 802.3 CRC32 ethernet polynomial: 0x04C11DB7<sup>1)</sup> -  
 $x^{32}+x^{26}+x^{23}+x^{22}+x^{16}+x^{12}+x^{11}+x^{10}+x^8+x^7+x^5+x^4+x^2+x+1$
  - CRC kernel 1: Autosar safety polynomial CRC32P4: 0xF4ACFB13 -  
 $x^{32}+x^{31}+x^{30}+x^{29}+x^{28}+x^{26}+x^{23}+x^{21}+x^{19}+x^{18}+x^{15}+x^{14}+x^{13}+x^{12}+x^{11}+x^9+x^8+x^4+x+1$
  - CRC kernel 2: CCITT CRC16 polynomial: 0x1021 -  $x^{16}+x^{12}+x^5+1$
  - CRC kernel 3: SAE J1850 CRC8 polynomial: 0x1D -  $x^8+x^4+x^3+x^2+1$
- Parallel CRC implementation
  - Data blocks to be computed by FCE shall be a multiple of the polynomial degree
  - Start address of Data blocks to be computed by FCE shall be aligned to the polynomial degree
- Parallel Channels of CRC context

1) The polynomial hexadecimal representation covers the coefficients (degree - 1) down to 0.

## Flexible CRC Engine (FCE)

- The FCE supports up to 8 parallel channels of CRC context.
- A channel can be configured to use any one of the implemented algorithms.
- Different channels can use the same or different CRC algorithms concurrently.
- Register Interface for CRC computation:
  - Input Register
  - CRC Register
  - Configuration Registers enabling to control the CRC operation and perform automatic checksum checks at the end of a message.
  - Extended register interface to control reliability of FCE execution in safety applications.
  - FCE supports endianness conversion.
- FCE can be reset independently by a module reset controlled by software. The reset affects all CRC channels.
- Error notification scheme via dedicated interrupt node for:
  - Transient error detection: error interrupt generation (maskable) with local status register (cleared by software)
  - Checksum failure: error interrupt generation (maskable) with local status register (cleared by software)
- FCE provides one interrupt line to the interrupt system.

## Flexible CRC Engine (FCE)

### 17.2 Overview

This chapter provides an overview of the features, applications and architecture of the FCE module.

#### 17.2.1 Application Mapping

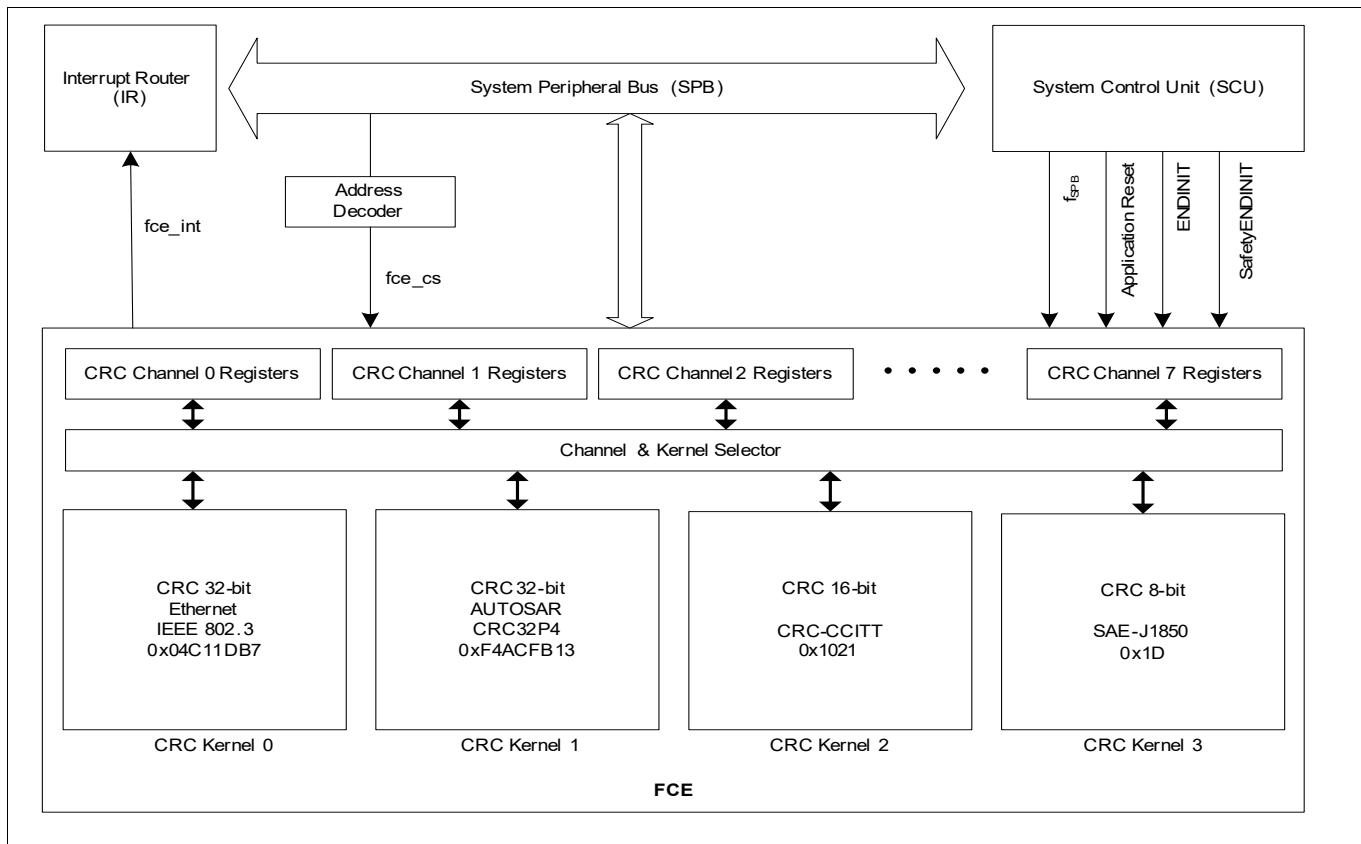

Among other applications, CRC algorithms are commonly used to calculate message signatures to:

- Check message integrity during transport over communication channels like internal busses or interfaces between micro-controllers
- Sign blocks of data residing in variable or invariable storage elements
- Compute signatures for program flow monitoring

#### 17.2.2 Block Diagram

The FCE is a standard peripheral slave module which is controlled over a set of memory mapped registers. The FCE is fully synchronous with the peripheral bus clock and runs with a 1:1 clock ratio.

The block diagram of the FCE in the AURIX™ TC3xx Platform is shown in the [Figure 180](#).

**Figure 180 FCE Block Diagram**

An FCE kernel is the instantiation of the CRC algorithm as a parallel matrix. Each FCE kernel implements a different CRC algorithm.

The FCE module contains 8 channels (Channel 0 - Channel 7). Each channel is provided with its own set of registers which allows the software to configure the channel, choose the algorithm kernel used, write the inputs and read the results and status from the CRC computation.

Each channel has an interrupt associated with it. The interrupt lines from all the channels are ORed together, and the FCE only presents a single interrupt node to the system. A status register associated with each channel

---

## Flexible CRC Engine (FCE)

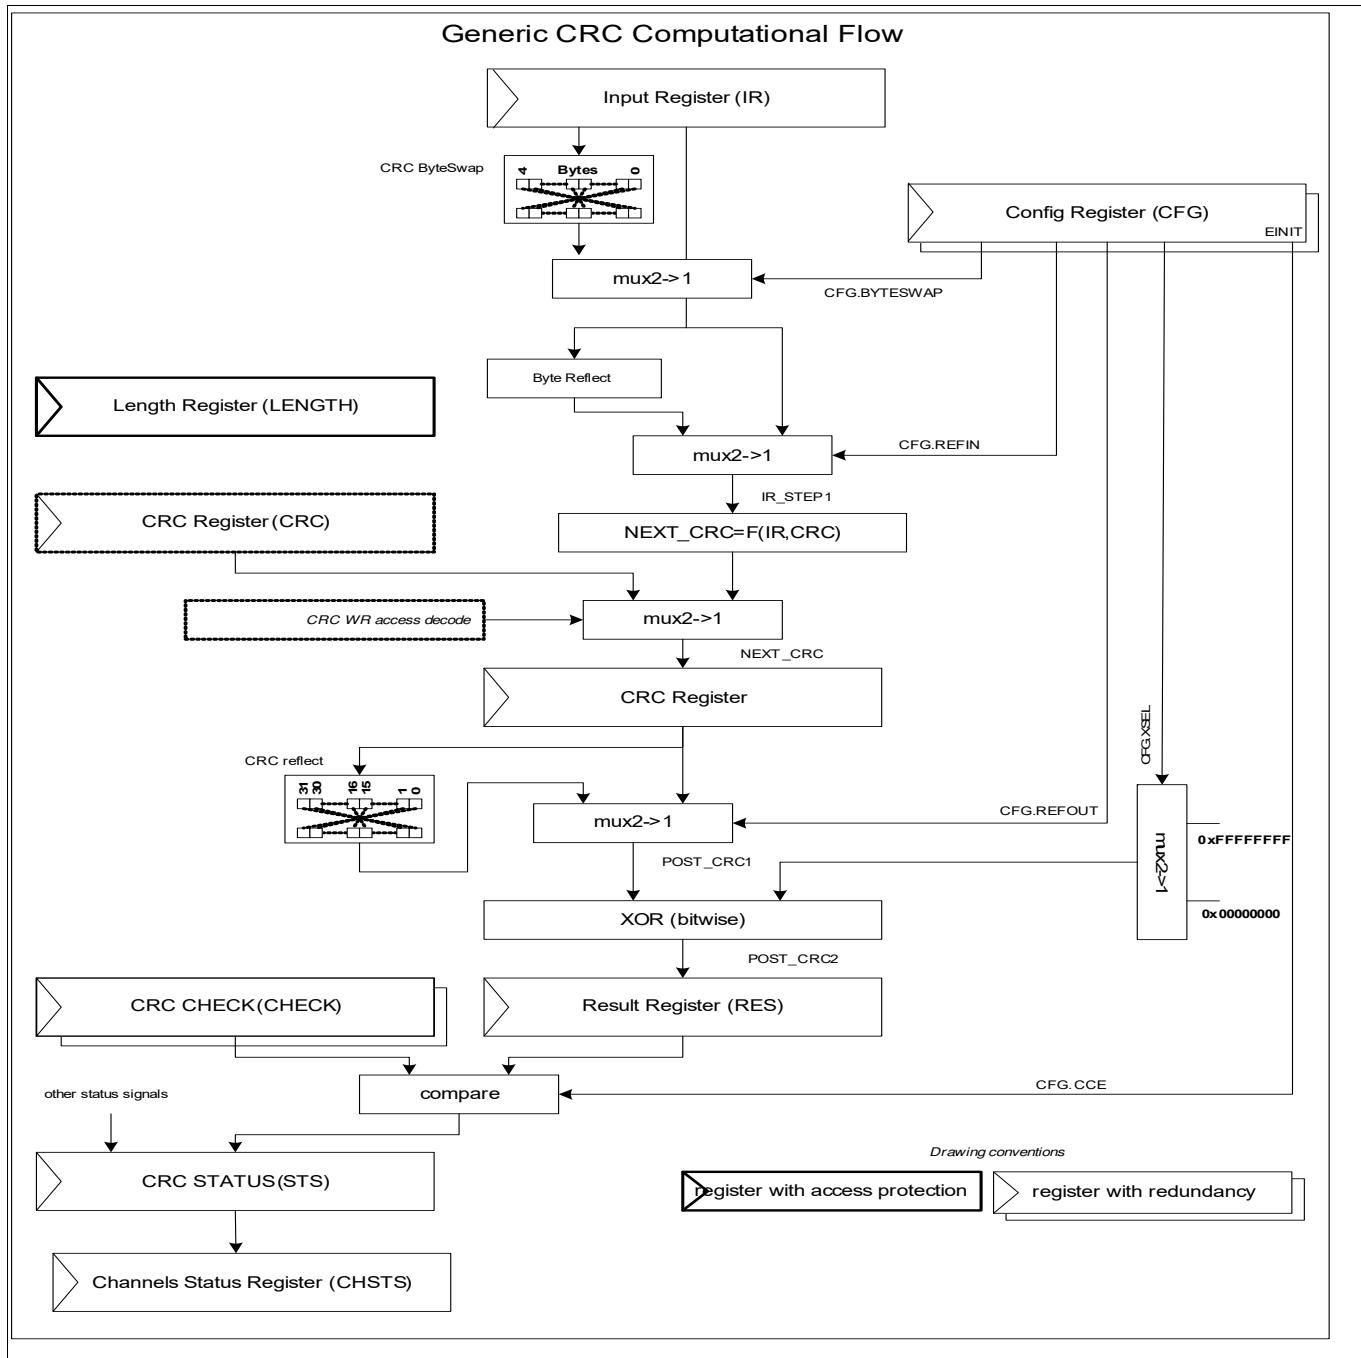

enables the software to identify which interrupt source is active. In addition, to aid fast interrupt handling in the software, a channels status register is provided, which basically ORs together the status from each channel. Thus the software can read this one register to get information regarding the pending status from each channel. Please refer to the **STS<sub>i</sub> (i=0-7)** register for a detailed description of the status and interrupt handling.

Each FCE channel presents the same hardware and software architecture for computing the CRC. The rest of this document will focus only on the description of the generic CRC computational flow, since each channel can be independently configured to use any CRC kernel.

## Flexible CRC Engine (FCE)

### 17.3 Functional Description

The generic CRC computational flow is presented in [Figure 181](#).

**Figure 181 CRC Computational flow**

A checksum algorithm based on CRC polynomial division is characterized by the following properties:

1. polynomial degree (e.g. 32, that represents the highest power of two of the polynomial)
2. polynomial (e.g. 0x04C11DB7: the 33rd bit is omitted because always equal to 1)
3. init value: the initial value of the CRC register
4. input data reflected: indicates if each byte of the input parallel data is reflected before being used to compute the CRC
5. result data reflected: indicates if the final CRC value is reflected or not.

## Flexible CRC Engine (FCE)

6. XOR value: indicates if a final XOR operation is done before returning the CRC result.
7. BYTESWAP: If set, the order of bytes in the input register (when 16- or 32-bit CRC is used) is swapped before the CRC conversion (For endianness conversion).

All the properties are fixed once a polynomial has been chosen. However the FCE provides the capability to control the two reflection steps and the final XOR as depicted in [Figure 181](#) through the CFG register. The reset values are compatible with the implemented algorithm. The final xor control enables to select either 0xFFFFFFFF or 0x00000000 to be xored with the POST\_CRC1 (see [Figure 181](#)) value. These two values are those used by the most common CRC polynomials.

As shown in the figure, when the software writes a value to the IR register, the CRC register is updated in the next clock cycle. The RES register is updated after the output operations (REFOUT, XSEL) still one more cycle later. (ie, there are 2 cycles from a write to the IR until the result gets updated in the RES register).

It shall be ensured by the programmer that the CFG register is configured before starting the CRC computation, and is not changed until the final result is obtained.

Note that the CRC computation of the FCE is equivalent to a bitwise shift CRC computation considering that the MSB bit is shifted in first.

**Note:** *The reflection steps and final XOR do not modify the properties of the CRC algorithm in terms of error detection, only the CRC final signature is affected.*

The next two figures provides an overview of the control and status features of a CRC channel.

## Flexible CRC Engine (FCE)

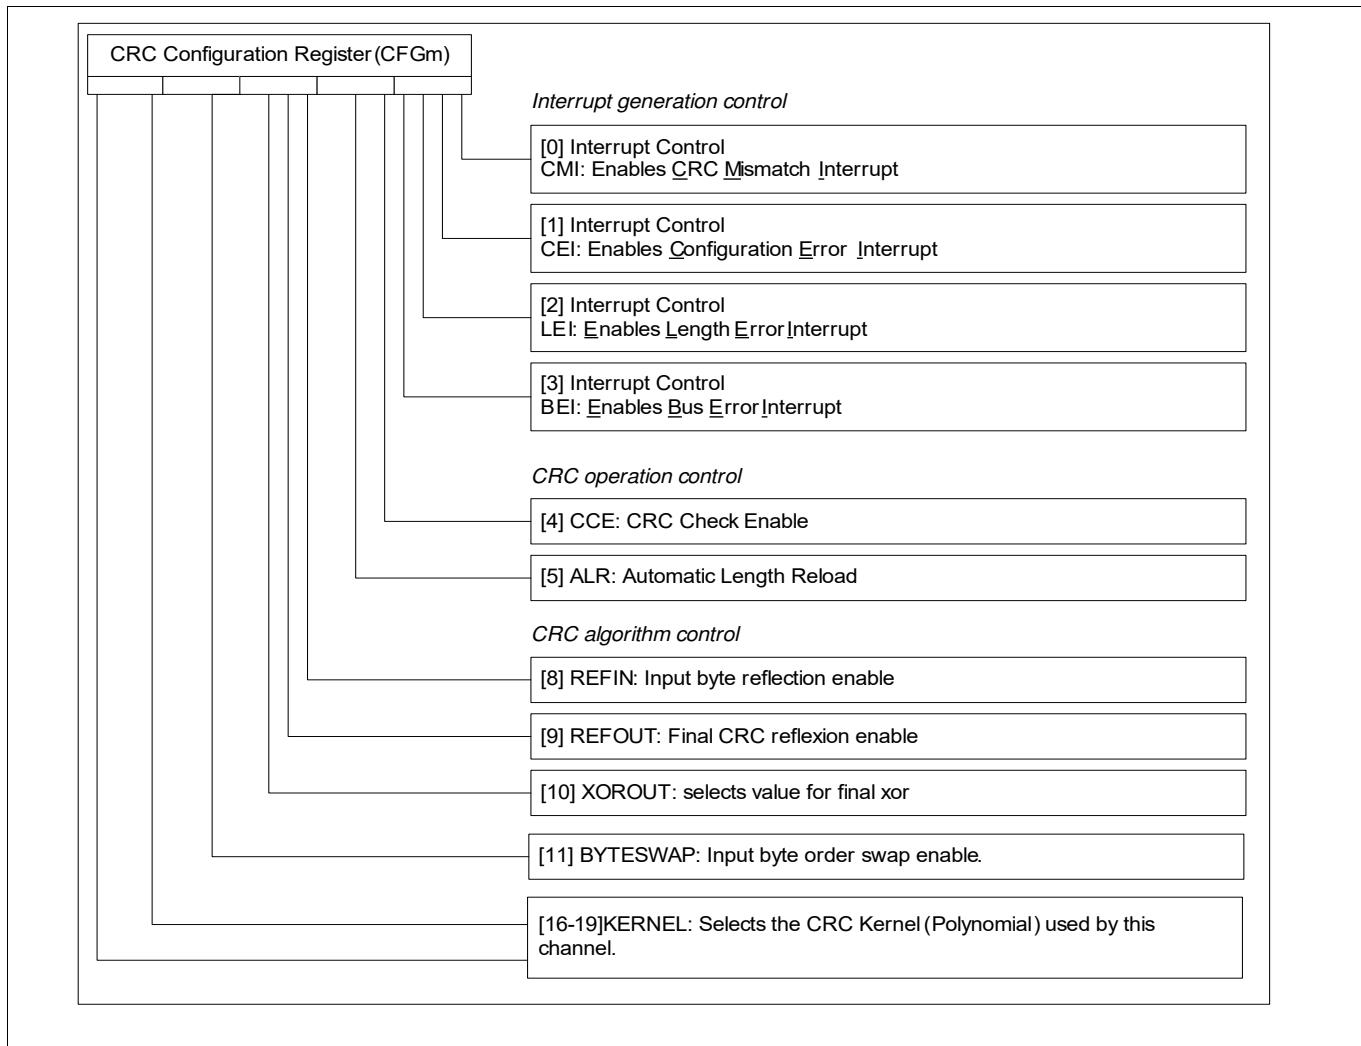

Figure 182 CRC Channel configuration register

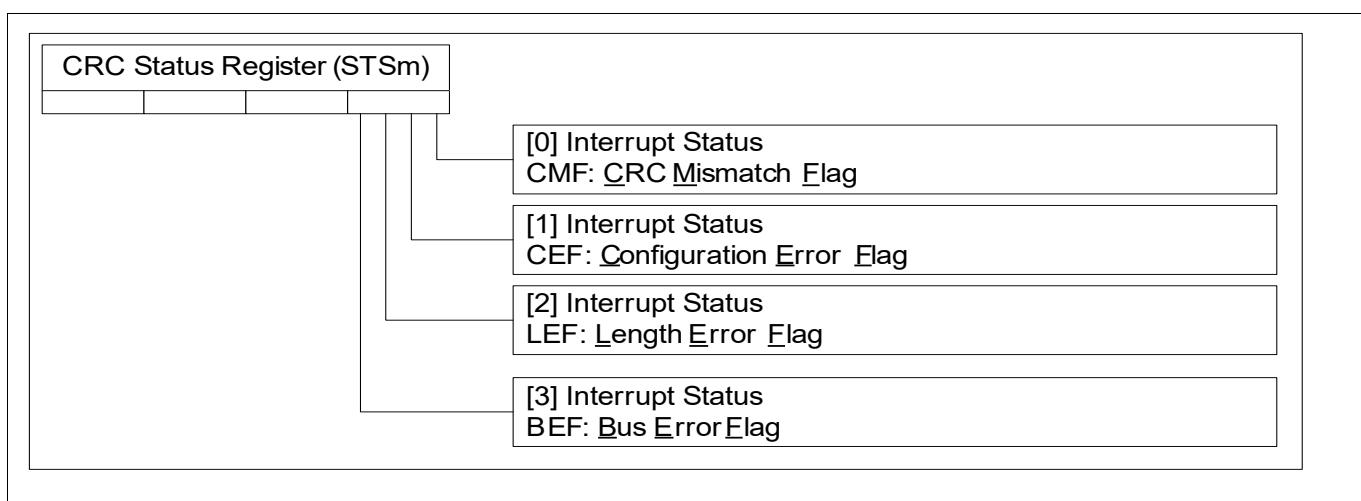

Figure 183 CRC kernel status register

## Flexible CRC Engine (FCE)

### 17.3.1 Initialization

The FCE is enabled by writing 0x0 to the CLC register. Software must first ensure that the CRC channel is properly configured, especially the initial CRC register value written via the CRC register, the CRC kernel, input and result reflection as well as the final xored value via the CFG register. The following source code is an example of initialization for the basic operation of the FCE channel 0:

```
//enable FCE
FCE_CLC.U = 0x0;
//Use Kernel-1, final result to be xored with 0xFFFFFFFF, no reflection
FCE_CFG0.U = 0x10400;
//set CRC initial value (seed)
FCE_CRC0.U = 0xFFFFFFFF;
```

### 17.3.2 Basic Operation

The software must first ensure that the CRC channel is properly configured; especially 1)The configuration, including the CRC kernel used in the CFG register; 2) Length of the data stream in the LENGTH register; and 3) The initial CRC value written via the CRC register. Then, it writes as many times as necessary into the IR register according to the length of the message. The resulting signature is stored in the result register, RES, which can be read by the software.

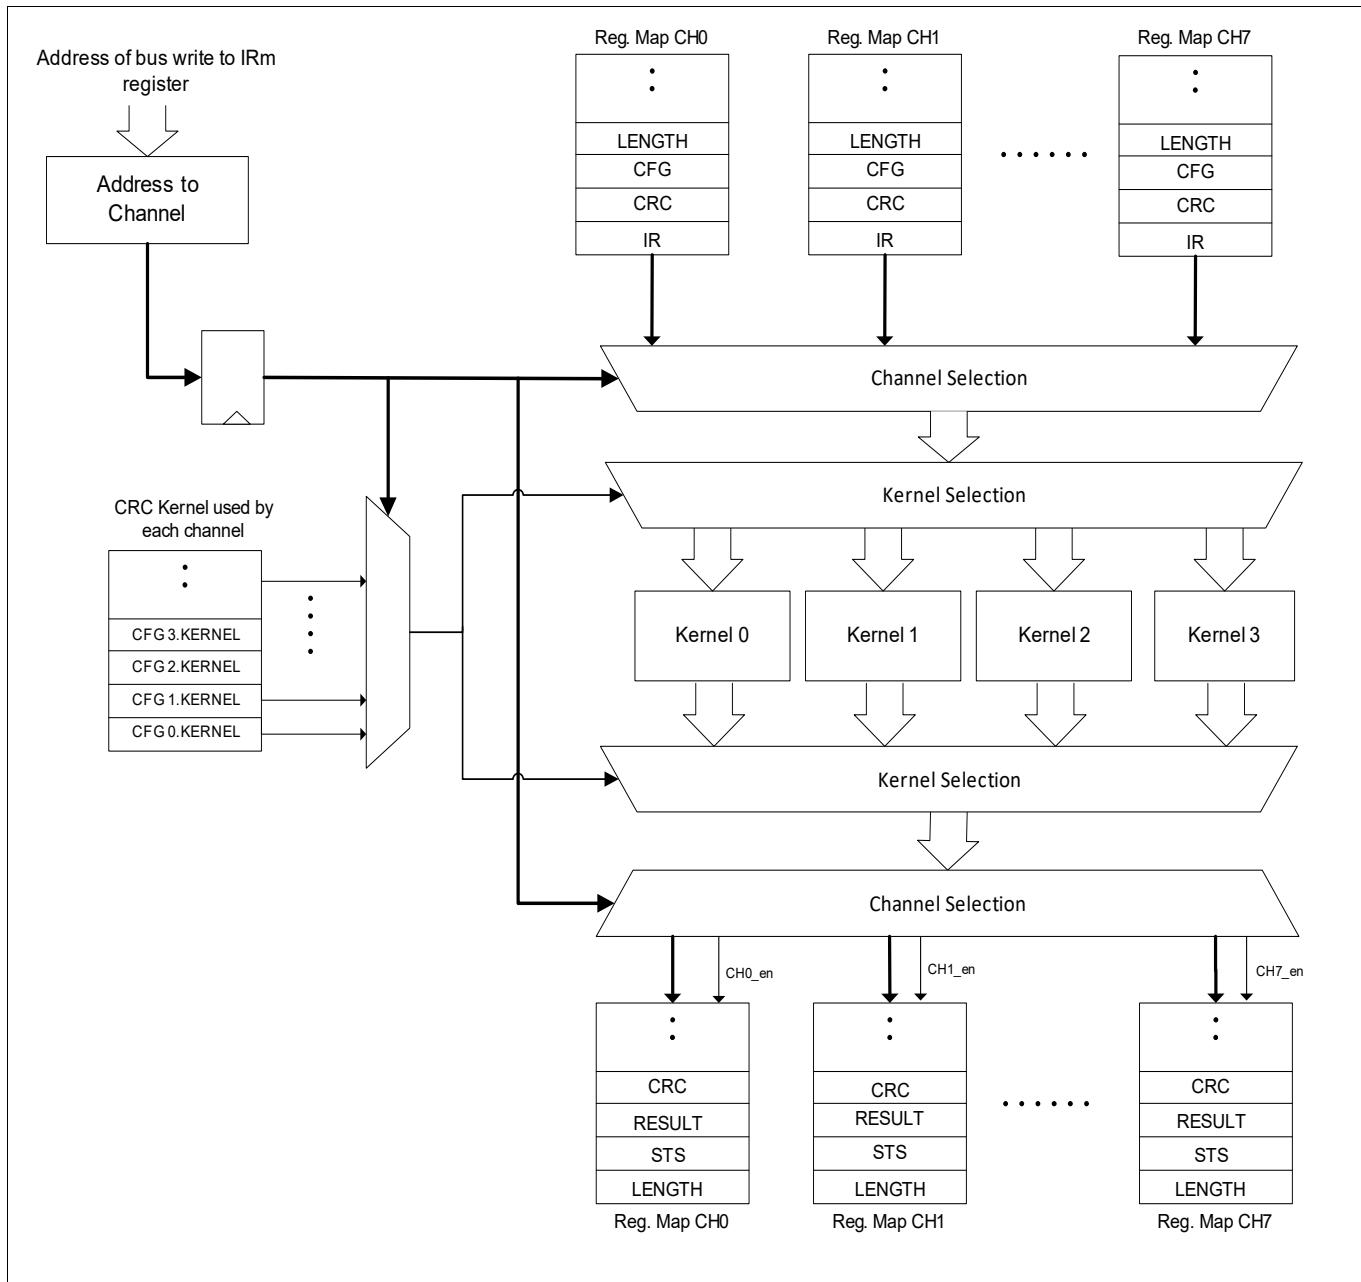

Depending on the CRC kernel that is configured to be used by the channel, the following rules apply:

- When using a CRC kernel of degree  $<N>$  only the bits N-1 down to 0 are used. The upper bits are ignored on write. When reading from a CRC kernel register the non-used upper bits are set to 0.

Each of the 8 channels can be configured to use any of the implemented CRC algorithm kernels. Multiple channels may be configured to use the same kernel, thereby enabling concurrent access of the same CRC algorithm by software.

When software writes to an IR register, based on the bus address of the IR register, the registers of the corresponding channel are selected to be used in the CRC computation (shown in [Figure 181](#)). The CRC kernel used by this channel is selected based on the CFG.KERNEL bits of the selected channel (see [CFG<sub>i</sub> \(\*i\*=0-7\)](#)). The logical representation of the channel and kernel selection based on the bus address of the IR register is shown in [Figure 184](#).

## Flexible CRC Engine (FCE)

**Figure 184 FCE channel and kernel selection**

### 17.3.3 Automatic Signature Check

The automatic signature check compares the signature at the end of a message with the expected signature configured in the CHECK register. In case of a mismatch, an event is generated (see [Section 17.3.7](#)). This feature is enabled by the CFG.CCE bit field (see [CFG<sub>i</sub> \(i=0-7\)](#) register).

If the software wishes to use this feature, the LENGTH register and CHECK registers of the channel must be configured with respectively the length as number of words of the message and the expected signature (CHECK). The word length is defined by the degree of the polynomial used. The CHECK value takes into account the final CRC reflection and XOR operation.

When the CFG.CCE bit field is set, every time the IR register is written, the LENGTH register is decremented by one until it reaches zero. The hardware monitors the transition of the LENGTH register from 1 to 0 to detect the end of the message and proceed with the comparison of the result register RES (see [Figure 181](#)) value with the CHECK register value. If the automatic length reload feature is enabled by the CFG.ALR bit field (see [CFG<sub>i</sub> \(i=0-7\)](#)), the

## Flexible CRC Engine (FCE)

LENGTH register is reinitialized with the previously configured value. This feature is especially suited when the FCE is used in combination with a DMA engine.

In the case the automatic length reload feature is not enabled, if LENGTH is already at zero but software still writes to IR (by mistake) every bit of the LENGTH is set to 1 this value is held until software initializes it again for the processing of a new message. In such case the STS.LEF (Length Error Flag) is set and an interrupt generated if the CFG.LEI (Length Error Interrupt) is set, and the corresponding written value is completely ignored, and no CRC calculation update done. In such an error case, further decrement and reload of the length as well as CRC check is disabled. Software shall clear the LEF error flag for further correct operation.

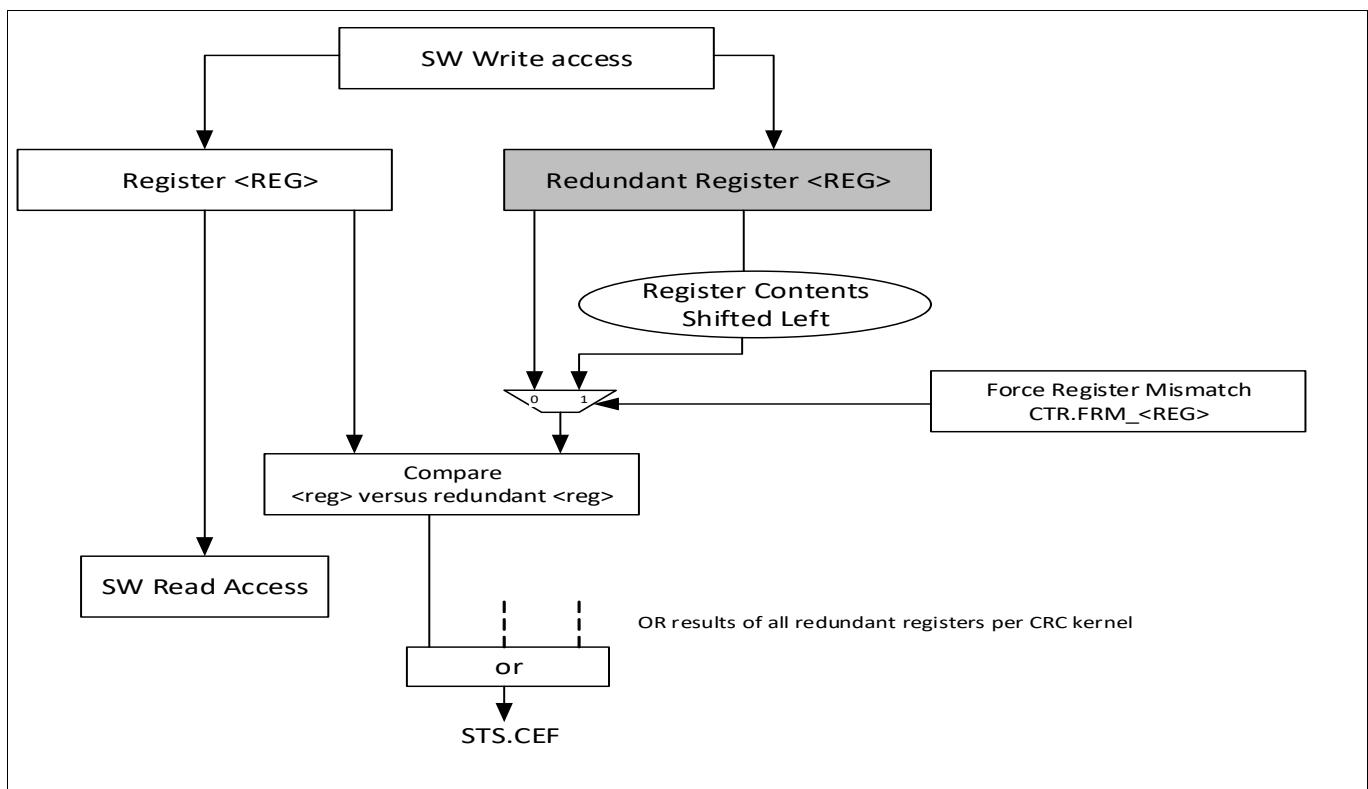

Usually, the CRC signature of a message M0 is computed and appended to M0 to form the message M1 which is transmitted. One interesting property of CRCs is that the CRC signature of M1 shall be zero. This property is particularly useful when automatically checking the signature of data blocks of fixed length with the automatic length reload enabled. LENGTH should be loaded with the length of M1 and CHECK with 0.

## Flexible CRC Engine (FCE)

### 17.3.4 Register protection and monitoring methods

Register Monitoring: applied to CFG and CHECK registers

Because CFG and CHECK registers are critical to the CRC operation, some mechanisms to detect and log transient errors are provided. Early detection of transient failures enables to improve the failure detection time and assess the severity of the failure. The monitoring mechanisms are implemented using two redundant instances as presented in [Figure 185](#).

**Figure 185 Register monitoring scheme**

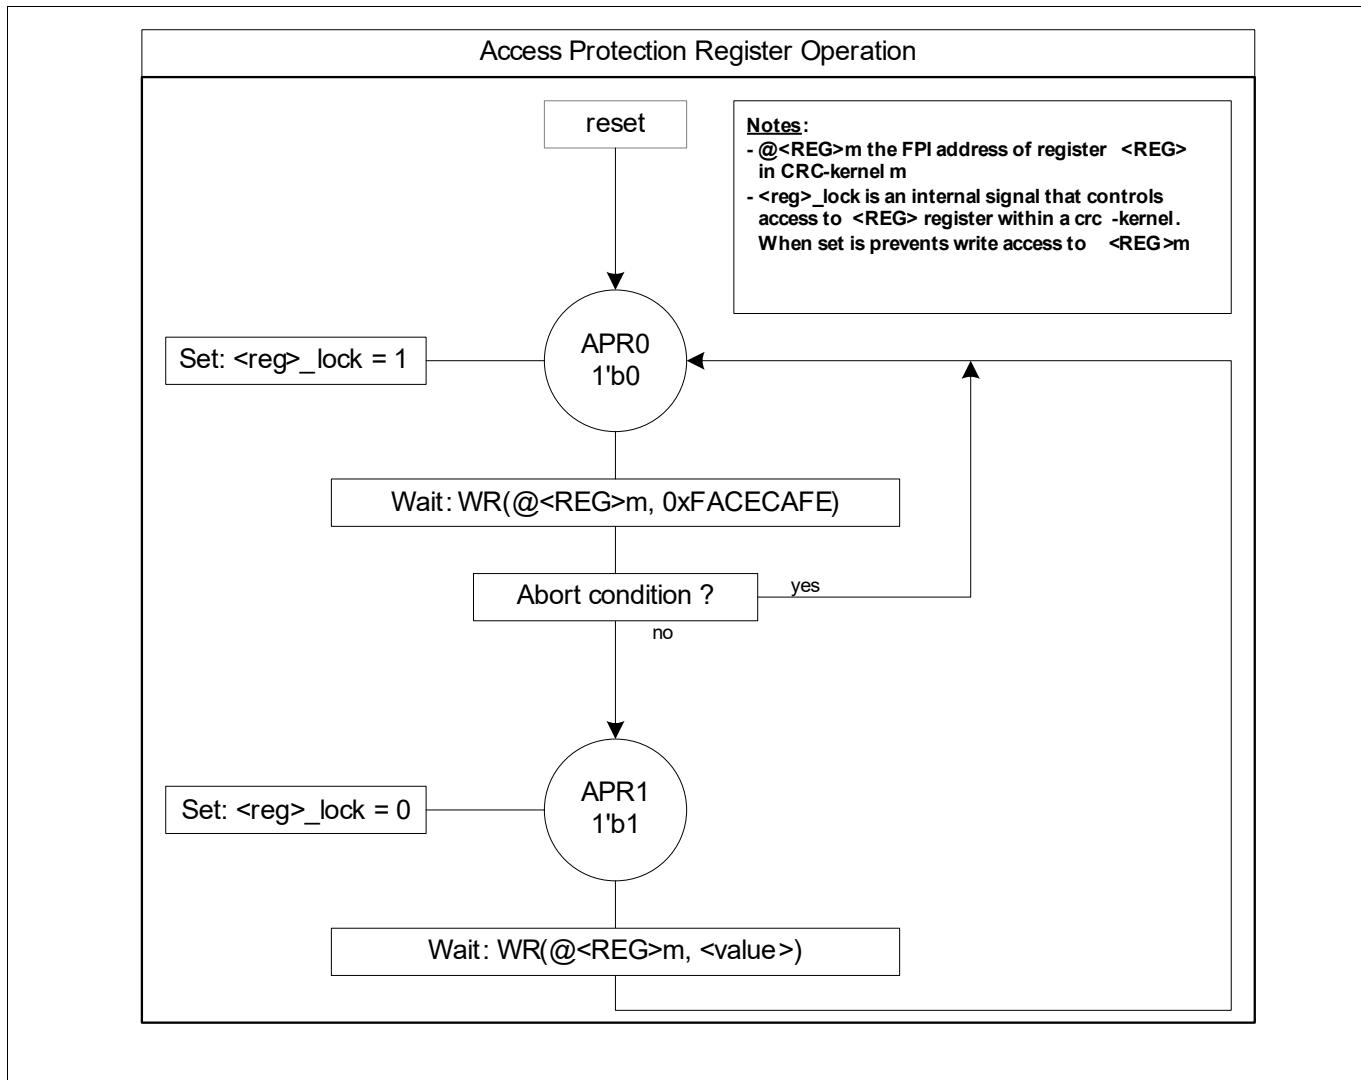

Let  $\langle \text{REG} \rangle$  designate either CFG or CHECK registers. When a write to  $\langle \text{REG} \rangle$  takes place the redundant register is also updated. Redundant registers are not visible to software. Bits of  $\langle \text{REG} \rangle$  reserved have no storage and are not used for redundancy. A compare logic continuously compares the two stored values and provides a signal that indicates if the compare is successful or not. The result of all compare blocks are ored together to provide a single flag information. If a mismatch is detected the STS.CEF (Configuration Error Flag) bit is set. For run-time validation of the compare logic a Force Register Mismatch bit field (CTR.FRM\_<REG>) is provided. When set to 1 by software the contents of the redundant register is shifted left by one bit position (redundant bit 0 position is always replaced by a logical 0 value) and is given to the compare logic instead of the redundant register value. This enables to check the compare logic is functional. Using a walking bit pattern, the software can completely check the full operation of the compare logic. Software needs to clear the CTR.FRM\_<REG> bit to '0' to be able to trigger again a new comparison error interrupt.

Register Access Protection: applies to LENGTH and CHECK registers

In order to reduce the probability of a mis-configuration of the CHECK and LENGTH registers (in the case the automatic check is used), the write access to the CHECK and LENGTH registers must follow a procedure:

This procedure is depicted in [Figure 186](#):

## Flexible CRC Engine (FCE)

**Figure 186 Access control to CHECK register**

Let <REG> designate CHECK or LENGTH registers. Before being able to configure a new <value> value into the <REG> register of a CRC kernel, software must first write the 0xFACECAFE value to the <REG> address. The 0xFACECAFE is not written into the <REG> register. The next write access will proceed as a normal bus write access. The write accesses shall use full 32-bit access only. This procedure will then be repeated every time software wants to configure a new <REG> value. If software reads the CHECK register just after writing 0xFACECAFE it returns the current <REG> contents and not 0xFACECAFE. A read access to <REG> has no effect on the protection mechanism.

The following C-code shows write accesses to the CHECK and LENGTH registers following this procedure:

```

//set CHECK register
FCE_CHECK0.U = 0xFACECAFE;
FCE_CHECK0.U = 0;
//set LENGTH register
FCE_LENGTH0.U = 0xFACECAFE;
FCE_LENGTH0.U = 256;

```

---

## Flexible CRC Engine (FCE)

### 17.3.5 Power, Reset and Clock

The FCE is inside the core power domain, therefore no special considerations about power up or power down sequences need to be taken. For an explanation about the different power domains, please address the SCU (System Control Unit) chapter.

A power down mode can be achieved by disabling the module using the **CLC** register.

The FCE module has one reset source. This reset source is handled at system level and it can be generated independently via a system control register (address SCU chapter for full description).

After reset, the complete IP is set to default configuration. The default configuration for each register field is addressed on [Section 17.4](#).

## Flexible CRC Engine (FCE)

### 17.3.6 Properties of CRC code

#### Hamming Distance

The Hamming distance defines the error detection capability of a CRC polynomial. A cyclic code with a Hamming Distance of D can detect all D-1 bit errors. **Table 563** shows the dependency of the Hamming Distance with the length of the message.

**Table 563 Hamming Distance as a function of message length (bits)<sup>1)</sup>**

Hamming Distance	IEEE-802.3 CRC32	CCITT CRC16	J1850 CRC8
15	8 - 10	Information not available	Information not available
14	8 - 10		
13	8 - 10		
12	11 - 12		
11	13 - 21		
10	22 - 34		
9	35 - 57		
8	58 - 91

### 17.3.7 Service Request Generation

Each FCE CRC channel provides one internal interrupt source. The interrupt lines from each CRC channel are ORed together to be sent to the interrupt system. The system interrupt is an active high pulse with the duration of one cycle (of the peripheral clock). The FCE interrupt handler can use the status information located within the STS status register of each CRC channel.

Each CRC channel provides the following interrupt sources:

- CRC Mismatch Interrupt controlled by CFG.CMI bit field and observable via the status bit field STS.CMF (CRC Mismatch Flag).
- Configuration Error Interrupt controlled by CFG.CEI bit field and observable via the status bit field STS.CEF (Configuration Error Flag).
- Length Error Interrupt controlled by CFG.LEI bit field and observable via the status bit field STS.LEF (Length Error Flag).
- Bus Error Interrupt controlled by CFG.BEI bit field and observable via the status bit field STS.BEF (Bus Error Flag). This error is triggered by a write to the IR register with write width less than the selected kernel's polynomial width.

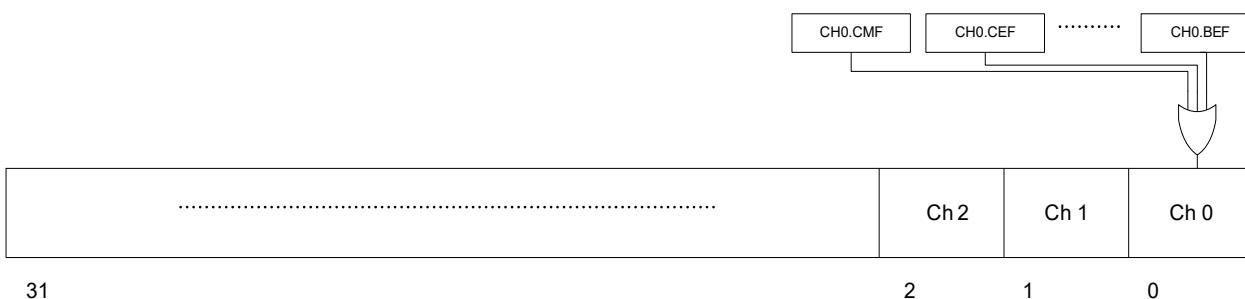

Interrupt generation rules

## Flexible CRC Engine (FCE)

- A status flag shall be cleared by software by writing a 0 to the corresponding bit position in the STS register.
- If an status flag is set and a new hardware condition occurs, no new interrupt is generated by the kernel: a set STS.<FLAG> bit field masks the generation of a new interrupt from the FCE module. If a SW access to clear the interrupt status bit takes place and in the same cycle the hardware wants to set the bit, the hardware condition wins the arbitration.

To aid faster interrupt handling in the software, the status flags from all channels each channel are ORed together and provided as individual bits in a Channels Status Register (see [Figure 187](#)). The software can read this single register to learn the channel status, rather than reading the registers of each channel separately.

Since there is only a single interrupt from the FCE, the software has to clear the status flags from all the channels to forward a further FCE interrupt.

**Figure 187 Channels Status Register**

## 17.4 Registers

[Table 564](#) show all registers associated with the FCE module. All FCE channel register names are described in this section. They should get the prefix “FCE\_” when used in the context of a product specification.

The registers are numbered by one index to indicate the related FCE CRC Channel ( $m = 0\text{-}7$ ).

[Figure 188](#) shows the FCE module register map.

### Access Mode Rules

The **Table 564** uses the standard access mode conventions.

### Disabling the FCE

The FCE module can be disabled using the **CLC** register.

When the disable state is requested all pending transactions running on the bus slave interface must be completed before the disabled state is entered. The CLC Register Module Disable Bit Status CLC.DISS indicates whether the module is currently disabled (DISS == 1). Any attempt to write any of the BPI writable registers with the exception of the CLC Register will generate a bus error. A read operation of BPI registers is allowed and does not generate a bus error.

### Resetting the FCE

The FCE module can be reset using the **KRST0**, **KRST1**, and **KRSTCLR** registers. This action affects all the CRC kernels and channels.

## Flexible CRC Engine (FCE)

To reset the FCE it is necessary to set the RST bits by writing with '1' in both Reset Registers **KRST0**, **KRST1**. The RST bit will be re-set by the BPI with the end of the BPI kernel reset sequence.

Reset Register 0 includes a reset status bit that is set to '1' by the BPI in the same clock cycle the RST bit is re-set by the BPI. This bit can be used to detect that a reset was processed. The bit can be re-set to '0' by writing to KRSTCLR.CLR with '1'.

Additionally, when a channel is reprogrammed to use a different kernel, then software should take care to reset or reprogram the channel registers (esp. IR, RES, CRC and CHECK). Otherwise masked bits (eg. for a Lower width polynomial Kernel) may become visible and used.

## Flexible CRC Engine (FCE)

### 17.4.1 System Registers description

This section describes the registers related to the product system architecture.

#### Clock Control Register

The Clock Control Register allows the programmer to adapt the functionality and power consumption of the module to the requirements of the application.

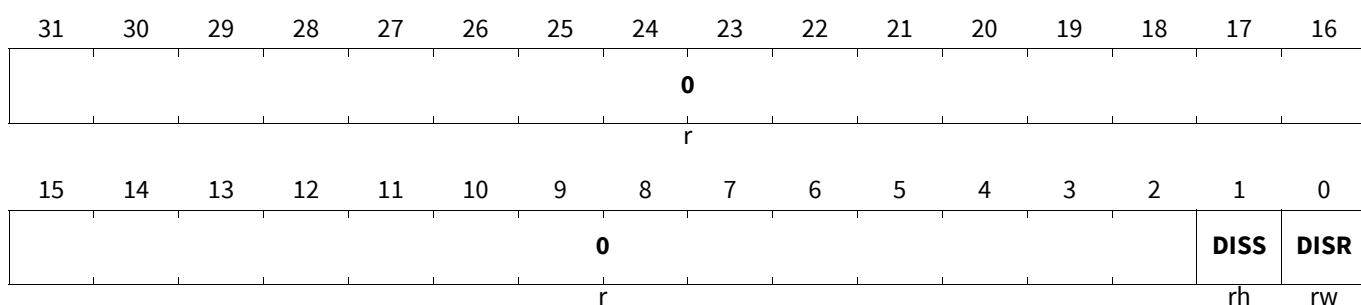

**Note:** *The features related to the pre-defined FDIS, EDIS and RMC fields are not supported by the FCE. Therefore the corresponding fields have been removed from the CLC register.*

#### CLC

##### Clock Control Register

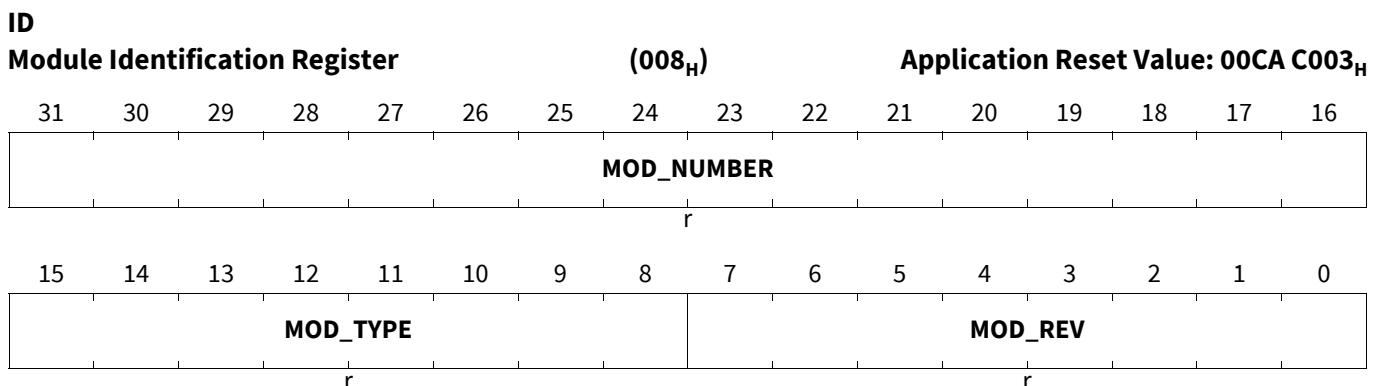

(000<sub>H</sub>)

Application Reset Value: 0000 0003<sub>H</sub>

Field	Bits	Type	Description
DISR	0	rw	<b>Module Disable Request Bit</b> Used for enable/disable control of the module.
DISS	1	rh	<b>Module Disable Status Bit</b> Bit indicates the current status of the module.
0	31:2	r	<b>Reserved</b> Read as 0; should be written with 0.

#### Module Identification Register

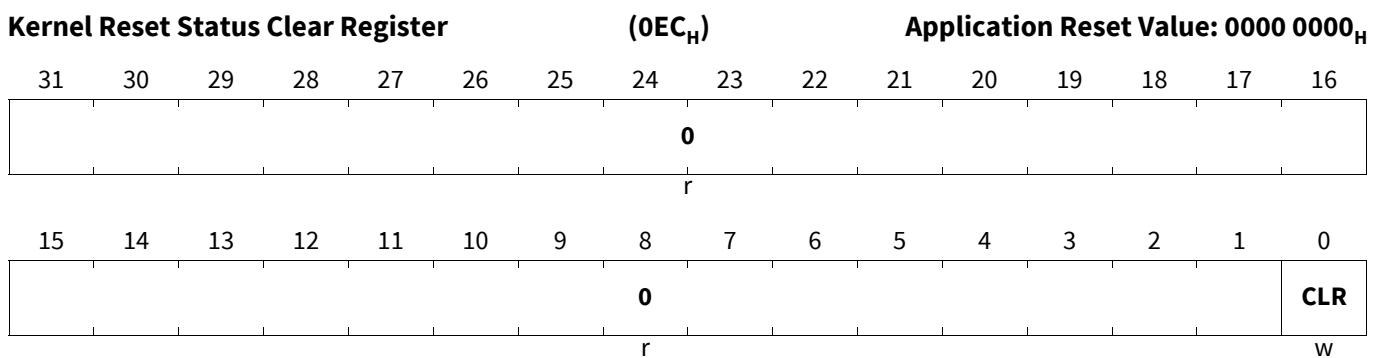

## Flexible CRC Engine (FCE)

Field	Bits	Type	Description
<b>MOD_REV</b>	7:0	r	<b>Module Revision Number</b> This bit field defines the module revision number. The value of a module revision starts with 01H (first revision). The current revision number is 03H.
<b>MOD_TYPE</b>	15:8	r	<b>Module Type</b> The bit field is set to C0H which defines the module as a 32-bit module.
<b>MOD_NUMBE R</b>	31:16	r	<b>Module Number Value</b> This bit field defines a module identification number. The value for the FCE module is 00CA <sub>H</sub> .

### Kernel Reset Status Clear Register

Refer to “[Resetting the FCE](#)” on Page 17 for the usage of the register.

#### KRSTCLR

Field	Bits	Type	Description
<b>CLR</b>	0	w	<b>Kernel Reset Status Clear</b> Read always as 0. 0 <sub>B</sub> No action 1 <sub>B</sub> Clear Kernel Reset Status KRST0.RSTSTAT
<b>0</b>	31:1	r	<b>Reserved</b> Read as 0; should be written with 0.

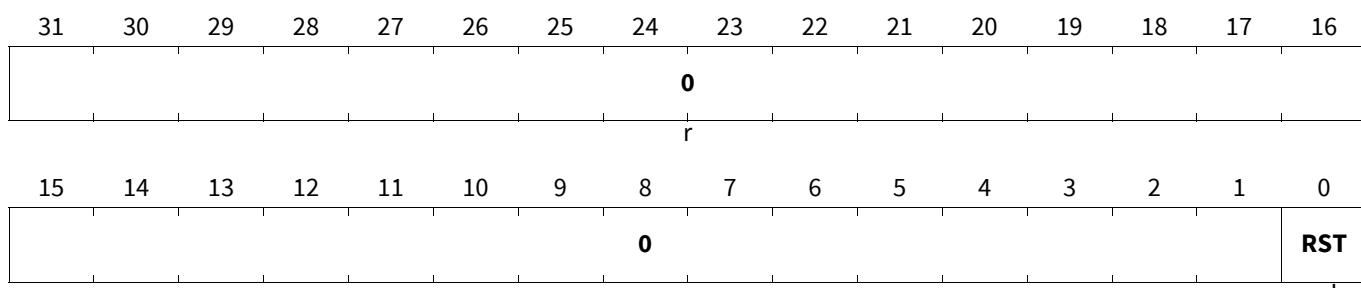

### Kernel Reset Register 1

Refer to “[Resetting the FCE](#)” on Page 17 for the usage of the register.

## Flexible CRC Engine (FCE)

### KRST1

#### Kernel Reset Register 1

(0F0<sub>H</sub>)Application Reset Value: 0000 0000<sub>H</sub>

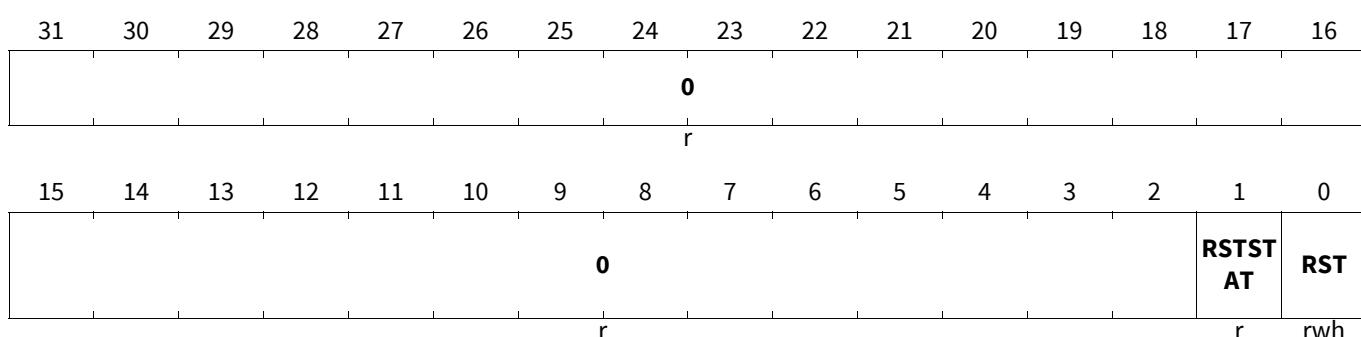

Field	Bits	Type	Description
RST	0	rwh	<b>Kernel Reset</b> This reset bit can be used to request for a kernel reset. The kernel reset will be executed if the reset bits of both kernel reset registers is set. The RST bit will be cleared (re-set to '0') by the BPI_FPI after the kernel reset was executed. 0 <sub>B</sub> No kernel reset was requested 1 <sub>B</sub> A kernel reset was requested
0	31:1	r	<b>Reserved</b> Read as 0; should be written with 0.

### Kernel Reset Register 0

Refer to “Resetting the FCE” on Page 17 for the usage of the register.

### KRST0

#### Kernel Reset Register 0

(0F4<sub>H</sub>)Application Reset Value: 0000 0000<sub>H</sub>

Field	Bits	Type	Description
RST	0	rwh	<b>Kernel Reset</b> This reset bit can be used to request for a kernel reset. The kernel reset will be executed if the reset bits of both kernel registers are set. The RST bit will be cleared (re-set to '0') by the BPI_FPI after the kernel reset was executed. 0 <sub>B</sub> No kernel reset was requested 1 <sub>B</sub> A kernel reset was requested

## Flexible CRC Engine (FCE)

**Flexible CRC Engine (FCE)**

Field	Bits	Type	Description
<b>CH7</b>	7	rh	<b>Channel7 Status</b> This bit is the result of an OR operation of the various status bits of channel 7 (see STS register).
<b>0</b>	31:8	r	<b>Reserved</b> Read as 0. Should be written with 0.

## Flexible CRC Engine (FCE)

### 17.4.3 CRC Channel Control/Status Registers

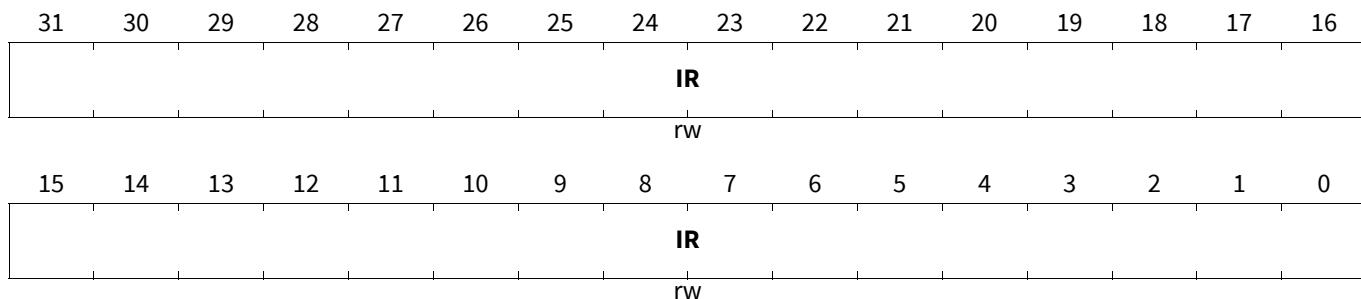

#### Input Register i

**IR<sub>i</sub> (i=0-7)**

#### Input Register i

(100<sub>H</sub>+i\*20<sub>H</sub>)

Application Reset Value: 0000 0000<sub>H</sub>

Field	Bits	Type	Description
IR	31:0	rw	<b>Input Register</b> This bit field holds the input data to be computed. In case the channel is configured to use 16-bit or 8-bit CRC, only the LSB 16 or 8-bits will be used as input.

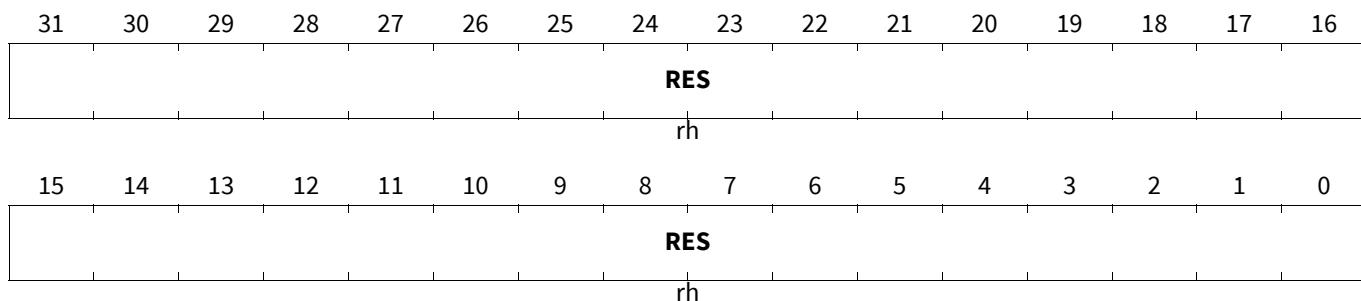

#### CRC Result Register i

**RES<sub>i</sub> (i=0-7)**

#### CRC Result Register i

(104<sub>H</sub>+i\*20<sub>H</sub>)

Application Reset Value: FFFF FFFF<sub>H</sub>

Field	Bits	Type	Description
RES	31:0	rh	<b>Result Register</b> Returns the final CRC value including CRC reflection and final XOR according to the CFG register configuration. Writing to this register produces a bus error. If the channel is configured to use 16-bit or 8-bit CRC, the MSB 16 or 24 bits respectively shall be read as 0.

## Flexible CRC Engine (FCE)

## CRC Configuration Register i

CFG*i* (*i*=0-7)

## CRC Configuration Register i

(108<sub>H</sub>+*i*\*20<sub>H</sub>)Application Reset Value: 0000 0700<sub>H</sub>

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
0												KERNEL

### CRC Length Register i

**LENGTH<sub>i</sub> (i=0-7)**

**CRC Length Register i**

(110<sub>H</sub>+i\*20<sub>H</sub>)

**Application Reset Value: 0000 0000<sub>H</sub>**

Field	Bits	Type	Description
<b>LENGTH</b>	15:0	rwh	<b>Message Length Register</b> Number of words (bit width of each word in terms of KERNEL polynomial width) building the message over which the CRC checksum is calculated. This bit field is modified by the hardware: every write to the IR register decrements the value of the LENGTH bit field. If the CFG.ALR field is set to 1, the LENGTH field shall be reloaded with its configuration value at the end of the cycle where LENGTH reaches 0.
<b>0</b>	31:16	r	<b>Reserved</b> Read as 0; should be written with 0.

## Flexible CRC Engine (FCE)

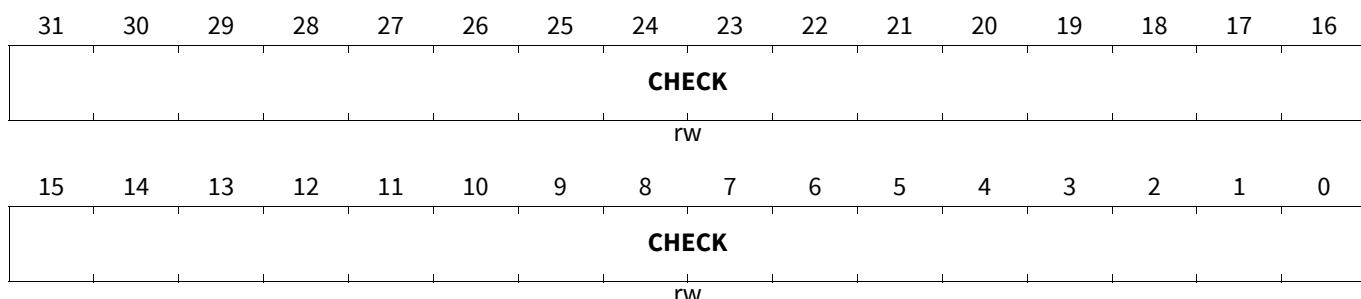

### CRC Check Register i

**CHECK<sub>i</sub> (i=0-7)**

**CRC Check Register i**

**(114<sub>H</sub>+i\*20<sub>H</sub>)**

**Application Reset Value: 0000 0000<sub>H</sub>**

Field	Bits	Type	Description
<b>CHECK</b>	31:0	rw	<b>CHECK Register</b> Expected CRC value to be checked by the hardware upon detection of a 1 to 0 transition of the LENGTH register. The comparison is enabled by the CFG.CCE bit field

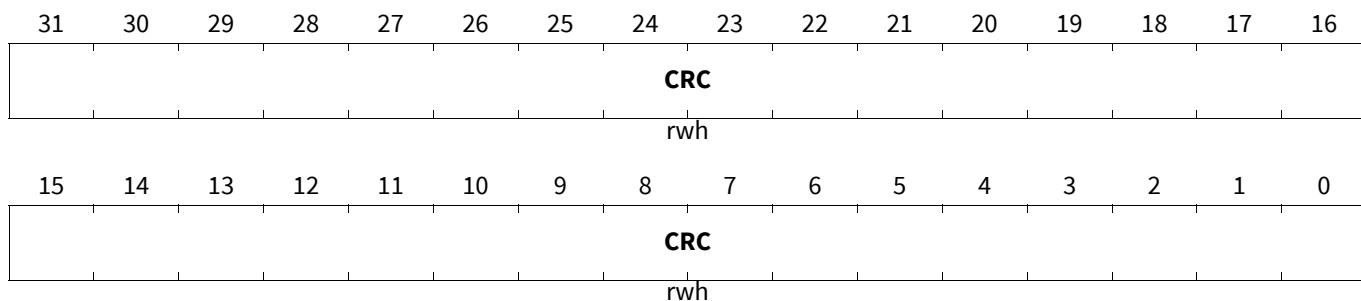

### CRC Register i

**CRC<sub>i</sub> (i=0-7)**

**CRC Register i**

**(118<sub>H</sub>+i\*20<sub>H</sub>)**

**Application Reset Value: 0000 0000<sub>H</sub>**

Field	Bits	Type	Description
<b>CRC</b>	31:0	rwh	<b>CRC Register</b> This register enables to directly access the internal CRC register

## Flexible CRC Engine (FCE)

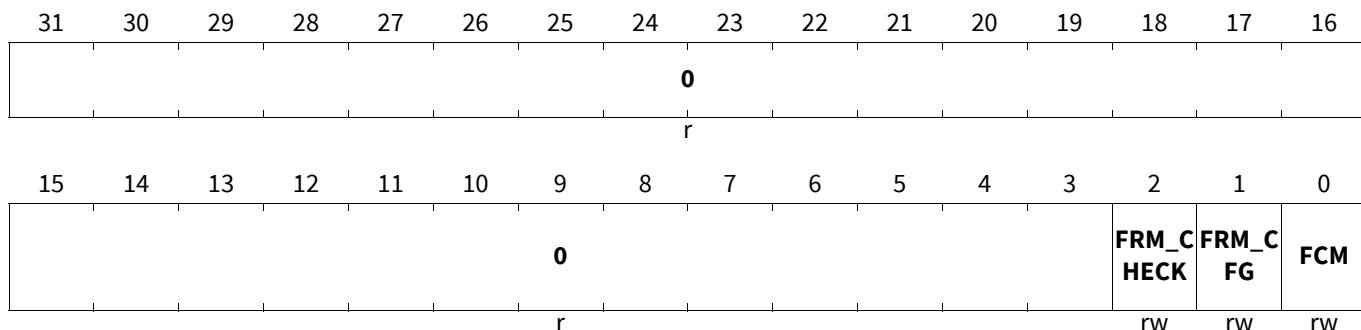

### CRC Test Register i

**CTR<sub>i</sub> (i=0-7)**

**CRC Test Register i**

(11C<sub>H</sub>+i\*20<sub>H</sub>)

**Application Reset Value: 0000 0000<sub>H</sub>**

Field	Bits	Type	Description
<b>FCM</b>	0	rw	<b>Force CRC Mismatch</b> Forces the CRC compare logic to issue an error regardless of the CHECK and CRC values. The hardware detects a 0 to 1 transition of this bit field and triggers a CRC Mismatch interrupt
<b>FRM_CFG</b>	1	rw	<b>Force CFG Register Mismatch</b> This field is used to control the error injection mechanism used to check the compare logic of the redundant CFG registers. This is a one shot operation. When the hardware detects a 0 to 1 transition of this bit field it triggers a Configuration Mismatch interrupt (if enabled by the corresponding CFGm register).
<b>FRM_CHECK</b>	2	rw	<b>Force Check Register Mismatch</b> This field is used to control the error injection mechanism used to check the compare logic of the redundant CHECK registers. This is a one shot operation. The hardware detects a 0 to 1 transition of this bit field and triggers a Check Register Mismatch interrupt (if enabled by the corresponding CFGm register).
<b>0</b>	31:3	r	<b>Reserved</b> Read as 0; should be written with 0.

### 17.5 Debug

The FCE has no specific debug feature.

## Direct Memory Access (DMA)

### 18 Direct Memory Access (DMA)

The DMA (at [Figure 189](#)) shall move data from a source module to a destination module without CPU intervention.

**Figure 189 Block Diagram of DMA**

#### DMA Glossary

**Table 567 DMA Acronyms**

Acronym	Description
ACLL	Accumulated Linked List
CONLL	Conditional Linked List
CH	Channel
DER	Destination Error
DLER	Linked List Error
DMA	Direct Memory Access
DMALL	Direct Memory Access Linked List
DMARAM	Direct Memory Access Random Access Memory
EH	Error Handler

## Direct Memory Access (DMA)

**Table 567 DMA Acronyms (cont'd)**

Acronym	Description
ME	Move Engine
PATDET	Pattern Detection
RAMER	RAM Error
RDCRC	Read Data Cyclic Redundancy Check
RP	Resource Partition
RROAT	Reset Request Only After Transaction
SAFLL	Safe Linked List
SDCRC	Source Destination Cyclic Redundancy Check
SER	Source Error
SLLER	Safe Linked List Error
TCS	Transaction Control Set
TRL	Transaction/Transfer Request Lost
TS	Trigger Set

**Table 568 DMA Terms**

Term	Description
DMA Configuration Data	The DMA configuration data configures the DMA configuration structure.
DMA Configuration Structure	The DMA configuration structure is used to configure CH, RP and ME. The DMA configuration structure is defined by the DMA address map.  Note: <i>The DMA configuration structure does not include IR, SMU, etc. which is needed to make the DMA function within the system.</i>  3. <i>The DMA configuration structure and DMA configuration data defines all DMA move functions.</i>
DMA Software Request	The CPU initiates a DMA transfer or a DMA transaction in a DMA channel.
DMA Hardware Request	The Interrupt Router initiates a DMA transfer or a DMA transaction in a DMA channel.
DMA Daisy Chain Request	As soon as the current DMA transaction completes, the DMA channel initiates a DMA transfer or a DMA transaction in the next lower priority DMA channel.
DMA Auto Start Request	As soon as the current DMA transaction completes, a linked list operation loads a new TCS and initiates a DMA transfer or a DMA transaction.
DMA Request	DMA software request, DMA hardware request, DMA daisy chain request or DMA auto start request.
DMA Read Move Data	Data read from the source module.
DMA Write Move Data	Data written to the destination module.
DMA Channel Interrupt Triggers	DMA signalling of the successful completion of a DMA move function.
DMA RP Error Interrupt Triggers	DMA signalling of a DMA move function error.
DMA Alarms	DMA signalling of a DMA safety error.

## Direct Memory Access (DMA)

**Table 568 DMA Terms (cont'd)**

Term	Description
DMA Address Checksum	Cyclic redundancy checksum calculated according to the IEEE 802.3 standard for addresses generated during a DMA transaction.
DMA Data Checksum	Cyclic redundancy checksum calculated according to the IEEE 802.3 standard for data moved during a DMA transaction.
DMA Timestamp	Appendage of timestamp to a DMA transaction.

The terms (at [Table 569](#)) are used to define the structure of the data move function.

**Table 569 Structure of Data Move Function**

Term	Description
DMA Move	A DMA move is an operation that always consists of two parts: 1. A DMA read move that loads DMA read move data from a source module to the DMA. 2. A DMA write move that stores DMA write move data from the DMA to a destination module.
DMA Transfer	A DMA transfer shall be composed of 1, 2, 3, 4, 5, 8, 9 or 16 DMA moves.
DMA Transaction	A DMA transaction shall be composed of at least one DMA transfer.
Linked List	A linked list is a series of DMA transactions executed in the same DMA channel.

## 18.1 Feature List

The DMA is a fast and flexible DMA controller that has the following features:

- **Resource Partitions**
  - An application running one set of defined move data functions shall be free from interference by another application running another set of defined move data functions.
  - Each RP has independent **Access Enable** control via enabling individual Master TAG identifiers to have write access enable to the RP and assigned DMA channels.
  - Each RP has a unique master tag identifier driven onto the on chip bus during a DMA move.
  - Each RP executes on chip bus accesses in supervisor or user mode.
- **DMA Channels**
  - The DMA supports multiple independent DMA channels.
  - Each DMA channel shall be assigned to a RP.
  - Each DMA channel shall be individually programmable.
  - Each DMA channel TCS shall be stored in DMARAM.
  - The DMA channel source and destination address pointers shall be 32-bit wide address counters.
  - Wrap buffer addressing mode with flexible circular buffer sizes.
  - The DMA channel source and destination wrap buffers shall be selectable.
  - Programmable data width of DMA moves.
- **Double Buffering Operations**
  - The DMA transaction can execute read or fill DMA transfers from one of two source or destination buffers.
  - A control bit allows the re-direction of DMA transfers from the one buffer to the other buffer.
- **DMA Linked List (DMALL)**
  - The current DMA transaction can load the next DMA channel TCS into the DMARAM by overwriting the existing DMA channel TCS.

## Direct Memory Access (DMA)

- The next DMA transaction may be auto started.
- **DMA Channel Request Control**
  - **DMA Software Request**
  - **DMA Hardware Request**
  - **DMA Daisy Chain Request**
  - **DMA Auto Start Request**
- **Move Engine**
  - Any ME shall service a DMA request from any DMA channel.
  - DMA requests from the highest number DMA channel are serviced first by a ME.
  - Multiple MEs support the parallel servicing of DMA requests.
  - SRI-source to SRI-destination data block move throughput <8 Mbyte DMA moves per DMA transaction.
  - SPB-source to SPB-destination data block move throughput <1 Mbyte DMA moves per DMA transaction.
- **DMA On Chip Bus Switch**
  - DMA read moves and DMA write moves are directed by the DMA on chip bus switch to different sources and destinations depending on the source or destination address.
  - Buffer capability for move actions on the buses (at least 1 x DMA move per bus is buffered).
- Interrupt Triggers
  - Each DMA channel generates one interrupt trigger with an unique interrupt vector and priority level.
  - Each DMA RP generates one error interrupt trigger with an unique interrupt vector and priority level.
- Operating frequencies
  - The DMA configuration and request control function works at the SPB clock frequency.
  - The ME function works at the SRI clock frequency in order to maximise the data throughput for DMA moves from SRI source addresses to SRI destination addresses.

### 18.2 Overview

The DMA moves data from source locations to destination locations without the intervention of the CPU or other on chip devices. A data move is controlled by the TCS of an active DMA channel executed by a ME. A DMA channel is activated by a DMA request.

---

## Direct Memory Access (DMA)

### 18.3 Functional Description

#### 18.3.1 Configuration Interface

The DMA implements a standard FPI slave interface compliant with the FPI bus protocol on the SPB bus. The DMA configuration interface supports single data transfers and does not support block transfers.

#### 18.3.2 Resource Partitions

During DMA configuration, each DMA channel shall be assigned to a RP.

##### 18.3.2.1 Access Enable

Each RP has its own access enable protection. A slave destination controls access to its bus peripheral interfaces and kernel address space. Each on chip resource with bus master capability has a unique master tag identifier that is used to identify the source of an on chip bus transaction. The master tag identifier based access protection is used to enable write accesses to individual slave address ranges.

##### 18.3.2.2 DMA Moves

Each RP has a unique master tag identifier driven onto the on chip bus during a DMA read move or DMA write move. Mode control selects if a DMA move on chip bus access is made in supervisor mode or user mode.

*Note:* See *On-Chip System Connectivity chapter* for on chip bus master TAG identifier assignments.

##### 18.3.2.3 DMA RP Error Interrupt Service Request

Each RP generates one error interrupt service request to cover all error events for DMA channels assigned to that RP including servicing of DMA requests by the ME:

- DMA channel **TRL** interrupt service request.
- ME SER and DER error interrupt service request.
- ME **DMARAM Integrity Error** error interrupt service request.
- ME **Linked List Operation TCS Load Error** error interrupt service request.
- ME **SAFLL DMA Address Checksum Error** error interrupt service request.

If a DMA RP error interrupt service request is triggered then the software RP application EH shall read the contents of the error status registers to identify the origin of the error.

### 18.3.3 DMA Channels

Each DMA channel is assigned to a RP and stores the context of an independent DMA operation.

#### 18.3.3.1 DMA Channel Request Control

The DMA channel request control (at **Figure 190**) is implemented for each DMA channel.

The DMA channel operation is individually programmable. The following types of DMA requests are possible:

- **DMA Software Request** initiated by a CPU.
- **DMA Hardware Request** initiated by the Interrupt Router (IR) Interrupt Control Unit (ICU).
- **DMA Daisy Chain Request** initiated by the next higher priority DMA channel.

## Direct Memory Access (DMA)

- **DMA Auto Start Request** initiated by the loading of the next TCS during a **DMA Linked List (DMALL)**, **Accumulated Linked List (ACLLL)**, **Safe Linked List (SAFLL)** or **Conditional Linked List (CONLL)** operation.

The DMA channel status flag TSR.CH indicates if a DMA request is pending. TSR.CH may be cleared at the start of a DMA transfer or at the end of a DMA transaction. It follows that a DMA request may trigger a single **DMA Transfer** or one complete **DMA Transaction**.

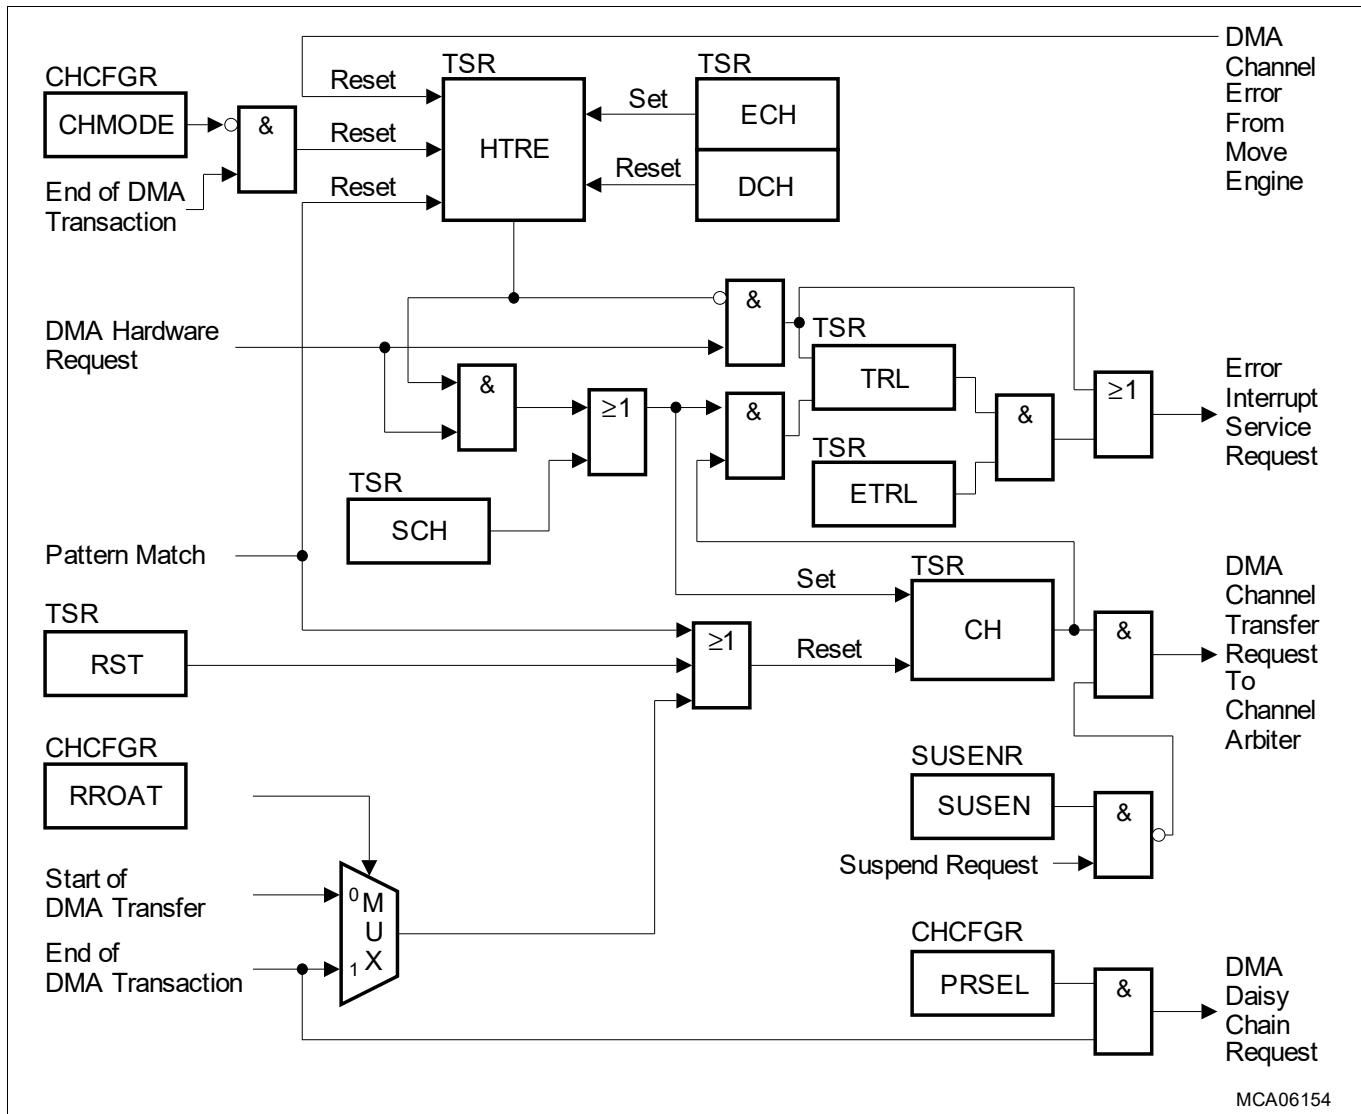

Figure 190 DMA Channel Request Control

### 18.3.3.1.1 DMA Channel States

Table 570 DMA Channel States

State	Status	Comments
Idle State	DMA channel TSR.CH = 0 <sub>B</sub>	No <b>DMA Request</b> is pending.
<b>Reset State</b>	DMA channel TSR.CH = 0 <sub>B</sub>	No <b>DMA Request</b> is pending. DMA channel TCS bits cleared.
<b>Halt State</b>	DMA channel TSR.HLTACK = 1 <sub>B</sub>	A <b>DMA Request</b> shall not be serviced by a ME.
Pending State	DMA channel TSR.CH = 1 <sub>B</sub>	<b>DMA Request</b> is waiting to be serviced by a ME.
Active State		ME is servicing a <b>DMA Request</b> .

## Direct Memory Access (DMA)

### 18.3.3.1.2 Reset Request Only After Transaction (RROAT)

The clearing of the DMA channel TSR.CH bit is controlled as follows:

- CHCFGR.RROAT = 0<sub>B</sub>
  - DMA channel TSR.CH is cleared at the start of each DMA transfer.
  - One **DMA Request** starts one single **DMA Transfer**.
- CHCFGR.RROAT = 1<sub>B</sub>
  - DMA channel TSR.CH is cleared at the end of each DMA transaction.
  - One **DMA Request** starts one complete **DMA Transaction**.

### 18.3.3.2 DMA Software Request

One **DMA Software Request** may start one complete DMA transaction or one single DMA transfer.

If the DMA channel is triggered only by software then a **DMA Hardware Request** should be disabled.

Software must set TSR.DCH to 1<sub>B</sub> to disable a **DMA Hardware Request** (TSR.HTRE = 0<sub>B</sub>).

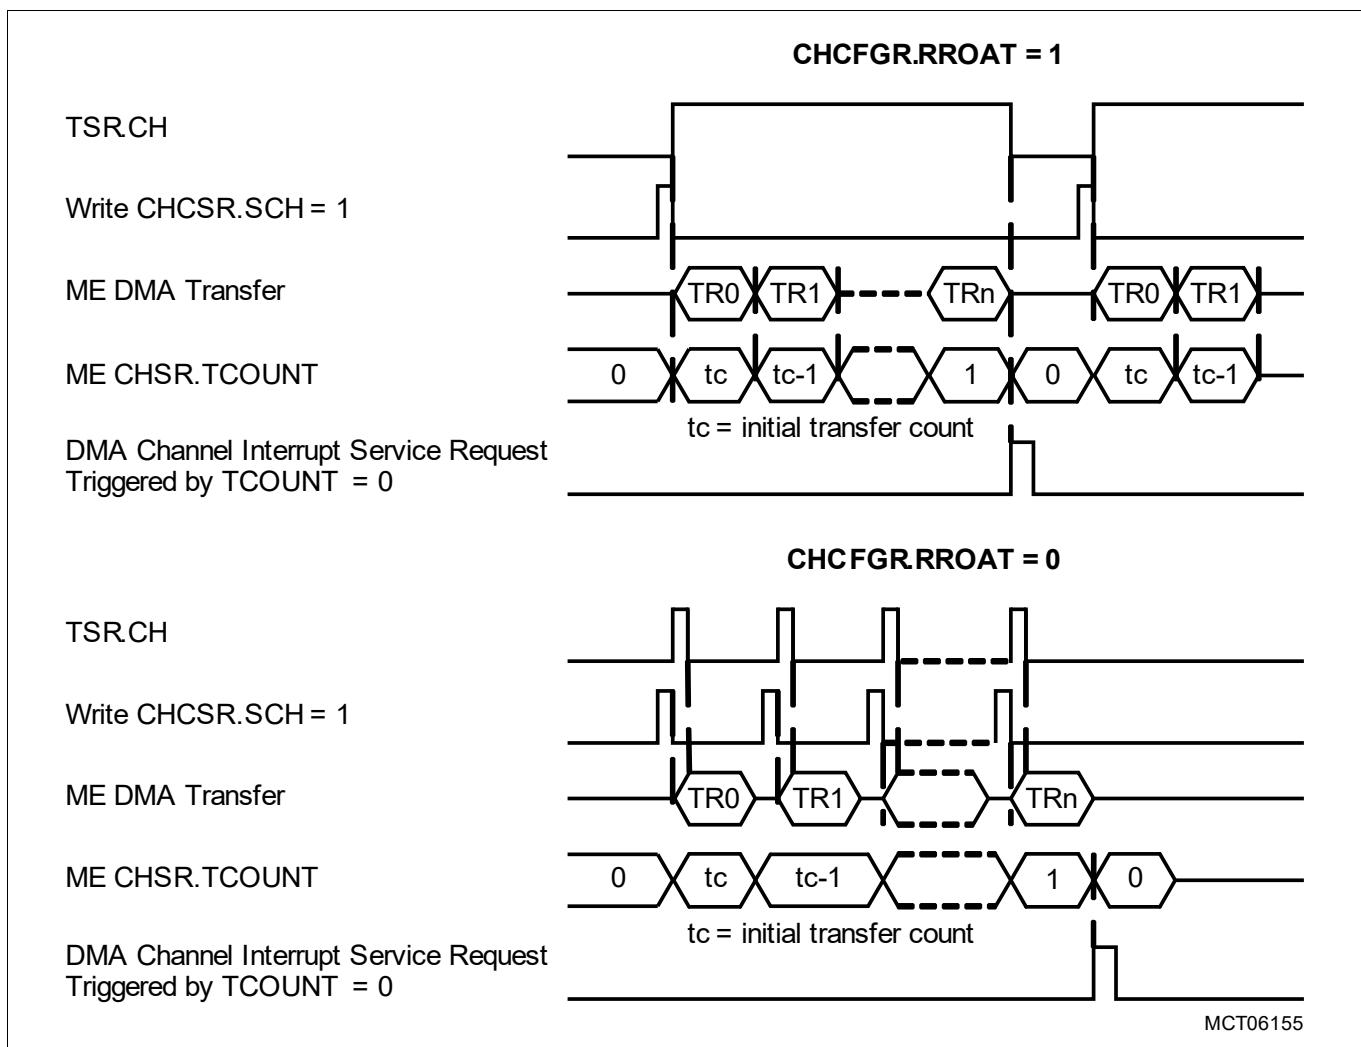

Figure 191 Software Control

The following DMA channel configuration is required to initiate one complete **DMA Transaction** under software control:

- DMA channel CHCFGR.RROAT = 1<sub>B</sub>

## Direct Memory Access (DMA)

A **DMA Software Request** is initiated by setting the DMA channel CHCSR.SCH to  $1_B$  with the result that TSR.CH is set to  $1_B$ . At the start of the DMA transaction, the value of the DMA channel reload value CHCFG.RTREL is loaded into ME CHSR.TCOUNT and DMA transfers are executed. After each DMA transfer, ME CHSR.TCOUNT is decremented and the next source and destination addresses are calculated. When TCOUNT decrements to  $0_D$ , the DMA channel status flag TSR.CH is reset. Setting the DMA channel CHCSR.SCH =  $1_B$  again starts a new DMA transaction of the DMA channel with the stored TCS parameters.

The following DMA channel configuration is required to initiate each single DMA Transfer under software control:

- DMA channel CHCFG.RRQAT =  $0_B$

A **DMA Software Request** must be initiated for each DMA transfer by setting the DMA channel CHCSR.SCH to  $1_B$ .

### 18.3.3.3 DMA Hardware Request

A **DMA Hardware Request** is enabled/disabled by the DMA channel Hardware Transaction/Transfer Request Enable (HTRE) bit TSR.HTRE. The HTRE functionality is as follows:

- Software may set (TSR.ECH =  $1_B$ ) or clear (TSR.DCH =  $1_B$ ) DMA channel TSR.HTRE.
- Cleared as a result of the ME reporting an error for the DMA channel.
- Single Mode: at the start of the last DMA transfer of a DMA transaction.

**Table 571 Conditions to Set/Reset DMA channel TSR.HTRE**

DMA channel TSR.ECH	DMA channel TSR.DCH	Start of last DMA transfer of a DMA transaction <sup>1)</sup>	Modification of DMA channel TSR.HTRE
0	0	0	Unchanged
1	0	0	Set
X	1	X	Reset
X	X	1	Reset

1) In **Single Mode** only. In **Continuous Mode**, the end of a DMA transaction has no impact.

### DMA Channel Mode

The DMA channel mode bit CHCFG.CHMODE controls the DMA channel mode as follows:

- **Single Mode** (DMA channel CHCFG.CHMODE =  $0_B$ )
  - **DMA Hardware Request** is disabled by hardware on completion of a DMA transaction.
- **Continuous Mode** (DMA channel CHCFG.CHMODE =  $1_B$ )
  - **DMA Hardware Request** is not disabled by hardware on completion of a DMA transaction.

### Single Mode

The following DMA channel configuration is required to initiate one complete DMA Transaction under hardware control in Single Mode:

- DMA channel CHCFG.CHMODE =  $0_B$
- DMA channel CHCFG.RRQAT =  $1_B$
- DMA channel CHCFG.PRSEL =  $0_B$
- DMA channel TSR.ECH =  $1_B$

Setting DMA channel TSR.ECH to  $1_B$  enables a **DMA Hardware Request** (TSR.HTRE =  $1_B$ ) for the DMA channel. When the ICU generates a **DMA Hardware Request**, TSR.CH is set high. If the DMA channel wins channel arbitration then the DMA channel transitions to the active state. The value of CHCFG.RTREL is loaded into the ME CHSR.TCOUNT and the DMA transaction is started by executing the first DMA transfer. After each DMA transfer, ME

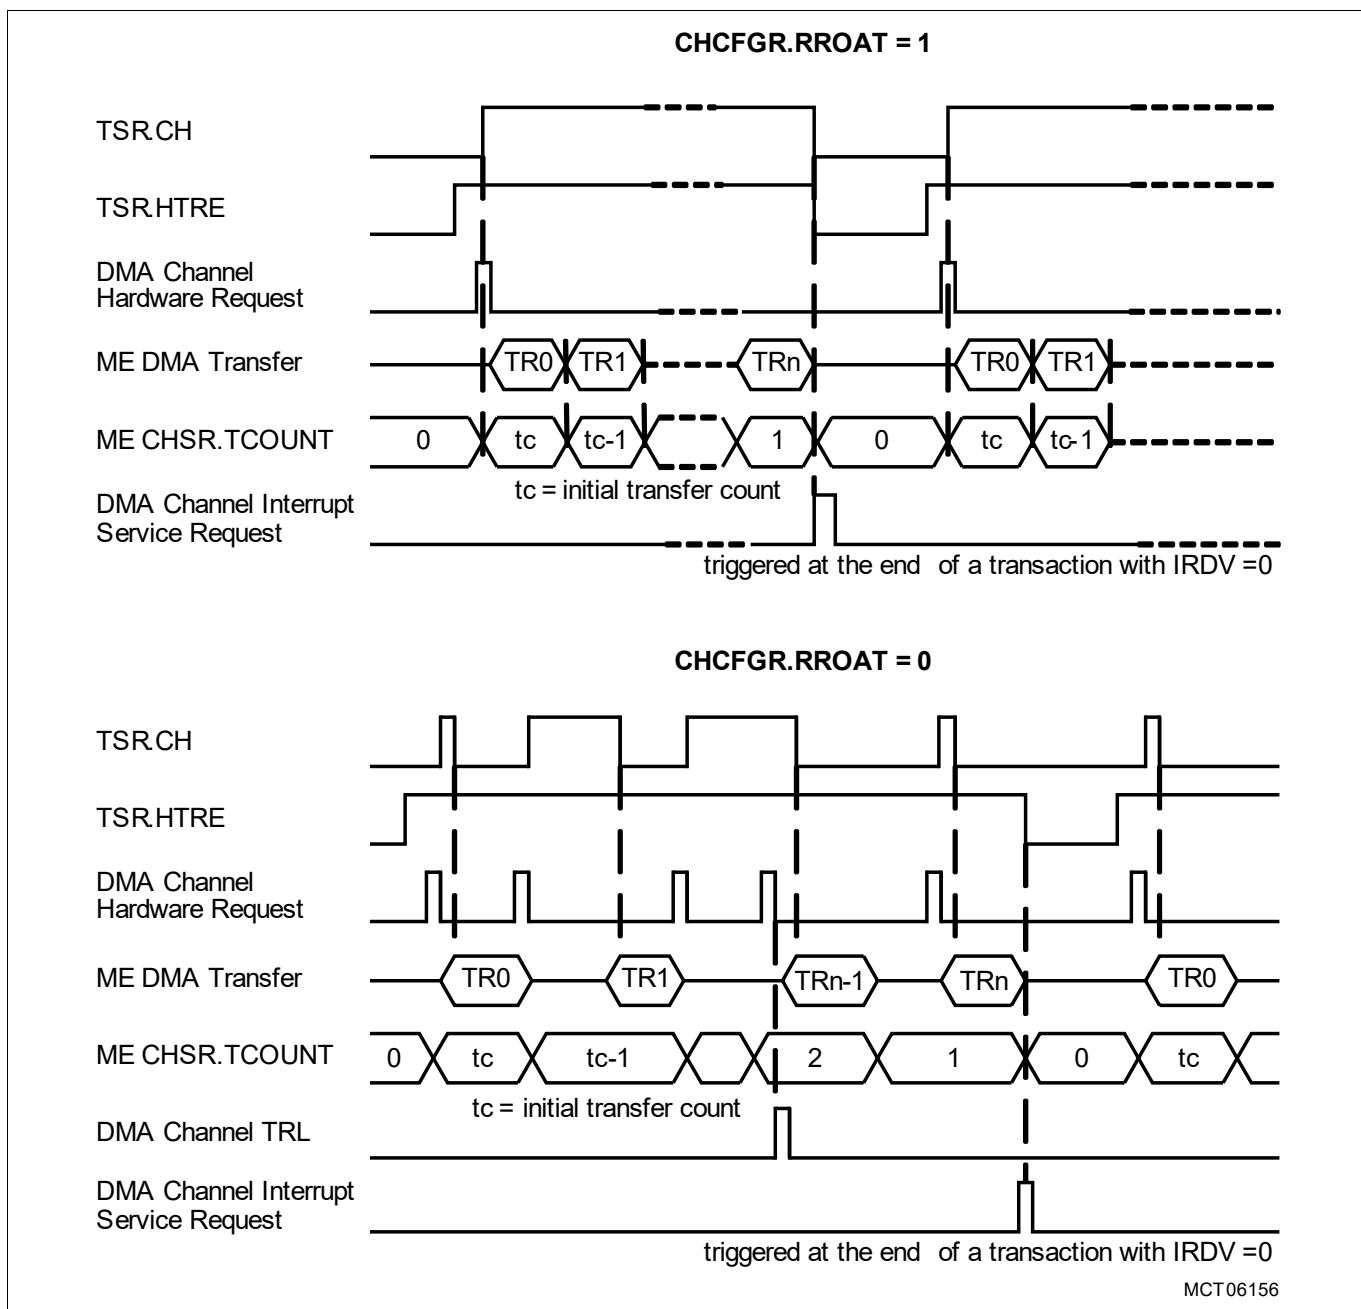

## **Direct Memory Access (DMA)**

CHSR.TCOUNT is decremented and the next source and destination addresses are calculated. When TCOUNT decrements to 0<sub>B</sub>, **DMA Hardware Request** is disabled and status flags TSR.CH and TSR.HTRE are reset. In order to start a new hardware-controlled DMA transaction, a **DMA Hardware Request** must be enabled again by software writing TSR.ECH = 1<sub>B</sub> to set TSR.HTRE. The hardware request disable function in Single Mode is typically needed to reprogram a DMARAM channel TCS before the next **DMA Hardware Request** initiates a DMA transaction.

The following DMA channel configuration is required to initiate each single **DMA Transfer** under hardware control in Single Mode:

- DMA channel CHCFG.RROAT = 0<sub>B</sub>

In this DMA channel configuration, TSR.CH is cleared at the start of each DMA transfer and a new **DMA Hardware Request** must be generated to start the next DMA transfer.

Downloaded by IFXDMZ\par-guowill 09/06/2020 03:48:39

**Figure 192 Hardware Control in Single Mode**

## Direct Memory Access (DMA)

### Continuous Mode

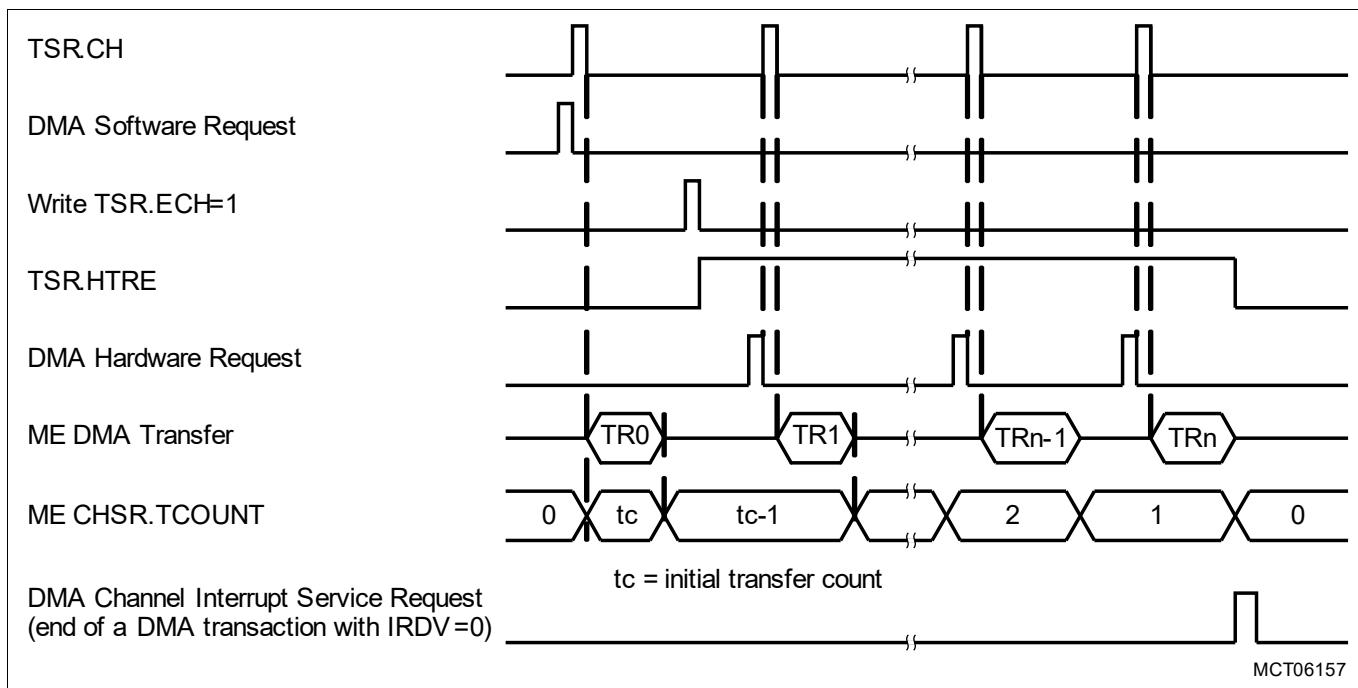

If the DMA channel is configured for Continuous Mode (CHCFGR.CHMODE = 1<sub>B</sub>), then TSR.HTRE is not reset at the end of a DMA transaction. On completion of the current DMA transaction (ME CHSR.TCOUNT = 0<sub>D</sub>) each new **DMA Hardware Request** will start a new DMA transaction with the stored DMA channel TCS.

### 18.3.3.4 Combined DMA Software Request and DMA Hardware Request

A DMA channel may be operated under combined software and hardware control. The example (at **Figure 193**) demonstrates combined control:

- The first DMA transfer is triggered by a **DMA Software Request** setting the DMA channel CHCSR.SCH = 1<sub>B</sub>.
- A **DMA Hardware Request** is still disabled i.e. DMA channel TSR.HTRE = 0<sub>B</sub>.
- Software enables a **DMA Hardware Request** by setting the DMA channel TSR.ECH = 1<sub>B</sub>.
- Each subsequent DMA transfer is triggered by a **DMA Hardware Request** from the ICU.

In the example, the DMA channel operates in Single Mode (DMA channel CHCFGR.CHMODE = 0<sub>B</sub>). In single mode, the DMA channel TSR.HTRE is reset by hardware when ME CHSR.TCOUNT = 0<sub>D</sub> at the end of the DMA transaction.

**Figure 193 Transaction Start by Software, Continuation by Hardware**

### Transaction Request Lost (TRL)

When a DMA channel is configured to be triggered by parallel hardware and software requests, if a **DMA Software Request** and a **DMA Hardware Request** collide in the same clock cycle then a **TRL** event shall be flagged.

### 18.3.3.5 DMA Daisy Chain Request

DMA channels shall be configured for DMA daisy chain request by setting DMA channel CHCFGR.PRSEL.

When a higher priority DMA channel completes a DMA transaction it will initiate a DMA transaction in the next lower priority DMA channel by setting the access pending bit TSR.CH bit. **DMA Daisy Chain Request** is limited to a higher priority DMA channel initiating a DMA request in the next lower priority DMA Channel.

Enabling the daisy chain disables the **DMA Channel Interrupt Service Request** trigger in the next higher priority DMA channel. In a typical DMA daisy chain application only the lowest priority DMA channel is required to

## Direct Memory Access (DMA)

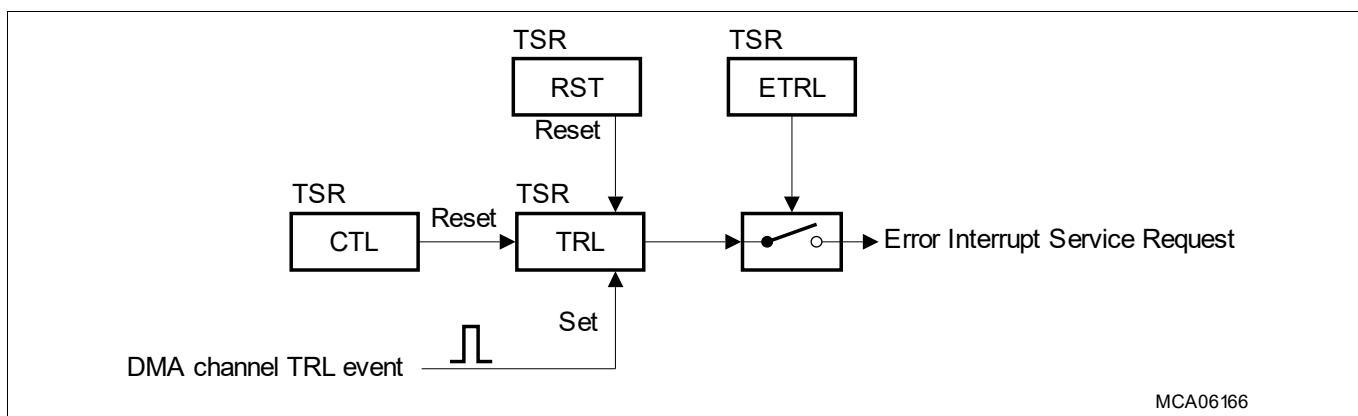

generate a **DMA Channel Interrupt Service Request**. When the sequence of DMA transactions from the highest to lowest priority DMA channel has completed then the lowest priority DMA channel in the daisy chain will generate a **DMA Channel Interrupt Service Request** to signal the end of the DMA operation.

If DMA channels are configured in a daisy chain, a DMA transfer or DMA transaction in the highest priority DMA channel is initiated by a **DMA Software Request** or a **DMA Hardware Request**. DMA transactions in the lower priority DMA channels are triggered by a **DMA Daisy Chain Request** in order to improve DMA latency.

### 18.3.3.6 DMA Channel Transaction Request Lost Interrupt Service Request

A DMA channel **TRL** event occurs for the following conditions:

- If a **DMA Request** is detected and the DMA channel TSR.CH is set, the DMA channel shall set the DMA channel TRL bit ( $TSR.TRL = 1_B$ ). If the DMA channel enable TRL bit is set ( $TSR.ETRL = 1_B$ ), the DMA shall trigger a **DMA RP Error Interrupt Service Request** (at **Figure 194**).
- If the DMA channel is disabled for hardware requests and a **DMA Hardware Request** is detected, the DMA shall set the DMA channel TRL bit ( $TSR.TRL = 1_B$ ) and trigger a **DMA RP Error Interrupt Service Request**.

**Figure 194 DMA Channel Transaction Request Lost Interrupt Service Request**

An **Error Handler** shall interrogate the DMA channels to identify the source of the error. Software may clear TSR.TRL by setting the DMA channel TSR.CTL or TSR.RST.

### 18.3.3.7 DMA Service Requests

Interrupt Requests are prioritized by the Interrupt Router and processed by one of the Service Providers (CPU or DMA). The DMA interfaces to an Interrupt Control Unit (ICU) instantiated in the Interrupt Router (IR).

DMA channels are associated with the Service Request Priority Number (SRPN) bit field programmed in the Service Request Control (SRC) Register SRC.SRPN. For example:

- DMA channel 000 equates to  $SRC.SRPN = 0_D$  programmed in IR.
- DMA channel 001 equates to  $SRC.SRPN = 1_D$  programmed in IR.
- DMA channel 002 equates to  $SRC.SRPN = 2_D$  programmed in IR.
- DMA channel 003 equates to  $SRC.SRPN = 3_D$  programmed in IR.
- DMA channel 004 equates to  $SRC.SRPN = 4_D$  programmed in IR.

The routing of a hardware service request to a service provider destination is determined by the IR Type Of Service (TOS) control bit field SRC.TOS. The DMA will acknowledge all service requests. If the value programmed in the SRC.SRPN is for an invalid DMA channel then the DMA will take no action. The user must programme valid SRC.SRPN values for the DMA.

## Direct Memory Access (DMA)

### 18.3.3.8 DMA Request Arbitration

The DMA arbiter continuously monitors all DMA channels for a pending **DMA Request** when the DMA channel is not in the halt state ( $\text{TSR.HLTREQ} = 1_B$ ) and/or the suspend state ( $\text{SUSASR.SUSAC} = 1_B$ ).

The highest number DMA channel with a pending **DMA Request** wins the DMA channel arbitration. The pending DMA request is forwarded to the highest number available ME. The ME reads the DMA channel TCS from the DMARAM and loads the TCS into the ME active channel register set and executes a DMA transfer. On completion of each DMA transfer the DMA performs an **Arbitration Sequence**.

#### Arbitration Sequence

- **Rule 1:** If there is a higher priority DMA channel with a pending **DMA Request** then
  - **Rule 1.1:** The ME shall write back the active DMA channel updated TCS to the DMARAM.
  - **Rule 1.2:** The ME reads the higher priority DMA channel TCS from the DMARAM to the ME.
  - **Rule 1.3:** The ME shall execute a DMA transfer.
  - **Rule 1.4:** On completion of the DMA transfer, the DMA performs an **Arbitration Sequence**.
- **Rule 2:** If there is not a higher priority DMA channel pending **DMA Request** and for the ME active DMA channel  $\text{CHCFG.RROAT} = 0_B$  then
  - **Rule 2.1:** The updated TCS shall be written back from the ME to the DMARAM.
  - **Rule 2.2:** During each clock cycle the DMA shall perform an **Arbitration Sequence**.
  - **Rule 2.3:** If a **DMA Request** is received then the ME shall execute a DMA transfer.
  - **Rule 2.4:** On completion of the DMA transfer, the DMA shall perform an **Arbitration Sequence**.
- **Rule 3:** If there is not a higher priority DMA channel pending **DMA Request** and for the ME active DMA channel  $\text{CHCFG.RROAT} = 1_B$  then
  - **Rule 3.1:** The ME shall execute a DMA transfer.
  - **Rule 3.2:** On completion of the DMA transfer, the DMA shall perform an **Arbitration Sequence**.
- **Rule 4:** On completion of the last DMA transfer, the DMA channel request bit is cleared ( $\text{TSR.CH} = 0_B$ ).
- **Rule 5:** The **Arbitration Sequence** continues until all DMA channel access pending requests are serviced by ME.

### 18.3.3.9 DMA Channel Reset

Software shall reset an individual DMA channel by setting the DMA channel reset bit ( $\text{TSR.RST} = 1_B$ ). When a **DMA Channel Reset** is applied to a DMA channel, the transition to the **Reset State** ( $\text{TSR.RST} = 0_B$ ) is as follows:

- **Idle State** and **Pending State**: the DMA channel shall transition to the **Reset State**.
- **Active State**: on completion of the current DMA transfer, the DMA channel transitions to the **Reset State**.

#### Reset State

On completion of a **DMA Channel Reset** the DMA channel enters the **Reset State** defined as:

- The following DMA channel bits are reset:
  - DMA Transaction State Register:  $\text{TSR.HLTREQ}$ ,  $\text{TSR.HLTACK}$ ,  $\text{TSR.HTRE}$ ,  $\text{TSR.CH}$  and  $\text{TSR.TRL}$ .
  - DMARAM TCS:  $\text{CHCFG.PRSEL}$ ,  $\text{CHCSR.ICH}$ ,  $\text{CHCSR.IPM}$ ,  $\text{CHCSR.WRAPD}$ ,  $\text{CHCSR.WRAPPS}$ ,  $\text{CHCSR.FROZEN}$ ,  $\text{CHCSR.BUFFER}$ ,  $\text{CHCSR.LXO}$  and  $\text{CHCHSR.TCOUNT}$ .
- If a circular buffer ADICR.SCBE and/or ADICR.DCBE is enabled for the DMA channel then the source and/or destination address register will be set to the wrap boundary else the address registers are cleared.
- DMA channel shadow address register (SHADR) shall be cleared.

## Direct Memory Access (DMA)

### Resetting a DMA Channel

A user program must execute the following steps to reset a DMA channel:

1. If a **DMA Hardware Request** is enabled then disable hardware requests (TSR.DCH =  $1_B$ ).
2. Software requests a DMA channel reset (TSR.RST =  $1_B$ ).
3. Software shall monitor the DMA channel reset and the DMA channel SADR, DADR and SHADR registers.
4. As soon as the DMA has cleared the DMA channel reset (TSR.RST =  $0_B$ ) and the DMA has reset the DMA channel SADR, DADR and SHADR registers, the **DMA Channel Reset** has completed.

During a **DMA Channel Reset** operation, a **DMA Software Request** must not be initiated by setting CHCSR.SCH =  $1_B$ .

### Restarting a DMA Channel

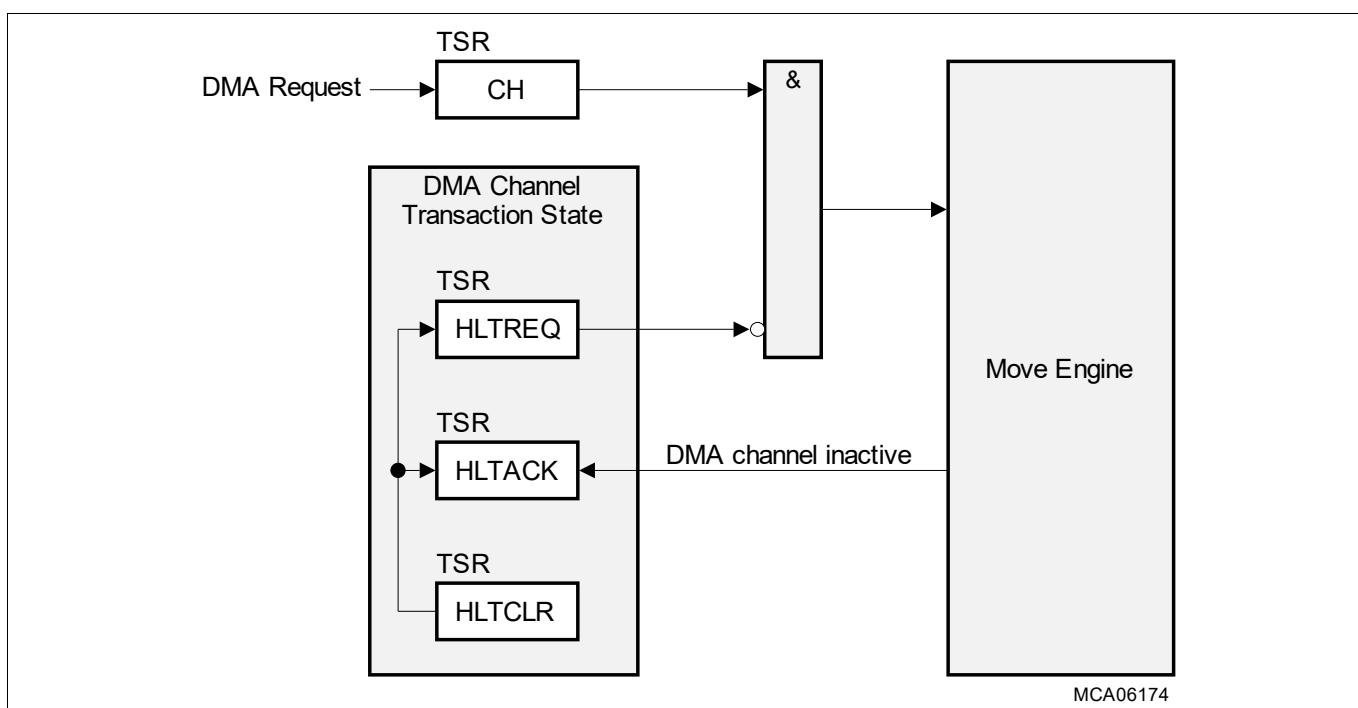

A user program must execute the following steps to restart a DMA channel after a **DMA Channel Reset**:

1. Configure the DMA channel TCS including:
  - a) DMA double buffering: program address pointers to the base address.
2. The DMA channel shall be restarted as follows:
  - a) **DMA Software Request**: software initiates a DMA request (DMA channel CHCSR.SCH =  $1_B$ ).
  - b) **DMA Hardware Request**: software enables a DMA request (DMA channel TSR.ECH =  $1_B$ ).

### 18.3.3.10 DMA Channel Halt

A DMA channel may be halted during a DMA transaction and the state frozen to allow a background RAM test to be run over a destination memory in order to detect stuck bits and distinguish between static errors and transient errors. On completion of the RAM test the DMA channel may be re-started and the DMA transaction completed.

The DMA channel halt logic (at **Figure 195**) utilizes a set/clear mechanism to request the DMA channel transitions to and from the HALT state on completion of the current DMA transfer. Only writing a logic ‘1’ to set or clear a halt request (at **Figure 196**) to a DMA channel has an effect. The status of other DMA channels shall be ignored.

**Figure 195 DMA Channel Halt Logic**

## Direct Memory Access (DMA)

### Halt State

A DMA channel is defined to be in the **Halt State** when DMA channel TSR.HLTACK = 1<sub>B</sub>.

### Entering DMA Channel Halt

A DMA channel shall be halted by software writing the DMA channel halt request bit (TSR.HLTREQ = 1<sub>B</sub>). The DMA channel enters the **Halt State** as follows:

- **Idle State, Reset State** and **Pending State**: as soon as the DMA channel receives the halt request, the DMA channel shall transition to the **Halt State**.
- **Active State**: on completion of the current DMA transfer, the DMA channel shall transition to the **Halt State**.

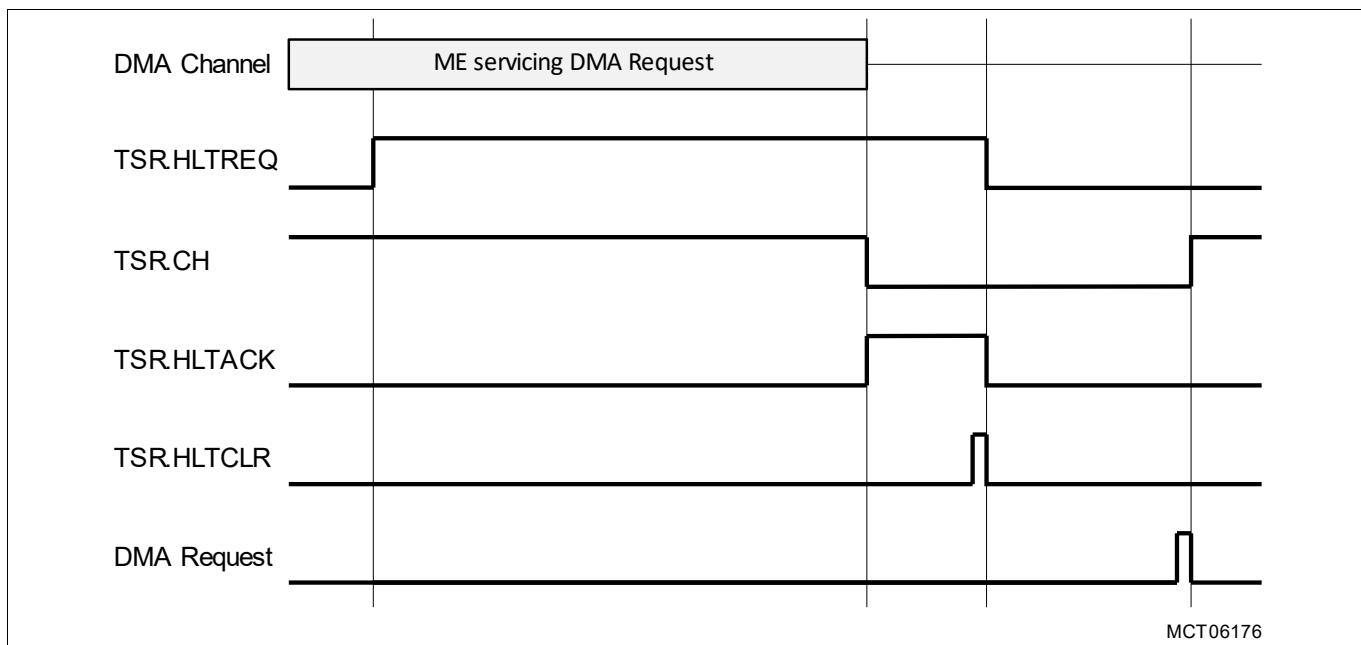

Figure 196 DMA Channel Halt Operation

### Exiting DMA Channel Halt

A DMA channel is released from the **Halt State** by software writing the DMA channel halt clear bit (TSR.HLTCLR = 1<sub>B</sub>). The DMA operation is resumed. If the halt request is cleared before it is acknowledged then there is no effect on DMA operation.

### DMA Channel Hardware Request during DMA Channel Halt

If a DMA channel is in the **Halt State** and Hardware Transaction Request is enabled (TSR.HTRE = 1<sub>B</sub>) then the DMA channel will respond to a **DMA Hardware Request** as follows:

- No DMA request pending (TSR.CH = 0<sub>B</sub>): the DMA channel shall set the access pending bit (TSR.CH = 1<sub>B</sub>). The **DMA Hardware Request** shall be serviced when DMA channel exits the **Halt State**.
- DMA request pending (TSR.CH = 1<sub>B</sub>): the DMA channel shall record a TRL event. If the DMA channel TRL enable bit is set (TSR.ETRL = 1<sub>B</sub>), then the DMA shall trigger a **DMA RP Error Interrupt Service Request**.

## Direct Memory Access (DMA)

## 18.3.4 DMA Random Access Memory

Software stores a DMA channel TCS (at [Figure 197](#)) in the DMARAM to define the move function of each DMA channel.

111 <sub>B</sub>	0 <sub>B</sub>	0000 <sub>B</sub>	<b>Move Operation<sup>2)</sup></b> <b>Pattern Detection for 32-bit Channel Data Width</b> <b>Complete Data Word compared to PRR1</b>	No	No	No	Yes	No	No
Others		<b>Reserved<sup>3)</sup></b>		N/A	N/A	N/A	N/A	N/A	N/A

- 1) DMA timestamp shall only be appended on completion of a DMA transaction.
- 2) DMA channel operation “Pattern Detection” shall function for all types of DMA channel Shadow Operation.
- 3) If a DMA channel is configured for a reserved value of DMA channel ADICR.SHCT and a DMA request is received, the DMA clears DMA channel TSR.CH and performs no DMA moves.

## 18.3.4.2 DMA Channel Updates

Software shall only configure the DMARAM channel TCS when the DMA channel is in the **Idle State** (DMA channel CHCSR.TCOUNT=0<sub>D</sub>) or **Reset State**. If the DMA channel is in the **Idle State** (DMA channel CHCSR.TCOUNT!=0<sub>D</sub>), **Pending State** or **Active State**, software shall not update the DMARAM channel TCS. The following DMA channel update exceptions apply for **Shadow Operations** and **Double Buffering Operations**:

## 18.3.4.2.1 Shadow Operations

If the DMARAM channel TCS is configured for **Shadow Operation** and the DMA channel is in the **Idle State** (DMA channel CHCSR.TCOUNT!=0<sub>D</sub>), **Pending State** or **Active State**, software shall be restricted to updating the DMARAM channel TCS words marked ‘X’:

Table 573 DMARAM channel TCS updates during Shadow Operation

SHCT	Description	CHCSR	SHADR	CHCFGR	ADICR	DADR	SADR	SDCRCR	RDCRCR
0001 <sub>B</sub>	<b>Shadow Operation Read Only Mode</b> <b>Source Address</b>						X		
0010 <sub>B</sub>	<b>Shadow Operation Read Only Mode</b> <b>Destination Address</b>					X			

## Direct Memory Access (DMA)

**Table 573 DMARAM channel TCS updates during Shadow Operation (cont'd)**

SHCT	Description	CHCSR	SHADR	CHCFG	ADICR	DADR	SADR	SDCRCR	RDCRCR
0101 <sub>B</sub>	<b>Shadow Operation Direct Write Mode</b> Source Address		X						
0110 <sub>B</sub>	<b>Shadow Operation Direct Write Mode</b> Destination Address		X						

### 18.3.4.2.2 Double Buffering Operations

If the DMARAM channel TCS is configured for **Double Buffering Operations** and the DMA channel is in the **Idle State** (DMA channel CHCSR.TCOUNT!=0<sub>D</sub>), **Pending State** or **Active State**, software shall be restricted to updating the DMARAM channel TCS words marked 'X':

**Table 574 DMARAM channel updates during Double Buffering Operations**

SHCT	Description	CHCSR	SHADR	CHCFG	ADICR	DADR	SADR	SDCRCR	RDCRCR
1000 <sub>B</sub>	<b>DMA Double Source Buffering</b> <b>Software Switch Only</b> DMA channel CHCSR.BUFFER = 0 <sub>B</sub>	X	X						
1000 <sub>B</sub>	<b>DMA Double Source Buffering</b> <b>Software Switch Only</b> DMA channel CHCSR.BUFFER = 1 <sub>B</sub>	X					X		
1001 <sub>B</sub>	<b>DMA Double Source Buffering</b> <b>Software Switch and Automatic Hardware Switch</b> DMA channel CHCSR.BUFFER = 0 <sub>B</sub>	X	X						
1001 <sub>B</sub>	<b>DMA Double Source Buffering</b> <b>Software Switch and Automatic Hardware Switch</b> DMA channel CHCSR.BUFFER = 1 <sub>B</sub>	X					X		
1010 <sub>B</sub>	<b>DMA Double Destination Buffering</b> <b>Software Switch Only</b> DMA channel CHCSR.BUFFER = 0 <sub>B</sub>	X	X						
1010 <sub>B</sub>	<b>DMA Double Destination Buffering</b> <b>Software Switch Only</b> DMA channel CHCSR.BUFFER = 1 <sub>B</sub>	X				X			
1011 <sub>B</sub>	<b>DMA Double Destination Buffering</b> <b>Software Switch and Automatic Hardware Switch</b> DMA channel CHCSR.BUFFER = 0 <sub>B</sub>	X	X						
1011 <sub>B</sub>	<b>DMA Double Destination Buffering</b> <b>Software Switch and Automatic Hardware Switch</b> DMA channel CHCSR.BUFFER = 1 <sub>B</sub>	X				X			

### 18.3.4.3 DMA Channel Reconfiguration

If a DMA channel is to be configured, software shall apply a **DMA Channel Reset** to initialize the DMA channel.

## Direct Memory Access (DMA)

After the DMA channel has entered **Reset State**, software shall configure the DMA channel for a DMA operation.

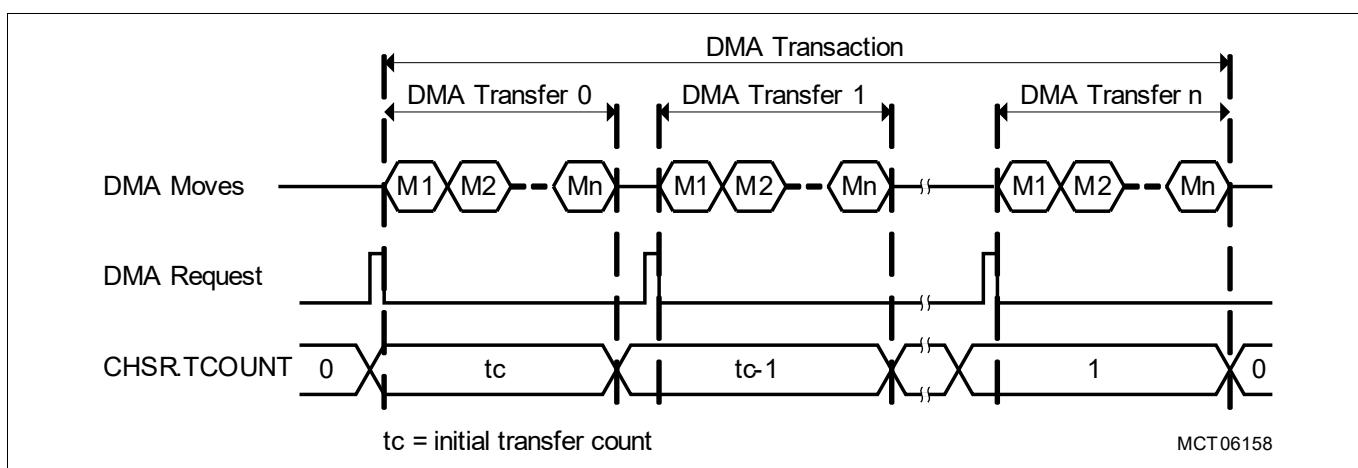

### 18.3.4.4 Move Operation

The number of DMA moves (at **Figure 198**) may be calculated from the following:

- Block Mode (CHCFGR.BLKM) defines the number of DMA moves in a DMA transfer.
- Transfer Reload (CHCFGR.TREL) defines the number of DMA transfers in a DMA transaction.

After a DMA move, the next source and destination addresses are calculated. Source and destination addresses are calculated independently of each other. The following address calculation parameters may be selected:

- The address offset, which is a multiple of the selected data width.
- The offset direction: addition, subtraction, or none (unchanged address).

**Figure 198 Block Mode and Transfer Count**

#### 18.3.4.4.1 Address Generation

Address control bits (in DMA channel ADICR) determine how the addresses increment or decrement. The data width is defined in CHCFGR.CHDW and is taken into account during the address calculation. The Address Offset Calculation Tables (at **Table 575** and **Table 576**) show the offset values that are added or subtracted to/from the source address (SMF and INCS parameters) and destination address (DMF and INCD parameters) after each DMA move.

**Table 575 Address Offset Calculation Table (8-bit, 16-bit and 32-bit)**

CHCFGR.CHDW = 000 <sub>B</sub> (8-bit Data Width)			CHCFGR.CHDW = 001 <sub>B</sub> (16-bit Data Width)			CHCFGR.CHDW = 010 <sub>B</sub> (32-bit Data Width)		
SMF DMF	INCS INCD	Address Offset	SMF DMF	INCS INCD	Address Offset	SMF DMF	INCS INCD	Address Offset

## 18.3.4.4.2 Address Calculation Examples

The following example demonstrate address generation for a data width of 16-bit (CHCFGR.CHDW = 001<sub>B</sub>):

## Direct Memory Access (DMA)

### Programmable Address Generation - Example 1

16-bit half-words are moved from a source memory with an incrementing source address offset of  $10_{\text{H}}$  to a destination memory with a decrementing destination address offset of  $08_{\text{H}}$ .

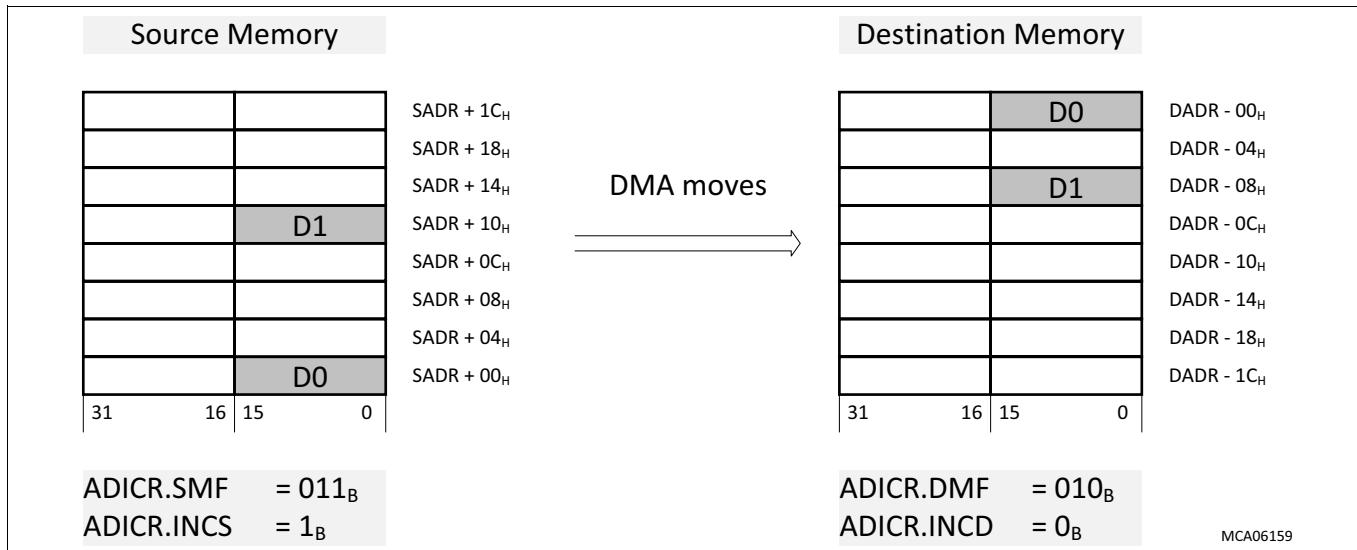

Figure 199 Programmable Address Generation - Example 1

### Programmable Address Generation - Example 2

16-bit half-words are moved from a source memory with an incrementing source address offset of  $02_{\text{H}}$  to a destination memory with an incrementing destination address offset of  $04_{\text{H}}$ .

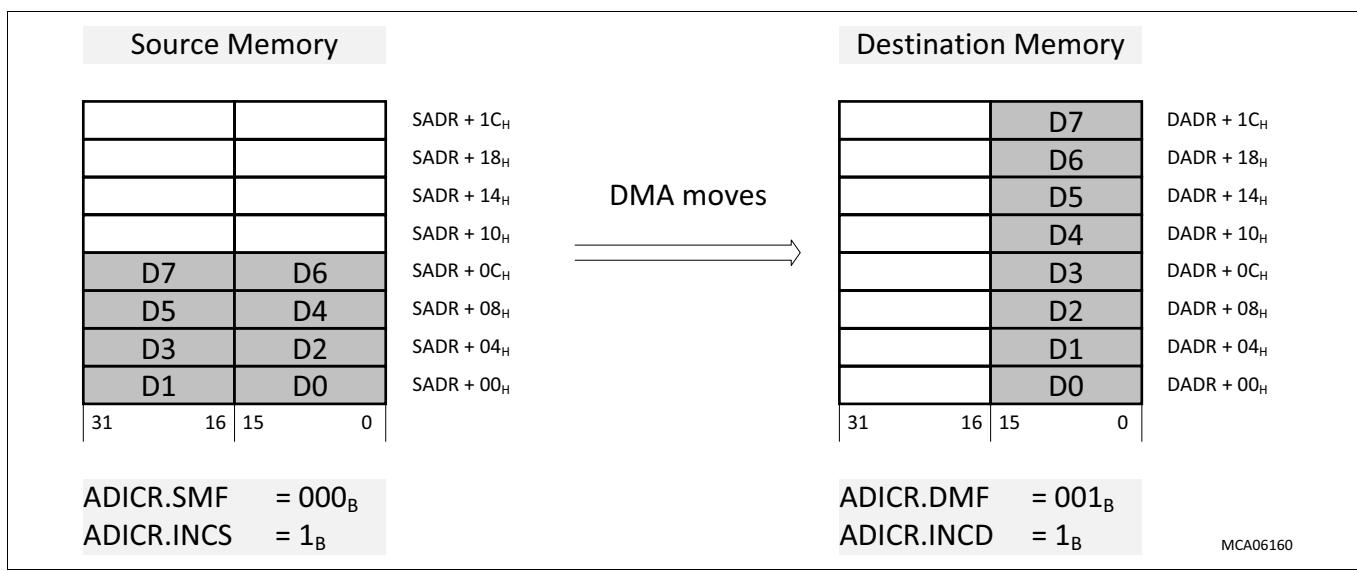

Figure 200 Programmable Address Generation - Example 2

### 18.3.4.4.3 Circular Buffer

The source and destination circular buffers are enabled by setting the DMA channel circular buffer enable bits ADICR.SCBE and ADICR.DCBE respectively. The source address and destination address may be configured to build a circular buffer separately for source and destination data. Within a circular buffer, the addresses are updated within the circular buffer wrap-around limits. The circular buffer length is determined by bit fields ADICR.CBLS (for the source buffer) and ADICR.CBLD (for the destination buffer). These 4-bit wide bit fields determine which bits of the 32-bit address remain unchanged during an address update. Possible buffer sizes of

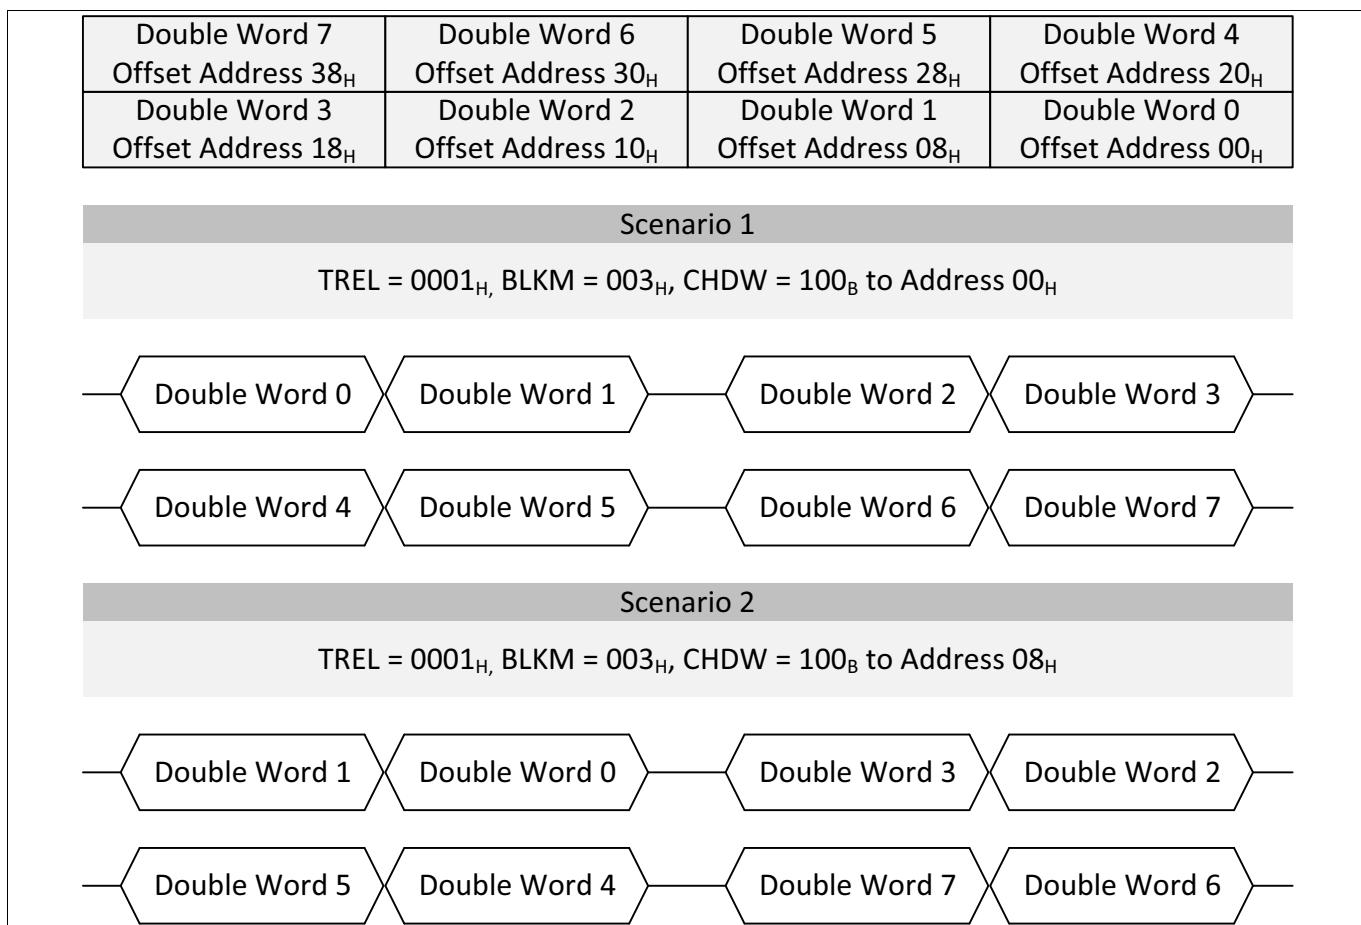

## Direct Memory Access (DMA)

the circular buffers can be  $2^{\text{CBLS}}$  or  $2^{\text{CBLD}}$  bytes (=1, 2, 4, 8, 16, ... up to 64k bytes). Source and destination addresses are incremented or decremented during a DMA move, all upper bits [31:CBLS] of source address and [31:CBLD] of destination address are frozen and remain unchanged, even if a wrap-around from the lower address bits [CBLS-1:0] or [CBLD-1:0] occurred. This address-freezing mechanism always causes the circular buffers to be aligned to a multiple integer value of its size. If the circular buffer size is less than or equal to the selected address offset then the same circular buffer address will always be accessed.

### 18.3.4.4.4 Address Alignment

The DMA shall comply with the SRI bus protocol. All source addresses and destination addresses shall be aligned to the correct address boundary defined by the channel data width (CHCFGR.CHDW) as follows:

- Single transfers: the source address and destination address boundaries shall align with the channel data width (byte, half-word, word or double-word).
- Block transfers: the source address and destination address boundaries shall align to a double-word boundary. The SRI bus protocol defines a wrap around addressing scheme for block transfers not starting with a block transfer sized start address. The effect on a DMA transaction is demonstrated by different scenarios for BTR2 (at [Figure 201](#)) and BTR4 (at [Figure 202](#)).

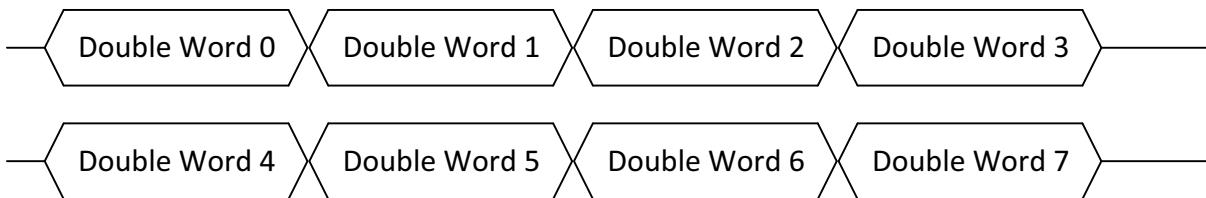

**Figure 201 SRI Bus Protocol Block Transfer Request - 2 Transfers**

## Direct Memory Access (DMA)

Double Word 7 Offset Address 38 <sub>H</sub>	Double Word 6 Offset Address 30 <sub>H</sub>	Double Word 5 Offset Address 28 <sub>H</sub>	Double Word 4 Offset Address 20 <sub>H</sub>
Double Word 3 Offset Address 18 <sub>H</sub>	Double Word 2 Offset Address 10 <sub>H</sub>	Double Word 1 Offset Address 08 <sub>H</sub>	Double Word 0 Offset Address 00 <sub>H</sub>

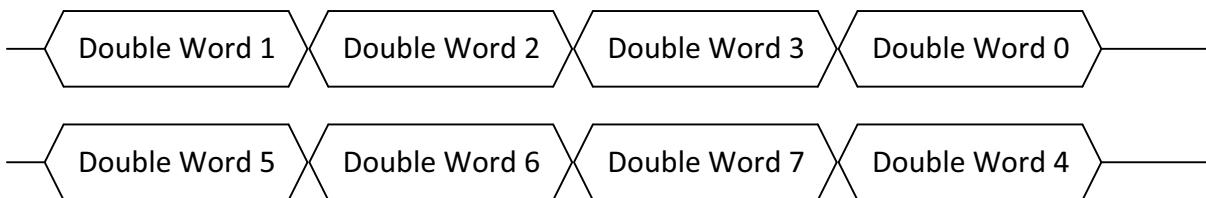

### Scenario 1

TREL = 0001<sub>H</sub>, BLKM = 001<sub>H</sub>, CHDW = 101<sub>B</sub> to Address 00<sub>H</sub>

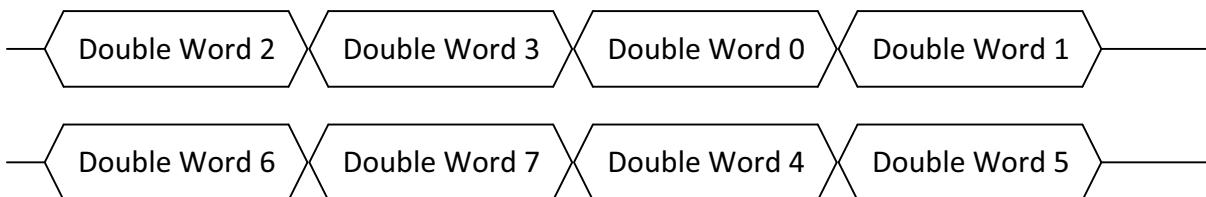

### Scenario 2

TREL = 0001<sub>H</sub>, BLKM = 001<sub>H</sub>, CHDW = 101<sub>B</sub> to Address 08<sub>H</sub>

### Scenario 3

TREL = 0001<sub>H</sub>, BLKM = 001<sub>H</sub>, CHDW = 101<sub>B</sub> to Address 10<sub>H</sub>

### Scenario 4

TREL = 0001<sub>H</sub>, BLKM = 001<sub>H</sub>, CHDW = 101<sub>B</sub> to Address 18<sub>H</sub>

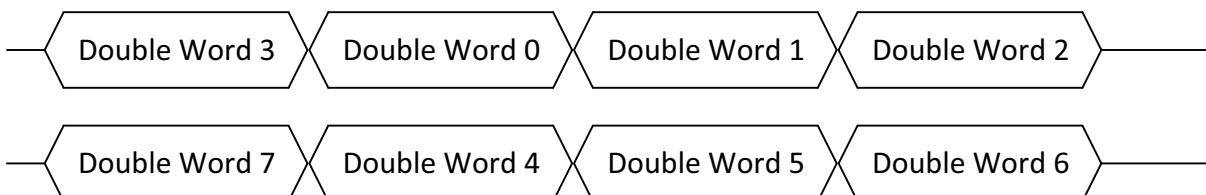

Figure 202 SRI Bus Protocol Block Transfer Request - 4 Transfers

## Direct Memory Access (DMA)

### 18.3.4.4.5 Address Counter

If the source/destination circular buffer is not enabled (ADICR.SCBE/DCBE = 0<sub>B</sub>) then the source/destination address will increment or decrement across the entire 32-bit address field. The address offset is determined by the DMA channel CHCFGR.CHDW. The address will wrap around on the 32-bit address boundary:

- If the address is incrementing then will wrap from FFFFFFFF<sub>H</sub> to 00000000<sub>H</sub>.
- If the address is decrementing then will wrap from 00000000<sub>H</sub> to FFFFFFFF<sub>H</sub>.

### 18.3.4.4.6 DMA Address Checksum

The DMA shall calculate a **SDCRC** checksum in accordance with the IEEE 802.3 standard using the source and destination addresses presented to the on chip bus as input data. Software shall compare the calculated **DMA Address Checksum (SDCRC)** with an expected **DMA Address Checksum** stored in memory to validate the address generation during a DMA transaction. To check the DMA channel address generation use the following steps:

- Software shall initialize the DMA channel **DMA Address Checksum** stored in DAMRAM to a known initial value.
- The DMA channel receives a DMA request.
- If the DMA channel is in the **Active State** and no error or retry event is reported, the ME shall calculate an updated **DMA Address Checksum** for each DMA read move and DMA write move.
- On completion of the DMA transaction, the DMA shall store the final **DMA Address Checksum** in DMARAM.
- Software shall compare the calculated **DMA Address Checksum** and expected **DMA Address Checksum**.
  - If the calculated and expected **DMA Address Checksum match**, then the DMA has correctly calculated the source and destination address. If the checksums do not match, then software shall report a fault.

The **DMA Address Checksum** is not available for the following configurations of **DMA Channel Operation**:

- **DMA Double Source Buffering Software Switch Only**
- **DMA Double Source Buffering Software Switch** and **Automatic Hardware Switch**
- **DMA Double Destination Buffering Software Switch Only**
- **DMA Double Destination Buffering Software Switch** and **Automatic Hardware Switch**
- **Conditional Linked List (CONLL)**

### 18.3.4.4.7 DMA Channel Interrupt Service Request

Each DMA channel generates an interrupt service request (at [Figure 203](#)) to report DMA channel events:

- **DMA Channel Transfer Interrupt Service Request**
- **DMA Channel Pattern Match Interrupt Service Request**
- **DMA Channel Wrap Buffer Interrupt Service Request**

### 18.3.4.4.8 DMA Channel Transfer Interrupt Service Request

If a DMA channel is in the **Active State** then a DMA channel transfer interrupt service request may be activated on completion of a DMA transfer, or when ME CHSR.TCOUNT matches with the value of bit field ADICR.IRDV after it has been decremented after a DMA transfer. An interrupt service request from a DMA channel is indicated when status flag CSR.ICH is set. The status flag shall be reset by software setting DMA channel CHCSR.CICH = 1<sub>B</sub> (or TSR.RST = 1<sub>B</sub>). The DMA channel interrupt service request is enabled when DMA channel ADICR.INTCT[1] is set.

Bit ADICR.INTCT[0] selects one of two types of interrupt source. For the compare operation, bit field ADICR.IRDV (4-bit) is zero-extended to 14-bit and then compared with the 14-bit TCOUNT value. This means that a TCOUNT match interrupt may be generated after one of the last 16 DMA transfers of a DMA transaction. Note that with IRDV = 0000<sub>B</sub>, the match interrupt is generated at the end of a DMA transaction (after the last DMA transfer).

### Direct Memory Access (DMA)

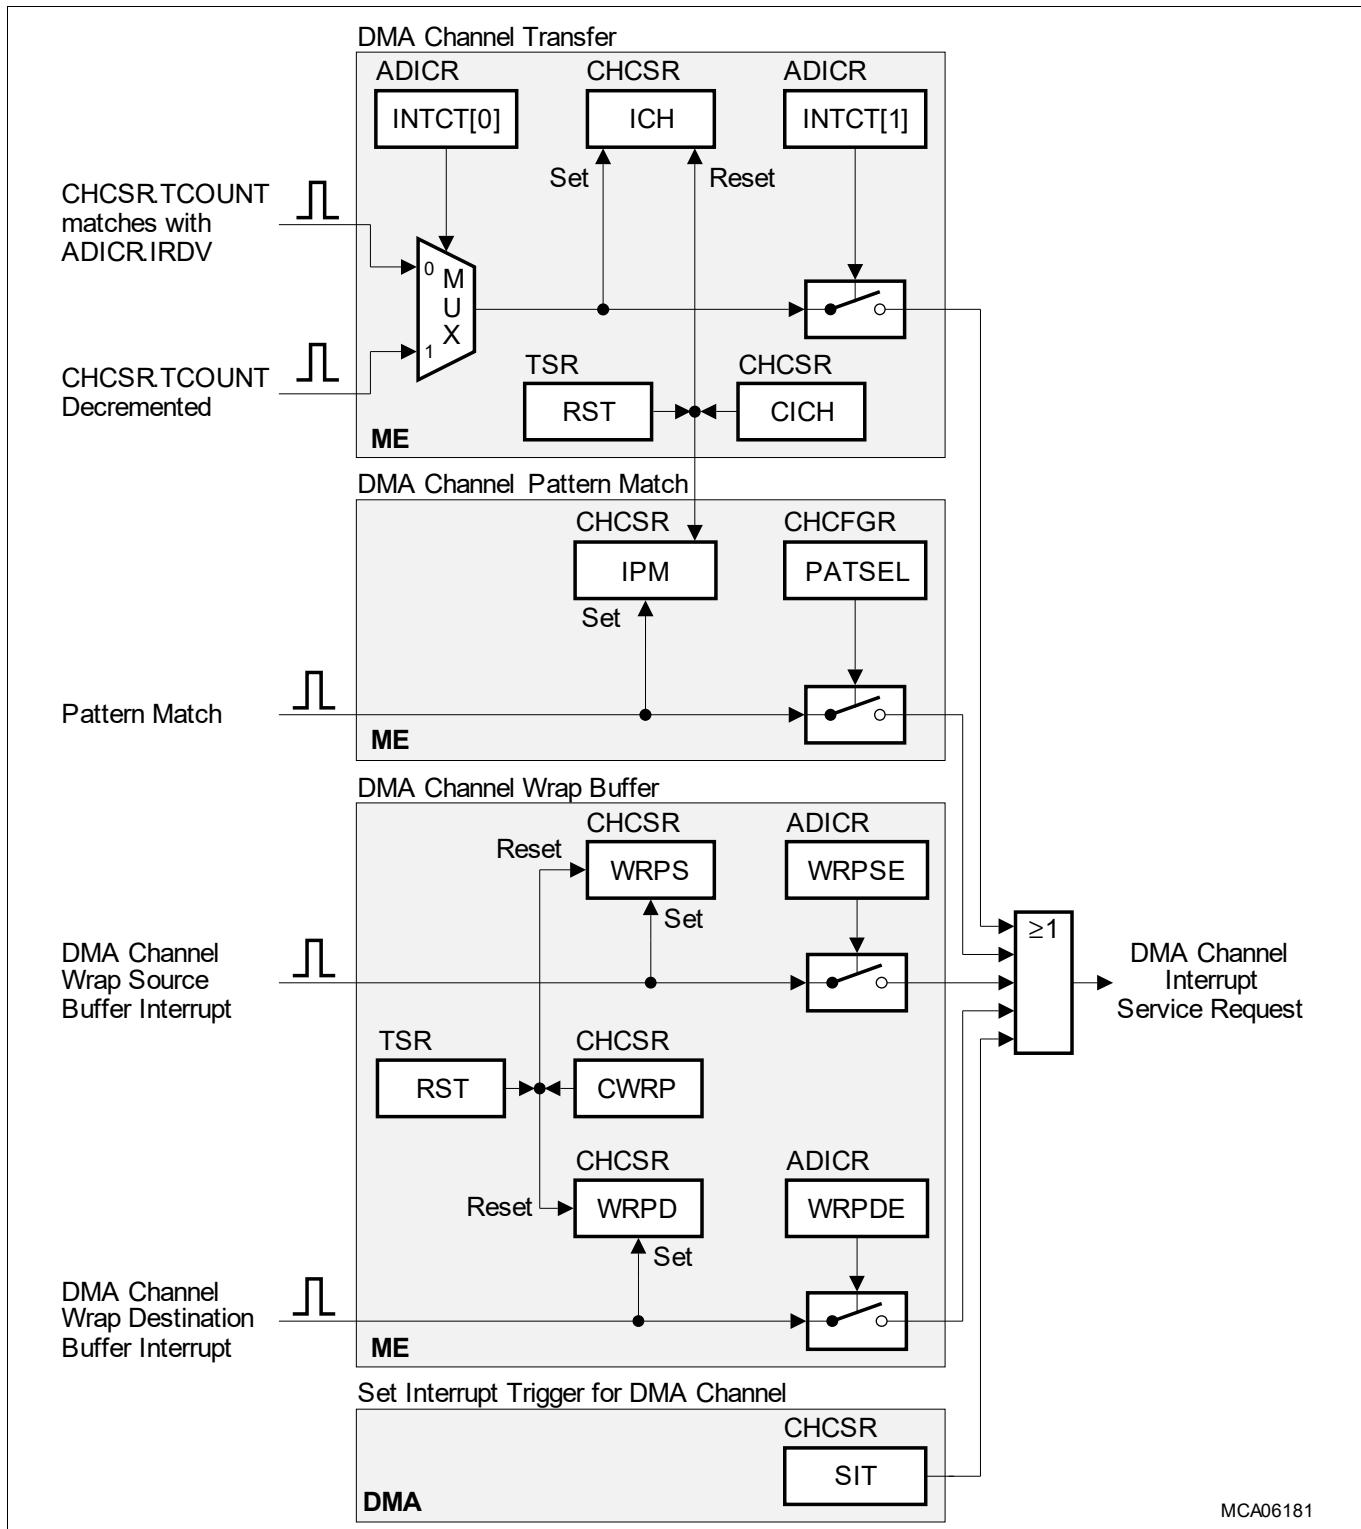

Figure 203 DMA Channel Interrupt Service Request

#### 18.3.4.4.9 DMA Channel Pattern Match Interrupt Service Request

The DMA channel pattern detection interrupt service request is enabled when CHCFGR.PATSEL[1:0] is not equal to  $00_B$ . The pattern detection interrupt is indicated when status flag CHCSR.IPM is set. The status flag CHCSR.IPM shall be reset by software setting bit DMA channel CHCSR.CICH =  $1_B$  (or TSR.RST =  $1_B$ ).

## Direct Memory Access (DMA)

### 18.3.4.4.10 DMA Channel Wrap Buffer Interrupt Service Request

Each DMA channel reports a source buffer wraparound and/or a destination buffer wraparound as follows:

- A wrap source buffer wraparound is indicated by status flag CHCSR.WRPS.
- A wrap destination buffer wraparound is indicated by the status flag CHCSR.WRPD.

Software may reset both buffer wraparound status flags by setting CHCSR.CWRP = 1<sub>B</sub> (or TSR.RST = 1<sub>B</sub>).

A DMA channel wrap buffer interrupt service request is enabled as follows:

- A DMA channel wrap source buffer interrupt service request is enabled when bit ADICR.WRPSE is set.
- A DMA channel wrap destination buffer interrupt service request is enabled when bit ADICR.WRPDE is set.

The DMA channel wrap source buffer wraparound interrupt service request and the DMA channel wrap destination buffer wraparound interrupt service request are OR-ed together with other DMA channel interrupt service requests to form one DMA channel interrupt service request.

### 18.3.4.5 Shadow Operation

If a DMA channel is configured for shadow operation, the DMA buffers a variable source or destination address.

#### 18.3.4.5.1 Application of Shadow Operation

In a typical application, an ASC module that receives data (fixed DMA channel source address) has to deliver the data to a memory buffer using a DMA transaction (variable DMA channel destination address). After a certain amount of data has been transferred, a new DMA transaction should be initiated to deliver further ASC data into another memory buffer. While the destination address register is updated during a running DMA transaction with the actual destination address, a shadow mechanism allows programming of a new destination address without disturbing the content of the destination address register. In this case, the new destination address is written and buffered in the shadow address register. At the start of the next DMA transaction, the destination address register shall use the new address without CPU intervention. The shadow operation avoids the CPU having to check for the end of a DMA transaction before reprogramming address registers.

#### 18.3.4.5.2 Shadowed Address Register

The shadow address register stores either a new source address, or a new destination address. If both the source address and destination address have to be updated for the next DMA transaction, a running DMA transaction for this DMA channel must be finished. After that, source and destination address registers may be written before the next DMA transaction is started.

Only one address register may be shadowed while a DMA transaction is running, because the shadow register can only be assigned either to the source address or to the destination address. Note that the shadow address transfer mechanism has the same behavior in **Single Mode** and **Continuous Mode**.

The function of the shadow address register shall be defined by the mode of the shadow operation:

- **Read Only Mode:** if software writes to the shadow address register, the DMA shall return a bus error.
- **Direct Write Mode:** if software writes to the shadow address register, the DMA shall store a new shadow address in the shadow address register.

#### 18.3.4.5.3 Read Only Mode

If software writes a new DMA channel source or destination address value, the DMA shall store the new address value as follows:

- **Idle State** (DMA channel CHCSR.TCOUNT=0)

## Direct Memory Access (DMA)

- If software writes a new DMA channel source address value, the DMA shall store the new source address value in the DMA channel SADR.
- If software writes a new DMA channel destination address value, the DMA shall store the new destination address value in the DMA channel DADR.
- **Idle State** (DMA channel CHCSR.TCOUNT!=0) or **Pending State**
  - If software writes a new DMA channel source or destination address value, the DMA shall store the new address value in the DMA channel SHADR.
- **Active State**
  - If software writes a new DMA channel source or destination address value, the DMA shall store the new address value in the ME SHADR.

### End of DMA Transaction

As soon as the DMA completes a DMA transaction, the DMA shall check the value of ME SHADR.

If ME SHADR is not equal to 0000 0000<sub>H</sub>, the ME shall write back data to the DMARAM as follows:

- Shadow Operation Read Only Mode Source Address
  - The DMA shall store the ME SHADR value into DMA channel SADR.
  - The DMA shall store 0000 0000<sub>H</sub> into DMA channel SHADR.
- Shadow Operation Read Only Mode Destination Address
  - The DMA shall store the ME SHADR value into DMA channel DADR.
  - The DMA shall store 0000 0000<sub>H</sub> into DMA channel SHADR.

If software has not executed a shadow address update, ME SHADR is equal to 0000 0000<sub>H</sub>. The ME shall write back data to the DMARAM as follows:

- Shadow Operation Read Only Mode Source Address
  - The DMA shall store 0000 0000<sub>H</sub> into DMA channel SADR (see **Error Conditions**).
- Shadow Operation Read Only Mode Destination Address
  - The DMA shall store 0000 0000<sub>H</sub> into DMA channel DADR (see **Error Conditions**).

### 18.3.4.5.4 Direct Write Mode

If software writes a new DMA channel shadow address value, the DMA shall store the new shadow address value as follows:

- **Idle State** or **Pending State**
  - If software writes a new DMA channel shadow address value, the DMA shall store the new shadow address value in the DMA channel SHADR.
- **Active State**
  - If software writes a new DMA channel shadow address value, the DMA shall store the new shadow address value in the ME SHADR. As soon as the ME shall write back data to the DMA RAM, the DMA shall store the ME SHADR value in the DMA channel SHADR word.

### Start of DMA Transaction

As soon as the DMA services a DMA request, the DMA shall perform a shadow address transfer as follows:

- Shadow Operation Direct Write Mode Source Address
  - If DMA channel SHADR is not 0000 0000<sub>H</sub>, the DMA shall store the DMA channel SHADR value into ME SADR.
- Shadow Operation Direct Write Mode Destination Address

## Direct Memory Access (DMA)

- If DMA channel SHADR is not  $0000\ 0000_H$ , the DMA shall store the DMA channel SHADR value into ME DADR.

### End of Shadow Operation

If software writes a new DMA channel shadow address value of  $0000\ 0000_H$  or applies a **DMA Channel Reset**, the DMA shall not perform a shadow address update at the start of the next DMA transaction.

#### 18.3.4.5.5 Error Conditions

If a DMA channel is configured for **Shadow Operation** and a new DMA request is serviced before software updates the shadow address, the DMA shall perform a DMA move to address  $0000\ 0000_H$  resulting in a bus error.

#### 18.3.4.5.6 Transfer Count Update

The transfer count of a DMA transaction, stored in the DMA channel bit field CHCFGR.TREL, may be programmed if a DMA transaction is running. At the start of a DMA transaction, CHCFGR.TREL is transferred to the ME CHSR.TCOUNT. No reload of address or counter will be done if ME CHSR.TCOUNT is not equal to 0.

The reprogramming of channel specific values (except for the selected shadow address register) must be avoided while a DMA channel is active as the data transfer maybe corrupted.

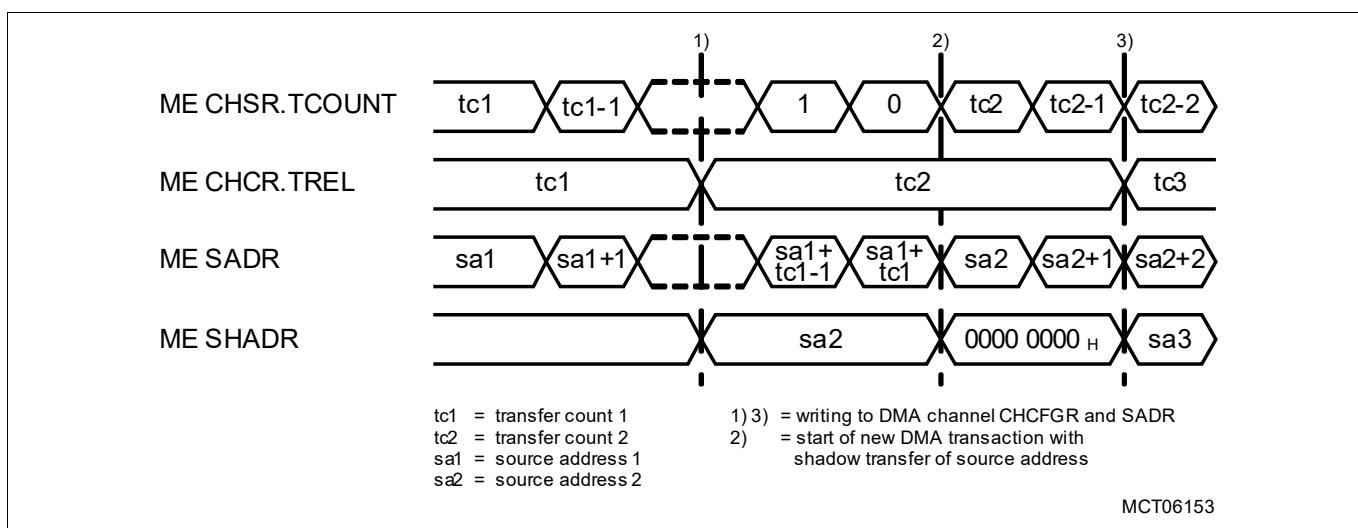

#### Transfer Count and Source Address Update - Example

The contents of the ME transfer count and the ME source address register are updated (at **Figure 204**) during two DMA transactions with a transfer count and a shadowed source address update.

At reference point 2) the DMA transaction 1 is finished and DMA transaction 2 is started. At 1) the DMA channel is reprogrammed with two new parameters for the next DMA transaction: Transfer count tc2 and source address sa2. Source address sa2 is buffered in ME SHADR and transferred to ME SADR when the new DMA transaction is started at 2). At this time, transfer count tc2 is also transferred to ME CHSR.TCOUNT. Note that the shadow address register is only reset by hardware to  $0000\ 0000_H$  as shown in this example, if Read Only Mode is selected.

In the event that DMA channel CHCFGR.TREL is written while DMA channel is active:

- A write to DMA channel CHCFGR.TREL will update the ME CHCR.TREL value.
- On write back DMA channel CHCFGR.TREL is updated with the latest ME CHCR.TREL value.
- ME CHSR.TCOUNT is updated to the new DMA channel CHCFGR.TREL value at the start of the next DMA transaction.

**Figure 204 Shadow Operation Read Only Mode Source Address: Transfer Count and Source Address Update**

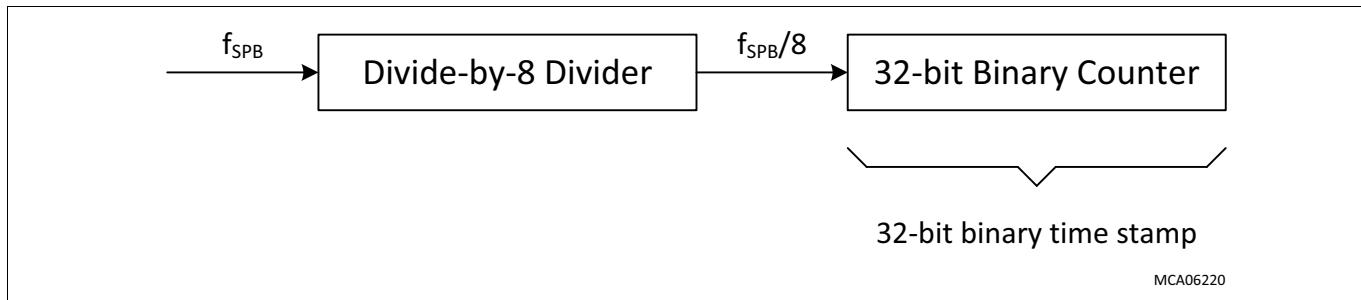

## Direct Memory Access (DMA)

### 18.3.4.6 DMA Timestamp

As soon as the last DMA transfer has completed, a 32-bit DMA timestamp may be appended to record the occurrence of a DMA operation. The DMA timestamp is the time at which the event was recorded by the DMA and not the real time. The DMA transaction completes after the DMA timestamp is written.

#### 18.3.4.6.1 Generation of DMA Timestamp

The DMA timestamp is generated from a 32-bit binary upwards synchronous counter clocked by the SPB clock divided by 8 as shown in [Figure 205](#). The counting starts automatically after the application reset is released. It is not possible to affect the counter during normal DMA operation. The current 32-bit timestamp value may be read through the TIME register.

**Figure 205 Generation of DMA Timestamp**

#### 18.3.4.6.2 Appendage of DMA Timestamp to Non Destination Circular Buffer

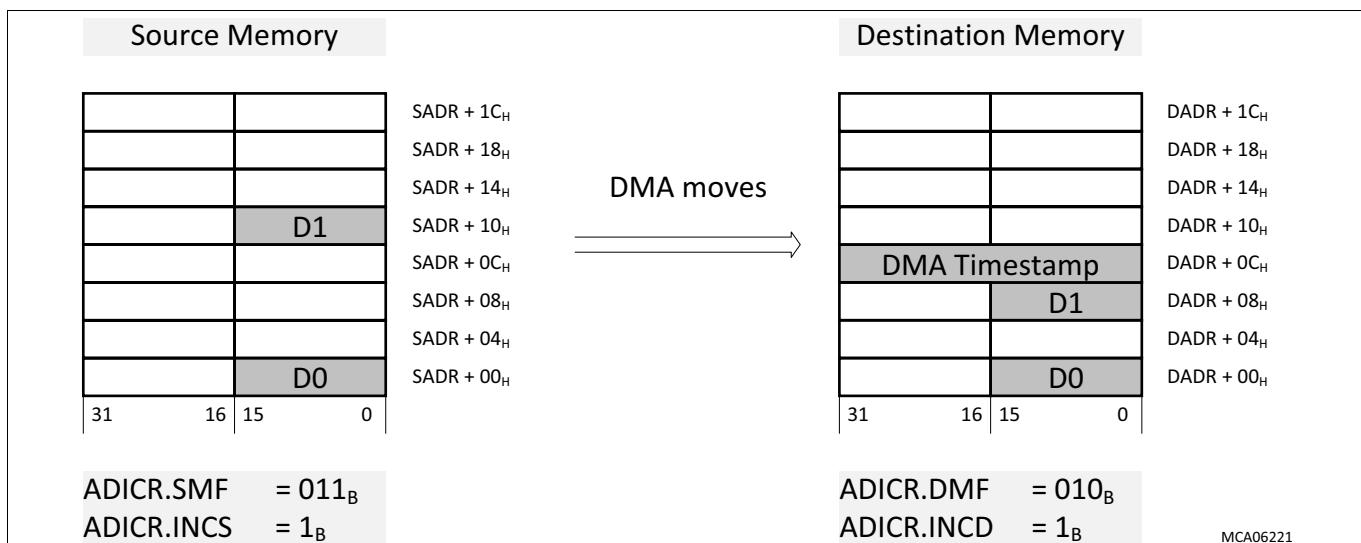

The appendage of a DMA timestamp to the destination data is controlled by the DMA channel ADICR.STAMP bit.

If a DMA channel is configured for the appendage of a DMA timestamp and not destination circular buffer operation (ADICR.DCBE = 0<sub>B</sub>), the ME shall write a DMA timestamp at a destination address defined by:

- If ADICR.INCD = 1<sub>B</sub>, the address of the DMA timestamp is the next higher word aligned destination address.
- If ADICR.INCD = 0<sub>B</sub>, the address of the DMA timestamp is the next lower word aligned destination address.

#### Appendage of DMA Timestamp - Example 1

16-bit half-words are moved from a source memory with an incrementing source address offset of 10<sub>H</sub> to a destination memory with an incrementing destination address offset of 08<sub>H</sub> (at [Figure 206](#)).

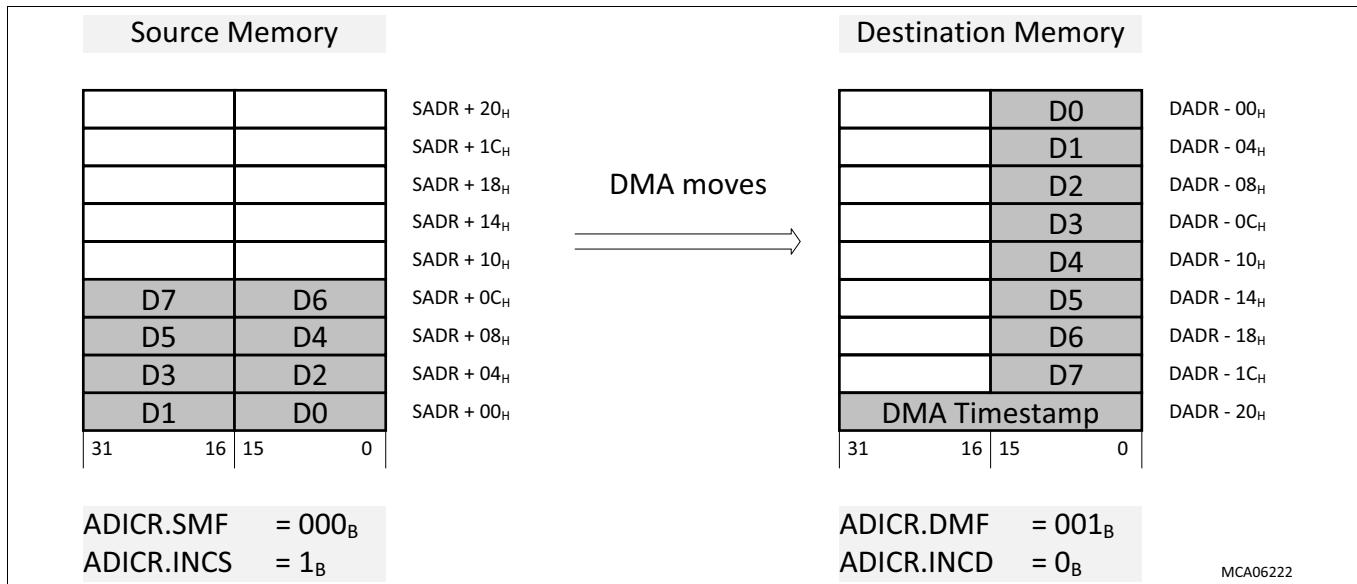

**Figure 206 Incrementing Destination Address: DMA Timestamp appended above DMA Write Move Data**

## Direct Memory Access (DMA)

### Appendage of DMA Timestamp - Example 2

16-bit half-words are moved from a source memory with an incrementing source address offset of  $02_{\text{H}}$  to a destination memory with a decrementing destination address offset of  $04_{\text{H}}$  (at [Figure 207](#)).

**Figure 207 Decrementing Destination Address: DMA Timestamp appended below DMA Write Move Data**

### Destination Address Generation

The destination address of the next DMA write move (of the next DMA transaction) shall be calculated using:

- The destination address of the last DMA write move (of the current DMA transaction).
- The destination address offset defined by ADICR.INCD, ADICR.DMF and CHCFGR.CHDW.

The ME checks the destination address of the next DMA write move.

If the currently calculated destination address of the next DMA write move shall result in DMA write move data overwriting the DMA timestamp of the current DMA transaction, the ME shall calculate a new destination address:

- If DMA channel ADICR.INCD =  $1_{\text{B}}$ , the ME shall select the greater value of the following:
  - Add ( $2_D \times$  destination address offset) to the destination address of last DMA write move.
  - Add  $8_D$  to the destination address of last DMA write move (of the current DMA transaction).
- If DMA channel ADICR.INCD =  $0_{\text{B}}$ , the ME shall select the lesser value of the following:
  - Subtract ( $2_D \times$  destination address offset) from the destination address of last DMA write move.
  - Subtract  $8_D$  from the destination address of last DMA write move (of the current DMA transaction).

The ME shall write back the DMA channel TCS (including updated destination address) to the DMARAM.

### 18.3.4.6.3 Appendage of DMA Timestamp to Destination Circular Buffer

If a DMA channel is configured for the appendage of a DMA timestamp and destination circular buffer operation (ADICR.DCBE =  $1_{\text{B}}$ ), the ME shall write a DMA timestamp at a destination address defined by:

- If ADICR.INCD =  $1_{\text{B}}$  AND ADICR.CBLD = 1 or 0, the address of the DMA timestamp =  $(\text{DADR}[31:2] + 1) \ll 2$
- If ADICR.INCD =  $1_{\text{B}}$  AND ADICR.CBLD > 1, the address of the DMA timestamp =  $(\text{DADR}[31:CBLD] + 1) \ll CBLD$
- If ADICR.INCD =  $0_{\text{B}}$  AND ADICR.CBLD = 1 or 0, the address of the DMA timestamp =  $(\text{DADR}[31:2] \ll 2) - 4$
- If ADICR.INCD =  $0_{\text{B}}$  AND ADICR.CBLD > 1, the address of the DMA timestamp =  $(\text{DADR}[31:CBLD]) \ll CBLD - 4$

The ME writes back to the DMARAM an incremented and wrapped destination address.

## Direct Memory Access (DMA)

### 18.3.4.6.4 Application of DMA Timestamp

The appendage of a DMA timestamp may be used by software to detect DMA failure modes:

- **Lost DMA operation:** DMA request is not serviced (i.e. no data).
- **Unintended DMA operation:** unintentional DMA request results in unexpected DMA transaction (i.e. unexpected data).
- **Delayed DMA transaction:** expected DMA transaction is completed too late.

Software may analyze relative DMA timestamp values to determine the correct sequencing of DMA transactions.

### 18.3.4.7 Pattern Detection

If a DMA channel is configured for **PATDET** then after each DMA read move, the ME compares move data with a value stored in a Pattern Read Register (PRR). The PATDET operation depends on the channel data width (CHCFGR.CHDW). The control field CHCFGR.PATSEL selects different PATDET operations for a specific value of CHDW.

The **Pattern Compare Logic** compares the move data stored in an ME read register to the selected PRR. If the bytes of move data to be compared are spread across different words of move data, the ME may combine the pattern match result of the current **DMA Move** and the pattern match result (stored in ME CHSR.LXO) of the previous **DMA Move**.

#### Configuration

If a DMA channel is configured for **PATDET**:

- The channel data width (CHCFGR.CHDW) shall be configured to 8-bit, 16-bit or 32-bit<sup>1)</sup>.
- The source address shall not be configured to a cached address (segments 8 and 9). A non-cached address (segments A and B) shall be configured to prevent the **ME Read Buffer** re-aligning the move data.

#### Interrupt Service Request

If a DMA channel is configured for PATDET and a pattern match is detected:

- The DMA transaction ends with the current DMA move.
- DMA channel TSR.HTRE is cleared to stop DMA transfers in the current active DMA channel.
- DMA channel TSR.CH will clear when the DMA write move has completed.
- The ME shall write back the next DMA move values of SADR and DADR.
  - If the DMA channel is configured for **Shadow Operation Read Only Mode**, the ME shall not perform a shadow address update. The ME write backs the current value of SHADR to the DMARAM.
- A PATDET interrupt service request shall be triggered.

Software may read the DMA channel status to identify the location of the pattern match in the data stream.

#### Errors

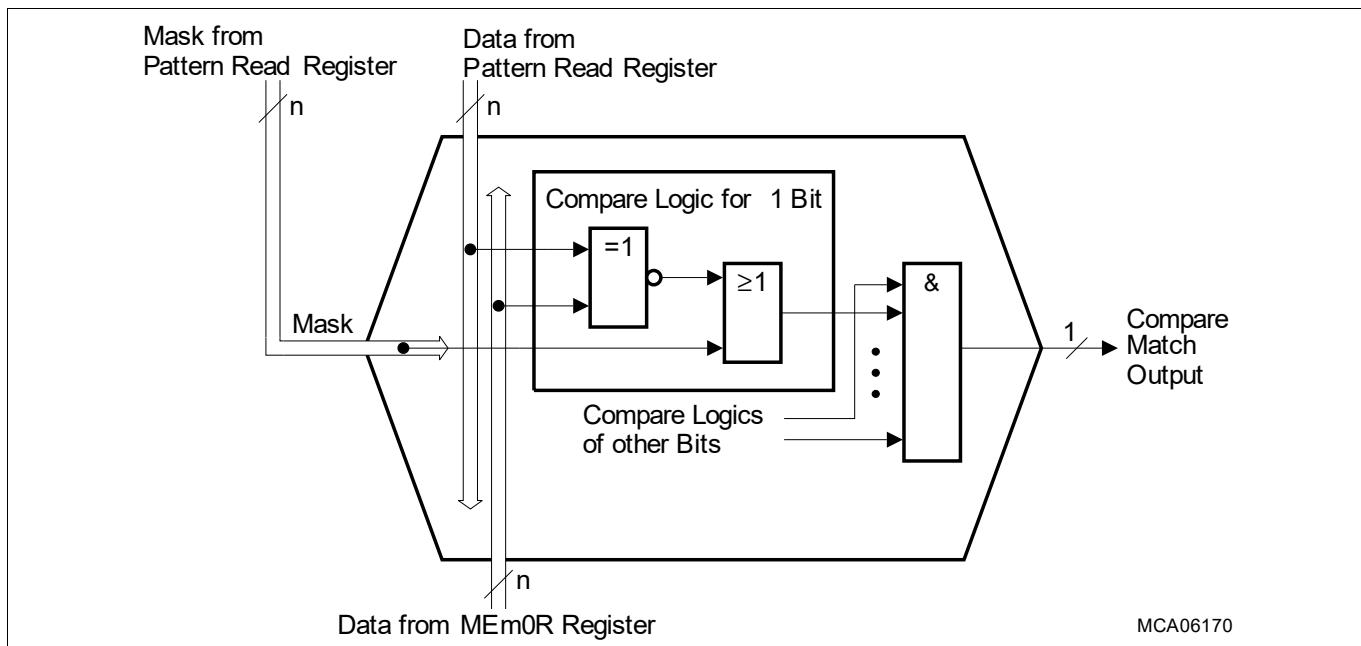

If a **SER** is reported during the current DMA read move, the ME shall not perform a pattern match.

### 18.3.4.7.1 Pattern Compare Logic

The ME COMPare (COMP) logic (at **Figure 208**) compares move data against a reference pattern at a bit-wise level. One COMP block controls either 8 bits or 16 bits of data. The COMP block may be configured to mask each data bit for the pattern compare.

<sup>1)</sup> If a DMA channel is configured for PATDET, the ME shall only store move data in MEm1R and/or MEm0R.

## Direct Memory Access (DMA)

**Figure 208 Pattern Compare Logic (COMP Block)**

In the COMP logic, one data bit from a ME read register is compared to the corresponding pattern bit stored in the selected PRR. If both bits are equal and a pattern mask bit stored in another PRR bit field is  $0_B$  then the compare matched condition becomes active. When the pattern mask bit is set to  $1_B$ , the compare matched condition is always active (set) for the related bit. When the compare matched conditions for each bit within the COMP logic are true, the compare match output line of the COMP block becomes active.

### 18.3.4.7.2 Pattern Detection for 8-bit Channel Data Width

If a DMA channel is configured for **Pattern Detection for 8-bit Channel Data Width**, the **ME** shall use the source address to select byte(s) of move data to be compared with patterns stored in PRR0 or PRR1. Three pattern compare configurations are possible defined by the DMA channel pattern select (CHCFG.R.PATSEL[1:0]).

The pattern compare logic allows a byte of DMA move data to be compared with two different patterns.

A mask operation of each compared bit is possible.

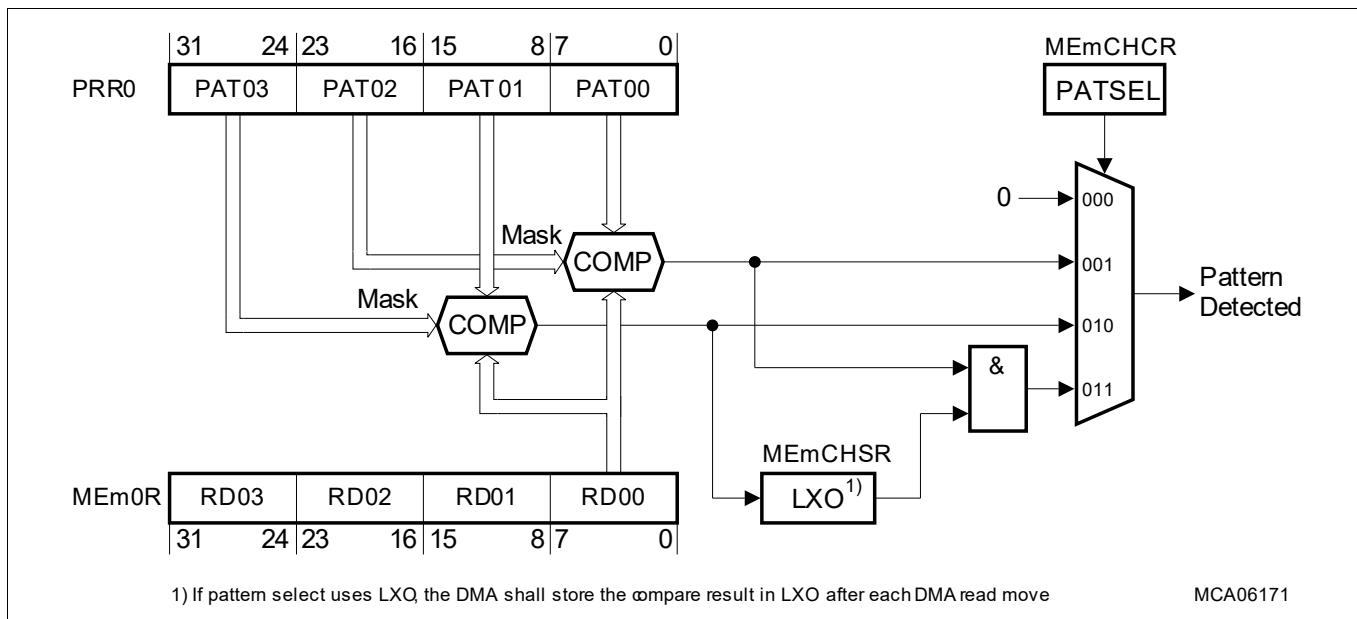

#### Example of PATDET for 8-bit Channel Data Width

The DMA channel (at **Figure 209**) is configured for PATDET for 8-bit channel data width (CHCFG.R.CHDW =  $000_B$ ).

If the current DMA read move stores the move data byte in MEm0R.RD00 then

- The **ME** uses the source address to select the move data byte stored in MEm0R.RD00.
- The **ME** compares move data byte stored in MEm0R.RD00 to PRR0.

## Direct Memory Access (DMA)

**Figure 209** PATDET for 8-bit Channel Data Width and Move Data Byte stored in MEm0R.RD00

The DMA channel may be configured for one of three pattern compare operations (at [Table 577](#)).

**Table 577** PATDET for 8-bit Channel Data Width and Move Data Byte stored in MEm0R.RD00

PATSE L	Pattern Detection Operating Modes
000 <sub>B</sub>	Pattern detection disabled
001 <sub>B</sub>	Pattern compare of MEm0R.RD00 to PRR0.PAT00, masked by PRR0.PAT02
010 <sub>B</sub>	Pattern compare of MEm0R.RD00 to PRR0.PAT01, masked by PRR0.PAT03
011 <sub>B</sub>	Pattern compare of MEm0R.RD00 to PRR0.PAT00, masked by PRR0.PAT02 of the <u>current</u> DMA read move <b>and</b> Pattern compare of MEm0R.RD00 to PRR0.PAT01, masked by PRR0.PAT03 of the <u>previous</u> DMA read move
100 <sub>B</sub>	Pattern detection disabled
101 <sub>B</sub>	Pattern compare of MEm0R.RD00 to PRR1.PAT10, masked by PRR1.PAT12
110 <sub>B</sub>	Pattern compare of MEm0R.RD00 to PRR1.PAT11, masked by PRR1.PAT13
111 <sub>B</sub>	Pattern compare of MEm0R.RD00 to PRR1.PAT10, masked by PRR1.PAT12 of the <u>current</u> DMA read move <b>and</b> Pattern compare of MEm0R.RD00 to PRR1.PAT11, masked by PRR1.PAT13 of the <u>previous</u> DMA read move

### Example of Two Byte PATDET Sequence

If a DMA channel is configured for a two byte PATDET sequence compared to PRR0 (CHCFGR.PATSEL[2:0] = 011<sub>B</sub>) then after each DMA move the pattern match result of move data compared with PRR0.PAT01, masked by PRR0.PAT03 is stored in bit MEmCHSR.LXO.

This DMA channel configuration allows, for example, two-byte sequences to be detected in an 8-bit data stream coming from a serial peripheral unit with 8-bit data width (e.g. recognition of carriage-return, line-feed characters, etc.).

## Direct Memory Access (DMA)

### 18.3.4.7.3 Pattern Detection for 16-bit Channel Data Width

If a DMA channel is configured for **Pattern Detection for 16-bit Channel Data Width**, the **ME** shall use the source address to select bytes of move data to be compared with patterns stored in PRR0 or PRR1. Three pattern match configurations are possible defined by the DMA channel pattern select (CHCFGFR.PATSEL[1:0]):

- Aligned Mode: compare complete half-word of one DMA move only.
- Unaligned Mode: compare upper and lower byte of two consecutive DMA moves.
- Combined Mode: combine Aligned Mode and Unaligned Mode.

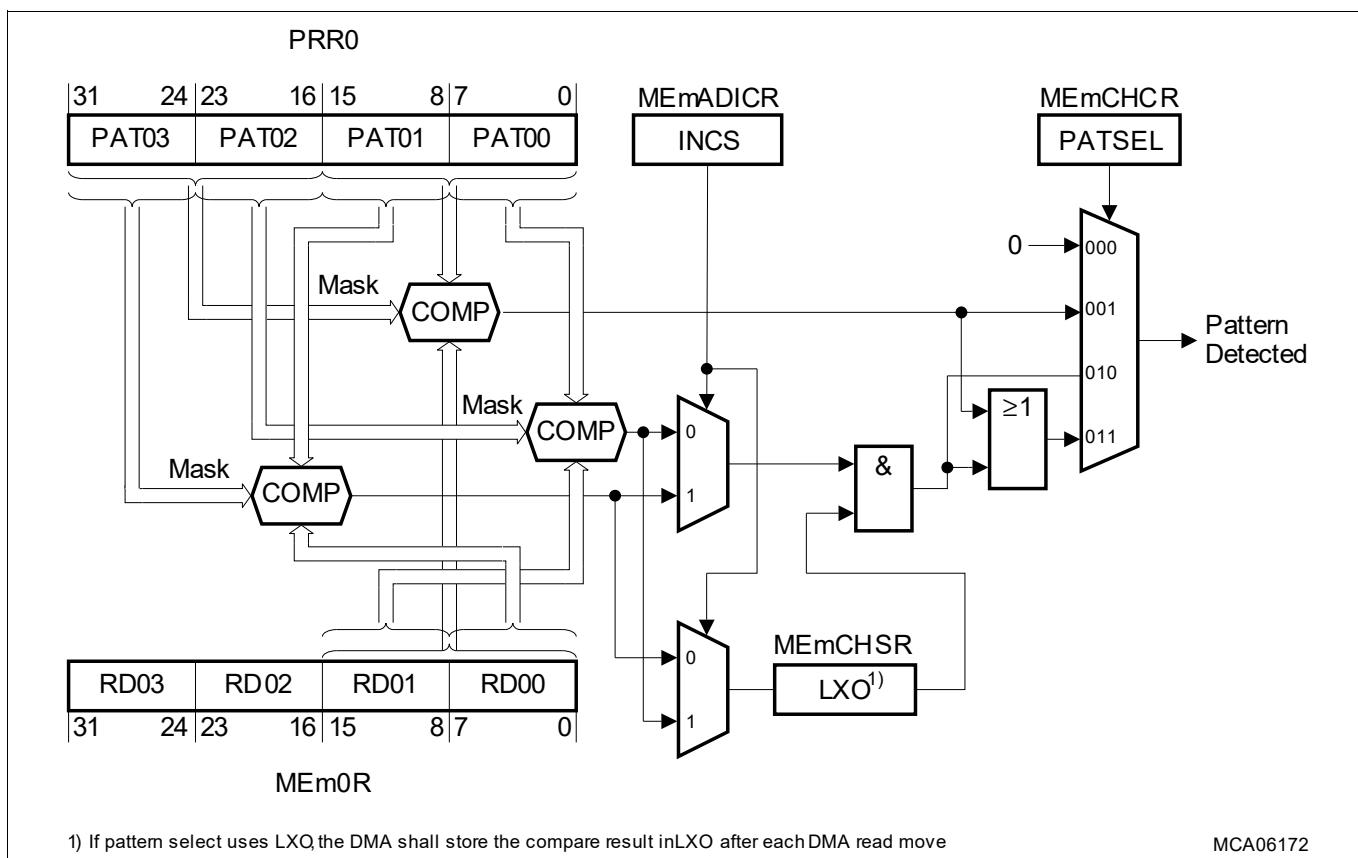

A mask operation of each compared bit is possible.

#### Example of PATDET for 16-bit Channel Data Width

The DMA channel (at [Figure 210](#)) is configured for PATDET for 16-bit channel data width (CHCFG.RCHD = 001<sub>B</sub>).

If the current DMA read move stores the move data half word in MEm0R.RD01||RD00 then

- The **ME** uses the source address to select the move data half word stored in MEm0R.RD01||RD00.
- The **ME** compares move data half word stored in MEm0R.RD01||RD00 to PRR0.

**Figure 210** PATDET for 16-bit Channel Data Width and Move Data stored in MEm0R.RD01||RD00

The DMA channel may be configured for one of three pattern compare operations (at [Table 578](#)).

- Aligned Mode
- Unaligned Mode 1 (Source Address Decrement)
  - The high byte of the current 16-bit DMA read move and the low byte of the previous 16-bit DMA read move are compared.
- Unaligned Mode 2 (Source Address Increment)

## Direct Memory Access (DMA)

- The low byte of the current 16-bit DMA read move and the high byte of the previous 16-bit DMA read move are compared.
- Combined Mode
  - If it is not known on which byte boundary (even or odd address) the 16-bit pattern to be detected is located, the DMA channel should be configured for combined mode.
  - The combined mode is the most flexible mode that combines the pattern search capability for aligned and unaligned 16-bit data searches.

**Table 578 PATDET for 16-bit Channel Data Width and Move Data stored in MEm0R.RD01||RD00**

PATSE L	INCS	Pattern Detection Operating Modes
000 <sub>B</sub>	-	Pattern detection disabled
001 <sub>B</sub>	-	<b>Aligned Mode</b> Pattern compare of MEm0R.RD01  RD00 to PRR0.PAT01  PAT00, masked by PRR0.PAT03  PAT02
010 <sub>B</sub>	0	<b>Unaligned Mode 1 (Source Address Decrement)</b> Pattern compare of MEm0R.RD01 to PRR0.PAT00, masked by PRR0.PAT02 of the <u>current</u> DMA read move <b>and</b> Pattern compare of MEm0R.RD00 to PRR0.PAT01, masked by PRR0.PAT03 (LXO) of the <u>previous</u> DMA read move
	1	<b>Unaligned Mode 2 (Source Address Increment)</b> Pattern compare of MEm0R.RD00 to PRR0.PAT01, masked by PRR0.PAT03 of the <u>current</u> DMA read move <b>and</b> Pattern compare of MEm0R.RD01 to PRR0.PAT00, masked by PRR0.PAT02 (LXO) of the <u>previous</u> DMA read move

## Direct Memory Access (DMA)

### 18.3.4.7.4 Pattern Detection for 32-bit Channel Data Width

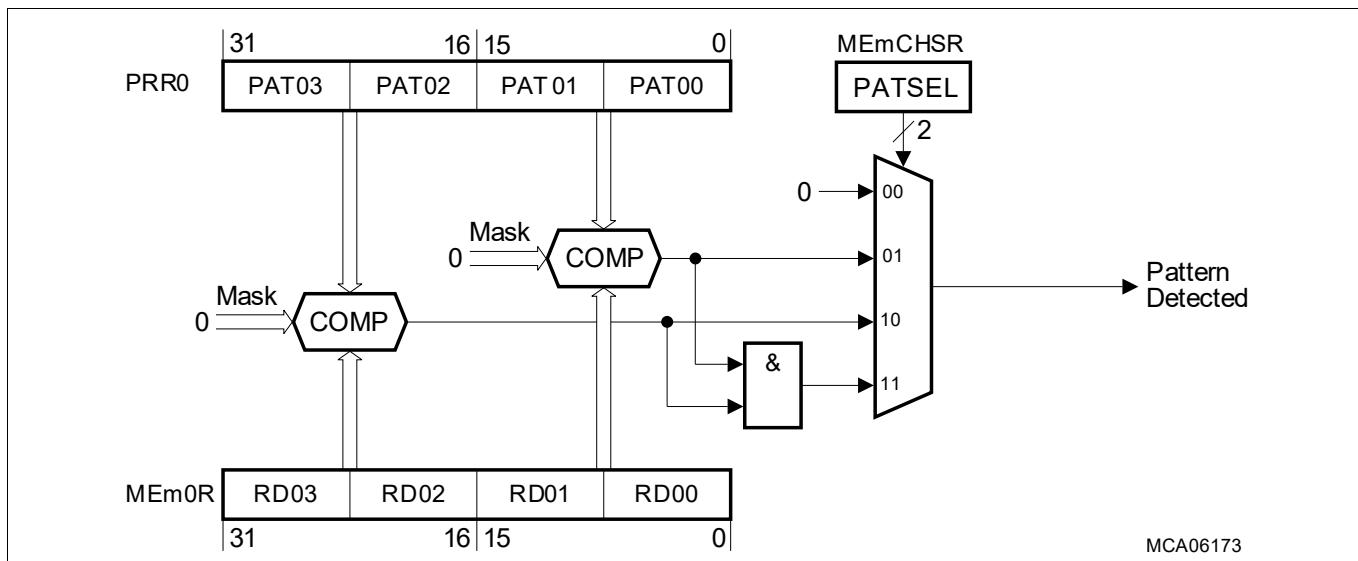

If a DMA channel is configured for **Pattern Detection for 32-bit Channel Data Width**, the **ME** shall compare a move data word with patterns stored in PRR0 or PRR1. Three pattern compare configurations are possible defined by the DMA channel pattern select (CHCFGFR.PATSEL[1:0]). A mask operation is not possible.

#### Example of PATDET for 32-bit Channel Data Width

The DMA channel (at [Figure 211](#)) is configured for PATDET and 32-bit channel data width (CHCFG.R.CHDW = 010<sub>B</sub>).

If the current DMA read move stores the move data word in MEm0R then

- The **ME** uses the source address to select the move data word stored in MEm0R.
- The **ME** compares move data word stored in MEm0R to PRR0.

**Figure 211** PATDET for 32-bit Channel Data Width and Move Data stored in MEm0R

The DMA channel may be configured for one of three pattern compare operations (at [Table 579](#)).

- Lower half-word only compared to pattern stored in PRR0 or PRR1.
- Upper half-word only compared to pattern stored in PRR0 or PRR1.
- Complete 32-bit word compared to pattern stored in PRR0 or PRR1.

**Table 579** PATDET for 32-bit Channel Data Width and Move Data stored in MEm0R

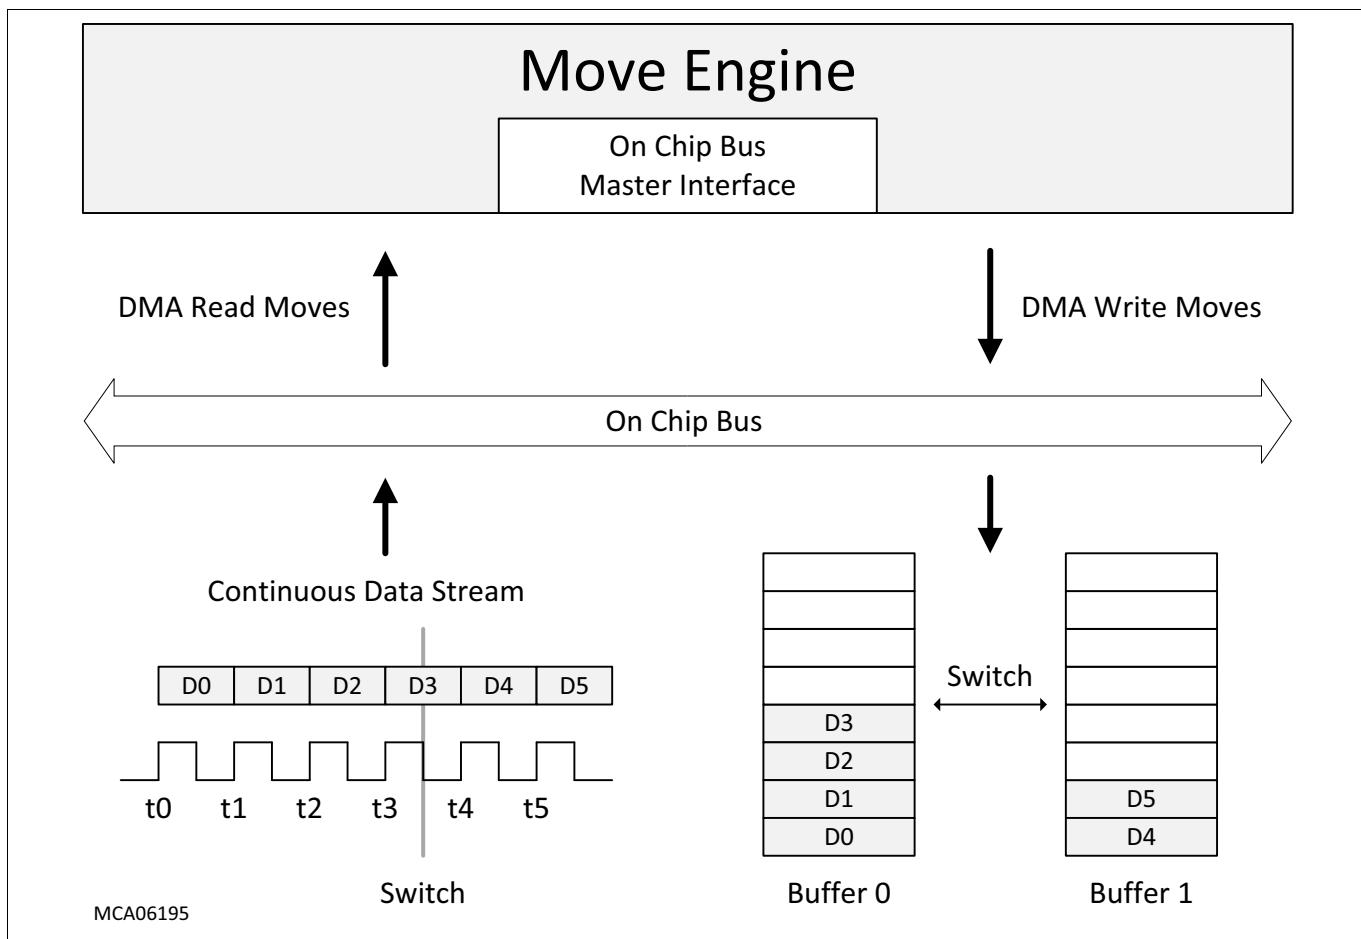

PATSEL	Pattern Detection Operating Modes
000 <sub>B</sub>	Pattern detection disabled
001 <sub>B</sub>	Unmasked pattern compare of MEm0R.RD01  RD00 to PRR0.PAT01  PAT00
010 <sub>B</sub>	Unmasked pattern compare of MEm0R.RD03  RD02 to PRR0.PAT03  PAT02
011 <sub>B</sub>	Unmasked pattern compare of MEm0R.RD03  RD02  RD01  RD00 to PRR0.PAT03  PAT02  PAT01  PAT00
100 <sub>B</sub>	Pattern detection disabled
101 <sub>B</sub>	Unmasked pattern compare of MEm0R.RD01  RD00 to PRR1.PAT11  PAT10
110 <sub>B</sub>	Unmasked pattern compare of MEm0R.RD03  RD02 to PRR1.PAT13  PAT12
111 <sub>B</sub>	Unmasked pattern compare of MEm0R.RD03  RD02  RD01  RD00 to PRR1.PAT13  PAT12  PAT11  PAT10

## Direct Memory Access (DMA)

### 18.3.4.8 Double Buffering Operations

The DMA supports double buffering. For example, Double Destination Buffering (at [Figure 212](#)) is as follows:

- DMA read moves transfer a continuous data stream from a peripheral to the DMA.
  - DMA write moves transfer the read data from the DMA to one of two destination buffers stored in memory.
- The dormant buffer is frozen and available for cyclic software tasks while the other buffer continues to be filled.

**Figure 212 DMA Double Buffering**

If a DMA channel is configured for one of the [Double Buffering Operations](#) AND is triggered by [DMA Hardware Request](#), software should configure the DMA channel for [Continuous Mode](#) (DMA channel CHCFGR.CHMODE = 1<sub>B</sub>).

#### 18.3.4.8.1 DMA Double Source Buffering

Data is streamed by the DMA from one of two data buffers (buffer 0 and buffer 1) stored in memory to a continuous output data stream. The Double Source Buffering addresses are:

- The source address SADR shall address source buffer 0.
- The shadow address SHADR shall address source buffer 1.

#### 18.3.4.8.2 DMA Double Destination Buffering

A continuous input data stream is directed by the DMA to one of two data buffers (buffer 0 and buffer 1) stored in memory. The Double Destination Buffering addresses are:

- The destination address DADR shall address destination buffer 0.

## Direct Memory Access (DMA)

- The shadow address SHADR shall address destination buffer 1.

### 18.3.4.8.3 Size of Buffer

The data size of the two source/destination buffers is equal and determined by the following TCS parameters:

- The channel data width (CHCFG.R.CHDW).
- The block mode value (CHCFG.R.BLKM).
- The transfer reload value (CHCFG.R.TREL).

The memory size of the two source/destination buffers is determined by the additional TCS parameters:

- The source/destination circular buffer enable/disable control (ADICR.SCBE/DCBE).
- The source/destination address modification factor (ADICR.DMF/SMF).
- The increment of the source/destination address (ADICR.INCD/INCS).

The size of one buffer is equal to the size of one DMA transaction.

### 18.3.4.8.4 Buffer Switch

The re-direction of the data stream from one buffer to the other buffer shall be controlled by a **Software Switch** and additionally **Automatic Hardware Switch**. During a buffer switch:

- No DMA requests shall be lost by the DMA.
- There shall be no loss, duplication or split of data across the two buffers.

#### Active Buffer Status

During DMA double buffering the DMA channel CHCSR.BUFFER bit is used to indicate which buffer is active.

- DMA channel CHCSR.BUFFER = 0<sub>B</sub>; buffer 0 is read or filled by the DMA.
- DMA channel CHCSR.BUFFER = 1<sub>B</sub>; buffer 1 is read or filled by the DMA.

#### Frozen Buffer Status

When the DMA switches buffers the DMA channel frozen bit is set (CHSR.FROZEN= 1<sub>B</sub>). The frozen buffer is then available for a cyclic software task. On completion of the software task the status bit CHSR.FROZEN is cleared by software and the buffer address pointer is re-programmed to the start address ready for the next DMA transaction that reads/fills the buffer.

#### Active Buffer Empty or Full

If the active buffer is emptied (in the case of DMA double source buffering) or filled (in the case of DMA double destination buffering) and no automatic hardware switch occurs before a software buffer switch is received then the DMA channel will stop and no more DMA transfers are made. When the DMA channel stops, the transfer count (CHCSR.TCOUNT) is equal to 0000<sub>H</sub>.

A buffer empty or full event may be signalled by a **DMA Channel Interrupt Service Request**. The DMA channel interrupt control ADICR.INTCT should be configured to 10<sub>B</sub> and the interrupt raise detect value ADICR.IRDV to 0000<sub>B</sub>. When the transfer count equals zero then the DMA channel will raise a DMA channel interrupt service request.

The DMA channel interrupt handler can interrogate the DMA to identify which DMA channel generated the interrupt service request. Software may initialize the DMA channel ready to restart double buffering operations.

#### Active Buffer Overflow

If the data rate is faster than the DMA is able to transfer the data to one of the buffers then a **TRL** event shall occur.

## Direct Memory Access (DMA)

### 18.3.4.8.5 Software Switch

Before a DMA transaction completes and the active buffer is full software shall re-direct the data stream from the active buffer to the other buffer by setting the DMA channel CHCSR.SWB. If a ME is actively servicing a DMA channel configured for double buffering then the current DMA transfer shall complete before the buffer switch is made. On completion of the DMA transfer the DMA shall:

- Automatically re-load DMA channel CHCSR.TCOUNT with CHCFGR.TREL
- Switch the address pointer:
  - Buffer 0 address pointer (source address or destination address).
  - Buffer 1 address pointer (shadow address).

The TCS address control factors remain the same. The next DMA transaction controlling the filling or reading of the new buffer will start when a DMA request is received.

If software re-directs the data stream by setting DMA channel CHCSR.SWB = 1<sub>B</sub>, software shall poll DMA channel CHCSR.FROZEN AND DMA channel CHCSR.BUFFER. If software reads DMA channel CHCSR.FROZEN = 1<sub>B</sub> and an active buffer transition, software may start to analyze the frozen buffer.

If a DMA channel is configured for Software Switch Only AND the DMA transaction is completed before the DMA receives a Software Switch, the DMA shall report a **TRL** event (DMA channel TSR.TRL = 1<sub>B</sub>). If the DMA channel enable TRL bit is set (TSR.ETRL = 1<sub>B</sub>), the DMA shall trigger a **DMA RP Error Interrupt Service Request**.

### 18.3.4.8.6 Automatic Hardware Switch

The DMA will automatically switch from the active buffer to the other buffer when the DMA transaction reading or filling the active buffer completes. On switching buffers the DMA channel CHCSR.FROZEN bit is set to indicate that one buffer is frozen and available for cyclic software tasks. The completion of a DMA transaction may be signalled by a **DMA Channel Interrupt Service Request**. On completion of the DMA transaction when ME CHSR.TCOUNT equals 0000<sub>H</sub> the DMA shall:

- Automatically re-load DMA channel CHCSR.TCOUNT with CHCFGR.TREL
- Switch the address pointer to select the other buffer:
  - Buffer 0 address pointer (source address or destination address).
  - Buffer 1 address pointer (shadow address).

The DMA channel TCS address control factors remain the same. The next DMA transaction controlling the filling or reading of the new buffer will start when a DMA request is received.

If DMA channel CHCSR.FROZEN is equal to 1<sub>B</sub>, the automatic hardware switch will not occur and the DMA shall report a **TRL** event (DMA channel TSR.TRL = 1<sub>B</sub>). If the DMA channel enable TRL bit is set (TSR.ETRL = 1<sub>B</sub>), the DMA shall trigger a **DMA RP Error Interrupt Service Request**.

### 18.3.4.8.7 Application of Double Buffering

A typical DMA double buffer application is shown in [Figure 213](#):

- DMA channel m is configured for **DMA Double Destination Buffering**. The DMA channel moves the input data generated by a sensor into the active destination buffer.
- A cyclic software task processes the input data stored in the frozen destination buffer and writes the output into the frozen source buffer. The CPU controls both the source and destination buffer switching.
- DMA channel n is configured for **DMA Double Source Buffering**. The DMA channel moves the processed data from the frozen source buffer to the actuator.

The system configuration shall balance the input data rate, the duration of cyclic software tasks and the buffer size in order to prevent **TRL** events.

### Direct Memory Access (DMA)

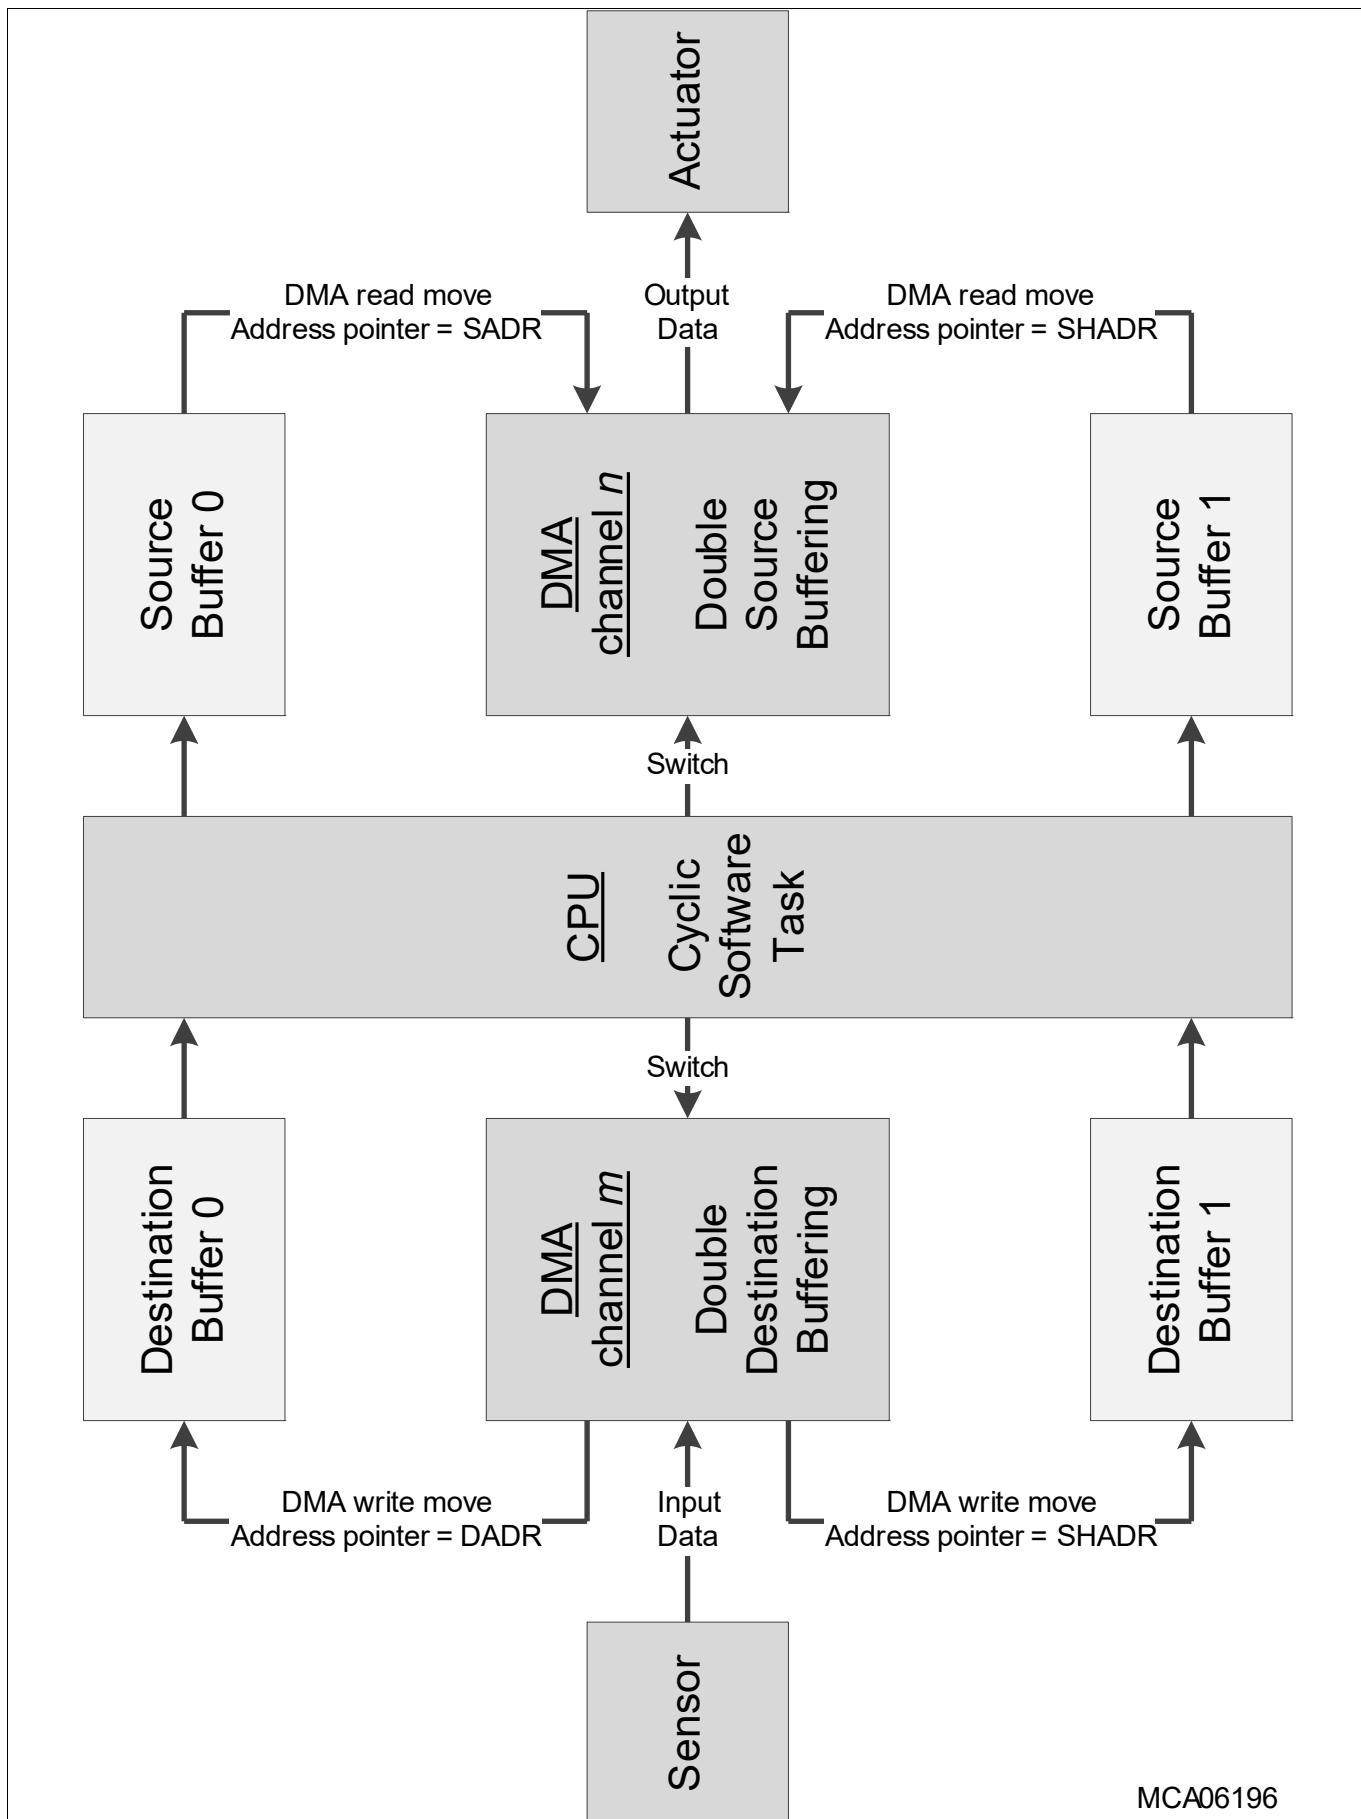

Figure 213 Application of Double Buffering

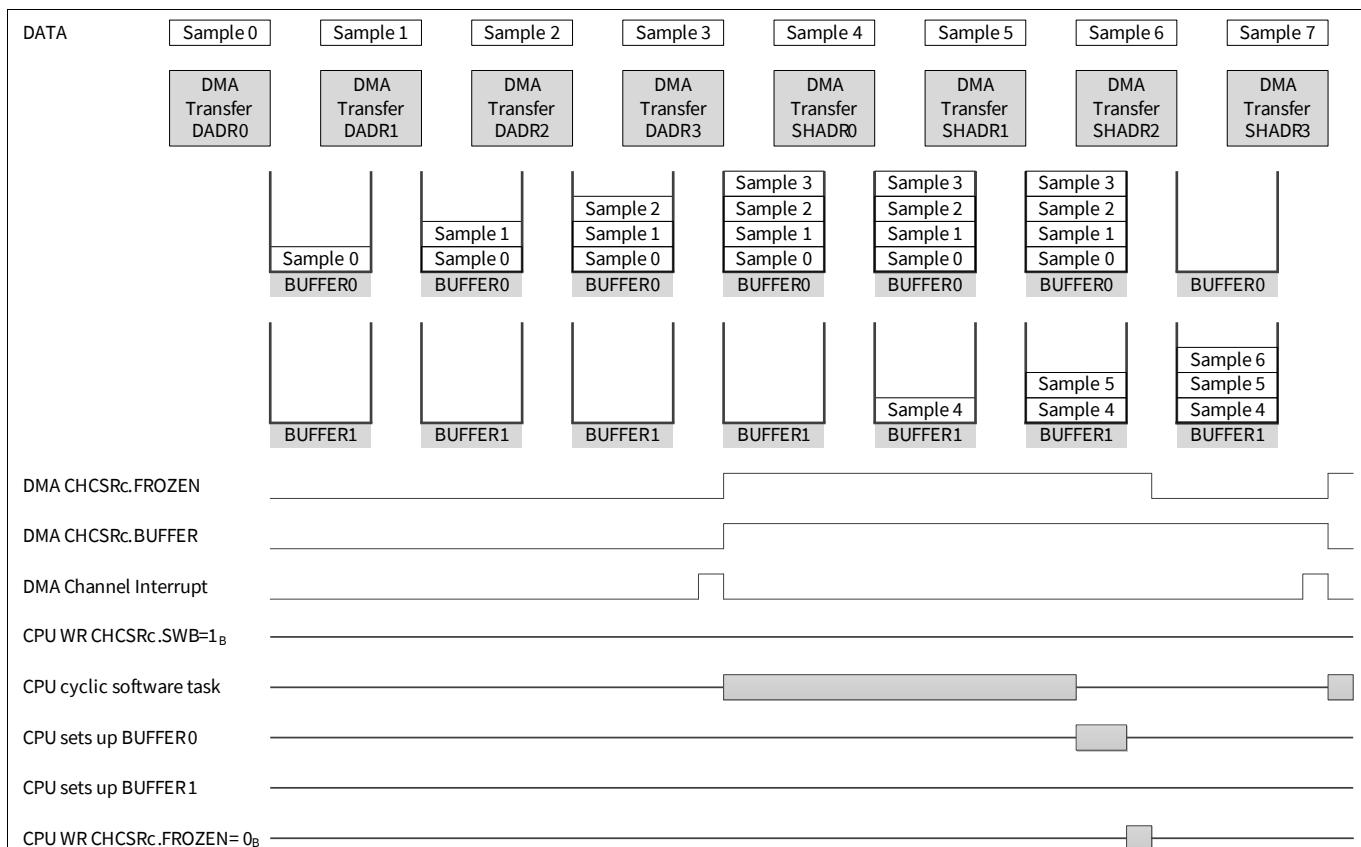

Figure 215 DMA Double Destination Buffering Software Switch and Automatic Hardware Switch

## Direct Memory Access (DMA)

### 18.3.4.9 Linked List Operations

Linked list operations are an extension of DMA channel functionality to support the more flexible use of the DMA. A linked list operation shall consist of a series of DMA transactions executed by the same DMA channel. Each DMA transaction shall have a unique TCS. The source and destination areas shall not have to exist in contiguous areas of memory.

If a DMA channel is configured for linked list operation then as soon as the ME completes the current DMA transaction, the ME shall read the next TCS from memory and overwrite the current TCS at the DMA channel location in DMARAM. The current DMA transaction uses a 32-byte aligned address pointer to point to the next TCS stored in either internal or external memory. The DMA shall start reading the next TCS from word 0 upwards. There is no limit to the number of DMA transactions in a linked list operation. The first DMA transaction in a linked list operation shall be initiated by a DMA hardware request or a DMA software request. Subsequent DMA transactions may additionally be initiated by a **DMA Auto Start Request**.

Each DMA channel supports the following types of linked list operation:

- **DMA Linked List (DMALL)**
- **Accumulated Linked List (ACLLL)**
- **Safe Linked List (SAFLL)**
- **Conditional Linked List (CONLL)**

#### 18.3.4.9.1 DMA Auto Start Request

If a **DMA Auto Start Request** is selected in the next TCS (CHCSR.SCH = 1<sub>B</sub>) then the next DMA transaction shall be initiated by the ME. The access pending bit TSR.CH shall be set. The DMA shall perform an **Arbitration Sequence** to determine the highest priority DMA request. A **DMA Auto Start Request** shall bypass the Interrupt Router so reducing the cumulative latency over a number of DMA transactions.

#### 18.3.4.9.2 Non Linked List Operation

If the next TCS is not configured for linked list operation, the next TCS should be configured for a **Move Operation**. The DMA channel exits linked list operation. A **DMA Auto Start Request** shall not initiate the next DMA transaction.

#### 18.3.4.9.3 Last DMA Transaction

A **DMA Channel Interrupt Service Request** may be used to signal the completion of the last DMA transaction in a sequence of linked list operations. The last DMA transaction will load the next TCS. **DMA Auto Start Request** shall not be selected.

#### 18.3.4.9.4 Circular Linked List Operations

A sequence of linked list operations may be configured for circular operation. The same series of DMA transactions shall be repeated.

## Direct Memory Access (DMA)

### 18.3.4.9.5 DMA Linked List (DMALL)

The DMA channel (at [Figure 216](#)) is configured for DMALL operation. The DMA channel shadow address register (SHADR) stores the 32-bit address pointer to the next TCS. As soon as the current DMA transaction completes, the ME reads the next TCS and stores it in DMARAM.

#### DMA Address Checksum & DMA Data Checksum

Software shall configure the initial value of **DMA Address Checksum** and **DMA Data Checksum** used during the first DMA transaction. When the ME reads the next TCS, the **DMA Address Checksum** and **DMA Data Checksum** shall be initialized to  $00000000_H$ .

### 18.3.4.9.6 Accumulated Linked List (ACCLL)

ACCLL is a variant of DMALL and has an identical footprint in memory (size and structure). The SDCRC and RDCRC checksums are accumulated across DMA transactions.

#### DMA Address Checksum & DMA Data Checksum

The **DMA Address Checksum** and **DMA Data Checksum** are not overwritten when the next TCS is loaded into the DMA channel. As long as the DMA channel is configured for ACCLL, the **DMA Address Checksum** and **DMA Data Checksum** are calculated across all DMA transactions.

### 18.3.4.9.7 Safe Linked List (SAFLL)

The DMA channel (at [Figure 217](#)) is configured for SAFLL operation. SAFLL provides protection against software errors. If the address pointer in a sequence of linked list operations is incorrectly written then the address pointer may point to any random area of memory and load the next TCS from the wrong location and execute it. As long as a DMA channel is configured for SAFLL, the ME checks that the calculated **DMA Address Checksum** matches an expected **DMA Address Checksum** stored in the next TCS.

#### DMA Address Checksum

The user is required to load the SDCRC word with an expected **DMA Address Checksum** value. As soon as the ME has read the next TCS from memory, the ME compares the **DMA Address Checksum** calculated by the current DMA transaction against the expected **DMA Address Checksum** stored in the next TCS. If the checksums match then the DMA proceeds with the execution of the next TCS. If the checksums do not match then the ME records a **SAFLL DMA Address Checksum Error** and triggers a **DMA RP Error Interrupt Service Request**. The DMA stops the execution of the linked list operation. Assuming all the **DMA Address Checksum** values match during the sequence of linked list operations then the **DMA Address Checksum** is calculated across all DMA transactions.

#### DMA Data Checksum

The **DMA Data Checksum** is not overwritten when the new TCS is loaded into the DMA channel. The **DMA Data Checksum** is calculated across all DMA transactions.

## Direct Memory Access (DMA)

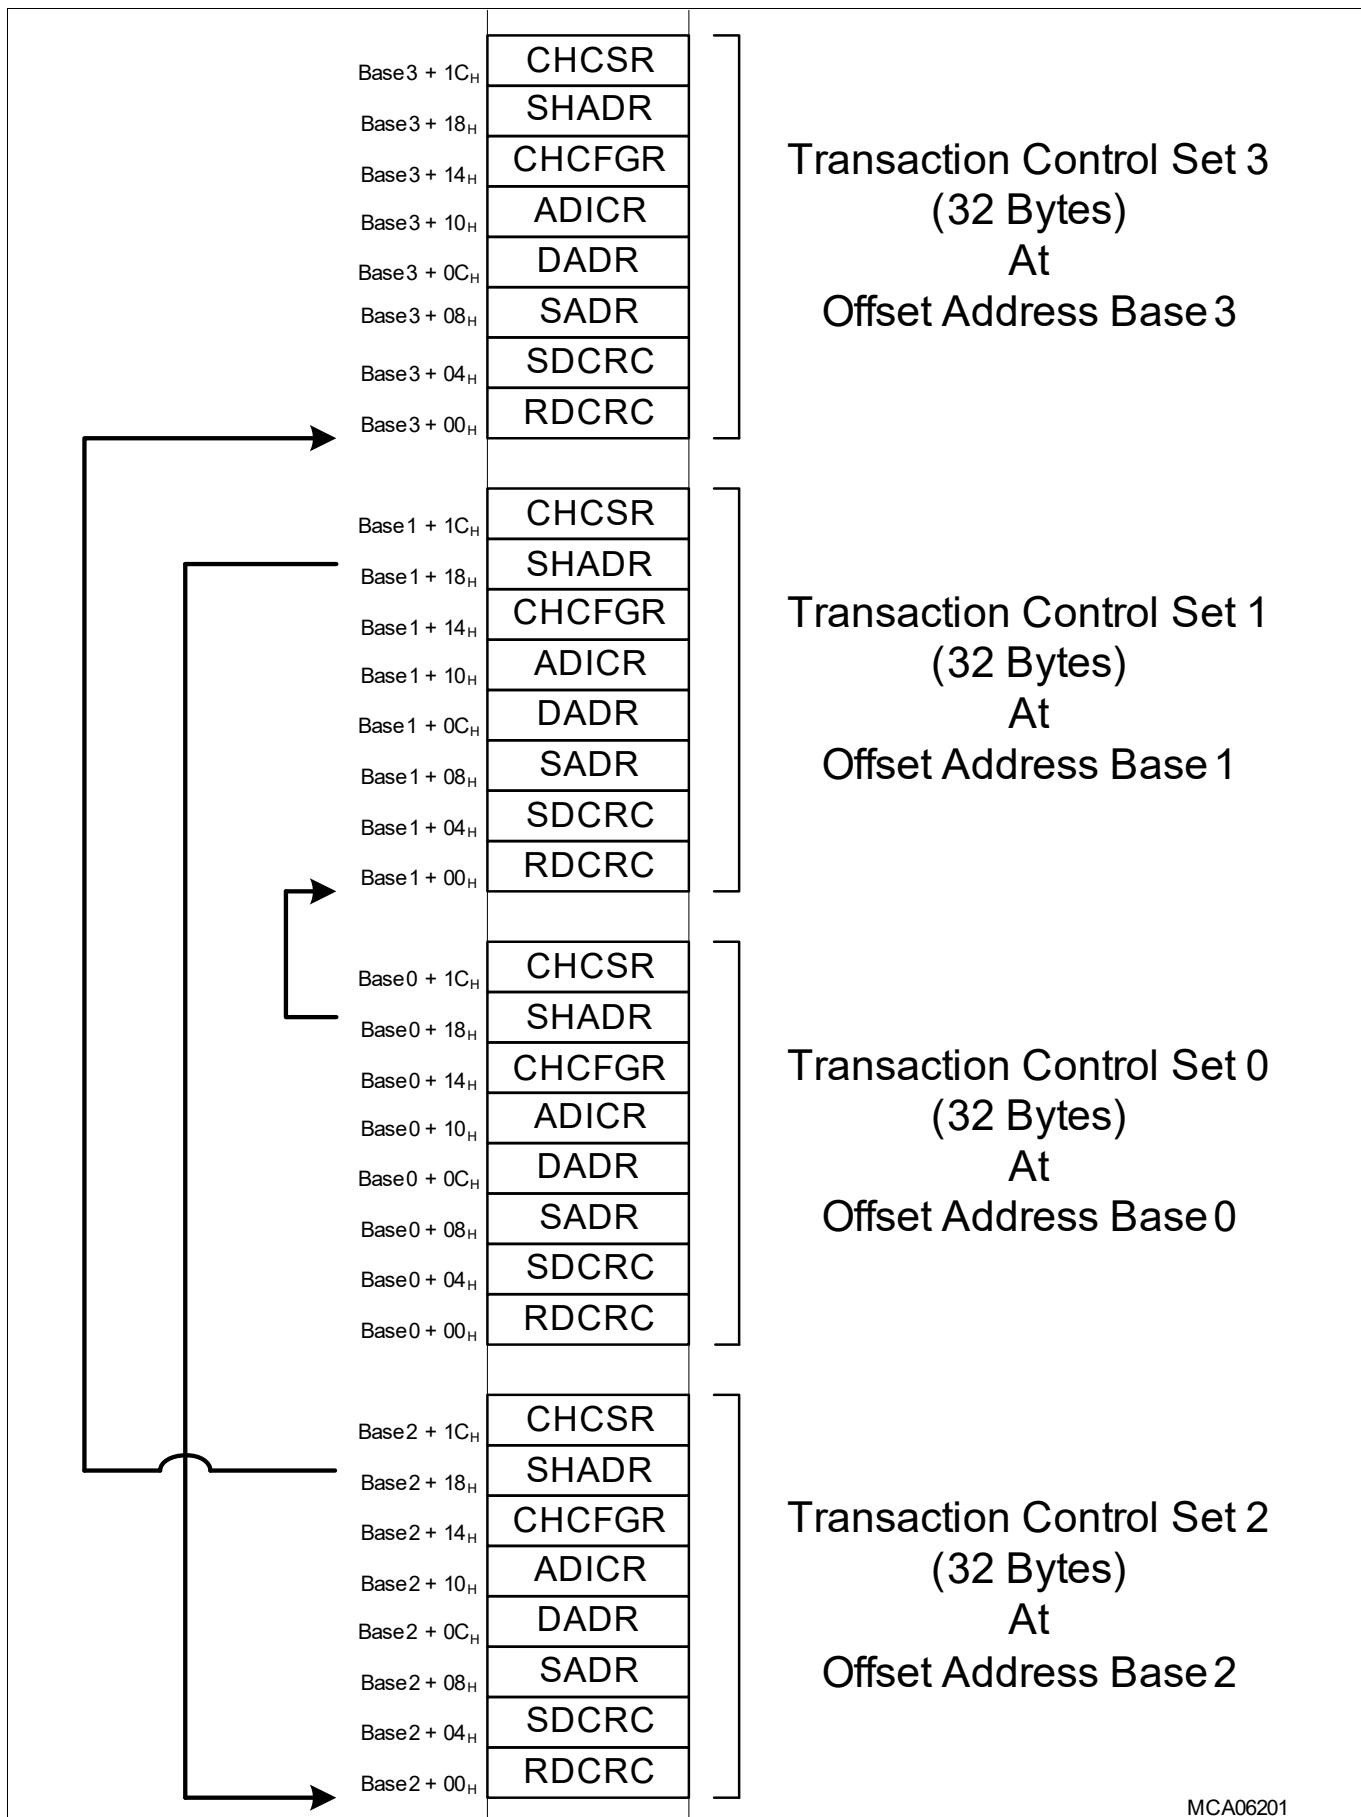

Figure 216 DMA Linked List

## Direct Memory Access (DMA)

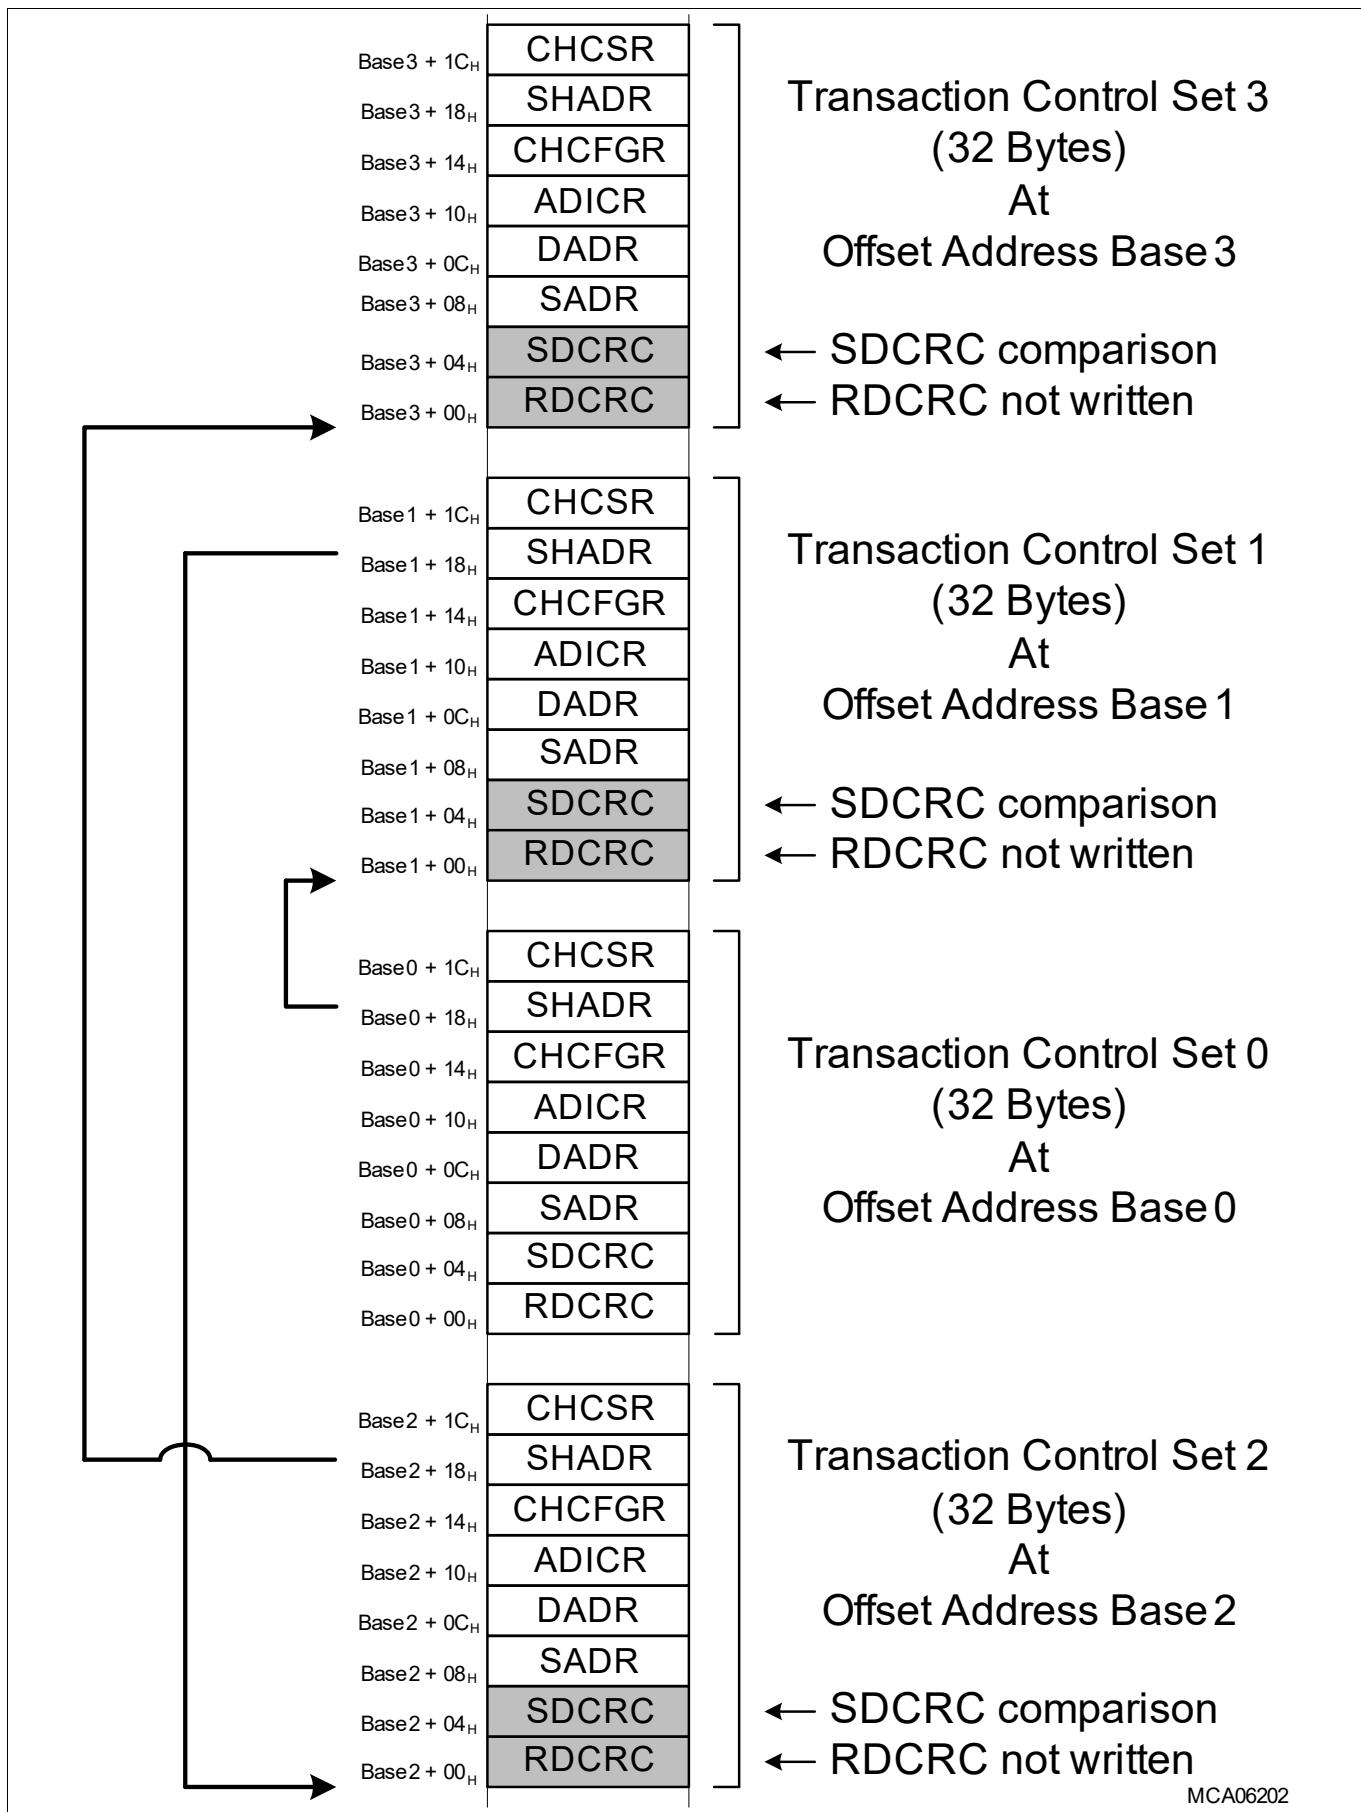

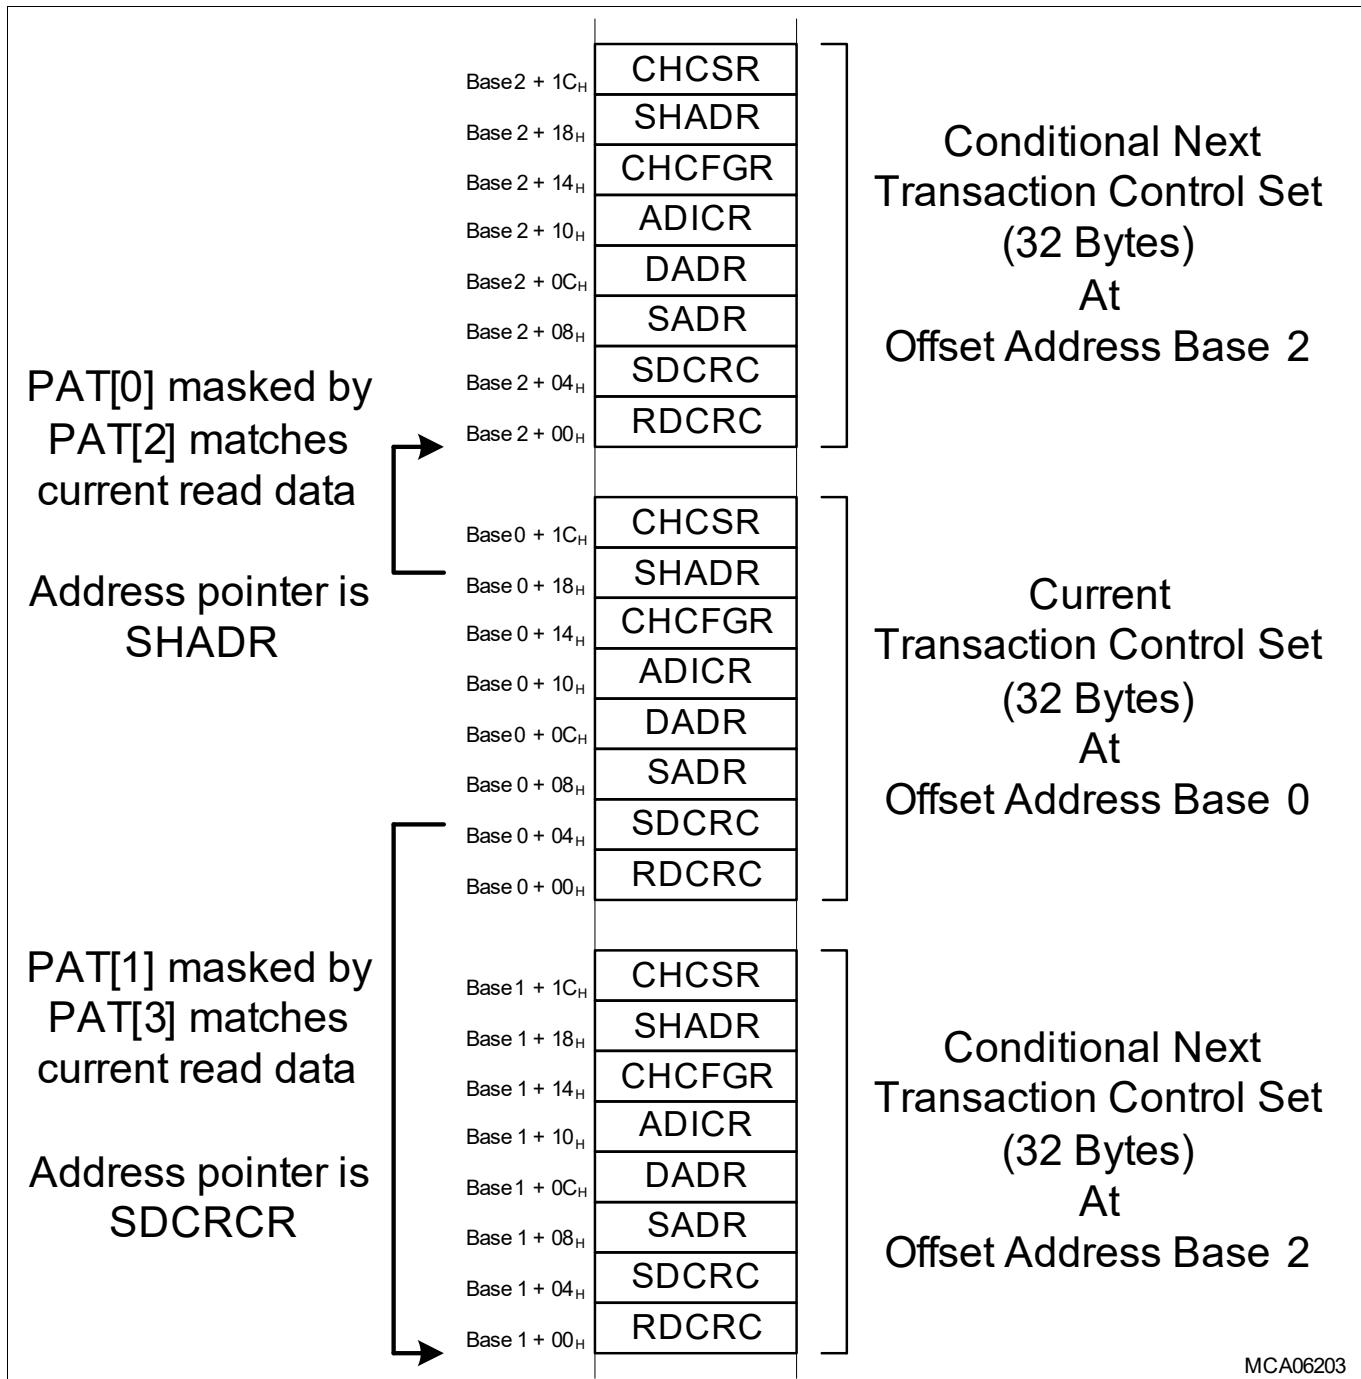

Figure 217 Safe Linked List

## Direct Memory Access (DMA)

### 18.3.4.9.8 Conditional Linked List (CONLL)

A special use of a linked list is CONLL (at [Figure 218](#)). Selection of the address pointer to the next TCS is determined by a conditional state. CONLL uses the shadow address (SHADR) and the source and destination address CRC registers (SDCRCR) as address pointers.

A CONLL operation is limited to 8-bit DMA moves ( $\text{CHCFGR.CHDW} = 000_B$ ). The source address shall not be configured to a cached address (segments 8 and 9). A non-cached address (segments A and B) shall be configured to prevent the [ME Read Buffer](#) re-aligning the move data.

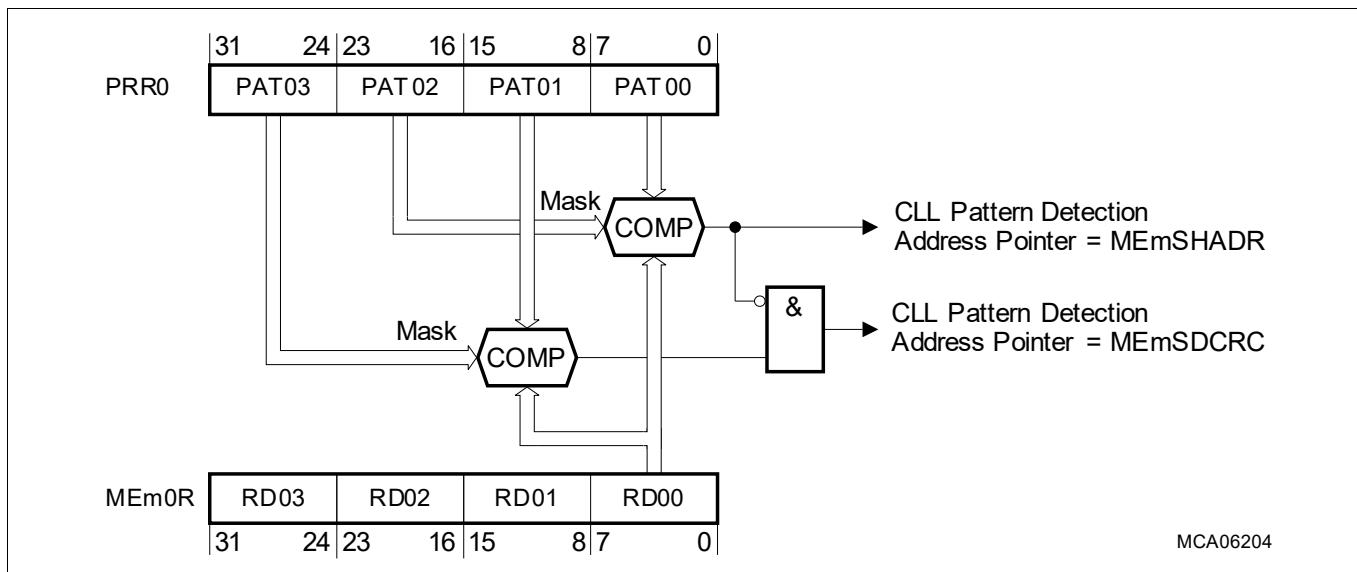

**Figure 218** Conditional Linked List

#### CONLL Pattern Detection

The DMA channel (at [Figure 219](#)) is configured for CONLL. The TCS selects PRR0 for a pattern compare.

## Direct Memory Access (DMA)

**Figure 219 Conditional Linked List and Pattern Compare Logic**

During each DMA move the pattern detection logic determines the selection of the address pointer:

- If PAT00 masked by PAT02 matches the DMA move data stored in MEm0R RD00 then as soon as the DMA move completes the ME shall load the DMA channel with the next TCS read from an address stored in SHADR.
- If PAT01 masked by PAT03 matches the DMA move data stored in MEm0R RD00 then as soon as the DMA move completes the ME shall load the DMA channel with the next TCS read from an address stored in SDCRCR.
- If both PAT00 masked by PAT02 and PAT01 masked by PAT03 match the DMA move data stored in MEm0R RD00 then as soon as the ME shall load the DMA channel with the next TCS read from an address stored in SHADR.
- If there is no pattern match then the ME continues with the DMA transaction.

If a pattern match is detected then:

- The DMA transaction ends with the current DMA move.
- The DMA channel TSR.CH will be cleared when the DMA write move has completed.

### Completion of Current DMA Transaction

If the current DMA transaction completes when ME CHSR.TCOUNT = 0<sub>D</sub> and there is no pattern match then the CONLL will load the DMA channel with the next TCS read from an address stored in SHADR.

### Multiple Pattern Detection Conditions

The user may intentionally program PAT00 masked by PAT02 shall not match with the DMA move data stored in MEm0R RD00 and transition across a series of DMA transactions in the CONLL. For each DMA transaction the user may programme a series of different PAT01 masked by PAT03 values and test if each value matches with the current DMA move data stored in MEm0R RD00. If PAT01 masked by PAT03 matches the current DMA move data stored in MEm0R RD00, then as soon as the DMA move is completed, the ME shall load the DMA channel with the next TCS read from an address stored in SDCRCR.

## Direct Memory Access (DMA)

### 18.3.4.10 DMA Data Checksum

To support enhanced data integrity checking the DMA calculates a 32-bit Read Data Cyclic Redundancy Checksum (**RDCRC**) in accordance with the IEEE 802.3 standard on DMA move data as it passes through the DMA.

#### Move Operation or Shadow Operation

To calculate a **DMA Data Checksum** for DMA move data the DMA channel RDCR must be initialized (e.g. written with  $00000000_H$  or another desired initial value) in addition to the standard DMA transaction configuration (source address, etc.) for the size of DMA move data.

If no error or retry event is reported during DMA move then the ME calculates an updated **DMA Data Checksum** value for each DMA move. On completion of the DMA transaction the ME stores the **DMA Data Checksum** in the DMA channel RDCR. Software may compare the calculated **DMA Data Checksum** with an expected **DMA Data Checksum** to verify the integrity of DMA move data.

#### Swap Byte

The **DMA Data Checksum** shall be calculated for all DMA channel data widths and may be configured to swap the byte order (at **Figure 220**). If DMA channel swap byte is selected (CHCFGR.SWAP =  $1_B$ ) then the order of bytes are swapped before **DMA Data Checksum** computation. Big-endian input is converted to little-endian and vice versa. If the DMA channel is configured for 8-bit channel data width (CHCFGR.CHDW =  $000_B$ ) then swap byte has no effect.

Swap byte does not change the byte order of data between a DMA read move and a DMA write move.

#### DMA Timestamp

If the DMA channel is configured to append a DMA timestamp then the DMA timestamp is not part of the **DMA Data Checksum** calculation.

#### Double Buffering Operations

The **DMA Data Checksum** is accumulated across all the DMA move data moved into both buffers. Software may re-initialize the **DMA Data Checksum** after a **Software Switch** and before the next data sample is received.

#### DMA Linked List (DMALL)

The **DMA Data Checksum** is initialized to  $00000000_H$  at the start of each DMA transaction.

#### Accumulated Linked List (ACLLL), Safe Linked List (SAFLL) and Conditional Linked List (CONLL)

The **DMA Data Checksum** is accumulated across all the DMA transactions in the linked list.

## Direct Memory Access (DMA)

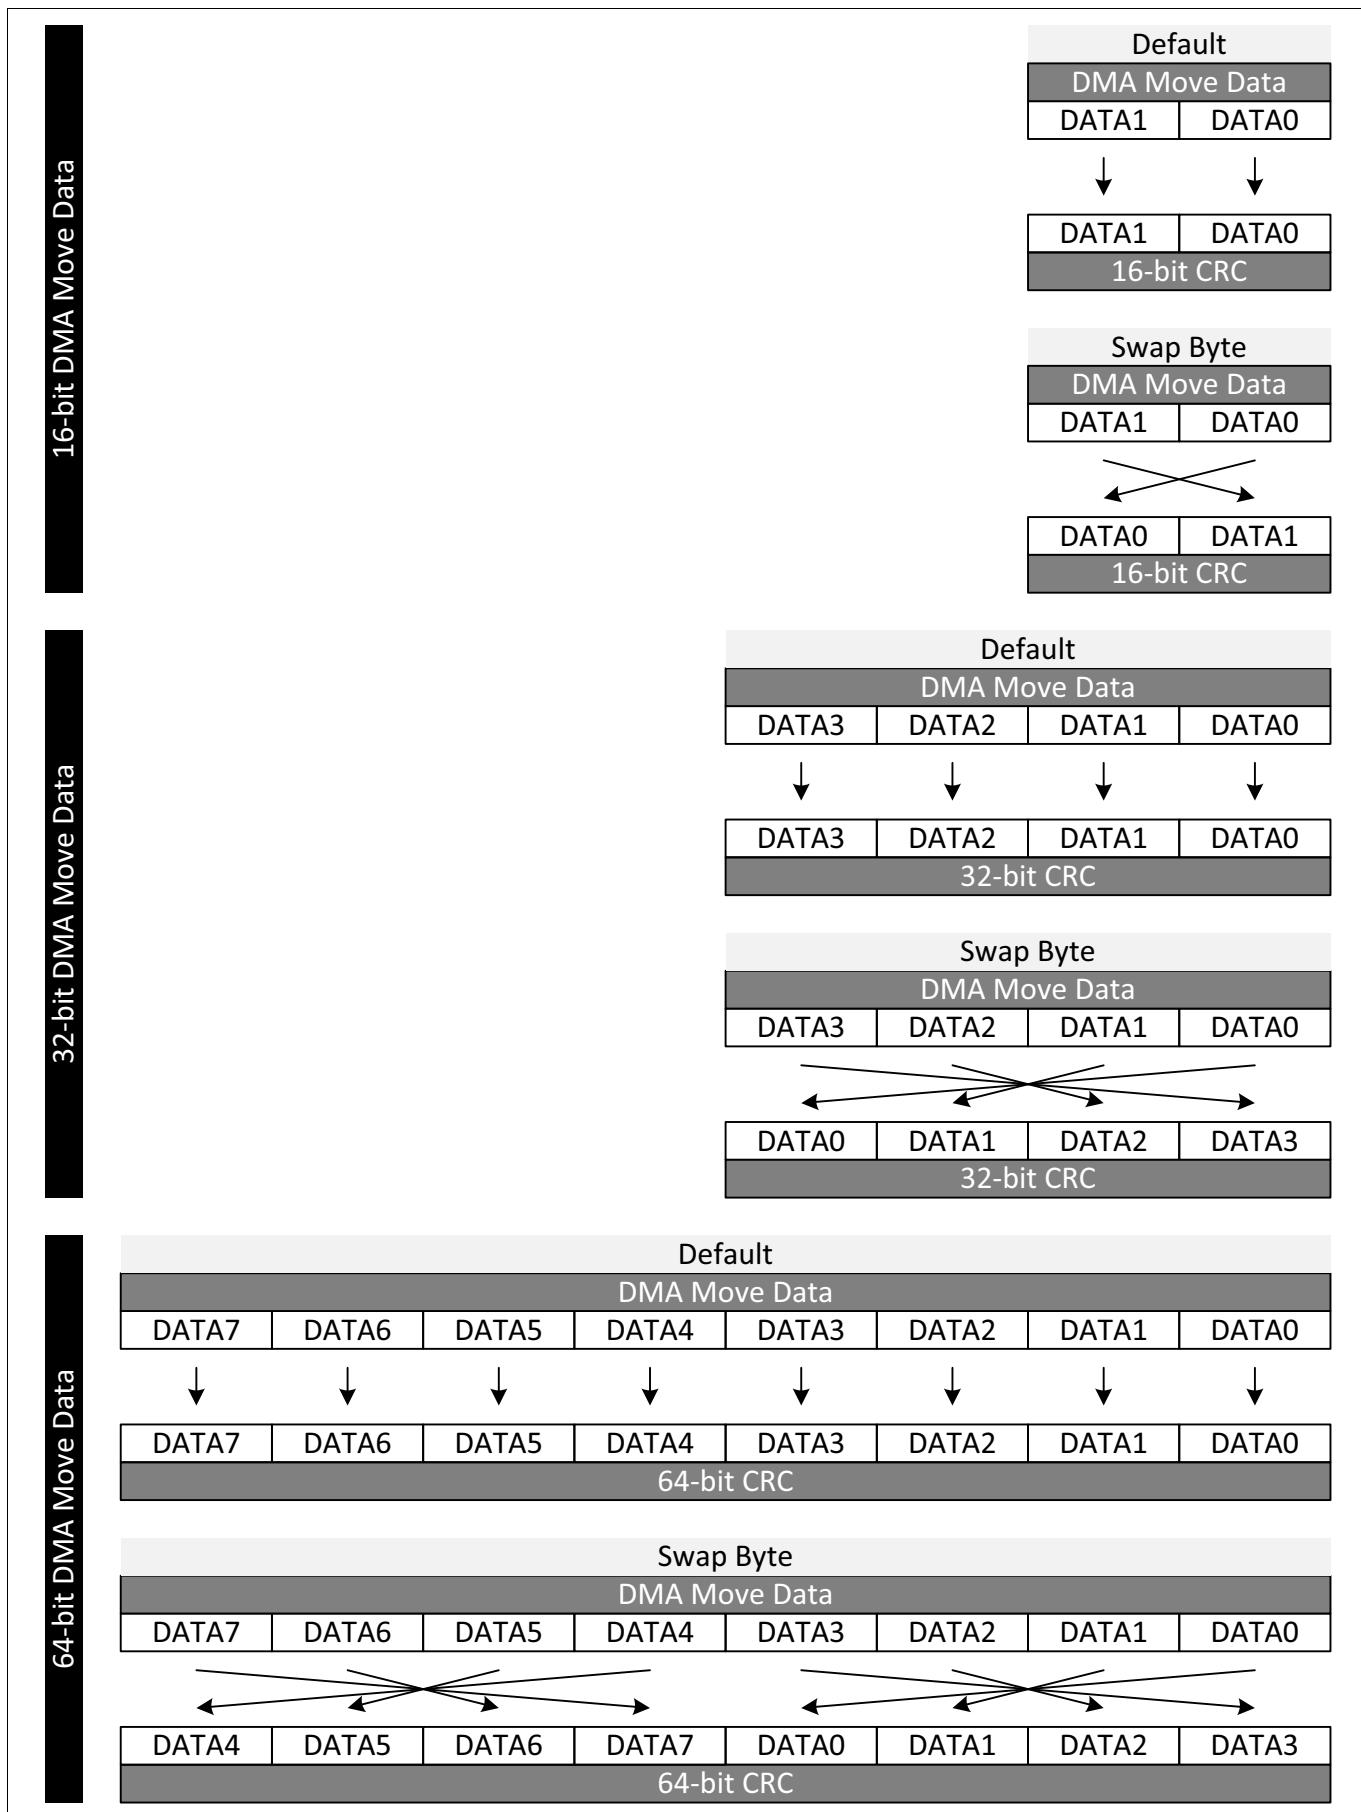

Figure 220 DMA Data Checksum - Swap Byte Order

## Direct Memory Access (DMA)

### 18.3.4.11 DMARAM Initialization

On the assertion of an application reset, the DMA shall initialize all DMARAM data to all zeros to prevent the triggering of DMARAM data integrity errors in the application.

### 18.3.5 Move Engine

Any ME shall service a DMA request from any DMA channel. As soon as a DMA channel wins arbitration, the TCS is copied from the DMARAM to the ME active channel registers and the DMA request is serviced. The ME requests the required buses and loads or stores data according to the TCS parameters of the active DMA channel. The ME is able to wait if the source or destination target is not available.

The processing of a DMA transfer (composed of several DMA moves) by the ME cannot be interrupted and is always completed. A DMA channel interrupt, reset, halt request or debug suspend only becomes active when the current DMA transfer is complete. Error conditions are reported. On completion of a DMA transaction or when a DMA channel loses channel arbitration the ME shall write the TCS back to the DMARAM.

#### 18.3.5.1 ME Read Buffer

The ME stores the DMA read move data in eight 32-bit read registers. If a DMA channel is configured for 8-bit, 16-bit, 32-bit, 64-bit or 128-bit channel data width and a DMA read move is to a cached address<sup>1)</sup>, the ME shall translate the read access to the on chip bus into a BTR4 access to a 32-byte aligned address. The ME stores the DMA read move data in the eight ME read registers together with the 32-byte aligned address to function as a ME read buffer as follows:

- **Hit**, if the 32-byte aligned address of the next DMA read move matches the 32-byte aligned address stored in the ME read buffer then the DMA read move data is read from the ME read buffer. No read access to the on chip bus occurs.
- **Miss**, if the 32-byte aligned address of the next DMA read move does not match the 32-byte aligned address stored in the ME read buffer then the ME invalidates the contents of the ME buffer. The ME executes the DMA read move by performing a read access to the on chip bus.

The ME invalidates the ME read buffer at the start of a DMA transfer.

##### 18.3.5.1.1 DMA Address Checksum

If a DMA read move is to a cached address, then the ME shall calculate the **DMA Address Checksum** using the 32-byte aligned address source address.

#### 18.3.5.2 ME Error Conditions

The ME reports TCS and source/destination error status. In the case of multiple errors, the error bits are set according to the error conditions (i.e. more than one error flag may be set). For all **ME Error Conditions**, the DMA shall perform the following actions:

- The ME shall record the number of the DMA channel in the ME last error channel bit field ERRSR.LEC.
- If the DMA channel is enabled for DMA channel hardware request then DMA channel TSR.HTRE is cleared.

#### DMARAM Integrity Error

When a DMA channel wins arbitration, a ME accesses the DMARAM to read the TCS. If an ECC error is detected, the ME shall set the error flag ERRSRm.RAMER. The DMA transaction shall not take place.

1) Segments 8 and 9 (see MEMMAP for details).

## Direct Memory Access (DMA)

### Source and Destination Errors

**SER** and **DER** include access protection errors and unsupported types of bus transaction.

- ME SER flag ERRSR.SER indicates an error occurred during a DMA read move from a source address.
  - ME DER error flag ERRSR.DER indicates an error occurred during a DMA write move to a destination address.
- If a SER or DER is reported then the ME completes the DMA transaction. If a SER is reported during a DMA read move then the DMA write move is not executed, but the destination address is updated.
- The ME bus error flag ERRSR.SPBER indicates an SPB bus error occurred during a DMA move.
  - The ME bus error flag ERRSR.SRIER indicates an SRI bus error occurred during a DMA move.

### Linked List Operation TCS Load Error

During DMALL, ACCL, SAFLL and CONLL operations if an error is reported during the loading of the next TCS from the on chip bus, the ME shall set the ME error flag ERRSR.DLLER. The linked list operation shall be aborted and the DMA channel transaction request state bit TSR.CH bit cleared.

### SAFLL DMA Address Checksum Error

The ME compares the **DMA Address Checksum** calculated by the current DMA transaction against the expected **DMA Address Checksum** stored in the next TCS. If the checksums do not match then the ME shall set the ME error flag ERRSR.SLLER.

### 18.3.5.3 Error Interrupt Service Request

#### 18.3.5.3.1 DMARAM Integrity Error Interrupt Service Request

A **RAMER** indicates that the ME detected a DMARAM integrity error:

- A RAMER is indicated by the ME error status flag ERRSRm.RAMER
- The DMA shall trigger a **DMA RP Error Interrupt Service Request**
- If software sets CLREm.CRAMER, the DMA shall clear error status flag ERRSRm.RAMER

#### 18.3.5.3.2 Source and Destination Error Interrupt Service Request

The ME shall detect the following error conditions (see [Figure 221](#)):

- A **SER** indicates a bus error occurred during a DMA read move from a source address.
  - A SER is indicated by the ME error status flag ERRSRm.SER
  - If EERm.ESER is set, the DMA shall trigger a **DMA RP Error Interrupt Service Request**.
  - If software sets CLREm.CSER, the DMA shall clear error status flag ERRSRm.SER
- A **DER** indicates a bus error that occurred during a DMA write move to a destination address.
  - A DER is indicated by the ME error status flag ERRSRm.DER
  - If EERm.EDER is set, the DMA shall trigger a **DMA RP Error Interrupt Service Request**.
  - If software sets CLREm.CDER, the DMA shall clear error status flag ERRSRm.DER

## Direct Memory Access (DMA)

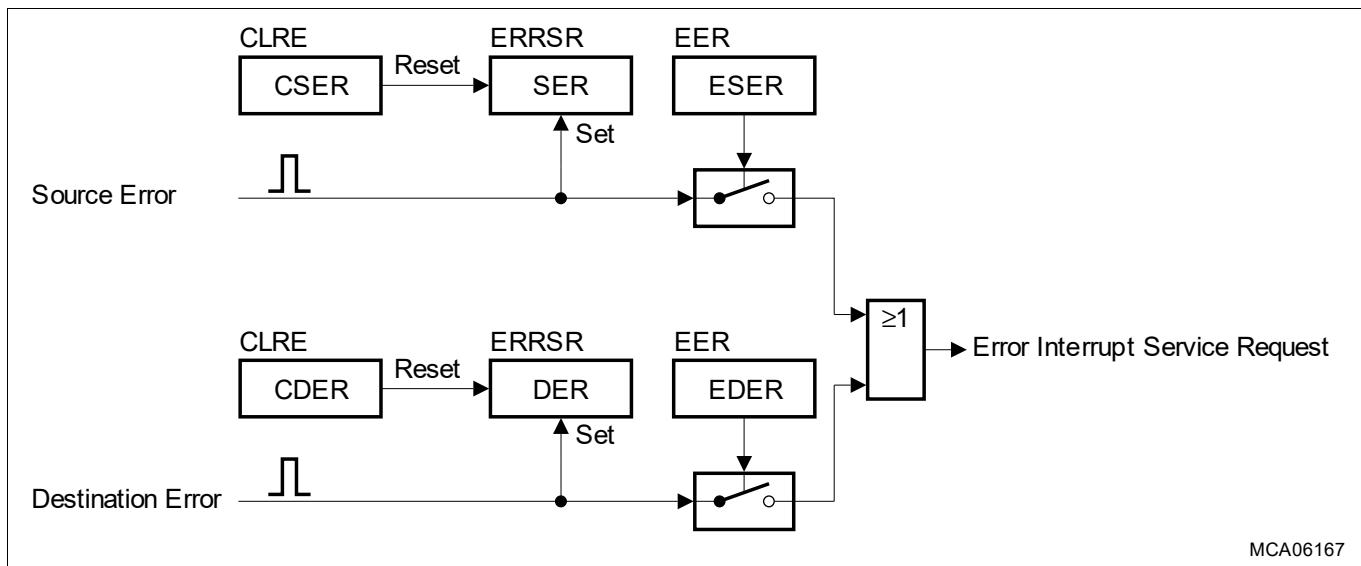

Figure 221 Source and Destination Error Interrupt Service Request

### 18.3.5.3.3 Linked List Operation TCS Error Interrupt Service Request

A **DLLER** indicates the ME detects an error when loading the next TCS from the on chip bus.

- A DLLER is indicated by the ME error status flag ERRSRm.DLLER
- The DMA shall trigger a **DMA RP Error Interrupt Service Request**.
- If software sets CLREm.CDLLER, the DMA shall clear error status flag ERRSRm.DLLER

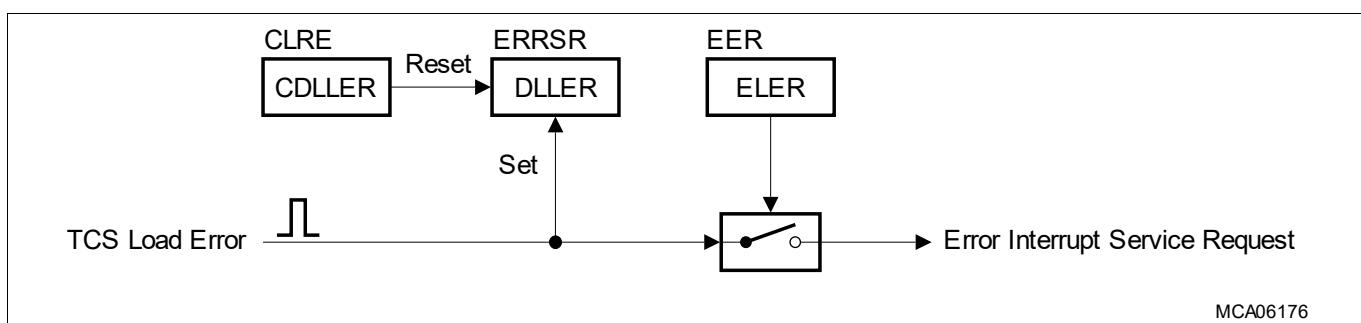

Figure 222 Linked List Operation TCS Error Interrupt Service Request

### 18.3.5.3.4 SAFLL DMA Address Checksum Error Interrupt Service Request

A **SLLER** indicates the ME detected a difference between the calculated and expected **DMA Address Checksum**.

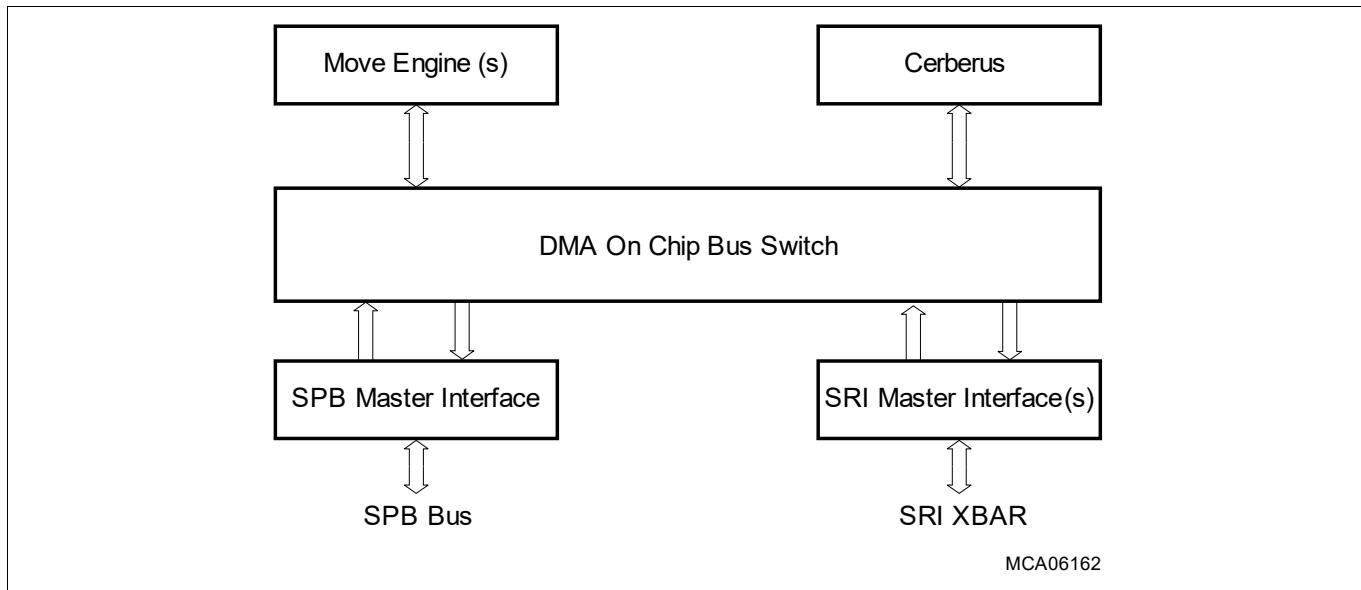

- A SLLER is indicated by the ME error status flag ERRSRm.SLLER
- The DMA shall trigger a **DMA RP Error Interrupt Service Request**.
- If software sets CLREm.CSLLER, the DMA shall clear error status flag ERRSRm.SLLER

## 18.3.6 DMA On Chip Bus

### 18.3.6.1 DMA On Chip Bus Switch

The DMA on chip bus switch (at [Figure 223](#)) arbitrates between each on chip bus request from the ME and Cerberus. Address routing across the whole memory map directs a request to an on chip bus master interface.

## Direct Memory Access (DMA)

**Figure 223 DMA On Chip Bus Switch**

### 18.3.6.1.1 SRI Master Interfaces

For production devices the DMA shall instance one SRI master interface (MIF0). For emulation devices the DMA may instance additional SRI master interfaces (MIF1 and MIF2)<sup>1)</sup> to be used as follows:

- DMA moves to EMEM Memory Banks 0 and 2 shall be routed through SRI master interface MIF1.
- DMA moves to EMEM Memory Banks 1 and 3 shall be routed through SRI master interface MIF2.

### 18.3.6.1.2 DMA On Chip Bus Switch Arbitration

If a ME and Cerberus request collide, the DMA on chip bus switch priorities (at **Table 580**) determine arbitration.

**Table 580 DMA On Chip Bus Switch Priorities**

Priority	Agent Requests	Comment
Highest	Cerberus to On Chip Bus High Priority.	Priority selection by software in Cerberus.
	ME write	For concurrent requests, the highest DMA channel wins.
	ME read	For concurrent requests, the highest DMA channel wins.
Lowest	Cerberus to On Chip Bus Low Priority.	Priority selection by software in Cerberus.

The on chip bus supports pipelining. High and low priority ME0, ME1 and Cerberus requests may be pipelined.

### 18.3.6.2 On Chip Bus Master Interfaces

The DMA instances on chip bus master interfaces to the SPB Bus and to the SRI Bus.

#### The DMA SPB master interface supports

- Single data read and write transactions (8-bit, 16-bit, 32-bit).
- Generation of interleaved FPI transactions from different access requesters (ME and Cerberus).
- De-assertion of request after retry in order to prevent bus blocking.

1) See MEMMAP and On-Chip System Connectivity for details.

## Direct Memory Access (DMA)

- Out of order transactions from different sources in order to avoid side effects (blocking) between the different access requesters (ME and Cerberus).

### The DMA SRI master interface supports

- Single data read and write transactions (8-bit, 16-bit, 32-bit, 64-bit)<sup>1)</sup>.
- Block transfer read and write transactions (128-bit, 256-bit)<sup>2)</sup>.
- Generation of interleaved SRI transactions from different access requesters (ME and Cerberus).

### Read Modify Write (RMW) Support

The DMA does not support RMW accesses to the on chip buses.

#### 18.3.6.3 SRI Alarm

The SRI bus protocol supports the reliable delivery of data between sources and destinations by extending the protocol to include ECC protection. During a DMA read move a ME checks the integrity of data received from SRI bus sources. A ME stores the DMA move data with ECC protection in the ME registers. During a DMA write move a ME generates ECC information compliant with the SRI bus protocol for write accesses to SRI destinations. A ME shall check the data integrity of DMA move data at the following locations:

- During a DMA read move the ME checks the integrity of data received from SRI source addresses.
- During a DMA write move the ME checks the integrity of data stored in the ME read register(s).

If a ME detects an ECC error then the DMA shall trigger an **SRI Alarm** to the SMU.

### System Peripheral Bus

DMA read move data received from an SPB source is not ECC protected. A ME shall generate ECC protection before the ME stores the data and ECC in the ME read register(s).

### Data Integrity Testing

Software may trigger an **SRI Alarm**. The CPU (CPUx\_SEGEN.ADFLIP = 01<sub>B</sub> and CPUx\_SEGEN.ADTYPE = 10<sub>B</sub>) may be used to generate an ECC error condition in a CPU slave interface used as a DMA read move source. When the data passes through the DMA it will generate an ECC error condition.

#### 18.3.7 Power Modes

The DMA disable status bit (DMA\_CLC.DISS) reports the state of the internal DMA clock signal ( $f_{DMA}$ ).

After the assertion of an application reset, the DMA is enabled (DMA\_CLC.DISS = 0<sub>B</sub>) i.e.  $f_{DMA}$  is enabled.

##### 18.3.7.1 Sleep Mode

The DMA shall enter **Sleep Mode** as follows:

- If the sleep mode enable control bit is enabled (DMA\_CLC.EDIS = 0<sub>B</sub>) AND the DMA sleep control is activated, the DMA shall enter **Sleep Mode** when the ME(s) have completed any pending DMA transfers.
- If software writes a DMA Disable Request (DMA\_CLC.DISR = 1<sub>B</sub>), the DMA shall enter **Sleep Mode** when the ME(s) have completed any pending DMA transfers.

If the DMA is in **Sleep Mode** (DMA\_CLC.DISS = 1<sub>B</sub>):

- The DMA shall disable  $f_{DMA}$  to minimize DMA power consumption.

1) 64-bit DMA move supported for DMA read move from SRI source to DMA write move to SRI destination.

2) Block transfer DMA move supported for DMA read move from SRI source to DMA write move to SRI destination.

## Direct Memory Access (DMA)

- DMA SFRs
    - If the DMA is in **Sleep Mode** AND software writes to DMA\_CLC, the DMA shall update DMA\_CLC.
    - If the DMA is in **Sleep Mode** AND software writes to other DMA SFRs, the DMA shall return a bus error.
    - If the DMA is in **Sleep Mode** AND software reads a DMA SFR, the DMA shall complete the read access.
  - DMARAM
    - If the DMA is in **Sleep Mode** AND software writes the DMARAM, the DMA shall return a bus error.
    - If the DMA is in **Sleep Mode** AND software reads the DMARAM, the DMA shall complete the read access.
- If the DMA sleep control is de-activated AND software clears the DMA disable request (DMA\_CLC.DISR = 0<sub>B</sub>):
- The DMA shall enable f<sub>DMA</sub>.
  - The DMA shall resume the servicing of DMA requests.

## Direct Memory Access (DMA)

### 18.4 Register

The DMA registers are accessed through the DMA slave interface.

**Table 581 Register Address Space - DMA**

Module	Base Address	End Address	Note

### 18.4.1 Safety Flip-Flops

Safety flip-flops are special flip-flops that implement a hardware mechanism capable to detect single event effects that may lead to single event upsets (bit flip). The configuration and control registers that are implemented with safety flip-flops are:

- TSRc.CH

## Direct Memory Access (DMA)

### 18.4.2 Register

#### DMA Clock Control Register

The Clock Control Register controls the internal  $f_{\text{DMA}}$  clock signal and sleep mode in order to control the power consumption. After the application of a reset, the DMA is enabled.

CLC

DMA Clock Control Register																(0000 <sub>H</sub> )				
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16					
0																r				
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	0				
r																rw	r	rh	rw	

Field	Bits	Type	Description
<b>DISR</b>	0	rw	<b>Module Disable Request Bit</b> Used for enable/disable control of the DMA $0_B$ DMA enable is requested. $1_B$ DMA disable is requested.
<b>DISS</b>	1	rh	<b>Module Disable Status Bit</b> Bit indicates the current status of the DMA $0_B$ DMA is enabled. $1_B$ DMA is disabled.
<b>EDIS</b>	3	rw	<b>Sleep Mode Enable Control</b> Used for DMA sleep mode control. $0_B$ Sleep control enabled. DMA may enter sleep mode. $1_B$ Sleep control disabled. DMA shall not enter sleep mode.
<b>0</b>	2, 31:4	r	<b>Reserved</b> Read as 0; must be written with 0.

#### DMA Identification Register

DMA Identification Register																(0008 <sub>H</sub> )			
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	MOD_NUMBER			
r

r																MOD_REV			

## Direct Memory Access (DMA)

Field	Bits	Type	Description
<b>MOD_REV</b>	7:0	r	<b>Module Revision Number</b> This bit field defines the module revision number.
<b>MOD_TYPE</b>	15:8	r	<b>Module Type</b> The bit field is set to C0 <sub>H</sub> which defines the module as a 32-bit module.
<b>MOD_NUMBE R</b>	31:16	r	<b>Module Number Value</b> This bit field defines a module identification number.

### DMA OCDS Trigger Set Select

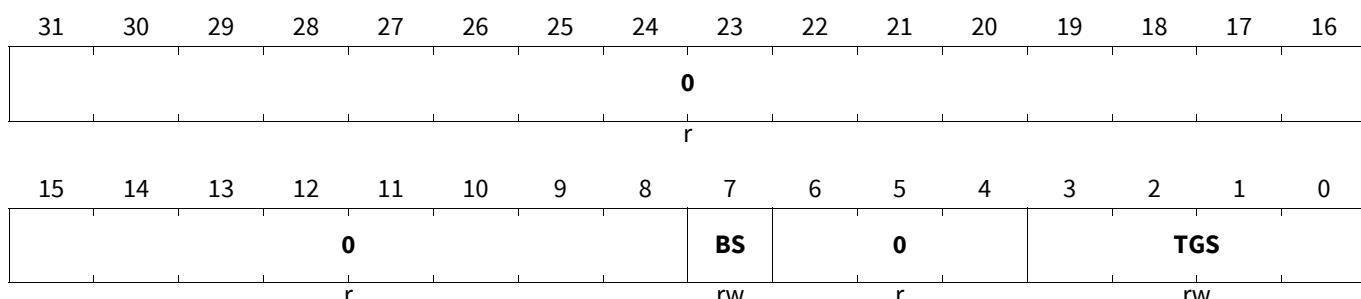

The OTSS register controls the selection of the OCDS Trigger Bus (OTGB).

The SCU controls the assertion of Power-on Reset to the OTSS register when OCDS is disabled or enabled. If OCDS is disabled then the OTSS register is reset by Power-on Reset else if OCDS is enabled then the OTSS register is not touched by Power-on Reset.

Write access requires OCDS to be enabled and Supervisor mode.

#### OTSS

**DMA OCDS Trigger Set Select** (1200<sub>H</sub>) Reset Value: [Table 583](#)

Field	Bits	Type	Description
<b>TGS</b>	3:0	rw	<b>Trigger Set for OTGB0 or OTGB1</b> 0 <sub>H</sub> No Trigger Set selected 1 <sub>H</sub> Trigger Set 1 2 <sub>H</sub> Trigger Set 2 3 <sub>H</sub> Reserved ... 7 <sub>H</sub> Reserved 8 <sub>H</sub> Trigger Set 8 9 <sub>H</sub> Trigger Set 9 A <sub>H</sub> Trigger Set 10 B <sub>H</sub> Trigger Set 11 C <sub>H</sub> Trigger Set 12 D <sub>H</sub> Trigger Set 13 E <sub>H</sub> Trigger Set 14 F <sub>H</sub> Trigger Set 15
<b>BS</b>	7	rw	<b>OTGB0 or OTGB1 Bus Select</b> 0 <sub>B</sub> Trigger Set is output on OTGB0 1 <sub>B</sub> Trigger Set is output on OTGB1

## Direct Memory Access (DMA)

Field	Bits	Type	Description
0	6:4, 31:8	r	<b>Reserved</b> Read as 0; must be written with 0.

## Direct Memory Access (DMA)

### RP r Access Enable Register 1

#### ACCENr1 (r=0-3)

##### RP r Access Enable Register 1

(0044<sub>H</sub>+r\*8)

Application Reset Value: 0000 0000<sub>H</sub>

Field	Bits	Type	Description
0	31:0	r	<b>Reserved</b> Read as 0; should be written with 0.

### 18.4.4 DMA Channel Registers

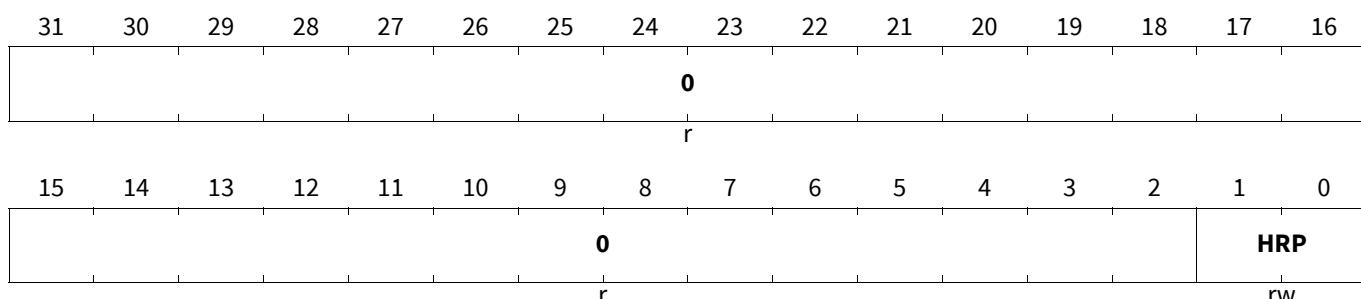

#### DMA Channel c Resource Partition Register

The Resource Partition Register assigns a DMA channel to a Resource Partition.

#### HRRc (c=000-127)

##### DMA Channel c Resource Partition Register (1800<sub>H</sub>+c\*4)

Application Reset Value: 0000 0000<sub>H</sub>

Field	Bits	Type	Description
HRP	1:0	rw	<b>DMA Channel Resource Partition</b> 00 <sub>B</sub> Resource Partition 0 (RP0). 01 <sub>B</sub> Resource Partition 1 (RP1). 10 <sub>B</sub> Resource Partition 2 (RP2). 11 <sub>B</sub> Resource Partition 3 (RP3).
0	31:2	r	<b>Reserved</b> Read as 0; must be written with 0.

#### DMA Channel c Suspend Enable Register

The Suspend Enable Register enables/disables soft suspend mode capability.

## Direct Memory Access (DMA)

### SUSENRc (c=000-127)

#### DMA Channel c Suspend Enable Register (1A00<sub>H</sub>+c\*4)

Reset Value: [Table 584](#)

Reset Type	Reset Value	Note
PowerOn Reset	0000 0000 <sub>H</sub>	
Debug Reset	0000 0000 <sub>H</sub>	

## DMA Channel c Transaction State Register

If an application reset is asserted, the DMA shall set DMA channel reset to all DMA channels. As soon as a DMA channel has entered the reset state, the DMA shall clear the DMA channel bit.

## TSRc (c=000-127)

**DMA Channel c Transaction State Register (1E00<sub>H</sub>+c\*4) Application Reset Value: 0000 0000<sub>H</sub>**

Field	Bits	Type	Description
RST	0	rwh	<b>DMA Channel Reset</b> The DMA channel reset bit is set by software (DMA channel TSR.RST = 1) and cleared by hardware when the DMA channel has been reset.  $0_B$ After the application of a DMA channel reset, the DMA channel is in the DMA channel reset state. Software write to 0 has no effect. $1_B$ A DMA channel reset is pending. See Functional Description.

**Direct Memory Access (DMA)**

Field	Bits	Type	Description
<b>HTRE</b>	1	rh	<p><b>DMA Channel Hardware Request Enable</b></p> <p>Note: See Functional Description for enable and disable. When a DMA channel is configured for single mode, HTRE is reset when ME CHSR.TCOUNT is decremented and ME CHSR.TCOUNT = 0. When a DMA channel error is reported or a pattern match is detected, DMA channel HTRE is reset.</p> <p>0<sub>B</sub> DMA hardware request is disabled for DMA channel. 1<sub>B</sub> DMA hardware request is enabled for DMA channel.</p>
<b>TRL</b>	2	rh	<p><b>DMA Channel Transaction/Transfer Request Lost</b></p> <p>This bit is reset by software clearing TRL (writing DMA channel TSR.CTL = 1) or resetting the DMA channel (writing DMA channel TSR.RST = 1).</p> <p>0<sub>B</sub> No TRL event has been detected for DMA channel. 1<sub>B</sub> TRL event has been detected for DMA channel.</p>
<b>CH</b>	3	rh	<p><b>DMA Channel Transaction Request State</b></p> <p>CH is reset when a pattern match is detected.</p> <p>0<sub>B</sub> No DMA request is pending for DMA channel. 1<sub>B</sub> DMA request is pending for DMA channel.</p>
<b>ETRL</b>	4	rw	<p><b>Enable DMA Channel Transaction/Transfer Request Lost Interrupt</b></p> <p>DMA channel control bit to enable the generation of an error interrupt service request when DMA channel TSR.TRL is set.</p> <p>0<sub>B</sub> Interrupt generation for DMA channel TRL event is disabled. 1<sub>B</sub> Interrupt generation for DMA channel TRL event is enabled.</p>
<b>HLTREQ</b>	8	rwh	<p><b>DMA Channel Halt Request</b></p> <p>The DMA channel halt request bit is set by software (writing DMA channel TSR.HLTREQ = 1) and cleared by software (writing DMA channel TSR.HLTCLR = 1).</p> <p>0<sub>B</sub> No action. 1<sub>B</sub> Halt request.</p>
<b>HLTACK</b>	9	rh	<p><b>DMA Channel Halt Acknowledge</b></p> <p>0<sub>B</sub> DMA channel is not halted. 1<sub>B</sub> DMA channel is halted.</p>
<b>ECH</b>	16	w	<p><b>Enable DMA Channel Hardware Transaction Request</b></p> <p>See Functional Description. Reading this bit returns a 0.</p>
<b>DCH</b>	17	w	<p><b>Disable DMA Channel Hardware Transaction Request</b></p> <p>See Functional Description. Reading this bit returns a 0.</p>
<b>CTL</b>	18	w	<p><b>Clear DMA Channel Transaction/Transfer Request Lost</b></p> <p>Software clear of the DMA channel TRL status flag.</p> <p>Reading this bit returns a 0.</p> <p>0<sub>B</sub> No action. 1<sub>B</sub> Clear DMA channel TRL flag (TSR.TRL).</p>

## Direct Memory Access (DMA)

Field	Bits	Type	Description
HLTCLR	24	w	<b>Clear DMA Channel Halt Request and Acknowledge</b> Reading this bit returns a 0. 0 <sub>B</sub> No action. 1 <sub>B</sub> Clear DMA channel halt request (TSR.HLTREQ) and halt acknowledge (TSR.HLTACK).
0	7:5, 15:10, 23:19, 31:25	r	<b>Reserved</b> Read as 0; must be written with 0.

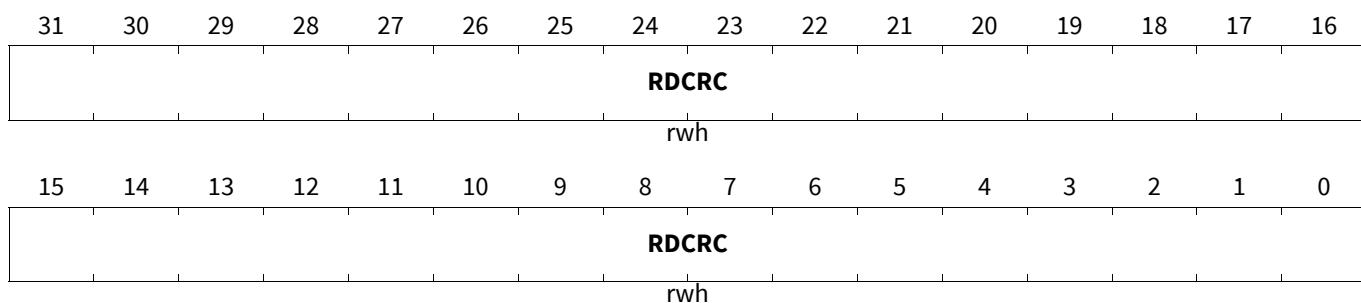

### 18.4.5 DMARAM Channel Registers

#### DMARAM Channel c Read Data CRC Register

RDCRCR<sub>c</sub> (c=000-127)

DMARAM Channel c Read Data CRC Register ( $2000_H + c * 20_H$ )

Application Reset Value: 0000 0000<sub>H</sub>

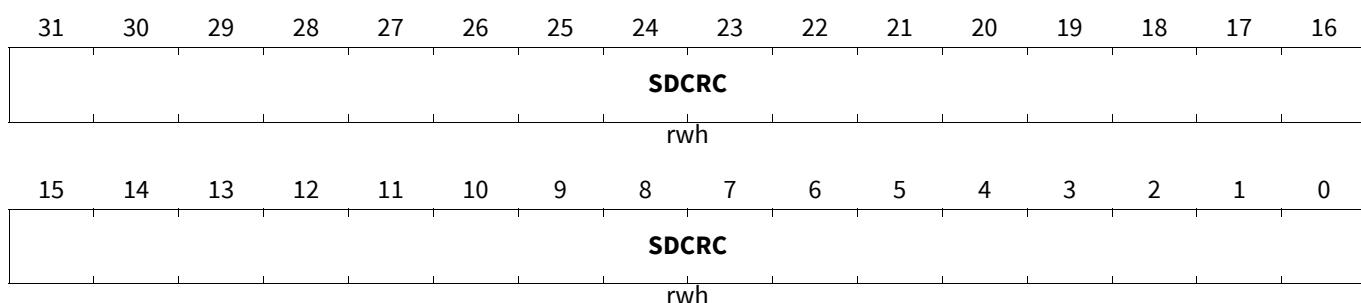

Field	Bits	Type	Description
RDCRC	31:0	rwh	<b>Read Data CRC</b> Checksum calculated for DMA read move data.

#### DMARAM Channel c Source and Destination Address CRC Register

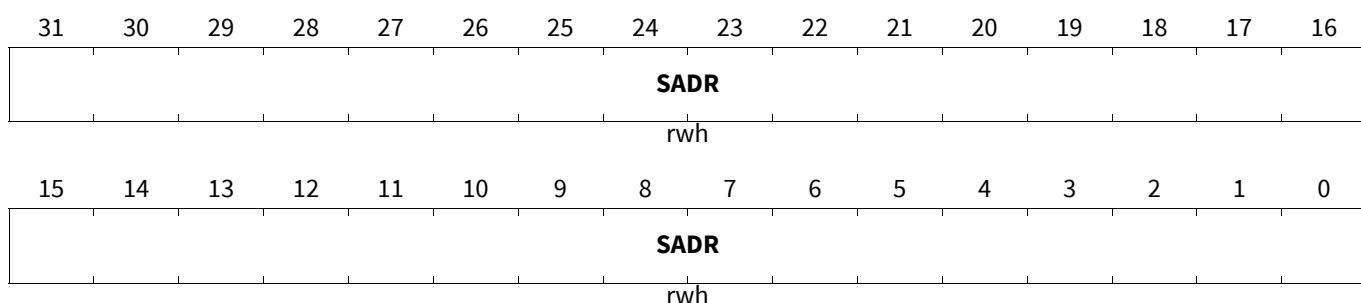

SDCRCR<sub>c</sub> (c=000-127)

DMARAM Channel c Source and Destination Address CRC Register( $2004_H + c * 20_H$ ) Application Reset Value:  
0000 0000<sub>H</sub>

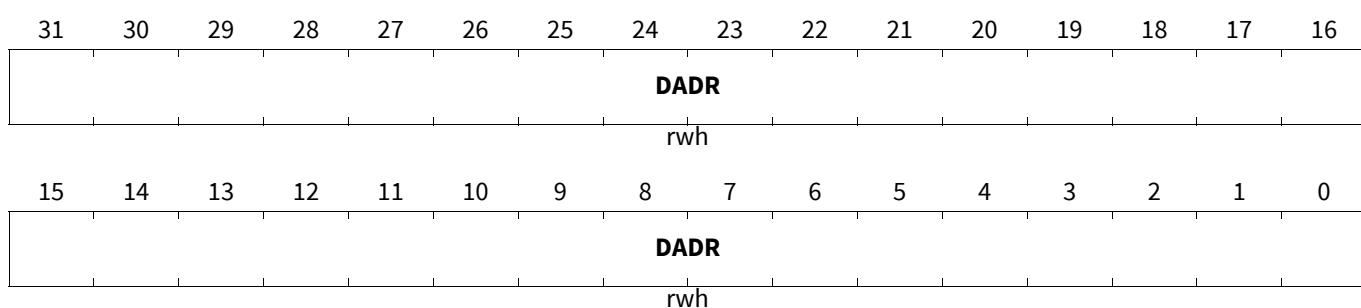

**Direct Memory Access (DMA)**

Field	Bits	Type	Description
<b>SDCRC</b>	31:0	rwh	<b>Source and Destination Address CRC</b> Checksum calculated for DMA move source and destination addresses.

**DMARAM Channel c Source Address Register****SADRC (c=000-127)****DMARAM Channel c Source Address Register ( $2008_H + c * 20_H$ )****Application Reset Value: 0000 0000<sub>H</sub>**

Field	Bits	Type	Description
<b>SADR</b>	31:0	rwh	<b>Source Address</b> 32-bit source address.

**DMARAM Channel c Destination Address Register****DADRC (c=000-127)****DMARAM Channel c Destination Address Register( $200C_H + c * 20_H$ )****Application Reset Value: 0000 0000<sub>H</sub>**

Field	Bits	Type	Description
<b>DADR</b>	31:0	rwh	<b>Destination Address</b> 32-bit destination address.

**Direct Memory Access (DMA)****DMARAM Channel c Address and Interrupt Control Register****ADICRc (c=000-127)**
**DMARAM Channel c Address and Interrupt Control Register(2010<sub>H</sub>+c\*20<sub>H</sub>) Application Reset Value: 0000 0000<sub>H</sub>**

<b>FROZEN</b>	23	rwh	<p><b>DMA Double Buffering Frozen Buffer</b></p> <p>If a DMA channel is configured for double buffering operation, the FROZEN bit indicates that one of the buffers is frozen and available for processing by a cyclic software task.</p> <p><i>Note:</i> <i>FROZEN bit shall only be set by the DMA and shall only be cleared by software.</i></p> <p><math>0_B</math> Buffer is not frozen.</p> <p><math>1_B</math> Buffer is frozen.</p>

**Direct Memory Access (DMA)**

Field	Bits	Type	Description
<b>SWB</b>	24	w	<p><b>DMA Double Buffering Switch Buffer</b>  When DMA double buffering is configured, the control bit is used to redirect data from one buffer to the other buffer.</p> <p><i>Note:</i> If a DMALL, ACCLL, SAFLL or CONLL operation is configured then SWB shall be 0<sub>B</sub>.</p> <p>0<sub>B</sub> No action.  1<sub>B</sub> Switch from buffer.</p>
<b>CWRP</b>	25	w	<p><b>Clear Wrap Buffer Interrupt</b>  Software clear of the DMA channel source and destination wrap buffer flags stored at CHCSR.WRPS and CHCSR.WRAPD. If the DMA channel is active in a ME then clear ME bit fields CHSR.WRPS and CHSR.WRAPD. Reading this bit returns a 0.</p> <p>0<sub>B</sub> No action.  1<sub>B</sub> Clear DMA channel bits CSR.WRPS and CSR.WRAPD.</p>
<b>CICH</b>	26	w	<p><b>Clear Interrupt for DMA Channel</b>  Software clear of the DMA channel flags stored at CHCSR.ICH and CHCSR.IPM. If the DMA channel is active in a ME then clear ME bit fields CHSR.ICH and CHSR.IPM. Reading this bit returns a 0.</p> <p>0<sub>B</sub> No action.  1<sub>B</sub> Clear DMA channel bits CSR.ICH and CSR.IPM.</p>
<b>SIT</b>	27	w	<p><b>Set Interrupt Trigger for DMA Channel</b>  Reading this bit returns a 0.</p> <p><i>Note:</i> If a DMALL, ACCLL, SAFLL or CONLL operation is configured then SIT must be 0<sub>B</sub>.</p> <p>0<sub>B</sub> No action.  1<sub>B</sub> DMA channel interrupt trigger will be activated.</p>
<b>SCH</b>	31	w	<p><b>Set Transaction Request</b>  Reading this bit returns a 0.</p> <p>0<sub>B</sub> No action.  1<sub>B</sub> DMA software request initiated for DMA channel. When SCH is set, DMA channel TSR.CH is set to indicate a DMA request is pending.</p>
<b>0</b>	14, 21:20, 30:28	r	<p><b>Reserved</b>  Read as 0; must be written with 0.</p>

## Direct Memory Access (DMA)

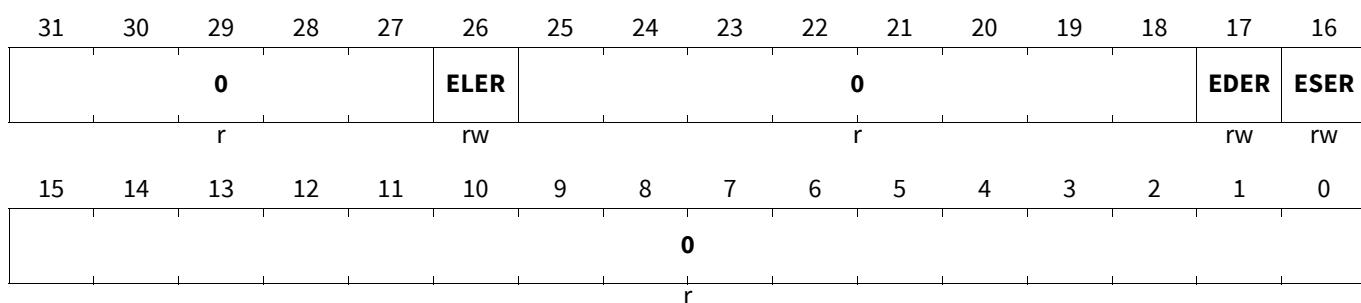

### 18.4.6 ME Registers

#### ME m Enable Error Register

The Enable Error Register enables an error interrupt service request for ME errors.

##### EER<sub>m</sub> (m=0-1)

**ME m Enable Error Register** **(0120<sub>H</sub>+m\*1000<sub>H</sub>)** **Application Reset Value: 0403 0000<sub>H</sub>**

Field	Bits	Type	Description
<b>ESER</b>	16	rw	<b>Enable ME Source Error</b> This bit enables the generation of a ME source error interrupt. $0_B$ ME source error interrupt is disabled. $1_B$ ME source error interrupt is enabled.
<b>EDER</b>	17	rw	<b>Enable ME Destination Error</b> This bit enables the generation of a ME destination error interrupt. $0_B$ ME destination error interrupt is disabled. $1_B$ ME destination error interrupt is enabled.
<b>ELER</b>	26	rw	<b>Enable ME DMA Linked List Error</b> This bit enables the generation of a ME DMA Linked List error interrupt. $0_B$ ME DMA Linked List error interrupt is disabled. $1_B$ ME DMA Linked List error interrupt is enabled.
<b>0</b>	15:0, 25:18, 31:27	r	<b>Reserved</b> Read as 0; must be written with 0.

#### ME m Error Status Register

The Error Status Register indicates if the DMA controller could not service a DMA request. It indicates that an SPB Bus access or an SRI Bus access has terminated with errors.

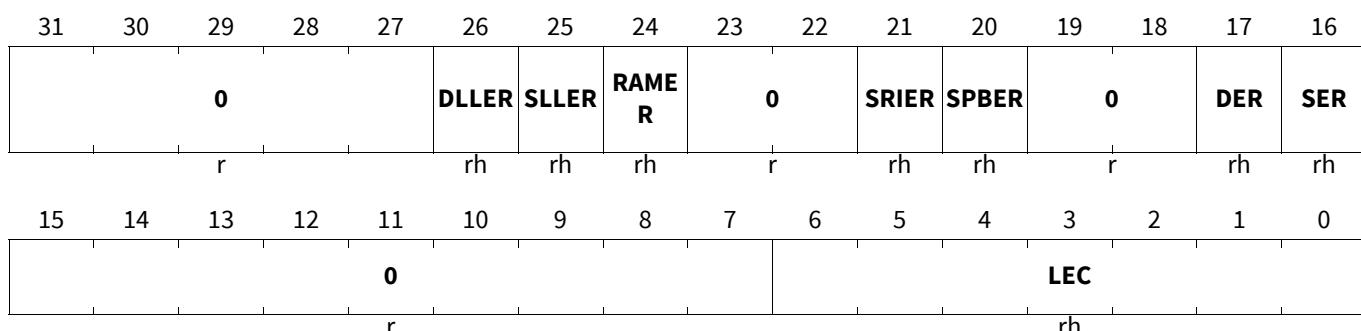

## Direct Memory Access (DMA)

### ERRSRm (m=0-1)

#### ME m Error Status Register

(0124<sub>H</sub>+m\*1000<sub>H</sub>)

Application Reset Value: 0000 0000<sub>H</sub>

Field	Bits	Type	Description
LEC	6:0	rh	<b>ME Last Error Channel</b> This bit field indicates the DMA channel number of the last DMA channel of ME generating an error i.e. RAM error DMA_ERRSRm.RAMER, Safe Linked List error DMA_ERRSRm.SLLER, DMA Linked List error DMA_ERRSRm.DLLER and all on chip bus errors.
SER	16	rh	<b>ME Source Error</b> This bit is set whenever a ME error occurred during a source (read) move of a DMA transfer, or a request could not be serviced due to the access protection. 0 <sub>B</sub> No ME source error has occurred. 1 <sub>B</sub> ME source error has occurred.
DER	17	rh	<b>ME Destination Error</b> This bit is set whenever a ME error occurred during a destination (write) move of a DMA transfer, or a request could not be serviced due to the access protection. 0 <sub>B</sub> No ME destination error has occurred. 1 <sub>B</sub> ME destination error has occurred.
SPBER	20	rh	<b>ME SPB Bus Error</b> This bit is set when a ME DMA Move that has been started by the DMA SPB master interface leads to an error on the SPB Bus. 0 <sub>B</sub> No error occurred. 1 <sub>B</sub> An error occurred on SPB Bus interface.
SRIER	21	rh	<b>ME SRI Bus Error</b> This bit is set when a ME DMA Move that has been started by the DMA SRI master interface leads to an error on the SRI Bus. 0 <sub>B</sub> No error occurred. 1 <sub>B</sub> An error occurred on SRI Bus interface.
RAMER	24	rh	<b>ME RAM Error</b> This bit is set whenever a ME error occurred during the loading of a TCS from the DMARAM to the ME channel registers. 0 <sub>B</sub> No error occurred. 1 <sub>B</sub> An error occurred during the load of a TCS.

## Direct Memory Access (DMA)

Field	Bits	Type	Description
<b>SLLER</b>	25	rh	<b>ME Safe Linked List Error</b> This bit is set when a ME error occurred during the comparison of a SDCRC checksums during a safe linked list. 0 <sub>B</sub> No error occurred. 1 <sub>B</sub> An error occurred during the SDCRC checksum comparison.
<b>DLLER</b>	26	rh	<b>ME DMA Linked List Error</b> This bit is set when a ME error occurred during a DMALL, ACPLL, SAFLL or CONLL operation when a new TCS is loaded from anywhere in memory to overwrite the current TCS stored in the DMARAM. 0 <sub>B</sub> No error occurred. 1 <sub>B</sub> An error occurred during the loading of a new TCS.
<b>0</b>	15:7, 19:18, 23:22, 31:27	r	<b>Reserved</b> Read as 0; must be written with 0.

### ME m Clear Error Register

The Clear Error Register contains bits to clear the corresponding ME error flags.

#### CLREm (m=0-1)

### ME m Channel Read Data CRC Register

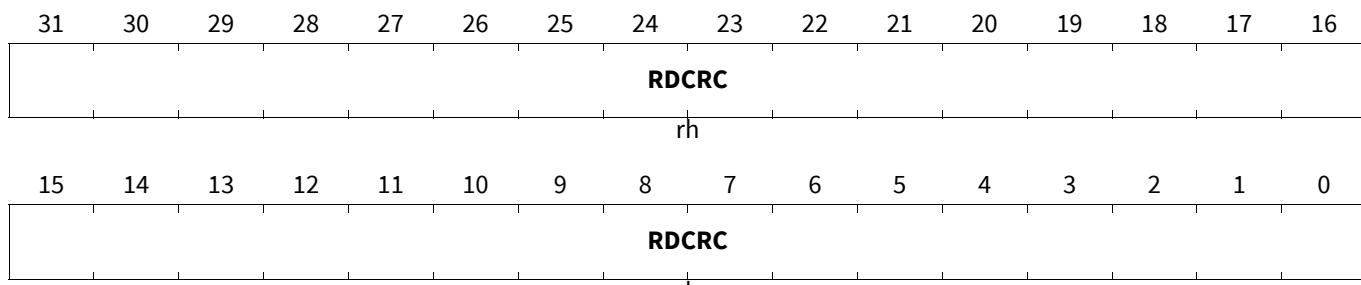

The read only DMA active channel Read Data CRC Register will store one polynomial calculation during each DMA read move provided that there is no retry or error condition flagged. In order to start a CRC32 sequence the MEmRDCRC must be initialized (e.g. written with  $00000000_H$  or with a desired start value) and an DMA transaction must be set up (start address, length, etc.).

## Direct Memory Access (DMA)

### MEmRDCRC (m=0-1)

**ME m Channel Read Data CRC Register (0180<sub>H</sub>+m\*1000<sub>H</sub>)**

**Application Reset Value: 0000 0000<sub>H</sub>**

### MEmSDCRC (m=0-1)

**ME m Channel Source and Destination Address CRC Register(0184<sub>H</sub>+m\*1000<sub>H</sub>)**

**Application Reset Value:**

**0000 0000<sub>H</sub>**

### ME m Channel Source and Destination Address CRC Register

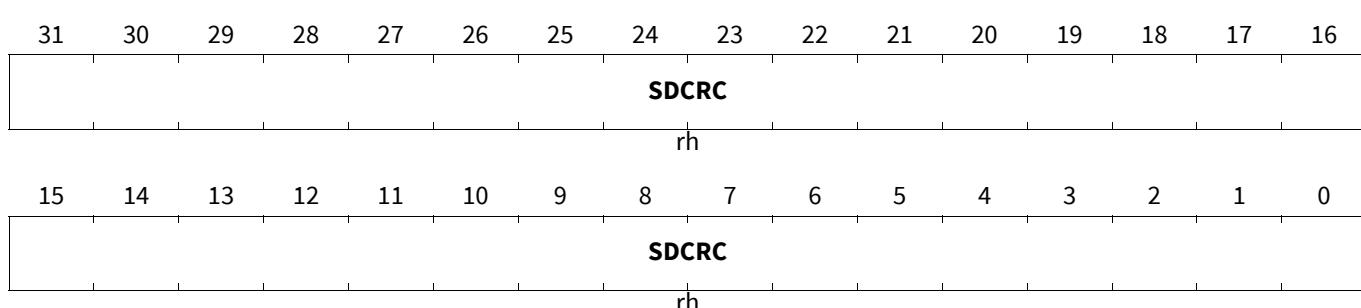

The read only DMA active channel Source and Destination Address CRC Register will store one polynomial calculation during each DMA read and each DMA write move provided there is no retry or error condition flagged.

### MEmSDCRC (m=0-1)

**ME m Channel Source and Destination Address CRC Register(0184<sub>H</sub>+m\*1000<sub>H</sub>)**

**Application Reset Value:**

**0000 0000<sub>H</sub>**

### ME m Channel Source Address Register

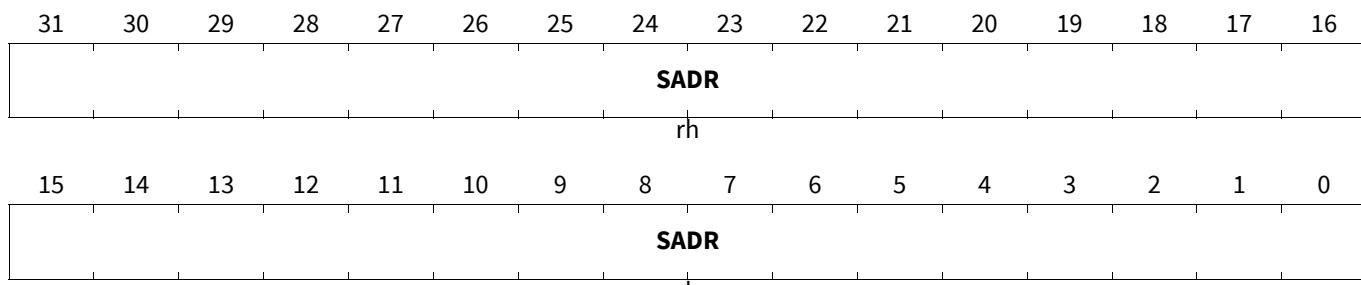

The read only DMA active channel Source Address Register holds the 32-bit source address. If a DMA channel is active, MEmSADR is updated continuously and shows the actual source address used for DMA read moves.

## Direct Memory Access (DMA)

### MEmSADR (m=0-1)

**ME m Channel Source Address Register (0188<sub>H</sub>+m\*1000<sub>H</sub>)**

**Application Reset Value: 0000 0000<sub>H</sub>**

Field	Bits	Type	Description
SADR	31:0	rh	<b>Source Address</b> Active DMA channel 32-bit source address used for DMA read moves.

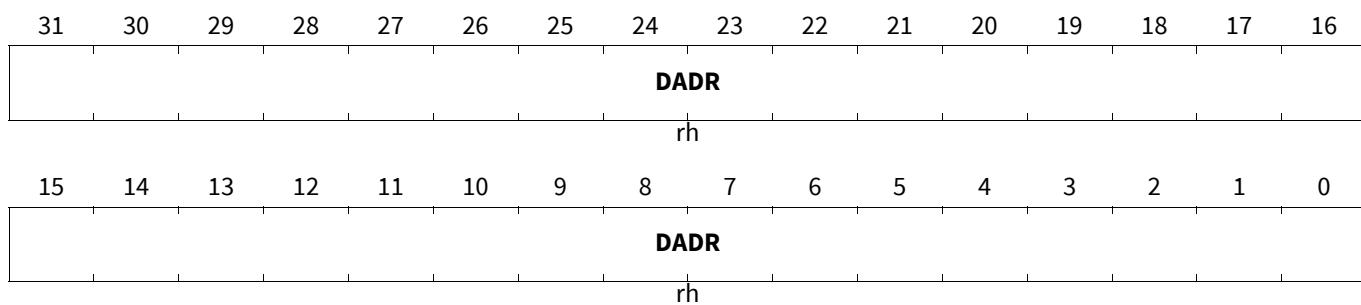

### ME m Channel Destination Address Register

The read only DMA active channel Destination Address Register holds the 32-bit destination address. If a DMA channel is active, MEmDADR is updated continuously and shows the actual destination address used for DMA write moves.

### MEmDADR (m=0-1)

**ME m Channel Destination Address Register(018C<sub>H</sub>+m\*1000<sub>H</sub>)**

**Application Reset Value: 0000 0000<sub>H</sub>**

Field	Bits	Type	Description
DADR	31:0	rh	<b>Destination Address</b> Active DMA channel 32-bit destination address used for DMA write moves.

### ME m Channel Address and Interrupt Control Register

The read only DMA active channel Address and Interrupt Control Register controls how source and destination addresses are updated after a DMA move. It determines whether or not a source or destination address register update is shadowed. The interrupt control bits enable the generation of DMA channel interrupt triggers.

## Direct Memory Access (DMA)

### MEmADICR (m=0-1)

BLKM	18:16	rh	<b>Block Mode</b> Active DMA channel Block Mode.
RROAT	19	rh	<b>Reset Request Only After Transaction</b> Active DMA channel Reset Request Only After Transaction.
CHMODE	20	rh	<b>Channel Operation Mode</b> Active DMA channel Channel Operation Mode.
CHDW	23:21	rh	<b>Channel Data Width</b> Active DMA channel DMA move Channel Data Width.
PATSEL	26:24	rh	<b>Pattern Select</b> Active DMA channel Pattern Select control.
SWAP	27	rh	<b>Swap Data CRC byte order</b> Active DMA channel swap data CRC byte order.
PRSEL	28	rh	<b>Peripheral Request Select</b> Active DMA channel Peripheral Request Select.
0	15:14, 31:29	r	<b>Reserved</b> Read as 0; must be written with 0.

### ME m Channel Shadow Address Register

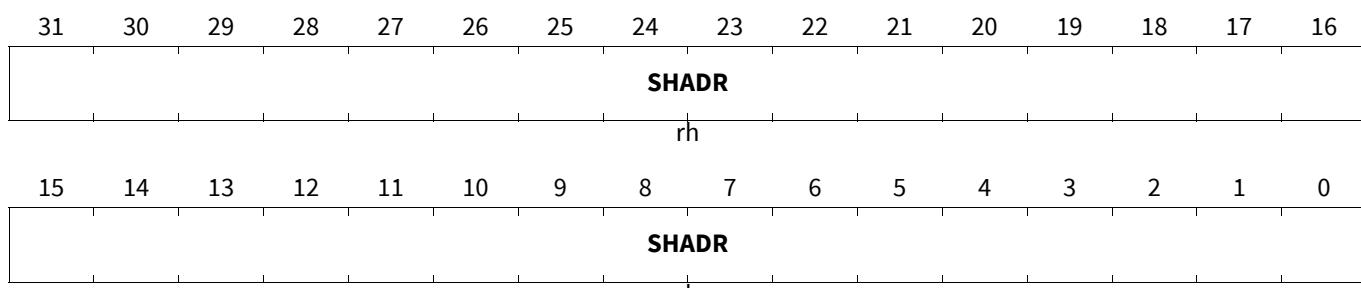

The read only DMA active channel Shadow Address Register holds the 32-bit shadow address.

## Direct Memory Access (DMA)

### MEMSHADR (m=0-1)

**ME m Channel Shadow Address Register (0198<sub>H</sub>+m\*1000<sub>H</sub>)**

**Application Reset Value: 0000 0000<sub>H</sub>**

Field	Bits	Type	Description
<b>SHADR</b>	31:0	rh	<b>Shadowed Address</b> This bit field holds the 32-bit shadow address of the active DMA channel. The function of the shadow address is set by the shadow control settings.

### ME m Channel Status Register

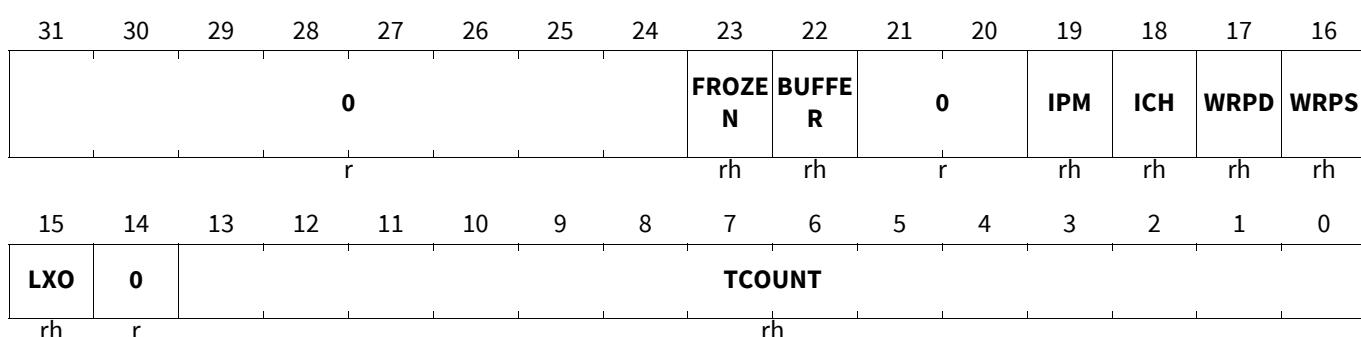

The read only DMA active channel Channel Status Register contains the current transfer count, pattern detection compare result and the status of traffic management interrupt triggers.

### MEMCHSR (m=0-1)

**ME m Channel Status Register**

(019C<sub>H</sub>+m\*1000<sub>H</sub>)

**Application Reset Value: 0000 0000<sub>H</sub>**

Field	Bits	Type	Description
<b>TCOUNT</b>	13:0	rh	<b>Transfer Count Status</b> Active DMA channel count of the number of DMA transfers. TCOUNT is loaded with the DMA channel value of CHCFGR.TREL when TSR.CH becomes set (and TCOUNT = 0). After each DMA transfer, TCOUNT is decremented by 1.
<b>LXO</b>	15	rh	<b>Old Value of Pattern Detection</b> Active DMA channel compare result of a pattern compare operation when 8-bit or 16-bit data width is selected.
<b>WRPS</b>	16	rh	<b>Wrap Source Buffer</b> Active DMA channel Wrap Source Buffer status bit.
<b>WRPD</b>	17	rh	<b>Wrap Destination Buffer</b> Active DMA channel Wrap Destination Buffer status bit.

**Direct Memory Access (DMA)**

Field	Bits	Type	Description
<b>ICH</b>	18	rh	<b>Interrupt from Channel</b> Active DMA channel detection of channel interrupt service request.
<b>IPM</b>	19	rh	<b>Pattern Detection from Channel</b> Active DMA channel detection of pattern match interrupt service request.
<b>BUFFER</b>	22	rh	<b>DMA Double Buffering Active Buffer</b> Active DMA channel DMA Double Buffering Active Buffer status bit. $0_B$ Buffer 0 read or filled by DMA. $1_B$ Buffer 1 read or filled by DMA.
<b>FROZEN</b>	23	rh	<b>DMA Double Buffering Frozen Buffer</b> Active DMA channel DMA Double Buffering Frozen Buffer status bit.
<b>0</b>	14, 21:20, 31:24	r	<b>Reserved</b> Read as 0; must be written with 0.

## Direct Memory Access (DMA)

### 18.5 Debug

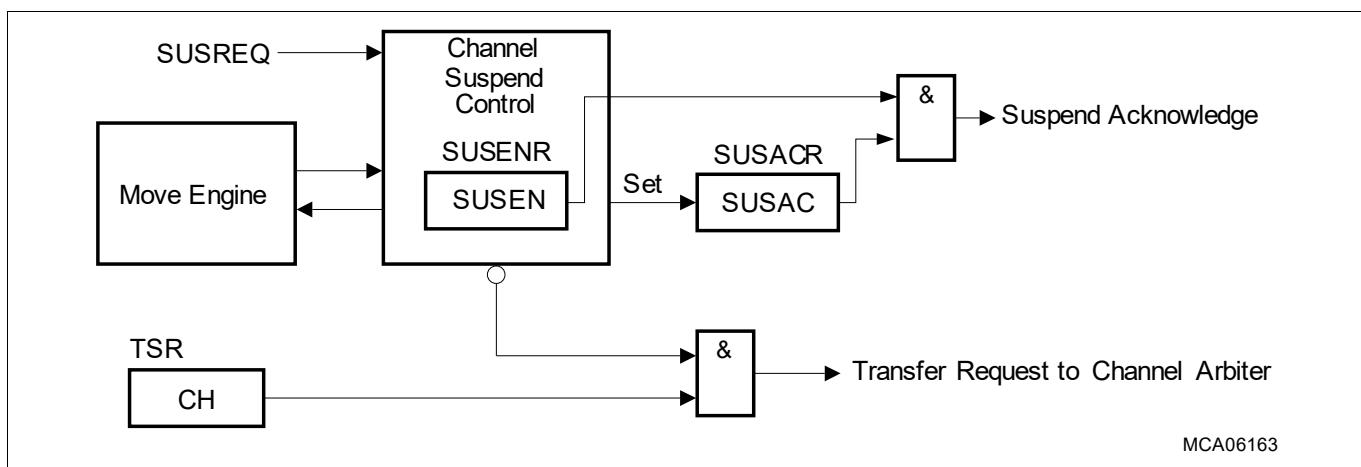

The DMA implements the following debug features:

#### 18.5.1 DMA Channel Suspend

Two DMA channel registers (at [Figure 224](#)) control and report the channel suspend operation:

- The Suspend Enable Register (SUSENR) enables and disables DMA channel soft suspend mode capability.
- The Suspend Acknowledge Register (SUSACR) indicates the DMA channel soft suspend status.

The On Chip Debug System (OCDS) is able to generate a DMA suspend request (SUSREQ). When the suspend request becomes active, the state of a DMA channel becomes frozen to ensure that the state of the DMA channels can be analyzed by reading the DMA channel register contents. If a DMA channel is active then the current DMA transfer is completed. The DMA signals the suspend mode status back to the OCDS via a suspend acknowledge.

**Figure 224 DMA Channel Suspend**

#### Entering Channel Suspend Mode

A DMA channel is configured for Suspend Mode when the DMA channel suspend enable bit in the Suspend Mode Enable Register SUSENR.SUSEN is set. When SUSREQ becomes active, for DMA channels enabled for [DMA Channel Suspend](#), the operation is as follows:

- **Idle State, Reset State, Halt State and Pending State:** the DMA channel suspend active status flag SUSACR.SUSAC is set and the DMA channel state is frozen.
- **Active State:** the DMA channel suspend active status flag SUSACR.SUSAC is set on completion of the current DMA transfer and the DMA channel state is frozen.

The DMA suspend acknowledge flag becomes active when all DMA channels that are enabled for [DMA Channel Suspend](#) have set their DMA channel suspend active status flag SUSACR.SUSAC. In [DMA Channel Suspend](#), the DMA channel contents may be modified. These modifications are taken into account for further DMA transfers or DMA transactions of the related DMA channel after [DMA Channel Suspend](#) has been left.

DMA channels that are disabled for [DMA Channel Suspend](#) (SUSENR.SUSEN = 0) continue to execute the DMA channel operation.

#### Exiting Channel Suspend Mode

[DMA Channel Suspend](#) mode is left and the DMA channel operation is resumed if either the SUSREQ signal becomes inactive, or if the enable bit SUSENR.SUSEN is reset by software.

## Direct Memory Access (DMA)

### 18.5.2 Software Activation of DMA Channel Interrupt Service Requests

Each DMA channel interrupt service request shall be activated by programming the DMA channel CHCSR.SIT = 1<sub>B</sub>.

### 18.5.3 Software Activation of DMA RP Error Interrupt Service Requests

Each DMA RP error interrupt service request shall be activated by programming the RP ERRINT.SIT = 1<sub>B</sub>.

### 18.5.4 OCDS Trigger Bus (OTGB) Interface

A **TS** is a collection of signals which supports a specific debug use case. The OCDS Trigger Set Select (OTSS) register controls which TS is applied to one of two DMA OTGB interfaces: OTGB0 or OTGB1. A TS is routed by the OCDS Trigger Multiplexer (OTGM) to the OCDS Trigger Switch (OTGS).

#### DMA Trigger Sets

The DMA Trigger Sets (at [Table 586](#)) are selected and routed to the 16 bit OTGB0 or OTGB1 interface by programming the OTSS register. Only one TS shall be output at a time either on OTGB0 or on OTGB1. The OTGB0 and OTGB1 have no dependency on the OCDS enabled state.

DMA TS are unique to each DMA configuration and dependent on the number of DMA channels and ME.

**Table 586 DMA Trigger Sets**

Index	Description	Details
0	No Trigger Set selected	
1	<b>Channels (TS16_PF)</b> Active channels	<a href="#">Table 587</a>
2	<b>Channels (TS16_ERR)</b> Error channel number and flags	<a href="#">Table 588</a>
8	<b>Transaction Request State (TS16_C15)</b> Transaction Request State Channel [15:0]	
9	<b>Transaction Request State (TS16_C31)</b> Transaction Request State Channel [31:16]	
10	<b>Transaction Request State (TS16_C47)</b> Transaction Request State Channel [47:32]	
11	<b>Transaction Request State (TS16_C63)</b> Transaction Request State Channel [63:48]	
12	<b>Transaction Request State (TS16_C79)</b> Transaction Request State Channel [79:64]	
13	<b>Transaction Request State (TS16_C95)</b> Transaction Request State Channel [95:80]	
14	<b>Transaction Request State (TS16_C111)</b> Transaction Request State Channel [111:96]	
15	<b>Transaction Request State (TS16_C127)</b> Transaction Request State Channel [127:112]	
Other	Reserved. No Trigger Set selected	

## Direct Memory Access (DMA)

### Performance Trigger Set

The performance **TS** (TS16\_PF) continuously monitors ME activity. While a ME is servicing a **DMA Request**, the ME idle/active bit TS16\_PF.ME0/1 is set and the TS16\_PF.CH0/1 field is set to the number of the DMA channel. When the ME is idle the idle/active bit TS16\_PF.ME0/1 goes low. The TS16\_PF.CH0/1 bit field retains the value of the last active DMA channel.

**Table 587 TS16\_PF Trigger Set Channels**

Bits	Name	Description
[6:0]	CH0	Number of DMA channel active in ME0
7	ME0	ME0 idle/active 0 <sub>B</sub> ME0 is idle 1 <sub>B</sub> ME0 is active
[14:8]	CH1	Number of DMA channel active in ME1
15	ME1	ME1 active 0 <sub>B</sub> ME1 is idle 1 <sub>B</sub> ME1 is active

### Error Trigger Set

The error **TS** (TS16\_ERR) triggers an event for DMA source errors and DMA destination errors.

If a **ME** detects a **SER** or **DER**, the DMA sets TS16\_ERR as follows:

- If **MEm** detects a **SER**, the DMA sets TS16\_ERR.MEmSE for one trigger cycle.
- If **MEm** detects a **DER**, the DMA sets TS16\_ERR.MEmDE for one trigger cycle.
- The DMA sets TS16\_ERR.LEC to the last error channel for one trigger cycle. If both MEs generate a **SER** and/or **DER** in the same clock cycle, the DMA shall set TS16\_ERR.LEC to the ME0 last error channel.

**Table 588 TS16\_ERR Trigger Set Channels**

Bits	Name	Description
[6:0]	LEC	Last error channel number
[11:7]		Reserved
12	ME0SE	ME0 Source Error
13	ME0DE	ME0 Destination Error
14	ME1SE	ME1 Source Error
15	ME1DE	ME1 Destination Error

### Request Trigger Sets

The request trigger sets (TS16\_C15, etc.) continuously monitor the state of the DMA channel TSR.CH bits.

### 18.5.5 MCDS Trace Interface

Each DMA on chip bus master interface generates a trace vector as follows:

- One 8 bit vector from SPB master interface via BCU\_SPB to BAL\_SPB inside MCDS (i.e. spb\_clk domain).
- One 8 bit vector from SRI master interface via SRI\_XBAR to BAL\_SRI inside MCDS (i.e. sri\_clk domain).

The trace vector (at **Table 589**) identifies the DMA channel and ME making an on chip bus access.

## Direct Memory Access (DMA)

**Table 589 Trace Vector Definition**

Bits	Trace
[6:0]	DMA Channel
[7]	Move Engine 0 <sub>B</sub> ME0 1 <sub>B</sub> ME1

The trace vector is used for OCDS Level 3 and OCDS Level 1 purposes:

### DMA Trace Signal Generation for OCDS Level 3

The trace mechanism enables the MCDS system to trace transactions on the on chip bus generated by one or a group of dedicated DMA internal sources.

### DMA Trace Signal Generation for OCDS Level 1

For OCDS Level 1 purposes the DMA provides 8 bit trace vectors.

## Direct Memory Access (DMA)

### 18.6 Use Cases

#### 18.6.1 Move Operation

A code example is provided to give an overview of core DMA functionality. The example realizes DMA channel 000 executing a one word (32 bit-length) single data transfer from a source module to a data module without the intervention of the CPU. The DMA transaction is triggered by a DMA software request in this example. The DMA also supports DMA hardware requests. No interrupt or further functions are created in this example, please see the respective registers for more details.

##### 18.6.1.1 Step Description to Initialize and Trigger a DMA Transaction

- (Line 1) The 32-bit source address (DMA\_SADR000\_ADD) gets stored in the source address register DMA\_SADR000.
- (Line 2) The 32-bit destination address (DMA\_DADR000\_ADD) gets stored in the destination address register DMA\_DADR000.
- (Line 3) The channel data width is defined in the channel configuration register DMA\_CHCFGR000. Setting DMA\_CHCFGR000.[23:21] = 010<sub>B</sub> configures the channel data width to 32 bit.
- (Line 4) DMA hardware requests are disabled in the transaction state register DMA\_TSR000. Writing DMA\_TSR000.[17] = 1 disables the hardware transfer requests.
- (Line 5) This line starts the data transfer between the source and destination memory address.

*Note:* The declaration of DMA\_SADR000\_ADD and DMA\_DADR000\_ADD must be done by the user.

#### DMA channel 000 Code

```
(1) DMA_SADR000 = DMA_SADR000_ADD; // source address
(2) DMA_DADR000 = DMA_DADR000_ADD; // destination address
(3) DMA_CHCFGR000.U = (0x2 << 21); // channel data width
(4) DMA_TSR000.U |= (1 << 17); // disable DMA hardware requests
(5) DMA_CHCSR000.U |= (1 << 31); // initiate DMA software request
```

*Note:* The DMA transaction can be started anywhere in the program.

#### 18.6.2 Error Handler

Each RP generates a single error interrupt trigger to signal a number of different parallel error conditions:

- ME detected errors during the execution of DMA moves.
- TRL errors when a DMA request is not serviced.

The DMA RP error interrupt service request shall be serviced by the CPU supervising the RP.

An EH shall read the following registers to identify the error type and the DMA error channel:

- ME Error Status Registers (ERRSR) to detect the following:
  - Last Error Channel (LEC)
  - Source Error (SER)
  - Destination Error (DER)
  - RAM Error (RAMER)
  - Safe Linked List Error (SLLER)
  - DMA Linked List (DLLER)
- DMA channel Transaction State Registers (TSR) to detect the following:

## Direct Memory Access (DMA)

- Transaction Request State (CH)
- Transaction Request Lost (TRL)

The error routine should disable further DMA requests from the DMA error channel:

- DMA hardware requests: the CPU shall write DMA error channel TSR.DCH = 1<sub>B</sub>
- DMA software requests: the CPU shall not write DMA error channel CHCSR.SCH = 1<sub>B</sub>

The error routine should clear the error status flag(s) as follows:

- ME error flags:
  - SER: the CPU error routine shall write ME CLRE.CSER = 1<sub>B</sub>
  - DER: the CPU error routine shall write ME CLRE.CDER = 1<sub>B</sub>
  - SPBER: the CPU error routine shall write ME CLRE.CSPBER = 1<sub>B</sub>
  - SRIER: the CPU error routine shall write ME CLRE.CSRIER = 1<sub>B</sub>
  - RAMER: the CPU error routine shall write ME CLRE.CRAMER = 1<sub>B</sub>
  - SLLER: the CPU error routine shall write ME CLRE.CSLLER = 1<sub>B</sub>
  - DLLER: the CPU error routine shall write ME CLRE.CDLLER = 1<sub>B</sub>
- DMA channel error flags:
  - TRL: the CPU error routine shall write the DMA error channel TSR.CTL = 1<sub>B</sub>

The user shall identify the origin of the error. The DMA configuration shall be changed to prevent a reoccurrence of the error. On completion DMA requests shall be serviced as follows:

- DMA hardware requests: the CPU shall write DMA channel TSR.ECH = 1<sub>B</sub>
- DMA software requests: the CPU shall write DMA channel CHCSR.SCH = 1<sub>B</sub>

### 18.6.3 Data Communication

From TC39xB DMA and TC38xA DMA onwards, the DMA has been enhanced to report **TRL** errors if the DMA channel is disabled for hardware requests and a **DMA Hardware Request** is detected.

For example, if the application is transmitting data via a QSPI, the software may perform one write to the TXFIFO or may set the interrupt flag in the TXFIFO interrupt node to initiate data transmission. After each data word is loaded into the TXFIFO, the QSPI triggers a TXFIFO interrupt service request. The system effect is that (n + 1) interrupts are generated to move (n) data words. If the application uses the DMA to move data into the TXFIFO and the DMA channel is configured for **Single Mode**, the DMA will disable **DMA Hardware Request** after the DMA has serviced (n) interrupts and report a **TRL** for the last interrupt.

To prevent this **TRL** event, the software should configure the DMA channel as a **DMA Linked List (DMALL)** composed of the following DMA transactions:

- DMA Transaction 1: perform (n) DMA moves to write data to TXFIFO.
- DMA Transaction 2: perform a dummy DMA move to read and write data to an unused address in DSPIR.

If the DMA is used for data communication, the application should consider the possibility of **TRL** generation after the last data word.

## Signal Processing Unit (SPU)

### 19 Signal Processing Unit (SPU)

The Signal Processing Unit (SPU) is a semi-autonomous accelerator for performing Fast Fourier Transforms (FFTs) on data from one or more dedicated ADC interfaces. The SPU uses a three stage, streaming architecture to provide data pre-processing, FFT, and data post-processing operations. The SPU uses the Radar Memory to store datasets and has internal buffer memories which are used to store the data currently progressing through the processing pipeline.

**Figure 225 SPU Architecture**

#### 19.1 Feature List

The radar SPU has the following top level features

- Up to 2 concurrent SPU instances active concurrently
- A maximum achievable performance can approach 1 clock per sample processed for large data cubes. (See [Section 19.7.14](#) of this document for a more detailed explanation of factors affecting SPU throughput.)
- A 256bit bus connection to Radar memory with 2 clocks per read or write access
- Radar sequencer to manage the automatic execution of linked list where execution units are reconfigured between computation steps
- Internal configuration memory for linked lists
- 2 selectable input data flows (ADC interface or main RAM)
  - The ADC Interface supports real or complex data

## Signal Processing Unit (SPU)

- Input / output precision selectable: 16 or 32bits
- Input DMA with HW transpose unit and data padding
- Multiple execution units
  - Windowing with complex windowing and HW support for phase demodulation
  - FFT from 8 to 2048 points
  - 2 x 1D-CFAR, thresholding units implementing 4 CA and 3 GOS algorithms
  - 1 x BIN rejection unit
  - Non coherent integration over 2 Radar SPU
  - Antenna signal integration for elevation
  - Basic thresholding (local maximum detection)
- RAM size optimisation by using configurable FFT strategy (in place, out of place, partially shifted)
- Output DMA with output FIFOs so that each data flow has its own FIFO and configurable DMA parameters
- A min/max/averaging unit.
- A histogram unit up to 4096 elements
- Support for up to 8 data lanes @ 400Mbit/s
- Low speed 60 Mb/s single ended IF
- The ability to lockstep 2 SPU units.

### 19.2 Overview

This section provides an overview of the SPU functionality

#### 19.2.1 Glossary of Terms

The following terms are used throughout this document

**Table 591 Definition of Terms**

Term	Definition
Ramp	A frequency sweep of the RF transmitter of the Radar system. Relevant here because each ramp will result in the acquisition of a number of linked ADC samples to be processed by the SPU
Transposition	Reading input data from non-contiguous addresses in memory so as to construct an FFT input dataset from equivalent elements in multiple FFT results stored in memory. So, if the input data consists of 128 FFTs of 256 samples, the output data will transpose the coordinates to generate 256 FFTs of 128 samples
First Stage FFT	The first stage FFT processes ADC data to obtain range information
In Place FFT	SPU specific term used when the results of FFT calculations are stored in the memory locations cleared by reading the input data for the FFT calculations. As the input data is overwritten, the “In Place FFT” operation destroys the input data.
Second Stage FFT	The second stage (or doppler) FFT is assumed to use equivalent output bins from the first stage FFT of each ramp as input (see transposition). This allows the output from the second stage FFT to be used to determine velocity.
Third Stage FFT	The third stage FFT is assumed to use equivalent output bins from each antenna of the second stage FFT results
Chirp	Synonym for “Ramp”

## Signal Processing Unit (SPU)

**Table 591 Definition of Terms (cont'd)**

Term	Definition
Data Cube	Each set of data stored in memory has three indices that are used to uniquely define each data point. These can be considered as co-ordinates in a three dimensional system which leads to the term “data cube”. For raw ADC data, the indices are sample index, ramp number (corresponding to time) and antenna number. For processed data, the axes would be bin index, FFT number (corresponding to time) and antenna number.
Dataset	a single set of FFT data, either inputs or outputs
Data block	one or more datasets stored in buffer memory intended for processing by the SPU in a single operation. This can be considered as a two-dimensional array of data where one axis is bin index and the other is FFT index
DBF	Digital Beam Forming. Adding the equivalent bins from each antenna together to produce a single, combined FFT result. Data format is complex so that phase information is used in the addition
NCI	Non-Coherent Integration. Adding the power of each equivalent bin from each antenna together to produce a 1-dimensional array of power values

### 19.2.2 Processing Flow

The SPU is intended to perform three operations simultaneously

- Processing of Input Data into FFT datasets, combining one or more datasets into data blocks
- performing an FFT on each of the datasets
- Postprocessing the datasets and writing the results to Radar Memory

To do this the SPU uses four buffer memories. This imposes a hard limit on the amount of data that can be handled in a single operation. The buffer RAMs are organised in two pairs. The first pair stores input data for the FFT accelerator and the second pair stores the output data from the FFT accelerator. Therefore the FFT accelerator can work on one set of data while the Output Data Processor is working on the results from the previous set of data and the Input Data Processor is preparing the next set of data.

Each input data block contains enough samples from each attached antenna to perform one FFT for each antenna. This amount of data can be referred to as a ramp and the processing step is referred to as the “inner loop”

The SPU processes a programmable number of these data blocks for each trigger. This can be referred to as a measurement cycle and the overall processing operation is referred to as the “outer loop”. Each completed outer loop sequence generates one complete set of results (a data cube) in the Radar Memory.

All arithmetic operations in the SPU are fixed point unless explicitly stated otherwise.

### 19.2.3 Use Case examples

The Signal Processing Unit supports 3 main configurations that can be defined by software at any time.

- Configuration 1: 1st stage FFT
- Configuration 2: 2nd stage and 3rd stage FFT
- Configuration 3: mathematical operations only (without FFT)

Please note that some operations possible from logic point of view do not make sense (e.g. thresholding after 1st stage FFT). They are shown here to demonstrate the capabilities of the SPU.

## Signal Processing Unit (SPU)

The SPU is intended to provide an infrastructure for radar signal preprocessing. Its configurability allows support of different data processing flows. This is shown by most configuration registers not being directly related to Radar characteristics such as number of antenna or number of ramps.

Many of the basic computing steps are defined by the number of operands to read, the address offset for inner loop and address offset for outer loop.

This document defines limitations imposed by memory size to allow system designers to maximize the use of the SPU according to their application case.

The focus on providing a flexible computing infrastructure means that SPU does not have specific HW to check SPU configuration. The coherency of the SPU configuration should be checked by developers.

Examples of different configurations are shown in the following paragraphs.

### 19.2.3.1 SPU Configuration 1

The figure below is showing the different computation blocks for 1st stage FFT.

**Table 592 SPU Configuration 1**

	De-Interleaving	Math1	FFT Accelerator	Math2 (signal power)	Math2 (FFT Bins)	HW-DMA-Out
<b>Processing stage Config.</b>	Enabled	Enabled	Enabled	Disabled	Optional	Enabled
<b>Processing Options</b>	N/A	Window Coefficients Real/Complex	Real/Complex 16 / 32 bits Nr. of points	Signal Power Non-coherent Integration Histogram Local Max with thresholding	Optional Bin Range cutoff Complex Rescaling	DMA parameters per enabled output data flow

The SPU supports arbitrary removal of preselected BINs of the FFT results during processing by Math2 unit

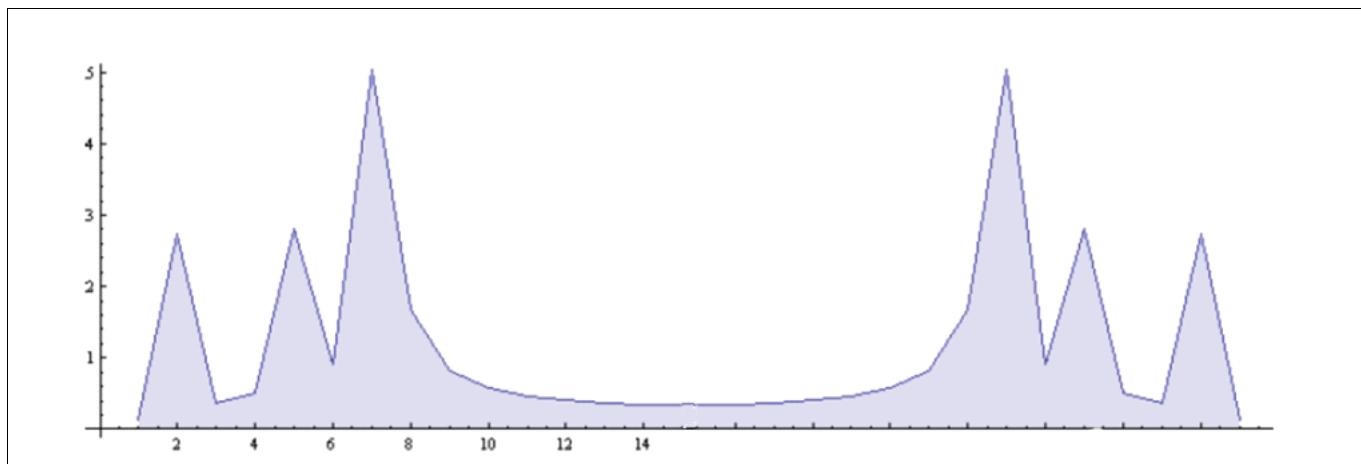

Ideally, the frequency sweep and other Radar parameters are chosen so that after the 1st stage FFT, only the BINs being symmetric with other ones are removed (e.g., keep the first 256 BINs from the 1st stage FFT512). Still, it might be necessary to remove some additional BINs.

- BINs from the real range to the equivalent range of the 256th BIN
- BINs on the very low range, which normally should have a 0 value

The FFT BIN removal HW in Math2 unit can be configured to remove any range BINs the user does not want to keep anymore.

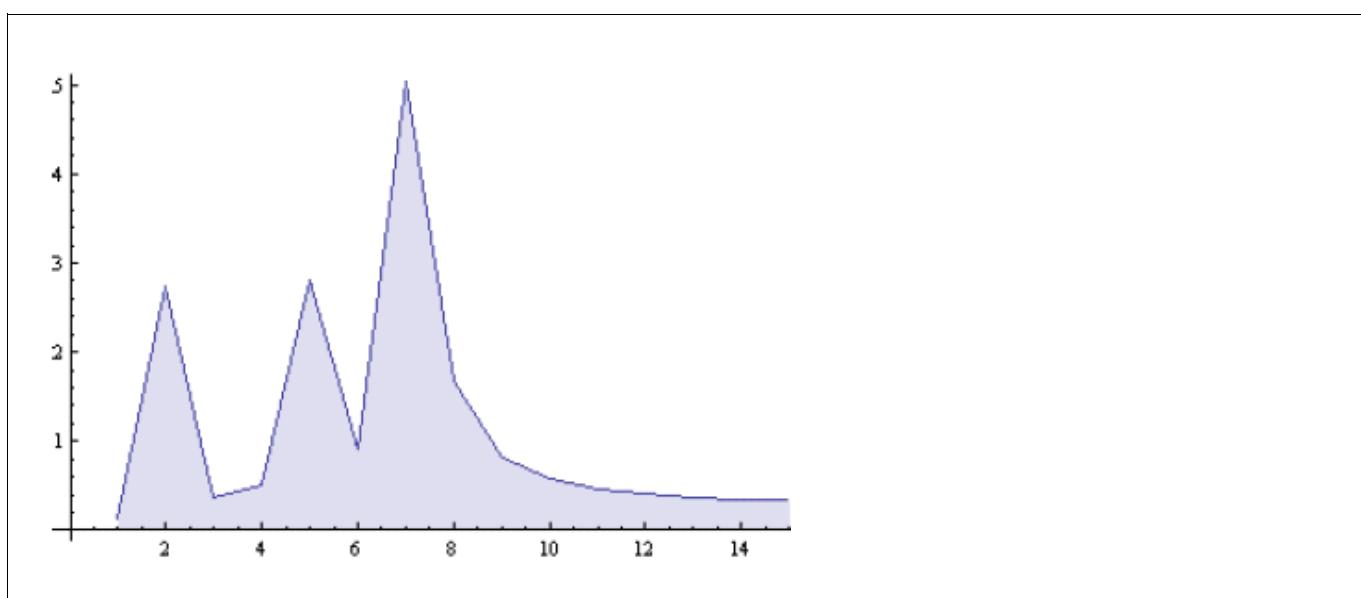

The symmetry of real FFT is illustrated in the figure below (FFT32 from 32 real samples).

## Signal Processing Unit (SPU)

**Figure 226 FFT Results Symmetry**

According to the above example, the range cut off would write to the Radar memory, only the first BINs (0 to 15) of the FFT results.

**Figure 227 Range Cut Off Example**

The Arbitrary BIN removal also allows additional optimization like removing the BIN0 and BIN1, so that only BINs outside the minimum range are stored in memory.

The Arbitrary BIN removal also allows additional optimization like removing the BIN13, BIN14 and BIN15 if the sampling of the Radar (frequency sweep, sampling time,..) is such that BIN13, BIN14 and BIN15 are not meaningful.

### 19.2.3.2 SPU Configuration 2

The main focus of this configuration is performing 2nd stage FFT, 3rd stage FFT and non coherent integration of the data from multiple antennae.

## Signal Processing Unit (SPU)

**Table 593 SPU Configuration 2**

	De-Interleaving	Math1	FFT Accelerator	Math2 (signal power)	Math2 (FFT Bins)	HW-DMA-Out
<b>Processing stage Config.</b>	Enabled. HW Transpose	Enabled	Enabled	Optional	Optional	Enabled
<b>Processing Options</b>	DMA Inner Loop Parameters DMA Outer Loop Parameters	Window Coefficients Real/Complex	Real/Complex 16 / 32 bits Nr. of points	Signal Power Non-coherent Integration Histogram Local Max with thresholding	Bin rejection / patch based on thresholding Complex Rescaling Bin Forcing to 0 Min / Max / Averaging Sum / Sum-abs. Sum-ant	DMA parameters per enabled output data flow (allows in-place FFT)

Comments on configuration2

- Non-coherent integration is done within 1 SPU, even when using 2 SPUs. Integration across two SPU instances is not supported.

### 19.2.3.3 SPU Configuration 3

The figure below shows the different computation blocks for the 3rd configuration.

Configuration 3 is used to do specific computations on FFT BINs or on the result of non coherent integration of teh data from multiple antennae

Configuration 3 is useful to do specific computations before or after FFTs like

- FFT result multiplication by another complex (scalar or vector)
- maximum search in the other dimension to the one used with configuration2
- complex thresholding algorithm like CFAR
- average computation

This dedicated stage has been specifically designed to allow the running of the 2nd stage FFT at full performance of the Radar SPU (so, at 2 clocks / BIN) and produce then additional and specific results at 4 clocks /BIN during the time the CPU is processing the results produced by the 2nd stage FFT.

This provides more flexibility in supporting computation flows.

## Signal Processing Unit (SPU)

**Table 594 SPU Configuration 3**

	De-Interleaving	Math1	FFT Accelerator	Math2 (signal power)	Math2 (FFT Bins)	HW-DMA-Out
<b>Processing stage Config.</b>	Enabled. HW Transpose	Optional	Disabled	Optional	Optional	Enabled
<b>Processing Options</b>	DMA Inner Loop Parameters DMA Outer Loop Parameters	Window Coefficients Real/Complex	Real/Complex 16 / 32 bits Nr. of points	Signal Power Non-coherent Integration Histogram Local Max with thresholding	Bin rejection / patch based on thresholding Rescaling Bin Forcing to 0 Min / Max / Averaging Sum / Sum-abs. Sum-ant	DMA parameters per enabled output data flow (allows in-place FFT)

Note: Comments on configuration 3

4. 2 independent thresholding algorithms are computed concurrently. Users can then select which of the thresholding results to use on any results based on their own software algorithm run on the TriCore.

### 19.2.3.4 Thresholding

The SPU provides hardware support for different thresholding methods

- user defined thresholding
- local min/max
- CFAR based thresholding methods

#### 19.2.3.4.1 User Defined Thresholding

The SPU is able to compute both a histogram and statistical data of the signal power over a selected region of the data (entire data cube, partial data cube, cube slice,...).

Once the histogram and statistical data are produced by the SPU, the CPU can then process it to compute the threshold to be applied for the next computation step.

For this, the CPU has to update the relevant entry in the radar sequencer with the suitable thresholding parameter and enable the Radar sequencer to load the next configuration and execute it.

#### 19.2.3.4.2 CFAR Based Thresholding Methods

CFAR algorithms can be quite complex and CPU time demanding. The CFAR module in the MATH2 unit can run two, CFAR algorithms concurrently and store their results in memory so that users can select, based on their own methodology, which results they apply for each part of the radar image.

### 19.2.3.5 Using Pre-acquisition Ramps

Running thresholding on FFT results from 1 ramp does not usually allow enough gain.

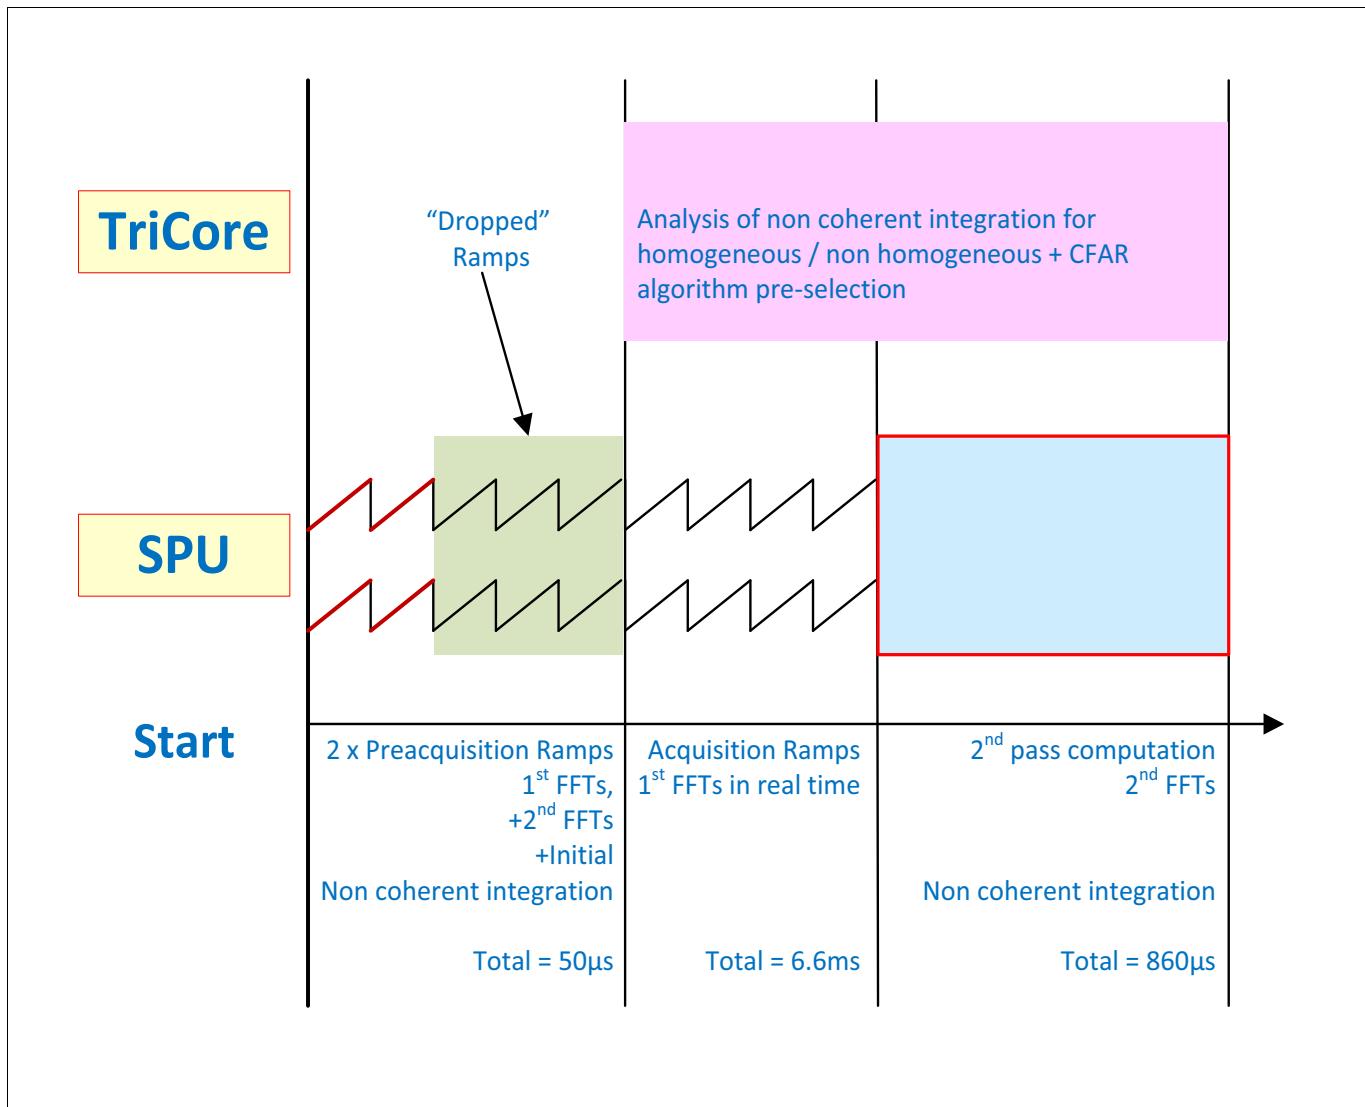

## Signal Processing Unit (SPU)

The SPU supports running a set of pre-acquisitions ramps to allow to an initial non coherent integration and initial thresholding to be performed.

Then, after few dummy ramps, regular acquisition ramps can start.

Such an approach allows the CPU to run a user defined SW to analyse an initial non coherent integration and initial thresholding of the pre-acquisition data to understand the complexity of the scenery.

This is illustrated in the figure below

**Figure 228 Pre-Acquisition Ramps Method**

This technique is not possible with slow ramps but can be used with fast ramps.

**Note:** pre-acquisition ramps could be seen as partial redundant acquisition so that a high integrity decision can be taken from 1 acquisition only.

### 19.2.4 Elevation support

Support of elevation computations is anticipated to become necessary as, when a car makes emergency brake decisions based on Radar, it is important to detect if a potential target is on the driving path or just above it.

Computation of elevation may require summing the signals from antenna pairs.

## Signal Processing Unit (SPU)

**Patents on antenna topologies:** Some antenna topologies have been patented. The Radar SPU is only providing an infrastructure for computations. It is the end user responsibility to make sure their system/application usage of the Radar SPU is not violating system or application level patents.

**Note:** *The Math1 supports automatic padding so that the 3rd stage FFT can be run automatically as an additional computing step after the sum of antenna pairs on 2nd stage FFT results is computed.*

### 19.2.5 Phase demodulation

2 methods are supported inside the Math1 unit.

- alternate chirp demodulation
- static demodulation

Principle: phase demodulation is done by performing a complex multiplication on input data by re-using the windowing function. i.e. the required phase demodulation is incorporated into the co-efficients of the windowing function.

**Note:** *as the demodulation scheme uses complex multiplication, the SPU supports demodulation of phases other than 180 degrees.*

#### 19.2.5.1 Alternate chirp demodulation

When doing demodulation per chirp, it is assumed that data are modulated on a chirp by chirp basis (odd/ even).

The SPU allows demodulation prior to 1st stage FFT or prior to 2nd stage FFT.

The output-DMA supports writing each flow of FFTs to different addresses. This allows the Radar SPU to run further FFTs over all ramps or over 1 set of ramps (odd or even ramp indexes) and, as part of the output-DMA features, to define where the FFT results are stored.

User can select their own method for doing phase demodulation as SPU support different implementations.

#### 19.2.5.2 Static demodulation

When doing static demodulation, the SPU provides resources to select between 2 sets of windowing coefficients.

#### 19.2.5.3 HW optimisation for demodulation

Demodulation using the windowing function in Math1 defines constraints on the number of active antenna and the number of bins in each FFT as the space available for storing window functions in the Configuration Memory is limited.

When using 0/90/180/270 phase demodulation, fast demodulation allows demodulation without using the windowing function and therefore without using Configuration Memory.

### 19.2.6 Debugging

For debugging purposes, it is possible to stop the execution of a sequence at a specific FFT execution step (e.g. 1st stage or 2nd stage). This is done by the radar sequencer.

To avoid excessive complexity, execution cannot be resumed.

Debugging is supported by

- the connections to the OCDS system (See [Section 19.5, “Debug”](#))
- the defined interrupt flags.
- the counters added to support functional safety.

## Signal Processing Unit (SPU)

### 19.2.7 Execution flow

The execution flow shown here shows the mapping of 1 FFT engine. Execution flow of the 2nd FFT engine is identical, only the base address is shifted.

#### 19.2.7.1 Execution flow for 4 Antennae

Use case shown is for a first stage FFT with 4 antennae. The Radar Interface will receive one set of sample data for each attached antenna per ramp of the acquisition cycle. In the example shown in [Table 595 “Execution Flow with 4 Antennae” on Page 10](#), 512 ramps are assumed. Since the buffer memories are relatively small, the SPU is constrained to process the data in order of acquisition. The SPU will iterate round the inner loop once for each antenna for each iteration of the outer loop. The number of outer loop iterations will match the number of ramps in the acquisition cycle.

It therefore follows that the amount of data generated by one ramp from each antenna must fit into the buffer memory. In all cases, ADC data is stored as sixteen bit quantities.

**Table 595 Execution Flow with 4 Antennae**

Outer Processing Loop (increasing time)	Inner Processing Loop (Increasing Time ->)			
1	FFT0, Antenna 0	FFT 0, Antenna 1	FFT 0, Antenna 2	FFT 0, Antenna 3
2	FFT1, Antenna 0	FFT 1, Antenna 1	FFT 1, Antenna 2	FFT 1, Antenna 3
3	FFT2, Antenna 0	FFT 2, Antenna 1	FFT 2, Antenna 2	FFT 2, Antenna 3
4	FFT3, Antenna 0	FFT 3, Antenna 1	FFT 3, Antenna 2	FFT 3, Antenna 3
5	FFT4, Antenna 0	FFT 4, Antenna 1	FFT 4, Antenna 2	FFT 4, Antenna 3
6	FFT5, Antenna 0	FFT 5, Antenna 1	FFT 5, Antenna 2	FFT 5, Antenna 3
7	FFT6, Antenna 0	FFT 6, Antenna 1	FFT 6, Antenna 2	FFT 6, Antenna 3
.	.	.	.	.
.	.	.	.	.
.	.	.	.	.
.	.	.	.	.
.	.	.	.	.
509	FFT508, Antenna 0	FFT 508, Antenna 1	FFT 508, Antenna 2	FFT 508, Antenna 3
510	FFT509, Antenna 0	FFT 509, Antenna 1	FFT 509, Antenna 2	FFT 509, Antenna 3
511	FFT510, Antenna 0	FFT 510, Antenna 1	FFT 510, Antenna 2	FFT 510, Antenna 3
512	FFT511, Antenna 0	FFT 511, Antenna 1	FFT 511, Antenna 2	FFT 511, Antenna 3

*Note:* In the case where only 3 antennae are used, Antenna 3 would be disabled.

### 19.2.8 Memory mapping

This section provides an overview with example use cases of the configuration options available for the input and output DMA engines.

## Signal Processing Unit (SPU)

### 19.2.8.1 Principle

The Input DMA engine is designed to do transfers with programmable address increments. Three separate increments are available which are combined with a base address to build the address to be accessed. This allows a DMA transfer to be configured which assembles elements from a 3-dimensional array (or data cube) stored as a flat (1-dimensional) array in Radar Memory by stepping along any axis in the cube with any arbitrary starting offset.

These increments are used in a “bin loop”, an “inner loop” and an “outer loop” processing flow. The inner loop can potentially be executed multiple times for each execution of the outer loop and the bin loop can be executed multiple times for each execution of the inner loop.

Processing starts with a pre-defined base address and a zero offset address for each loop. These are added together to form the access address. Each pass round the bin loop increments the bin loop offset, each pass round the inner loop will increment the inner loop offset address and finally each pass round the outer loop increments the outer loop offset. The increment for each offset register is programmable. When the programmed number of loops have completed, the outer loop restarts by resetting the offset address and loop counter to zero.

A complete execution of the “bin loop” will read the data for a single FFT input dataset. A complete execution of the “inner loop” would therefore be expected to create a data block but, in a lot of cases, this would create a data block too large to fit into the buffer memory. Smaller data blocks are therefore created. See [Section 19.2.8.3, “Data Block Construction Control” on Page 11](#) for details.

The Output DMA engine is much simpler. Data is written to sequential addresses in order of processing unless in-place FFT is enabled in which case, the output address will be calculated to write the data into the addresses made available by the reading of the input data.

### 19.2.8.2 Memory mapping for FFTs

FFTs can be arranged to be done “in-place” or “out-of-place”. When done “out-of-place”, a different memory space is used for input and output data. This can either be completely segregated (necessary for transposed addressing on the input data) or overlapping with a shift in base address (1 or few ramp differences/address offset).

Having a difference of only a few ramp allows some of the 1st stage FFT results to be retained in the Radar Memory after the 2nd stage processing is complete.

When using in-place operation with transposed addressing of the input data. A scatter algorithm will be used when writing data which is the inverse<sup>1)</sup> of the gather algorithm used for reading data.

### 19.2.8.3 Data Block Construction Control

The Input DMA constructs a data block in buffer memory consisting of multiple datasets. The point at which the data block is defined as complete and the buffer memory is switched so that the data can be processed can be configured in one of two modes:

#### 19.2.8.3.1 Default Memory Mode

This mode is used when there is no requirement to use either coherent or non-coherent integration across the FFT datasets stored in buffer memory. This allows maximum flexibility on switching the buffer memory during the execution of the inner loop.

<sup>1)</sup> “inverse” as the gather operation takes scattered input data and generates contiguous output data and the scatter operation takes contiguous input data and generates scattered output data

## Signal Processing Unit (SPU)

### 19.2.8.3.2 Integration Mode

This mode is used when there is a requirement to use either coherent or non-coherent integration across the FFT datasets in each data block. The normal use case anticipated for coherent or non-coherent integration is for combining results from multiple antennae into a single set of data.

For this to be useful, the data block constructed on the buffer memory must then contain one dataset for each value of the Inner Loop Count or the integration results will not be correct. In this case ID\_RM\_CONF.PM should be set to IM (Integration Mode). This forces the switching of the buffer memory to occur at the end of each iteration of the inner loop.

Provided that there is no address transposition (i.e. the datasets constructed in buffer memory are copies of data sets in radar memory, this makes efficient use of Radar Memory bandwidth as a single data block uses all of each 256 bit word read from Radar memory. If there is address transposition, then the bandwidth optimisation described below can be used

### 19.2.8.4 Bandwidth Optimised Integration Mode

Bandwidth Optimised Integration mode of the Input DMA can be used to optimise Radar Memory bandwidth usage when coherent or non-coherent integration across the antennae is required by the MATH2 Unit at the same time as using transposed addressing (i.e. building an FFT dataset from the same sample bin in multiple FFT results in Radar Memory).

The objective is to build an input data block containing one FFT dataset for each antenna. This can then be processed by the MATH2 streaming processor to generate the integration output.

For the four antenna use case, with 256 FFTs or ramps in the input data and 128 bins per FFT or ramp, the objective is to sequentially create the data blocks

- Data Block 0 (A{0,0:1,0:2,0:...:254,0:255,0},B{0,0:1,0:...:255,0},C{0,0:1,0:...:255,0},D{0,0:1,0:...:255,0})
- Data Block 1 (A{0,1: ... :255,1},B{0,1: ... :255,1},C{0,1: ... :255,1},D{0,1: ... :255,1})
- .
- .
- .
- Data Block 126 (A{0,126: ... :255,126},B{0,126: ... :255,126},C{0,126: ... :255,126},D{0,126: ... :255,126}),
- Data Block 127 (A{0,127: ... :255,127},B{0,127: ... :255,127},C{0,127: ... :255,127},D{0,127: ... :255,127})

where **A{n,m:n,m:...:n,m}** indicates an input data array assembled from antenna **A**. **{..}** is a colon separated array of datapoints where each datapoint is described by two numbers, **n** and **m**, where **n** is the FFT and **m** is the bin.

The issue addressed by bandwidth optimisation is that the first word read from memory will contain A{0,0:0,1:0,2:0,3}. This results in 75% of the data read being discarded (for 32 bit precision data) as A{0,0} is needed for data block 0; A{0,1} is needed for data block 1; A{0,2} is needed for data block 2 and A{0,3} is needed for data block 3.

Bandwidth optimisation allows multiple datablocks to be constructed simultaneously in the input buffer memory thus using all the data read from the Radar Memory. These datablocks are then passed sequentially through the streaming processors. This bandwidth optimisation is done by effectively executing multiple iterations of the outer loop simultaneously.

This mode can only work if the multiple data blocks can be fitted into the available space of the Buffer RAM. If this is not the case, Integration mode cannot be enabled and the input DMA will iterate over the data multiple times to sequentially build the data blocks one at a time.

## Signal Processing Unit (SPU)

Bandwidth optimisation of Integration mode is enabled by setting ID\_RM\_CONF.PM to IM (Integration Mode) and ID\_RM\_CONF.BLOCKS to a value other than 0<sub>D</sub>. The ID\_RM\_CONF.BLOCKS bitfield then controls the number of datablocks to be built.

See [Section 19.3.1.2.6, Bandwidth Optimisation Integration Processing Mode.](#), for information on configuring this mode.

### 19.2.8.5 Memory mapping for other SPU results

Other SPU results (non coherent integration, CFAR outputs) will be stored in a dedicated memory region.

### 19.2.8.6 Data sharing between SPU

Each SPU should have exclusive access to its memories. The Radar memory being organized in tiles, tiles can be statically allocated to any of the SPUs. The dependencies between the 2 x SPU (when 2nd SPU is implemented) is only visible to users for the 3rd stage FFTs and for support of elevation computations.

#### 19.2.8.6.1 Complex memory map via DMA reconfiguration

Because of the pipeline on acquisition, DMA reconfiguration during acquisitions is possible but will require use of the linked list configuration option.

FFT results of partial-acquisition ramps can be stored in separated memory tiles so that the CPU core(s) can read the results of partial-acquisition ramps during the time of acquisitions and FFTs on the main acquisition ramps.

This also applies for post /pre acquisition test data coming from the RF device.

As the memory mapping is configurable, the rest of the description of the memory mapping should be taken as examples rather than an exhaustive description of what is possible.

The memory mapping examples show the mapping of 1 SPU. Memory mapping of the 2nd FFT engine is identical; only the base address is shifted.

The writing strategy for FFT results is that FFT results for a single FFT are written in sequential memory locations. The start address for each FFT result set is 32 byte aligned to aid in efficient memory usage. One set of FFT results from each antenna will be grouped together in a single ramp result set.

The writing strategy for 2nd stage FFT results is to write the data in order of processing with each FFT result grouped in contiguous addresses and starting at a 32 byte aligned address. This holds unless in-place storage of the FFT results is required (“in place FFT”). In this case, data will be written to memory using the inverse of the transpose algorithm used to build the input data sets and the results will therefore be stored in non-linear addresses.

### 19.2.8.7 Example Memory mapping for 4 antenna and 16 bit operands

The figure below is showing the content of the 256bit words in Radar memory after 1st stage FFT. The example is for a 256 ramp acquisition cycle with four antennae storing 128, sixteen bit complex results (i.e. a 32 bit word representing a complex number with 16 bit signed integers for real and complex components). This results in eight being stored in each 256 bit word of Radar Memory.

## Signal Processing Unit (SPU)

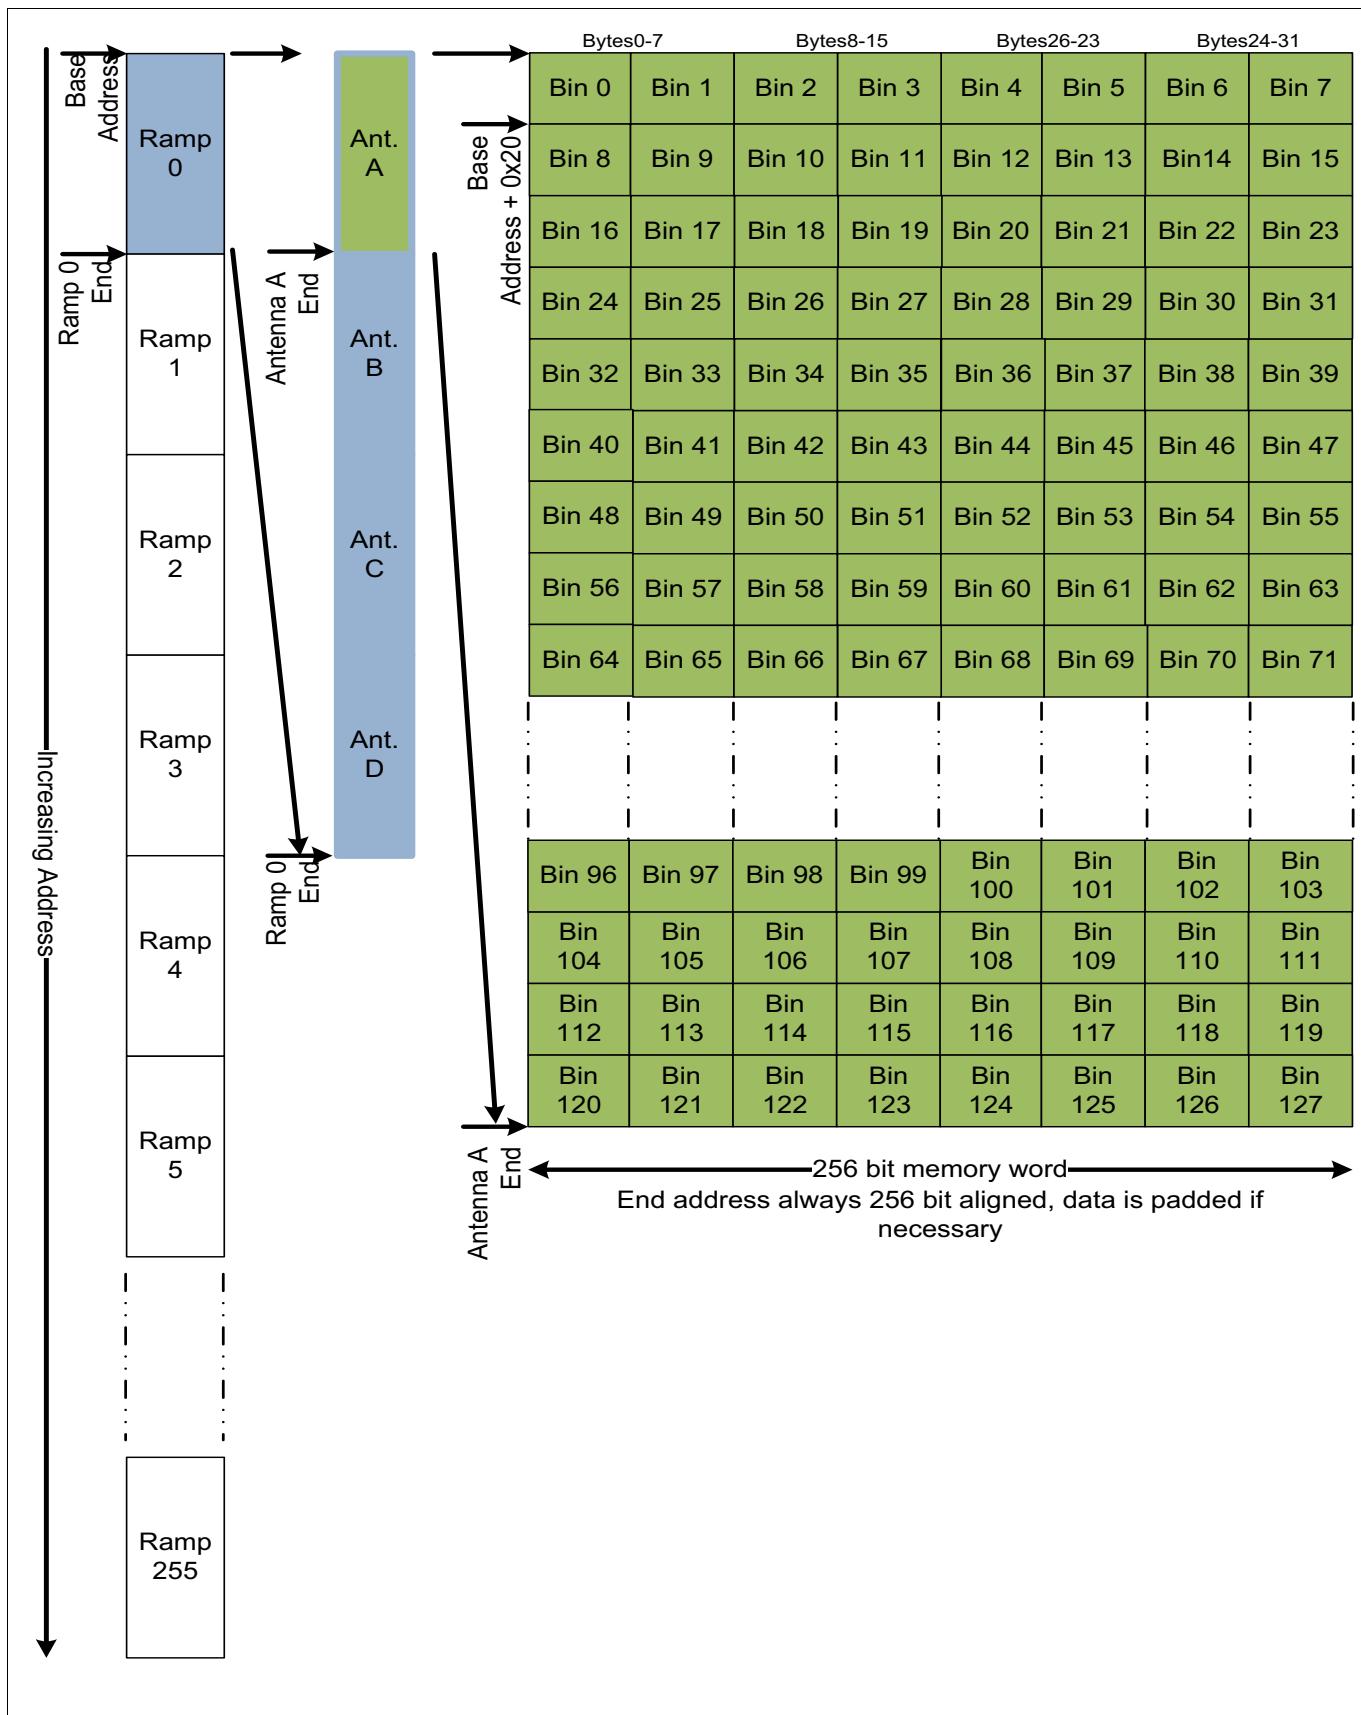

Figure 229 First Stage FFT Memory Organisation, 16 bit data, 4 antennae

## Signal Processing Unit (SPU)

### 19.2.8.8 Data Read Order for 2nd stage FFT with 4 antennae and 16 bit operands

The figure below show the default Input DMA Unit read sequence for transpose before 2nd stage FFTs with 16bit operands and 4 antenna. Here the data is labelled as  $X_{n,m}$ , where X is the antenna identifier, n, is the ramp number and m is the bin number. There is one bin loop for each execution of the inner loop.

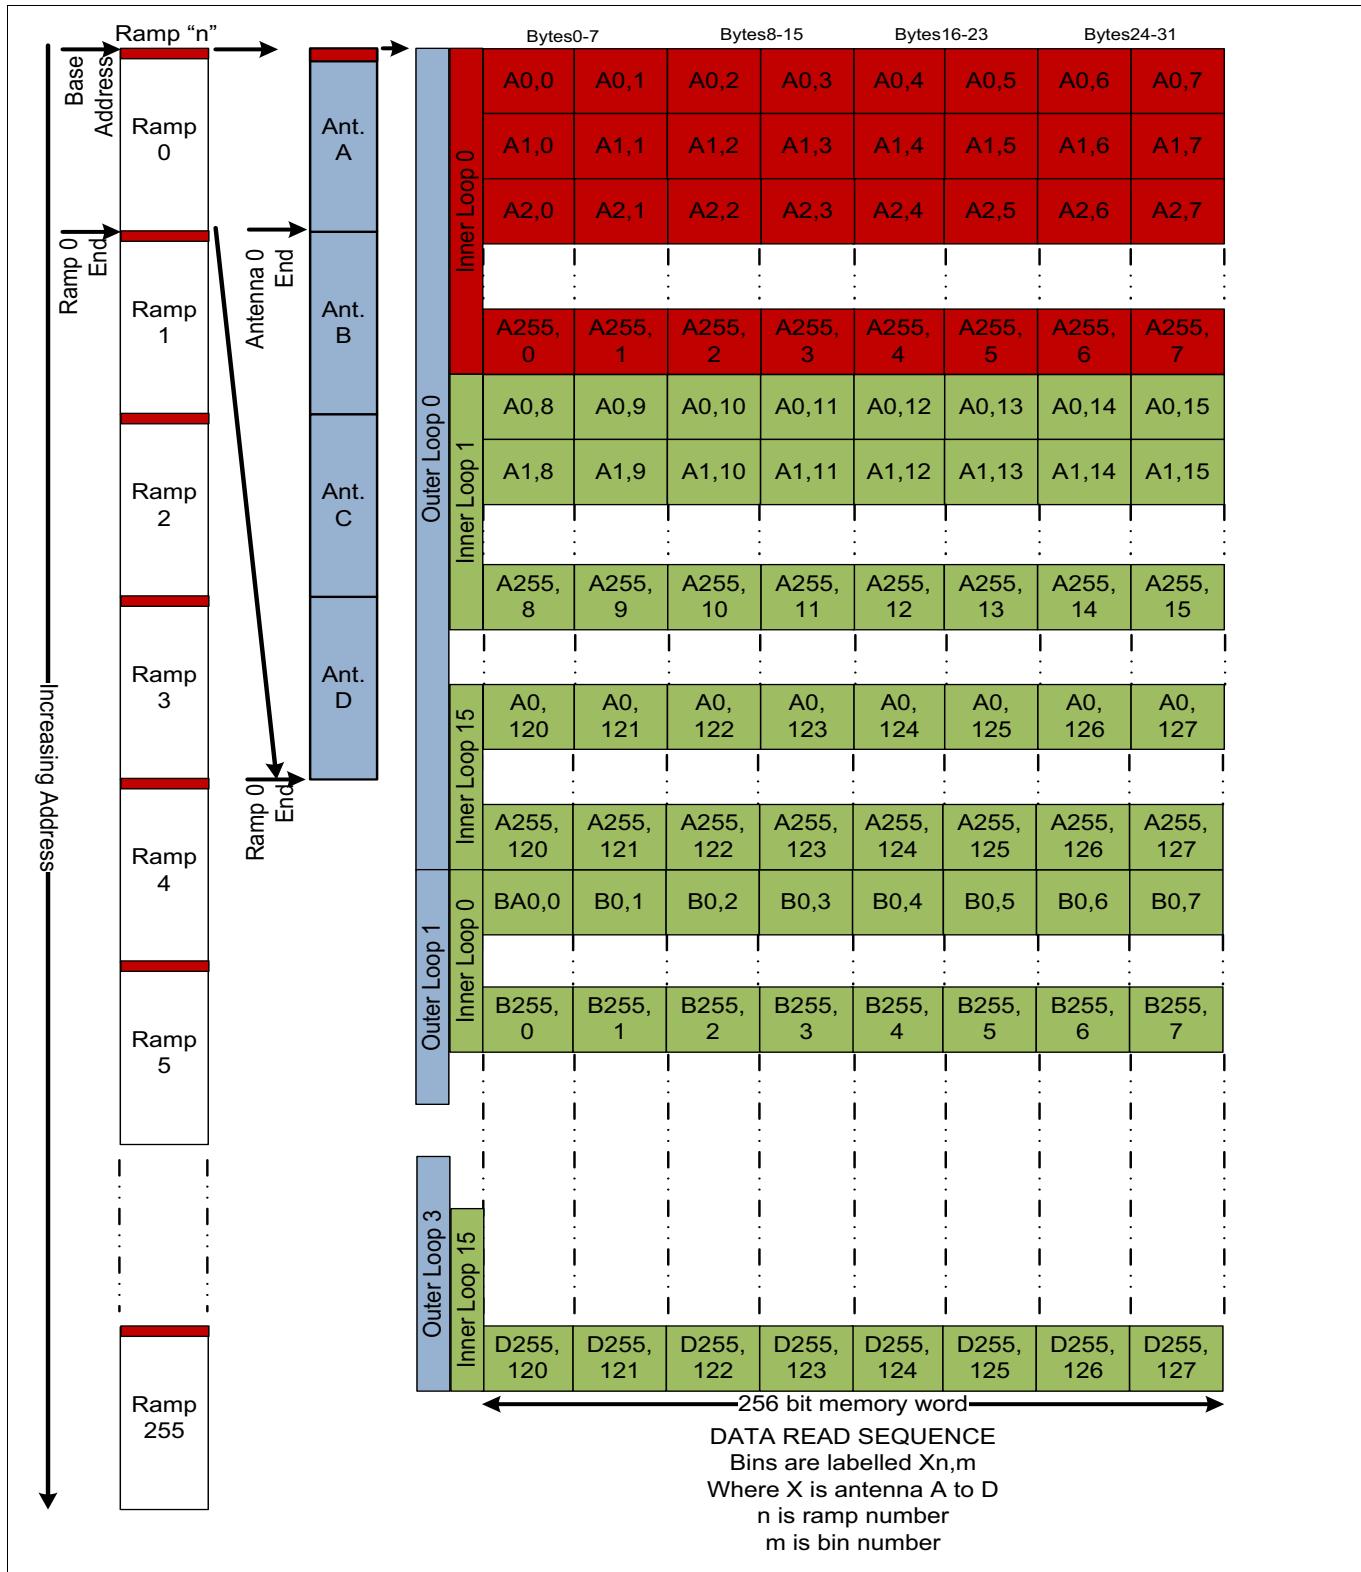

Figure 230 Transpose read order for 2nd stage FFT, 16 bit data, 4 antennae

## Signal Processing Unit (SPU)

For each 256 bit word, we read 8 bins of 1 antenna and go through the same antenna in the 2nd dimension of the datacube.

8x FIFOs are required in the transpose DMA for 16 bit data. This results in eight sets of input data being constructed in the buffer memory one for bin(m) from each ramp, one for bin(m+1), one for bin(m+2) and so on up to bin(m+7), where m is always divisible by eight.

In this case, the inner loop cycles over bins 0 to m(max) where m(max) is the number of bins in the input data divided by 8 and then the outer loop cycles over the antennae.

### 19.2.8.8.1 Data Mapping for 2nd Stage FFT results with 16bit Operands and 4 Antennae

The figure below is showing Radar memory for 16bit operands and 4 antenna and shows 256bit word content after 2nd stage FFT. This assumes no “in place FFT” with transposed addressing.

## Signal Processing Unit (SPU)

---

## Signal Processing Unit (SPU)

### 19.2.8.9 3rd stage FFT

Ability to run systematic 3rd stage FFTs is of interest for safety reason.

Ability of running systematic 3rd stage FFT might become mandatory for elevation support: during the time the CPU will run super resolution algorithm on DOA, the Radar SPU can compute low resolution angle of elevation. the Radar SPU, as it is defined here, is able to perform 3rd stage FFT

- operands alignment in memory is prepared for this (can use same DMA read sequence)
- Input DMA Unit supports “zero” padding on its input.

#### Notes: Comment on safety aspects

1. *when running complex angle estimation algorithms like MUSIC, ESPRIT, ROOT-MUSIC, you will then have an estimate of the angle position.*
2. *this estimate should match the gross estimate provided by the systematic 3rd stage FFT.*
3. *having them done by the accelerators allows to have the TriCore fully available to run the precise angle estimation algorithm.*
4. *So, here performance is not so much the focus.*

## Signal Processing Unit (SPU)

### 19.3 Functional Description

This section describes programming and using the SPU. It deals with each of the major functional blocks of the SPU in the order data flows through the processing pipeline.

#### 19.3.1 Input DMA Engine

The Input DMA Engine can either passively accept data pushed by the ADC interfaces (RIF or Radar Interface) or actively load part or all of an existing data cube from the Radar Memory. Its function is to structure the data in the Buffer RAM into FFT data sets. To do this, it uses the following general control data as well as control information specific to the data source used.

**Table 596 Input DMA Unit General Parameters for all Input Sources**

Parameter	Definition	Comments
Data Source	ADC IF 0, ADC IF 1, both ADC IF or Radar Memory	<b>ID_CONF.SRC</b>
start mode	trigger mode for the SPU ( <b>CTRL.MODE</b> ). Options are defined in <a href="#">Table 627, CTRL.MODE Value Definitions</a> :	

Please refer to [Section 19.2.8, Memory mapping](#) for background information.

#### 19.3.1.1 Load ADC data from the RIF

When loading data from the RIF or RIFs, processing mode is always default and the input data format and number of antennae must be aligned with the RIF configuration settings. In addition the following operating modes can be configured

**Table 597 Input DMA Unit Specific Parameters for ADC Data**

Parameter	Definition	Comments
Ramps per Measurement Cycle	Number of ramps to be acquired after trigger.	Excess ramps will be ignored unless the SPU is retriggered <b>ID_CONF.RAMPS</b>
Number of active antenna	Number of physical antennae connected to the ADC interfaces of the microcontroller	<b>ID_CONF.ANT</b>
Input format	Signed or unsigned	<b>ID_CONF.SIGNED</b>
Samples per Ramp or Bins per FFT	The number of sample points to be used in the input datasets for the FFT	<b>ID_CONF.SMPLCNT</b>
Input format	Real or complex,	<b>ID_CONF FORMAT</b>

#### 19.3.1.1.1 Principles of Operation (ADC IF)

There are some restrictions imposed on the physical configuration of the overall system by the Input DMA. The most significant of these are that, if both ADC IF<sup>1)</sup> instances are being processed by a single SPU:

- the configuration of the ADC IFs must be identical so that the quantity of data being fed to the SPU by each ADC IF is the same.

1) The ADC IF function is implemented in the RADAR Interface (RIF) module

## Signal Processing Unit (SPU)

- The data sources providing data to the ADC IFs must be synchronised. This is for two reasons
  - To enable meaningful integration (or other calculations) across the antennae, the sampling time for each antenna must be aligned and kept consistent to within very small limits
  - The ADC IFs contain buffers to ensure that the data fed to the SPU is aligned in the same clock cycle for equivalent antenna. The alignment of data is triggered by setting a configuration option in the RIF module registers. The data provided to the ADC IFs must be sufficiently aligned to prevent these buffers overflowing. The buffering is sufficient to allow for one complete sample misalignment at the serial inputs to the ADC IFs.

When configured for internal or software trigger mode, the SPU will accept all data from the ADC IFs. The ADC IF in this case must maintain synchronisation to the ramps and only pass valid data to the SPU (although there is a limited facility to remove undesired data by truncating the dataset in the MATH1 unit).

When configured for external trigger, the SPU will accept trigger pulses from the SPU Lockstep module and use these to maintain synchronisation. The trigger output from the SPU Lockstep module is set by writing to a field in a register and is connected to both SPUs. This allows both SPUs to be triggered simultaneously.

### Antennae (ID\_CONF.ANT)

The number of active antennae is the number of physical antennae attached to the configured data source (ADC IF0, ADC IF1 or both). For real data this can be up to four antennae per ADC IF. However for complex data, each antenna will require two data channels, one for the real data component and one for the complex data component. This halves the number of physical antennae that can be connected to each ADC IF to a maximum of two.

#### 19.3.1.1.2 Split Processing

This mode is used in systems with 2 RIF instances when there is too much data from the ADCs to be handled by the lockstepped SPUs in a single pass. ID\_CONF.SRC should be set to  $10_B$  (BOTH) and the antennae must be distributed symmetrically between the two RIF instances.

The data from RIF0 is processed and the data from RIF1 is written directly to Radar Memory for later processing. The address is stored in the ID\_CONF2.BPADDR field. The first pass is configured by setting ID\_CONF2.BYPASS with ID\_CONF2.BPRLD (Bypass Reload) cleared. This will process the RIF0 data and bypass the RIF1 data. The second pass is configured by setting both ID\_CONF2.BYPASS and ID\_CONF2.BPRLD. This will read the data from the address in the BPADDR field rather than the RIF interface.

All other register settings, apart from the ODP\_CONF.BASE should be the same. In particular, IDM\_CONF.SRC should remain at  $10_B$  to ensure that the IDM uses the correct format when loading the data. In Bypass Mode, the reloaded data is treated as an ADC IF (RIF) data stream rather than a datacube in Radar Memory. The same parameters therefore apply as when loading ADC data directly from a RIF. The parameters used when loading from Radar Memory are not applicable.

#### 19.3.1.2 Load from Radar Memory

The following options are specific to loading data from Radar Memory:

## Signal Processing Unit (SPU)

**Table 598 Input DMA Unit Parameters for Reading Data from Radar Memory**

Parameter	Definition	Comments
Input format	16bit or 32bit precision complex data, 16bit or 32bit precision real data, IEEE 754 half precision floating point real data, IEEE 754 half precision floating point complex data, or 32 bit power	<b>ID_RM_CONF FORMAT</b>
DMA base address	DMA base address when starting a new FFT sequence from Radar memory	Word (256 bit) address relative to start of Radar Memory <b>ID_RM_CONF BASE</b>
DMA outer loop address offset	Offset address to be added to base address (Radar Memory address calculation)	Byte offset <b>ID_RM_OLO.OLO</b>
DMA outer loop repeat value (parameter “m”)	Number of times of outer loop execution	e.g. for 2nd stage FFT, this would be the number of antennae to process in default mode. <b>ID_RM_IOLR.OLR</b>
DMA inner loop address offset	Offset address to be added to base address (Radar Memory address calculation)	Byte offset <b>ID_RM_ILO.ILO</b>
DMA inner loop repeat value (parameter “n”)	Number of times of inner loop execution	Inner loop count is incremented by one every time a complete FFT is read from memory <b>IDM_RM_IOLR.ILR</b>
Bin offset	Radar Memory address offset between adjacent bins in an input dataset	Byte offset. When reading a linear FFT from memory, this would be set to the size of one data element <b>IDM_RM_BLO.BLO</b>
Bin Offset Loop Repeat (parameter “p”)	Number of reads needed to traverse one input FFT. (number of bins in an input dataset)	The number of samples in each FFT input (dataset) being constructed <b>IDM_RM_BLR.BLR</b>
Addressing Mode	Linear or Transpose Addressing	<b>ID_RM_CONF TRNSPS</b>
Processing Mode	Default Mode or Integration Mode for bandwidth optimisation.	Integration Mode should be used when construct input datasets for use with the coherent or non-coherent integration functions in the MATH2 units <b>IDM_RM_CONF PM</b>

## Signal Processing Unit (SPU)

**Table 598 Input DMA Unit Parameters for Reading Data from Radar Memory (cont'd)**

Parameter	Definition	Comments
Number of simultaneous data blocks from RAM	For integration mode, defines the number of concurrent information sets (data blocks) that are fetched from memory.depends on memory organization.Number from 1 to 8.(1,2 4 and 8 supported).	Number of data blocks that will fit into the buffer memory. <b>IDM_RM_CONF.BLOCKS</b> Add one to this field to get the number of data blocks. Supported values are therefore: 0, 1, 3, and 7.
Mapping of FFT datasets to antenna	Defines how each dataset in the buffer memory is linked to an antenna ID for windowing and other antenna specific operations	<b>ID_RM_CONF.AM</b>

All address fields in registers are specified in words (256 bits or 32 bytes).

At any time the byte address that the Input DMA is reading from is defined as:

```
(base address<<5) + ((outer loop offset)*m) + ((inner loop offset)*n) + ((bin loop offset)*p)
```

where **n** and **m** are as defined above and **p** is the bin being read. This will be used to generate a word address for Radar Memory by truncating bits [4:0] of the generated address. Bits [4:0] will be used to select within the 256 bit word retrieved from radar Memory.

The input DMA engine will read (at least) one complete set of FFT input data per inner loop using the Bin Offset field to increment the byte address between sample reads.

See [Chapter 19.2.8.3.1](#) and [Chapter 19.2.8.4](#) for an overview of the effect of the Processing Mode options on memory usage. A more detailed description of the operating modes follows

### 19.3.1.2.1 Principles of Operation (Radar Memory)

The Input DMA is designed to allow autonomous processing of a three dimensional data array stored in the Radar memory. Typically the three axes of the array would be representing FFT sample number, ramp or acquisition count and antenna. The intention is to allow assembling input sets for the FFT accelerator by stepping across the axes in any arbitrary order.

This is accomplished by constructing the read address for the Input DMA from a base address and three independent address offsets (“bin loop address”, “inner loop address” and “outer loop address”).

The term “bin loop” is used as the bin loop repeat value maps directly to the number of bins in each FFT dataset constructed in the buffer RAM. The bin loop repeat value defines the size of the input dataset.

**Note:** *The maximum number of bins supported in an FFT dataset is 2048. Setting a Bin Loop Repeat value for an FFT size greater than this (i.e. ID\_RM\_BLR.BLR > 2047) is not supported and should be avoided.*

Some assumptions are made about the organisation of the data. Specifically that:

- Each dataset in memory starts at a 32 byte aligned address. This allows the bandwidth optimisation hardware to function and is enforced by the Output Data Manager. This restriction has to be observed when using software to build data arrays in memory for reading by the Input Data Manager
- The second assumption follows from the first. If all datasets are 32 byte aligned, it follows that 2 co-ordinate axes of the data array must be multiples of 32 byte. Only a single co-ordinate axis, the one used to step along data samples can be less than a multiple of 32 bytes and this must be set to the data sample size. The other axes will be used to step along datasets.

## Signal Processing Unit (SPU)

**Note:** The SPU is specified to cope with Radar Memory sizes up to 16 MiB. If programming causes it to generate an address outside the range of the available Radar Memory in the product, an error will be generated by the Input Data Manager

Each counter has an associated offset and a repeat count. Operation is then as follows:

**Table 599 Input DMA Execution Flow**

1	initialise the “bin loop address”, the “inner loop address” and the “outer loop address”.
2	loop
3	The read address is computed by adding the “base address”, the “bin loop address”, the “inner loop address” and the “outer loop address”.
4	An input value is then read from the address
5	“bin loop count” is incremented
6	If { the bin loop count has reached the “bin offset loop repeat” value } then
7	“bin loop count” is reset
8	“bin loop address” is reset
9	“inner loop count” is incremented
10	If { the “inner loop count” has reached the “inner offset loop repeat” value } then
11	“inner loop count” is reset
12	“inner loop address” is reset
13	“outer loop count is incremented”
14	If { the “outer loop count” has reached the “outer offset loop repeat” value } then
15	execution has completed, exit loop
16	else
17	“outer loop address” is set to “outer loop address” plus “outer loop offset”
18	end if
19	else
20	“inner loop address” is set to “inner loop address” plus “inner loop offset”
21	end if
22	else
23	“bin loop address” is set to “bin loop address” plus “bin loop offset”
24	end if
25	end loop
26	stop

The flow above is the basic operation flow without considering bandwidth optimisation. As the Radar Memory is organised as 256 bit words and the data element occupy either 32 or 64 bits depending on precision and format, then bandwidth usage can be optimised by using as much as possible of the 256 bit word<sup>1)</sup>. The Input DMA will attempt to do this based on register settings by “collapsing” one or more of the loops i.e. effectively performing multiple iterations of one of the loops in a single pass as described in the following sections.

1) The exceptions to this are the 16 bit precision, real only formats, REAL16BIT and REAL16FP. These formats can only be used if TRNSPS=0. If the SPU is configured with (FORMAT=REAL16BIT or FORMAT=REAL16FP) and TRNSPS=1, the resulting datasets will be corrupted.

## Signal Processing Unit (SPU)

**Table 600 Input DMA Loop Mapping**

Mode	Co-ordinate Mapping <sup>1)</sup>			Notes	ID_RM_CONF Register Settings <sup>2)</sup>
	Bin Loop Offset	Inner Loop Offset	Outer Loop Offset		
1	<b>Sample</b>	FFT	Antenna	Linear (Default) Addressing Mode. Each Radar Memory Read fetches multiple samples for the same FFT. ID_RM_CONF.FORMAT=REAL16FP not supported.	<b>TRNSPS=1</b> PM=1 BLOCKS=0,1,3,7

- 1) Incrementing the Offset counter increments address to next sample bin, next FFT dataset or next antenna
- 2) Mandatory settings are shown in bold. Options where multiple values are possible are shown as a commas separated list
- 3) Provided that ID\_RM\_IOLR.ILR is less than or equal to  $7_D$ .

## Signal Processing Unit (SPU)

### 19.3.1.2.2 Case 1: “Bin Offset” is set to Sample Size

In this case, the bins in Radar Memory to be used as consecutive inputs bins for each FFT dataset are stored in consecutive addresses in Radar Memory so each 256 bit read will load four, eight or sixteen bins depending on the precision of the data. The input DMA will therefore execute four, eight or sixteen iterations of the “bin offset” loop simultaneously. This is the [“Default Memory Mode” on Page 11, Section 19.2.8.3.1](#). As this does not require address transposition, the ID\_RM\_CONF.TRNSPS bit must be set to  $0_B$  (LIN).

Bandwidth optimisation is not needed in this mode as all data fetched in a 256 bit read is used in the same FFT dataset.

#### Buffer Memory Switching

If the ID\_RM\_CONF.PM bit is set to IM, this signals that the data block should contain one dataset for each antenna (i.e. the Inner Loop Offset is set to step across antennae) and the Buffer Memory will be switched when the Inner Loop Repeat Count is reached. Otherwise, the Input Buffer Memory will be switched every four (for 64 bit data) or eight (for 32 bit data) iterations of the Inner Loop or when all data has been read whichever occurs first.

**Note:** *Setting ID\_RM\_CONF.BLOCKS to a non-zero value with ID\_RM\_CONF.TRNSPS set to  $0_B$  is not supported and will result in undefined operation of the input DMA.*

### 19.3.1.2.3 Case 2: “Inner Loop Offset” is set to Sample Size

This is the first of the co-ordinate transposition cases, so the ID\_RM\_CONF.TRNSPS bit must also be set to explicitly signal the intent to use co-ordinate transposition to the logic of the SPU. The Bin Loop offset can be set to step either across antennae or across FFT result datasets.

The ID\_RM\_CONF.TRNSPS bit signals that the data from each 256 bit read will be used in different FFT input datasets and should therefore be written to different areas of the buffer memory (“scattered”).

As stated, the bins in Radar Memory to be used as consecutive input bins in each FFT dataset are stored in non-consecutive addresses in Radar Memory so each 256 bit read will load four or eight bins depending on the precision of the data<sup>1)</sup> but these samples will be from different FFT input sets. The input DMA will therefore execute four or eight iterations of the “inner loop” simultaneously. This bandwidth optimisation is described in [Section 19.2.8.3.1, “Default Memory Mode” on Page 11](#) and [Section 19.3.1.2.5, “Bandwidth Optimisation for Default Processing Mode” on Page 43](#).

ID\_RM\_CONF.PM must be set to DM for this operating case as the data from each 256 bit read is all needed for a single datablock.

#### Buffer Memory Switching

The Input Buffer Memory will be switched either when the Inner Loop Count is updated. i.e. every four (for 64 bit data) or eight (for 32 bit data) iterations of the Inner Loop or when all data has been read.

### 19.3.1.2.4 Case 3: “Outer Loop Offset” is set to Sample Size

This is the second of the co-ordinate transposition cases, so the ID\_RM\_CONF.TRNSPS bit must also be set to explicitly signal the intent to use co-ordinate transposition to the logic to the logic of the SPU. Either the Bin Loop Offset or Inner Loop Offset will be set to step across the FFT datasets stored in the Radar Memory. However in both of these cases, consecutive samples to be used as inputs to the FFT are stored in non-consecutive addresses in Radar Memory so, while each 256 bit read will load four or eight bins<sup>1)</sup> depending on the precision of the data, these samples will be from different FFT input sets. This differs from case 2 in that using the remaining data from

<sup>1)</sup> 16 bit precision real data (FORMAT=REAL16BIT) and 1 bit half precision floating point real data (FORMAT=REAL16FP) are not supported with TRNSPS=1.

## Signal Processing Unit (SPU)

the 256 bit read requires an increment of the outer loop. This is signalled to the logic by setting ID\_RM\_CONF.PM to IM ( $1_B$ ).

In this case, to avoid discarding data and wasting bandwidth, multiple data blocks can be built in memory by setting the ID\_RM\_CONF.BLOCKS bitfield to a value other than  $0_D$ . This bandwidth optimisation is described in **Section 19.2.8.4, “Bandwidth Optimised Integration Mode” on Page 12.** and **Section 19.3.1.2.6, “Bandwidth Optimisation Integration Processing Mode.” on Page 43.** This has the effect of collapsing the outer loop as well as the inner loop resulting in a three-dimensional array of input data in the buffer memory.

### Buffer Memory Switching

If the ID\_RM\_CONF.PM bit is set to IM, this signals that the data block should contain one dataset for each antenna (i.e. the Inner Loop Offset is set to step across antennae) and the Buffer Memory will be switched when the Inner Loop Repeat Count is reached. Note that in this case, the FFT accelerator will run ID\_RM\_CONF.BLOCKS+1 processing operations for each switch of the buffer memory. Otherwise, the Input Buffer Memory will be switched every four (for 64 bit data) or eight (for 32 bit data) iterations of the Inner Loop or when the Outer Loop Count is updated or all data has been read whichever occurs first.

### 19.3.1.2.5 Bandwidth Optimisation for Default Processing Mode

The memory mapping used to store data after the SPU processes ADC samples means that consecutive addresses in memory contain adjacent samples from the same FFT and that the same FFT result point from different antennae are always separated in the address space. Default mode is designed to work with this memory organisation to optimally construct multiple input datasets from each set of 256 bit reads. Each of the samples in a single data read will be allocated to different input datasets in the buffer memory.

The mode is enabled by setting ID\_RM\_CONF.TRNSPS=TRN and ID\_RM\_CONF.PM=DM

To work in default mode either the **ID\_RM\_BLO.BO** or **ID\_RM\_ILO.ILO** bitfields must be set to the sample size.

**Note:** One of the three fields, **ID\_RM\_OLO.OLO**, **ID\_RM\_ILO.ILO** and **ID\_RM\_BLO.BO** must always be set to the sample size.

### 19.3.1.2.6 Bandwidth Optimisation Integration Processing Mode.

Integration Mode Bandwidth Optimisation is intended for the use case where the MATH2 unit is required to integrate results across antennae while the input data manager is using transposed addressing. In this mode, the Input DMA Engine must load data into the Input Buffer Memory so that each constructed data block contains one dataset from each antenna.

The mode is enabled by setting ID\_RM\_CONF.TRNSPS=TRN and ID\_RM\_CONF.PM=IM.

In this case, the data block being constructed in memory would use only one sample point from each 256 bit read, as the first dimension of traversing the data cube (Bin Loop Offset) is across FFT results and the second (Inner Loop Offset) is across antennae (i.e. the data blocks constructed are suitable for use by the coherent or non-coherent integration functions of the MATH2 unit). This compares to the default transpose addressing mode, where the first dimension is still across FFT results but the second is across sample points and each read fetches several contiguous sample points which can be used to construct datasets that can be processed as a single data block.

To mitigate the inefficient use of Radar Memory bandwidth, an optimisation submode of Integration Mode controlled by the ID\_RM\_CONF.BLOCKS bitfield is available.

Enabling this submode allows multiple data blocks to be constructed in the buffer memory. Then, instead of switching the buffer memory between every data block, the base address the Loader Module uses for reads is adjusted instead. When IDM\_RM\_CON.PM is set to 1 and a non-zero value is written to ID\_RM\_CONF.BLOCKS, the

## Signal Processing Unit (SPU)

Input DMA Engine will try and use some of the excess data read to construct the additional data blocks in the buffer memory.

To support this, the Buffer RAM will be logically sub-divided into multiple segments based on the most significant address bits, one for each data block. The number of data blocks being equal to the value of the ID\_RM\_CONF.BLOCKS bitfield plus one. BLOCKS can be set to values between  $0_D$ ,  $1_D$ ,  $3_D$ , and  $7_D$ .

The Data Loader Unit will then read each data block sequentially rather than switching the buffer memory and only switch the buffer memory when all the data blocks have been processed. All units downstream of the FFT still process each data block discretely.

Application software must ensure that the data will fit into the sub-divided buffer memory.

**Note:** *If the number of data blocks built in the buffer memory does not use all of the 256 bits read from Radar Memory, then the same 256 bits will be read on successive passes until all the data is consumed. e.g. if the data in radar memory is 64 bit and BLOCKS is set to  $1_D$  then the Input DMA will make two passes through the data in Radar Memory. Each pass will create two data blocks in the Buffer Memory.*

### 19.3.1.3 Partial-acquisition Counter

The partial-acquisition counter is used to count ramps and hence to determine the absolute position in the measurement cycle. It is reset by software and will then use the configuration information (samples per ramp and number of antennae) valid at the point of reset to count ramps until the next time it is reset by software.

The intended use case of the counter is to allow the SPU to be triggered multiple times during a single measurement cycle while still retaining synchronisation with the input data stream from the Radar Interface(s). This allows the first few ramps of a measurement cycle to be processed to determine useful information about the input data. The SPU can then be reprogrammed to make most effective use of the input data and retriggered at a known ramp count to process the remaining data from the measurement cycle.

The counter can be configured to generate an error or attention interrupt if any particular value is reached with the counter still enabled.

The SPU can be configured to delay start of processing until a particular value is reached.

The operation of functions related to this counter are controlled by the bitfields of the PACTR register.

**Table 601 Partial-acquisition Counter Specific Parameters for ADC Data**

Parameter	Definition	Comments
Initialise the Counter	Reset the value of the partial-acquisition counter to $0_D$ .	<b>PACTR.RST</b>
Enable the Counter	Counter will increment every time the IDM requests a switch of the input buffers.	<b>PACTR.EN</b>
Limit Value for the counter	Comparison value for triggering a pre-programmed event Note that for comparison purposes, the first ramp of a measurement cycle is considered to be ramp 0.	<b>PACTR.LIMIT</b>
Trigger	Trigger SPU data processing on a limit event	<b>PACTR.TRIG</b>

## Signal Processing Unit (SPU)

**Table 601 Partial-acquisition Counter Specific Parameters for ADC Data (cont'd)**

Parameter	Definition	Comments
Error	Trigger an error interrupt on a limit event (unless TRIG bit is set and SPU is configured and waiting for data i.e. CTRL register written with MODE=INT)	<b>PACTR.ERR</b>
Attention	Trigger an attention request interrupt on a limit event	<b>PACTR.ATTN</b>
Counter Value	Current state of the Partial Acquisition Counter	<b>PACTR.COUNT</b>

Example use case for a measurement cycle with 1024 ramps of 256 samples and 4 antennae with the intention to process the first four ramps, skip two ramps while reprogramming the SPU and then process the remaining 1018 ramps:

- Program SPU for data from RIF, 256 samples and 4 antennae and four ramps, reset the partial-acquisition counter. Set the PACTR Error Interrupt and configure the limit field to 6 (as we expect to have reprogrammed the SPU by the start of the seventh ramp). Trigger the SPU by either internal (CTRL.MODE=INT) or external mode (CTRL.MODE=EXT).
  - This will initialise the Partial-acquisition counter with the correct information to keep track of the ramps
  - The SPU will process 4 ramps and then stop. The SPU DONE interrupt will then trigger the CPU to process the data. The CPU can then take decisions on how to best configure the SPU for the remainder of the measurement cycle
  - The Partial-acquisition counter will continue to track ramps. If the ramp counter reaches six (i.e. the seventh ramp has started) without the PACTR register being updated by the CPU, then the error interrupt will be asserted. This would indicate that the expected reconfiguration time has been exceeded.
- The CPU reprograms the SPU for the remainder of the measurement cycle<sup>1)</sup>. The partial-acquisition counter trigger bit is set and the error bit is set. The CTRL.MODE bitfield must be set to INT or EXT<sup>2)</sup>. The partial-acquisition counter is not reset.
  - The SPU is triggered at the start of ramp seven and the data from the seventh ramp to the one thousand and twenty-fourth ramp is acquired and processed. This trigger must be an internal trigger.
  - Setting the error bit eliminates the race condition of the start of the seventh ramp occurring between the write to the PACTR register and the write to the CTRL register. The error interrupt will be gated if TRIG is set and the CTRL register has been written with MODE=INT or with MODE=EXT and an external trigger has occurred.

The partial-acquisition counter can only be used to monitor input data sourced from the Radar Interface. It cannot be used to track data loaded from Radar Memory.

### Notes

1. *The SPU can process data from the Radar Memory without impacting the operation of the Partial Acquisition Counter once it is configured and running*

- 1) The reconfiguration of the SPU is not expected to change any setting in the ID\_CONF or ID\_CONF2 registers except the ID\_CONF.RAMPS field as the RIF(s) are still running the same measurement cycle and the format of the data input should not have changed. This restriction means that, although BYPASS could be used, reloading bypassed data before the end of the measurement cycle (i.e. in the gaps between partial acquisitions) is not supported.
- 2) If the partial-acquisition Counter trigger condition is reached before the CTRL register is programmed to enable the SPU, then an error interrupt will always be generated.

## Signal Processing Unit (SPU)

2. Setting the partial acquisition trigger (*PACTR.TRIG = 1*) without enabling the counter (*PACTR.EN = 0*) will still enable the trigger logic. Incoming Data will be filtered indefinitely waiting for a limit event which will not occur

### 19.3.1.4 FFT Data to Antenna Mapping

Some processing units (e.g. the complex windowing function) require that each set of FFT data be associated with an antenna. This is done using the information stored in the ID\_RM\_CONF.PM and ID\_RM\_CONF.AM bitfields.

If ID\_RM\_CONF.PM is set to  $1_B$ , then the buffer memory datablock will contain one dataset from each antenna. The processing units will therefore use the dataset index to identify the antenna.

If ID\_RM\_CONF.PM is set to  $0_B$ , then the data block is assumed to contain data from a single antenna. In this case, the setting of ID\_RM\_CONF.AM is used to define which of the loop repeat counters (Inner Loop Repeat or Outer Loop Repeat) is used to generate the antenna ID. Alternatively, the antenna ID can be forced to either  $0_D$  or “dataset index” (equivalent to ID\_RM\_CONF.PM= $1_B$ ). If the antenna ID is derived from one of the loop counters, only the three LSBs of the counter will be used to keep the antenna ID within the permitted range of  $0_D$  to  $7_D$ .

The loop repeat counter value used is chosen at the point the buffer memory is filled and before the counter is incremented for reading the next data. This leads to the following effects:

- If ID\_RM\_CONF.AM is set to BLR, the antenna ID will always be the three LSBs of the BLR value in the RM\_BLR register.
- If ID\_RM\_CONF.AM is set to ILR, the antenna ID will be as follows
  - for the final data block before incrementing the Outer Loop Counter, the antenna ID will be the 3 LSBs of the ILR value in RM\_IOLR
  - for other data blocks, the antenna ID will alternate between  $3_D$  and  $7_D$  for 32 bit precision complex data and will always be  $7_D$  for 16 bit precision data (real or complex format) or power data.
- If ID\_RM\_CONF.AM is set to OLR, the antenna ID will start at  $0_D$  and will then increment every time the Outer Loop Counter is incremented. If ID\_RM\_CONF.BLOCKS is not equal to zero, the value will be the final value of the Outer Loop Counter when the IDM completes loading of the buffer memory

### 19.3.1.5 Reading Power Data From Radar Memory

The Input DMA will normally read complex data from the Radar Memory as this is the expected format of FFT results. However, in some cases, further analysis of linear power data stored by a previous processing pass of the SPU may be desirable. As this data will be stored as a 32 bit, unsigned integer, ID\_RM\_CONF.FORMAT has an option for reading 32 bit power.

This setting is intended to allow power data to be processed by the MATH2 units and must only be used with the FFT accelerator and MATH1 complex data specific functions bypassed or disabled.

### 19.3.1.6 Reading 16 bit Real Data From Radar Memory

The Input DMA will normally read complex data from the Radar Memory as this is the expected format of FFT results. However, in some case, memory restrictions may require data to be stored as 16 bit precision, real only data. Reading 16 bit precision, real data can be done by setting ID\_RM\_CONF.FORMAT to REAL16BIT for integer data or REAL16FP for half precision floating point. If either of these options is used, then address transpose mode is not available and ID\_RM\_CONF.TRNSPS must be set to  $0_B$ .

For half precision floating point, denormalised numbers, Infinities and NaNs should be avoided in the input data. Denormalised numbers will be treated as zero. Infinities and NaNs will be set to either maximum negative or maximum positive values depending on the sign bit to allow processing to continue and will not propagate. The SPU has no capability to process signalling NaNs.

## Signal Processing Unit (SPU)

### 19.3.1.6.1 Buffer Memory Switching for 16 bit real data

If the ID\_RM\_CONF.PM bit is set to IM, this signals that the data block should contain one dataset for each antenna (i.e. the Inner Loop Offset is set to step across antennae) and the Buffer Memory will be switched when the Inner Loop Repeat Count is reached. Otherwise, the Input Buffer Memory will be switched every eight iterations of the Inner Loop or when all data has been read whichever occurs first.

### 19.3.1.7 Data Storage in Buffer Memory

The datasets will be stored linearly in the buffer memory in the order they should be processed. This allows the Data Loader module to progress sequentially through the buffer memory address space.

## 19.3.2 Streaming Processor 1

Streaming Processor 1 retrieves data from the buffer memory loaded by the Input DMA Engine and processes the information for use by the FFT accelerator

### 19.3.2.1 Double Pass Mode

The SPU allows all processing operations to be run twice per data block. This mode is enabled using the DPASS\_CONF.EN bitfield. Once the data has been loaded to Buffer RAM by the Input DMA Engine, the subsequent modules in the processing pipeline have the option to

- read the data twice and apply different processing options. This is the default “double pass” mode
- independently apply the different parameter sets defined for the window function to successive sequences of data blocks. See [Section 19.3.2.1.2](#) below.

This results in two sets of results being written to Radar Memory.

**Table 602 Parameters Specific to Double Pass Mode**

Parameter	Definition	Comments
Enable Mode	Configure SPU to process each data block twice.	<b>DPASS_CONF.EN</b>
Switch Mode	Configure SPU to process successive data blocks with different parameter sets. Number of data blocks between parameter switches configured by DPASS_CONF.COUNT	<b>DPASS_CONF.SWITCH</b>
Window Parameter Switch Count	Switch the window parameters when this many data blocks have been processed	<b>DPASS_CONF.COUNT</b>
Window Parameter Switch Count Enable	Enable the Window Parameter switch count	<b>DPASS_CONF.EN_CNT</b>

The values to be used in the second processing pass are stored in the BE1\_<REGNAME> registers. Primarily these are the settings for the MATH1 unit but the base address settings for the various data options in the MATH2 units are also duplicated.

The following register fields should not be changed between processing passes. A write to these fields in either copy of the register will be reflected in both registers.

## Signal Processing Unit (SPU)

**Table 603 Mirrored Register Fields**

Register	Field
LDR_CONF	DRPL
	DRPF
	EXPNT
	SIZE
	FFTBYPS
	IFFT
LDR_CONF2	PADF
UNLDR_CONF	FORMAT
	EXPNT

Note: Note that the mode of the FFT module (FFT or IFFT) cannot be varied between passes so the LDR\_CONF.IFFT bit is mirrored.

### 19.3.2.1.1 Double Pass Switch Mode

The behaviour of Double Pass Mode can be modified by setting the DPASS\_CONF.SWITCH bitfield. In this case, each data block is only processed once and the different parameter settings are applied to consecutive data blocks.

### 19.3.2.1.2 Window Parameter Switch

The switch of the two possible sets of parameters for the window function can be made independent of the double pass functionality by setting the DPASS\_CONF.EN\_CNT. When this bit is set, the window parameters are selected independently of the double pass function and applied to sequences of data blocks. The number of data blocks per sequence is configured by the DPASS\_CONF.COUNT bitfield and is set to COUNT+1. If COUNT=0, then the different parameter settings are applied to alternate data blocks. If COUNT=7, then the different parameter settings are applied to sequences of 8 data blocks.

### 19.3.2.2 Data Loader Unit

The Data Loader will read data from memory and reformat it before pushing it into the MATH 1 unit pipeline. It can modify the format of the input data by resizing it from 16 to 32 bit precision and by converting it from real to complex format. Operations will occur in the following order

- 16 to 32 bit precision
- real to complex conversion

**Table 604 Loader Configuration Parameters**

Parameter	Definition	Comments
number of samples	number of samples per FFT currently in the buffer RAM	passed from the Input DMA Engine
number of data sets	number of FFTs to run	passed from the Input DMA Engine

## Signal Processing Unit (SPU)

**Table 604 Loader Configuration Parameters (cont'd)**

Parameter	Definition	Comments
Data precision	16 or 32 bits	passed from the Input DMA Engine
Data type	Real or complex	passed from the Input DMA Engine
Data format	Integer or floating point	applicable to Radar Memory data only. passed from the Input DMA Engine
Integration Mode Bandwidth Optimisation	Buffer Memory Configuration. Number of Datablocks in the buffer memory	passed from the Input DMA Engine
Signed or Unsigned	Input Data is unsigned or 2's complement format	Applicable to ADC data only, passed from the Input DMA Engine

### 19.3.2.2.1 Data Reformatting

The format of the data in the buffer memory is known as it is programmed into the Input DMA Engine configuration. All data processed by the FFT accelerator must be in 32 bit complex format. Real data is converted to complex data with a zero imaginary component. 16 bit data is extended to 32 bit using the method specified by the LDR\_CONF.EXPNT bitfield. This controls how the 16 bit data is justified within the 32 bit output field. The type of data (signed or unsigned) is passed from the Input DMA Engine and is derived from the ID\_CONF.SIGNED bitfield. This determines whether a signed or unsigned extension to 32 bits is used.

When using data from Radar Memory, LDR\_CONF.EXPNT has a maximum permissible value of  $16_D$  and aligns 16 bit fixed exponent format data. When using data from the Radar Interface, the number of significant bits can be less than  $16_D$  so the maximum permissible value of LDR\_CONF.EXPNT can be increased to allow for 10 bit data right aligned in the 16 bit field.

If the shift operation causes a loss of significant data bits, then the output of the shift operation will saturate at full scale.

If the input data format is complex, then both real and imaginary components are treated in the same manner.

### 19.3.2.2.2 Integration Mode Bandwidth Optimisation

This is described in [Chapter 19.3.1.2.6, “Bandwidth Optimisation Integration Processing Mode.” on Page 43](#).

The Integration Mode Bandwidth Optimisation of the Input DMA Engine results in multiple datablocks being present in the buffer memory. The Buffer memory would normally be switched between datablocks. When this mode is enabled, instead of switching the buffer memory, the buffer memory address is offset to point to the next datablock. The MATH1, FFT and all units downstream of this point therefore see separate datablocks as normal.

### 19.3.2.2.3 Overview of Data Truncation and Padding

The diagram below gives a functional overview of how the operations described below affect the bins of the data loaded from the buffer memory

## Signal Processing Unit (SPU)

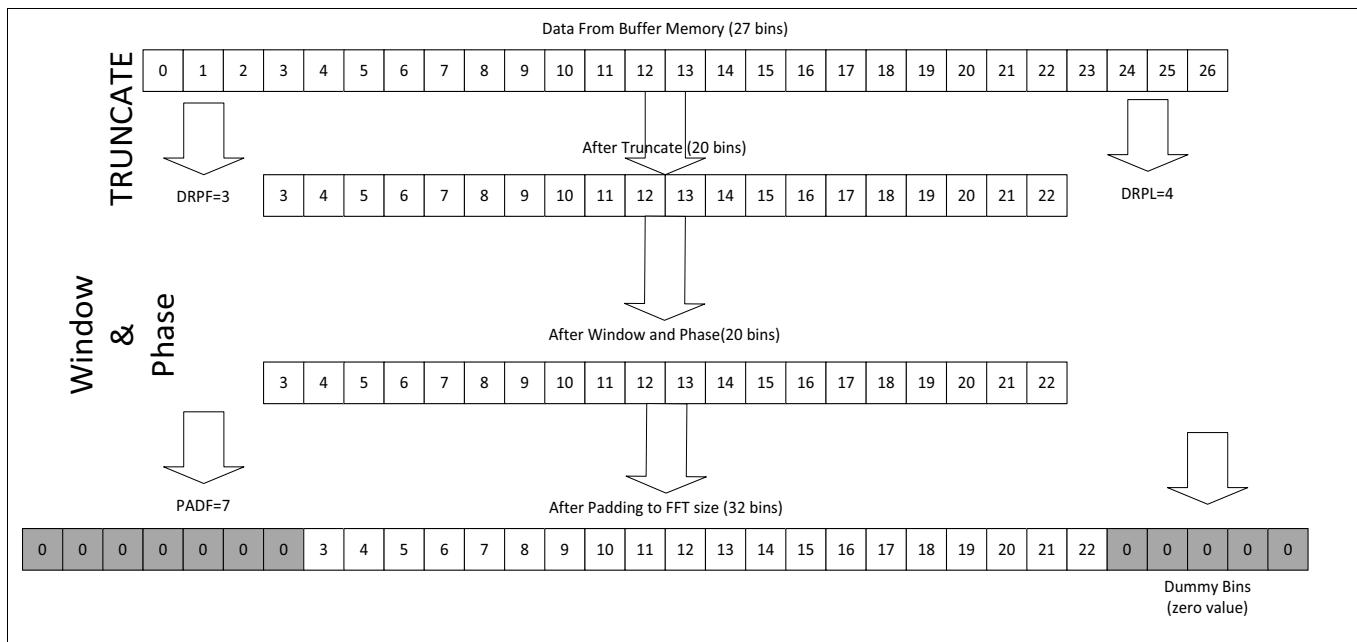

Figure 249 MATH1 Operation Overview

### 19.3.2.3 MATH1 Unit

The MATH1 unit handles all transforms applied to the data before the FFT processor. The operations will be applied in the following order

- Truncation
- Windowing
- Phase Shift
- Padding

Table 605 MATH1 Configuration Parameters

Parameter	Definition	Comments
Number of samples	Number of samples per FFT to be loaded into the FFT accelerator	<b>LDR_CONF.SIZE</b>
Number of data sets	Number of FFTs to run	passed from the Loader Unit
Window base address	Base address in Config Memory where the windowing functions are stored	<b>LDR_CONF2.WBASE</b>
Antenna window offset address	Offset from the Window base address of the window function for a particular antenna	<b>Ax_ANTFOST.ADROFSTy</b> <b>where x=0-3,y=0-1</b>
Padding activation	Padding enable / disable	implicit activation when the FFT size from the loader does not match the FFT size for the FFT accelerator
Leading padding	position of the 1st operand in the FFT (others being zeroed).	<b>LDR_CONF2.PADF</b>
Fast phase shift	does a 0/90/180/270 phase shift without using the windowing memory	<b>LDR_CONF.PHSHFT</b>

## Signal Processing Unit (SPU)

### 19.3.2.3.1 Truncation

Truncation is performed by two register fields, LDR\_CONF.DRPF and LDR\_CONF.DRPL. The reference for the dataset size is taken from the Input DMA Engine Configuration, IDM\_CONF.SMPLCNT field. DRPF is used to truncate from the beginning of the dataset and DRPL to truncate from the end of the dataset.

Truncation is not supported if the FFT is bypassed (LDR\_CONF.FFT\_BYPS = 1<sub>B</sub>) and both DRPF and DRPL must be set to 0<sub>D</sub> in this case. Behaviour if this restriction is not observed is undefined.

### 19.3.2.3.2 Windowing

Windowing is enable using the LDR\_CONF2.WINEN bit. The coefficients for the windowing function are stored in the configuration memory. The output of the windowing unit is scaled so that the maximum value of the window coefficients is +(2<sup>31</sup>-1)/2<sup>31</sup> and the minimum value is -1.

To retain precision, any needed truncation will be done at the output of arithmetic operations rather than the input. Where a result needs to be scaled down to fit into an output, the result will be rounded down to nearest integer after division.

The base address of the window coefficients is stored in LDR\_CONF2.WBASE. Additionally an address offset can be defined for each antenna. The offset is defined in bytes. If the address offsets are set to zero, the same window will be used for all antennae. Offsets are stored in the ANTOFST fields of the A[0|1]\_ANTOFST registers in the following order:

**Table 606 Antenna to Offset Register Mapping**

Antenna	Register	Bitfield
0	A0_ANTOFST	ADROFST0_ANT
1	A0_ANTOFST	ADROFST1_ANT
2	A1_ANTOFST	ADROFST0_ANT
3	A1_ANTOFST	ADROFST1_ANT
4	A2_ANTOFST	ADROFST0_ANT
5	A2_ANTOFST	ADROFST1_ANT
6	A3_ANTOFST	ADROFST0_ANT
7	A3_ANTOFST	ADROFST1_ANT

Antenna number selection is controlled by the ID\_RM\_CONF.AM and ID\_RM\_CONF.PM bitfields.

The window size must be the same as the truncated data set (i.e. before the padding operation).

The window data can be stored in several formats to save memory. Maximum precision is achieved using 32 bit complex window coefficients. However the data can also be stored in 32 bit real format, in which case the windowing function can affect magnitude but not phase. Further compression can be achieved by using 16 bit formats. Format is set using the LDR\_CONF.FRMT bitfield.

Window coefficients stored as 16 bit are extended to 32 bit by extending with 16 LSBs set to 0<sub>B</sub> so that the stored coefficient is left justified in the 32 bit value.

### 19.3.2.3.3 Phase Shift

The phase shift is achieved by sign manipulation of the real and imaginary components of the complex data values as described in the following table.

## Signal Processing Unit (SPU)

**Table 607 Phase Shift Operation**

Shift (degrees)	LDR_CONF.PHSHFT	Output to Input Mapping	
		Real OP	Imaginary OP
0	00	(Real IP) * 1	(Imag IP) * 1
90	01	(Imag IP) * -1	(Real IP) * 1
180	10	(Real IP) * -1	(Imag IP) * -1
270	11	(Imag IP) * 1	(Real IP) * -1

### 19.3.2.3.4 Padding

The truncated dataset is then padded to the FFT size set by the LDR\_CONF.SIZE bitfield. The LDR\_CONF2.PADF bitfield is used to determine how many zero data points are added to the front of the dataset. The remainder are added at the end.

These LDR\_CONF2.PADF field has no effect if the FFT is bypassed (LDR\_CONF.FFT\_BYPS = 1<sub>B</sub>) and no padding is performed on the data in this case.

Note that the dataset size cannot exceed the size set in the LDR\_CONF.SIZE bitfield. If the programmed value of LDR\_CONF2.PADF would violate this limit, then the behaviour of the loader is undefined but correct results will not be obtained. Similarly, LDR\_CONF.SIZE must not be set to a smaller number than the number of data points left after the Truncate operation.

### 19.3.2.4 FFT Accelerator

The FFT accelerator uses a pipelined architecture to implement the efficient radix 2<sup>2</sup> architecture.

The FFT accelerator can be completely bypassed using the LDR\_CONF.FFTBYP bit.

When performing an FFT, the accelerator will divide the output by the number of data points in the FFT to ensure that the output data does not overflow the integer output format.

An inverse FFT can be performed by setting the LDR\_CONF.IFFT bit. Setting the mode to IFFT will disable the descaling function of the FFT accelerator IP and the output will not be divided.

**Note:** *The inverse FFT function is intended to be used to post-process FFT results to recreate the original input data. If arbitrary input data is used or windowing or scaling is applied to the FFT results before attempting an inverse FFT, an overflow may occur at the output of the FFT accelerator which would normally be compensated for by the descaling operation. This overflow will be signalled to the processor by interrupt if the STAT.INTMSK[1] bit is set.*

Note that the dataset size cannot exceed the size set in the LDR\_CONF.SIZE bitfield. The number of datapoints read from the Buffer RAM is determined by the Input DMA configuration. If the programmed values of LDR\_CONF.DRPF, LDR\_CONF.DRPL and LDR\_CONF2.PADF results in a number of datapoints that violate this limit, then the behaviour of the loader is undefined but correct results will not be obtained.

**Table 608 FFT Engine Configuration Parameters**

Parameter	Definition	Comments
FFT length	defined in the global registers as the number of operands for the inner loop	<b>LDR_CONF.SIZE</b>
counter of actual FFT loads	counter. reset by user software	safety requirement

## Signal Processing Unit (SPU)

**Table 608 FFT Engine Configuration Parameters (cont'd)**

Parameter	Definition	Comments
counter of actual FFT unloads	counter. reset by user software.	safety requirement
FFT enable	FFT enabling / disabling	logically the same as “not FFT bypass” <b>LDR_CONF.FFT_BYPS</b>
Inverse FFT Mode	Configure the FFT accelerator to perform and Inverse FFT operation instead of the normal FFT	<b>LDR_CONF.IFFT</b>

### 19.3.3 Data Unloader

The Data Unloader writes the data from the FFT accelerator module into the output buffer RAM. All user programmable options are associated with the sideband processing of signal power to generate a histogram. By default, the Data Unloader writes 32 bit precision complex data to the Buffer RAM. As a space saving measure, the UNLDR\_CONF.FORMAT bitfield can be set to 16BIT and the UNLDR\_CONF.EXPNT bitfield used to set a common exponent value for the written data. The 32 bit values will then be shifted right by the number of bit positions programmed in the UNLDR\_CONF.EXPNT field before a saturating truncation to the 16 LSBs is performed (see “[Saturating Truncation” on Page 61](#) for further details). When using this mode, the value of the EXPNT should be restricted to values between 0 and 16. The behaviour of the Data Unloader with values outside this range is undefined.

If writing of 32 bit precision data is configured, then setting the EXPNT field to a non-zero value will cause the FFT output data to be shifted left by the number of bits set in the EXNPT field (preserving sign). If this causes the data value to overflow, then the data will be set to full scale minimum or maximum value depending on the sign.

*Note:* *If the data being processed is 32 bit precision linear power (ID\_RM\_CONF FORMAT=PWR32BIT, then compression is not supported and the data format (UNLDR\_CONF FORMAT) should always be set to 32BIT.*

The Data Unloader also tracks the number of sign bits (i.e. leading ones and zeros) in the FFT output data for use by the application software.

**Table 609 Unloader Configuration Parameters**

Parameter	Definition	Comments
Common Exponent	The 32 bit data will be shifted right by this number of bits before truncation to the 16 LSBs if the FORMAT selected is 16 bit and left if the format is 32 bit	<b>UNLDR_CONF.EXPNT</b>
Format	Select the format of the data to be written to the buffer memory. Options are 16 or 32 bit precision complex.	<b>UNLDR_CONF FORMAT</b>

#### 19.3.3.1 Power Histogram

The power histogram module stores a histogram of the FFT output power distribution into the configuration RAM. The method used derives the histogram bin index from the  $\log_2$  of the power. This method first requires the linear power to be calculated.

## Signal Processing Unit (SPU)

The linear power value used is derived in two possible ways:

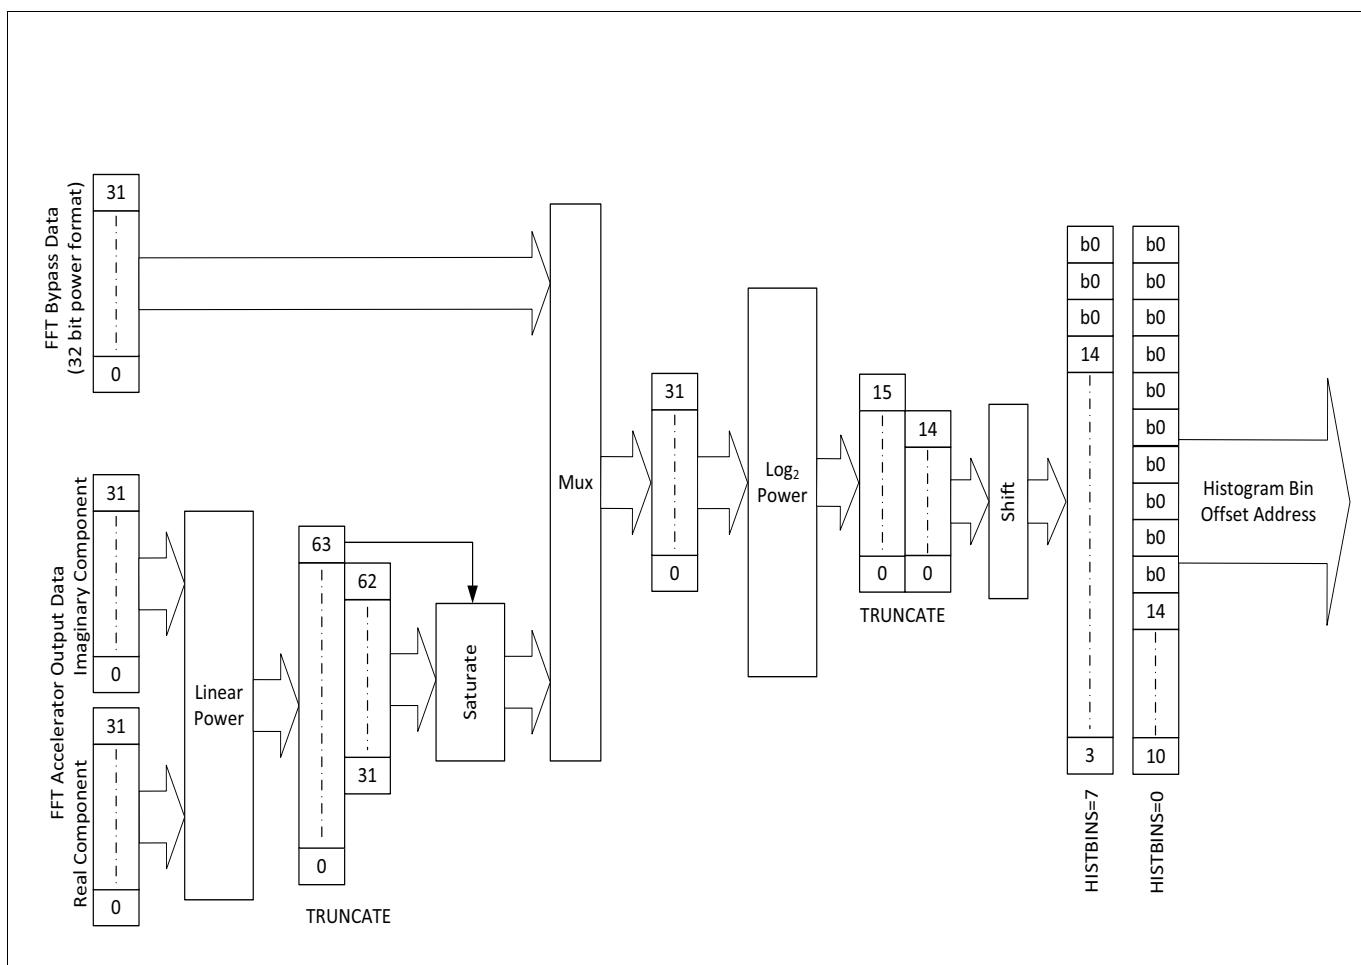

- If the data format is complex, it will be calculated to 32 bit precision using the method described in “[Pre-Processing Units” on Page 60](#). This method ensures that all 32 bits of the calculated power value contain useful data (i.e. all bits will toggle, no bits will be at a constant value over the full range of inputs)
- If the data format is 32 bit power, the data will be used directly.

**Note:** *The value of the ODP\_CONF.FTR bitfield is considered when calculating the power values used for the histogram. If ODP\_CONF.FTR is set, then the imaginary component of the FFT output data will be set to 0<sub>D</sub>.*

This 32 bit linear power value is used to derive a 16 bit log<sub>2</sub> power value. The log<sub>2</sub> power value is formatted as:

- bit 15: sign bit, always 0 (inputs of less than 2<sup>0</sup> are mapped to a result of 0)
- bits 14 downto 10: integer part
- bits 9 downto 0: fractional part

The log<sub>2</sub> power value is then right shifted by a programmable number of bits and used as a word address offset from the histogram base address in the configuration memory. The 64 bit word stored at this address is incremented. As bit 15 is always zero, it is specifically excluded from the address

**Figure 250 Diagrammatic Representation of Histogram Bin Offset Generation**

The histogram is enabled by writing an 1<sub>B</sub> to UNLDR\_CONF.HIST\_EN, the base address is stored in UNLDR\_CONF.HISTBASE. The number of bins is configured by the value in UNLDR\_CONF.HISTBINS. A minimum

## Signal Processing Unit (SPU)

of 32 bins and a maximum of 4096 bins are supported. The number of bins must always be a power of 2 and is given by  $2^{(\text{HISTBINS}+5)}$ . The size of the right shift referred to in the previous paragraph is therefore (10-HISTBINS).

The byte address of any given bin is UNLDR\_CONF.HISTBASE + ((BIN NR.) \* 8).

The power histogram will be calculated for the number of FFTs controlled by the values in the UNLDR\_CONF2.START and UNLDR\_CONF2.END fields. The FFTs of the measurement cycle are counted with the first FFT being FFT 0. If the count is greater than or equal to UNLDR\_CONF2.START and less than or equal to UNLDR\_CONF2.END, then the FFT is used to compute the histogram. If UNLDR\_CONF2.END is set to all 1, then accumulation of histogram data will run continuously from when the count reaches the UNLDR\_CONF2.START value until the end of the measurement cycle.

The calculation of the power histogram can be further filtered by considering antenna ID. This mode is enabled by setting UNLDR\_CONF.HAFE. If set, only FFT results associated with the antenna ID stored in the UNLDR\_CONF.AVF will contribute to the power histogram or update the FFT count used for checks against UNLDR\_CONF2.START and UNLDR\_CONF2.END values.

The histogram needs two clock cycles to process each bin as it needs to read the current value from the configuration memory and then write it back after updating. Consequently, the histogram must only be enabled if the FFT clock rate (CTRL.DIV) is set to something other than UNITY.

**Note:** *The histogram and the windowing function in the LOADER both require full bandwidth access to the Configuration RAM while the SPU is running. To prevent conflict, the Configuration Memory is split into two towers. One tower is addressed from offset 0 to CONFIG\_RAM\_SIZE/2-1 and the other tower from offset CONFIG\_RAM\_SIZE/2 to CONFIG\_RAM\_SIZE-1. The memory used for histogram and the memory used for the window functions must not be in the same tower if both functions are active at the same time. The memory allocated from the histogram must not be split between both towers under any circumstances as this is not supported by the hardware implementation.*

**Table 610 Histogram Configuration Parameters**

Parameter	Definition	Comments
Histogram enable	enable / disable for histogram	<b>UNLDR_CONF.HISTEN</b>
Number of classes	from 32 to 4096 classes	<b>UNLDR_CONF.HISTBINS</b>
Base address of the histogram in the RAM		note that we may have a modulo here to avoid too high complexity in address computations <b>UNLDR_CONF.HISTBASE</b>
Start Delay	FFTs to count before starting histogram calculation	<b>UNLDR_CONF2.START</b>
End Delay	FFTs to count before ending histogram calculation	<b>UNLDR_CONF2.END</b>
Filter by Antennae	Enable histogram data to be accumulated only for a single antenna	<b>UNLDR_CONF.HAFE</b>
Antenna Number to use for filtering	Index of Antenna to be used for histogram data accumulation	<b>UNLDR_CONF.AFE</b>
Real Data Format	Ignore imaginary component when computing power	<b>ODP_CONF.FTR</b>

## Signal Processing Unit (SPU)

### 19.3.3.2 Statistical Information

The Data Unloader can calculate the mean value of the power for each FFT while processing the data. The information will be stored in a FIFO for later use by the Output Data Processor. Calculation and storage of this information is enabled using the SBCTRL.EN bitfield.

The mean is always calculated from 32 bit data. If 16 bit complex format is selected by UNLDR\_CONF.FORMAT, the mean calculation will use the 32 bit data before the shift defined by UNLDR\_CONF.EXPNT is applied. If 32 bit complex format is selected, the mean calculation will use the 32 bit data after the shift defined in UNLDR\_CONF.EXPNT is applied. This ensures that the mean is calculated using the same data as used by the Output Data Processor.

The linear power value used is calculated using the method described in “[Pre-Processing Units” on Page 60](#).

This gives us half the information needed to compute the variance (square of standard deviation). To complete the variance calculation, a second pass through the data is needed. This will be done when the data is read by the Output Data Processor.

Statistical information for the measurement cycle can be stored in the Radar Memory. One set each of minimum power, maximum power, mean power and standard variance will be stored for each FFT processed.

The division used to complete the variance<sup>1)</sup> calculation is a “shift right” operation rather than a full hardware division. This causes some inaccuracies when the number of samples is not a power of two. This does not affect the statistical information computed from FFT results but does mean that calculation of the statistical information when the FFT engine is bypassed (LDR\_CONF.FFT\_BYPS = 1<sub>B</sub>) uses a mean which effectively pads the number of samples to the next power of two with zero values.

These operations are described in more detail in the relevant section in the Output Data Processor section.

**Note:** *To ensure that the data used for the statistical calculations is consistent the value of the ODP\_CONF.FTR bitfield is considered when calculating the power values used for the computing the mean. If ODP\_CONF.FTR is set, then the imaginary component of the FFT output data will be set to 0<sub>D</sub>.*

### 19.3.4 Streaming Processor 2, The Output Data Processor

The Output Data Processor module formats and writes the results datasets to the Radar Memory. It can also route the data through multiple processing modules working on complex data and power. The Output Data Processor is split into two submodules, the MATH2 Unit and the Output DMA Engine. When reading data from the Buffer RAM, the Processor uses the UNLDR\_CONF.FORMAT and UNLDR\_CONF.EXPNT to determine whether the stored data is in native 32 bit precision format or has been compressed to 16 bit precision and requires reformatting.

The ODP has a processing path for manipulating the base data and bin rejection working in parallel with multiple analysis units (CFAR, NCI, statistics and arithmetic).

#### 19.3.4.1 Streaming Processor 2 Data Fetch from Buffer Memory

There are two classes of processing path through the MATH2 which require the data to be read from Buffer RAM in two incompatible ways.

- Operations such as the FFT data output path through the bin rejection unit require the data to be read as consecutive points from each FFT result.
- Operations using the data integrated across antenna requires equivalent data points to be read consecutively from each FFT result stored in the buffer memory so the integrated value can be calculated.

<sup>1)</sup> The variance calculated is the population variance rather than a sample variance. The sum of the squares is divided by the number of samples rather than the number of samples minus one.

## Signal Processing Unit (SPU)

If both types of path are enabled by the programmed configuration options, then this conflict is addressed by reading the data from the buffer memory twice. The first fetch will be used for the operations requiring linear addressing by FFT result. The second fetch will be performed for operations requiring the integrated result across antennae. The number of fetches required is evaluated and executed independently for each pass if double pass mode is enabled.

### 19.3.4.2 In Place FFT

Setting ODP\_CONF.IPF configures the Output Data Processor to generate addresses using the same scheme as the Input DMA uses to read the data being processed. The intention is that the output data will be written to the memory locations cleared by the reading of the input data.

To do this the Output DMA uses an equivalent set of counter and offset registers to those instantiated in the Input DMA engine. The parameters used to configure this duplicate register set are inherited from the Input DMA configuration registers. This causes the address sequence generated by the Output DMA to exactly duplicate the address sequence used by the Input DMA to read the data. Addresses in this case refer to the 256 bit words of the EMEM. The Output DMA will always assemble enough results to completely fill each 256 bit word before moving to the next address in the sequence. This will result in fewer words being written than read if the output data size is smaller than the input data size. Conversely, if the output data requires more memory than the input data, results will be unpredictable and, consequently, use of in place FFT in these cases is not supported.

In Place FFT addressing only applies to the writing of the FFT results.

It is strongly recommended that bin rejection is not used with in place FFT when using transposed addressing as no additional memory saving will be possible (data will be written as a sparse array in memory) and addressing of the resultant data will be extremely complex.

#### 19.3.4.2.1 Restrictions

Correct operation of this mode requires that the Input DMA reads and uses all 32 bytes of each word in Radar Memory in a single pass. If only part of the word is used, it is probable that the Output Data Processor will overwrite the location before a further pass through the data cube by the Input DMA uses the rest of the word.

This mode cannot be used if Double Pass mode is used to write two sets of FFT results.

### 19.3.5 MATH2 Unit

The MATH2 Unit implements multiple parallel processing units as shown in [Figure 251](#) below. These processing units are grouped into two data flows, one working on the raw complex data and the other on linear or  $\log_2$  power. The following table shows the operating domain and concurrency of the various functions:

**Table 611 MATH2 Unit Functional Concurrency**

	Function - Only one function can be active for each O/P Channel										
	Stats	Local Max	CFAR CA	CFAR GOS	FFT Data <sup>1)</sup>	Log <sub>2</sub> Signal Power	Vector Add/ NCI <sup>2)</sup>	Vector Add/ CI <sup>2)3)</sup>	Sum-LinP	Sum	Sum Log <sub>2</sub> Power
Power Domain <sup>4)</sup>	Yes	Yes	Yes		No	Yes	Yes	No	Yes <sup>5)</sup>	No	Yes
Complex Domain <sup>6)</sup>	No	No			Yes	No	No	Yes <sup>7)</sup>	No	Yes	No
O/P Channel	PORT3	PORT4		PORT5 <sup>8)</sup>	PORT1	PORT2	PORT6	PORT7			PORT8

## Signal Processing Unit (SPU)

- 1) Incorporates any or all of scalar add, scalar multiply and bin rejection.
- 2) Running these functions simultaneously will be bandwidth limited
- 3) Sum Antenna on Complex Data
- 4) Function is possible using power as input
- 5) Sum of the linear power
- 6) Function is possible with Complex Values as Input
- 7) Vector add on the FFT result complex data is done only across antenna.
- 8) Using the CFAR GOS engine also blocks Local Max on Port 4

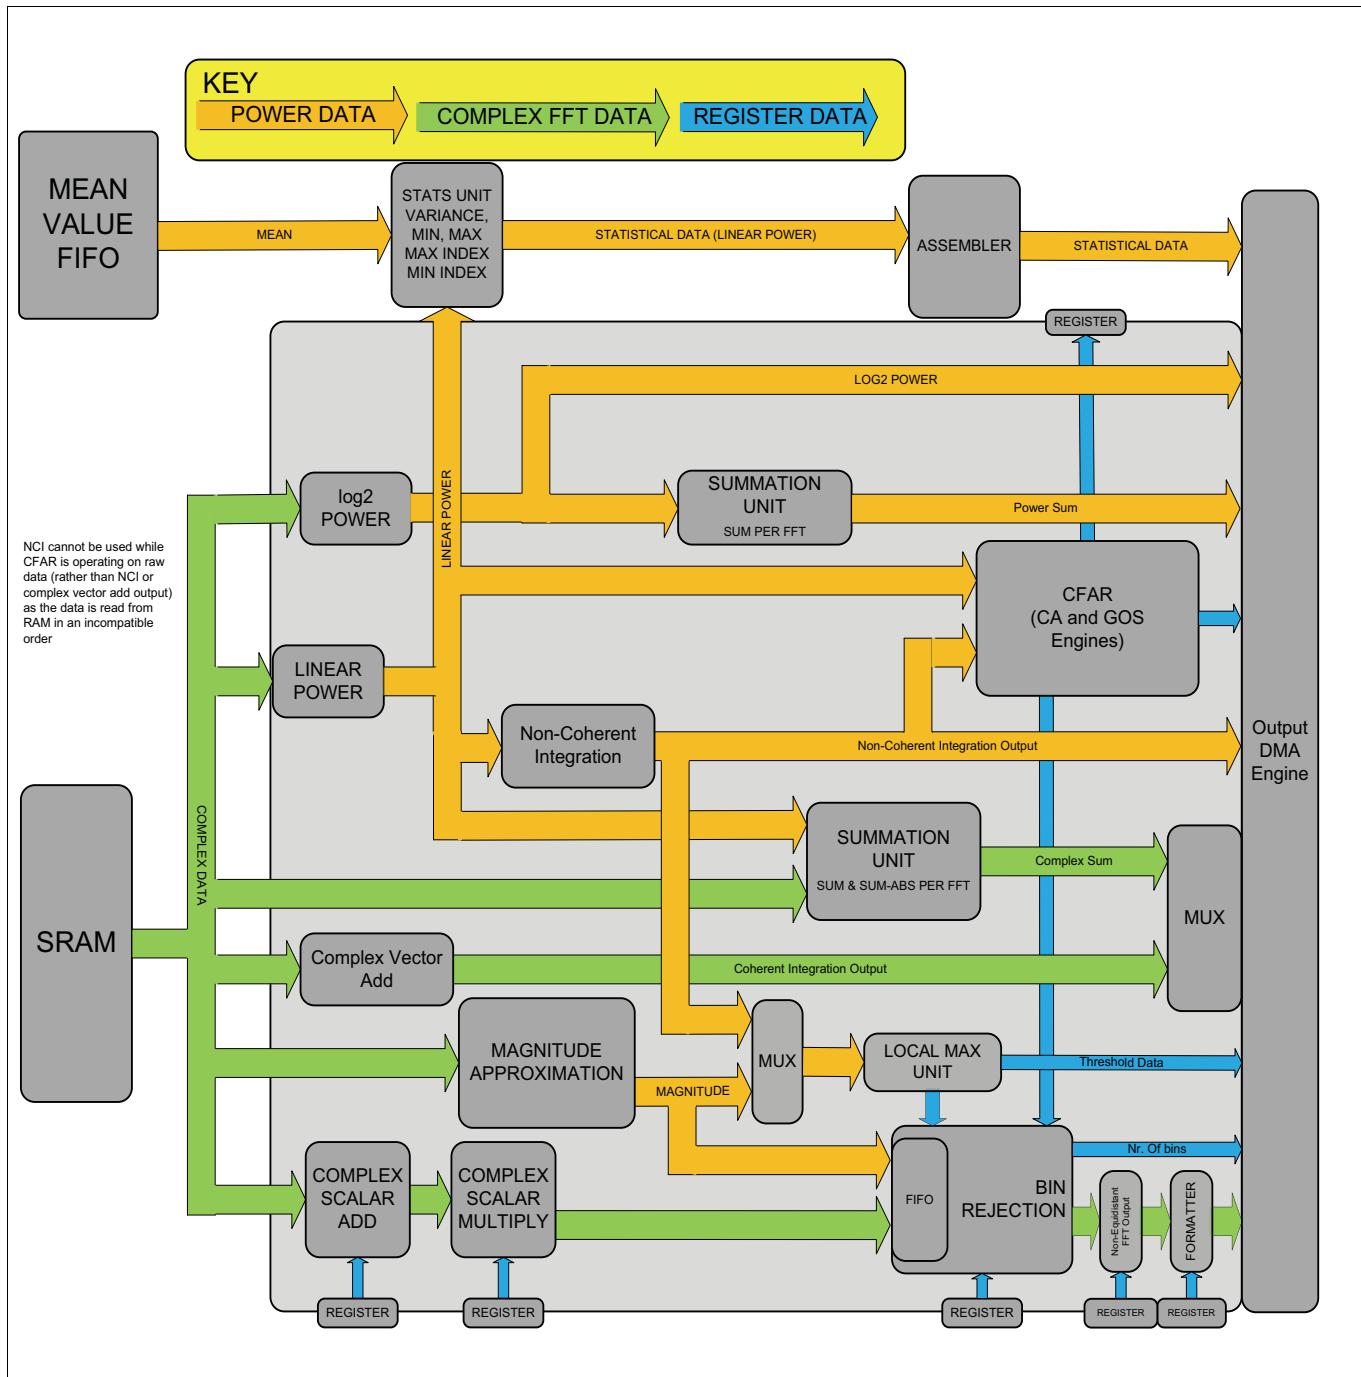

For expected performance using the MATH2 unit, refer to [Chapter 19.7.14.4, “MATH2/ODM Performance”](#)

**Table 612 Output DMA Engine Data Streams**

Output port	Definition	Comments	Precision. (Bits)	Padding <sup>1)</sup> per FFT or measurement cycle
Port1	3 sources of informationFFT unitFFT BIN rejection and zeroingadd scalar or complex to vector		16 or 32 bit precision, complex or real formats	FFT
Port2	$\log_2$ signal power		16 bits	FFT
Port3	min, max, average, (standard deviation) <sup>2)</sup>		32 bits	FFT
	index of min, index of max	12 bits of data, padded to 16 bits with leading zeroes	16 bit	
Port4	local max or CFAR (CA Engine)		1024 bits max	cycle
Port5	CFAR (GOS Engine)		1024 bits max	cycle
Port6	Vector add /sum, power domain	typically: non coherent integration	32 bits	FFT
Port 7	sum, sum-linp	summation over each FFT	32 bits	cycle
	sum-antenna	typically, sum for data preparation before elevation computations <sup>2)</sup>	16 or 32 bit complex	FFT
Port 8	Sum of Log <sub>2</sub> Power	Sum of log <sub>2</sub> power over each FFT	16 bits	cycle

- 1) Padding is used to ensure that the next set of data written starts on a 256 bit aligned address. Data intended to be read back into the SPU will have one element per FFT bin processed and each dataset must start on a 256 bit aligned address. These data streams will be padded per FFT. Other data streams will be padded per measurement cycle to optimise memory usage
- 2) Output from this operation is a 1D vector of the same length as the input FFTs

## Signal Processing Unit (SPU)

**Figure 251 MATH2 Unit Architecture**

The MATH2 unit will always expand the data read from the buffer memory to 32 bit precision before using it in any functions. The expansion function is the inverse of the compression operation used in the Unloader with any additional LSBs being padded with  $0_B$  and the MSBs being sign extended. See [Section 19.3.3, “Data Unloader” on Page 53](#).

Where 32 bit precision values are multiplied to generate a result at 32 bit precision, rescaling of the result will take place after the multiplication operation. Rescaling will always remove the least significant bits of the result.

When multiplying two signed 32 bit numbers, the result will be a 64 bit signed value and this will be scaled to 32 bits by dividing by  $2^{31}$  and rounding down to the nearest integer while discarding the MSB. As multiplying two full scale negative numbers will result in an overflow using this algorithm, this corner case will generate a full scale, positive result.

## Signal Processing Unit (SPU)

When multiplying two unsigned 32 bit numbers, the result will be a 64 bit unsigned value and this will be scaled to 32 bits by dividing by  $2^{32}$  and rounding down to the nearest integer.

If any calculation result is scaled to 16 bits, then the result will be rounded to the nearest integer after division. Results which fall exactly midway between two integers will be rounded away from zero.

Scaling of the results of 32 bit addition operations to produce a 32 bit output are handled in a similar manner. The intermediate result is always sized so that overflow does not occur and then this is scaled down to 32 bits by dividing and rounding down towards -Infinity to the nearest integer. The scaling to 32 bits will, in most cases, occur automatically unless the number of operands is configurable, in which case, a configurable scaling factor has been provided.

### 19.3.5.1 Pre-Processing Units

The pre-processing units convert the raw FFT data to  $\log_2$  power, linear power or magnitude or change the precision of the data.

#### 19.3.5.1.1 Linear Power Calculation

Linear power is calculated to 32 bit precision by

- squaring the real and imaginary components and scaling by dividing by  $2^{31}$ .
  - For full scale positive data, this gives a value of  $7FFF\_FFFE_H$
  - For full scale negative data, this gives a value of  $8000\_0000_H$
- adding the truncated squares of the real and imaginary components and saturating the results
  - $7FFF\_FFFE_H$  for both real and imaginary complex components gives  $FFFF\_FFFC_H$  when the squares are added and saturation does not take place
  - $8000\_0000_H$  for both real and imaginary complex components gives  $1\_0000\_0000_H$  when the squares are added and  $FFFF\_FFFF_H$  after saturation.

#### 19.3.5.1.2 $\log_2$ Power Calculation

$\log_2$  power is computed to a precision of 16 bits and will be stored as an unsigned integer value with 7 integer bits and 9 fractional bits. This is a representation of the 32 bit precision linear power value scaled to 64 bits by multiplying by  $2^{31}$ . This is done to be compatible with the  $\log_2$  power calculation used inside the CFAR module which uses a 64 bit linear power input. An input linear power value of  $2^{31}$  scales to a 64 bit value of  $2^{62}$ . A 64 bit value of  $2^{62}$  corresponds to a  $\log_2$  value of  $7E00_H$ . The MSB of the 16 bit value is a sign bit.

The algorithm used is as follows:

- In the first stage, the location of the first bit set in the 64 bit input value is used to determine the integer component of the output.
- In the second phase of the algorithm, the most significant eight bits of the residual from the first phase is used as the index into a 256 entry look up table used to apply an appropriate fractional correction to the integer value

The maximum granularity of the look up table output is 0.006. An input value of  $0000\_0000_H$  is mapped to an output value of  $0000_H$ .

## Signal Processing Unit (SPU)

### 19.3.5.1.3 Magnitude Approximation

For magnitude, the approximation:

(19.1)

$$\text{MAGNITUDE} = \alpha \times (\text{MAX}(\text{ABS}(I), \text{ABS}(Q))) + \beta \times \text{MIN}(\text{ABS}(I), \text{ABS}(Q))$$

is used. The two multiplication constants are stored in the ALPHA and BETA bitfields of the MAGAPPROX register. The magnitude value is calculated at 32 bit precision. ALPHA and BETA are unsigned constants scaled to have a value range of between 0 and 1 approximately (actually 0.99998 to five significant digits). The output is a 32 bit value scaled to have an overall gain of 1.

**Note:** *The ABS function used in the magnitude approximation maps a full scale negative number  $8000\_0000_H$  to a magnitude of  $7FFF\_FFFF_H$*

Later operations then use the magnitude value. Operations which use magnitude data are:

- Threshold Detection, [Section 19.3.5.3.3](#)
- Local Maximum, [Section 19.3.5.2](#)

### 19.3.5.1.4 Saturating Truncation

The saturating truncation operation will remove the 16 MSBs of a 32 bit quantity to leave a 16 bit result. The intention is that the 32 bit quantity is scaled such that no significant information is lost when doing this (i.e. the 17 MSBs contain only sign information). However if this not the case and one or more of the MSBs contain  $1_B$  for positive quantities or  $0_B$  for negative quantities, then the 16 bit result will be set to full scale positive in the first case and full scale negative in the second case.

### 19.3.5.2 Local Maximum Detection Unit

The module checks to see if the bin being checked is a local maximum by comparing against adjacent bins. If it is, then the bin will be flagged. The module can also simultaneously check the bin against a threshold value. The output information can either be written to Radar Memory or used by the bin rejection unit. The unit therefore has two operating modes:

- In-line Mode. In this mode, the first FFT result of the measurement cycle<sup>1)</sup> is used to set the bins to be flagged for the entire measurement cycle. This information is passed to the Bin Rejection Unit. This mode requires additional time and buffer RAM read accesses to read the first FFT data for processing Local Maximum Unit. The number of extra reads and therefore the delay will be dependent on the size of the Local Max window.
- Off-line Mode. In this mode, each FFT result is used to generate a set of data. This data is then written to Radar Memory as a table.

This module cannot be used concurrently with the CFAR module. The Local Maximum Detection Unit has the same options for range and velocity spectrum extension as the CFAR module. See [Section 19.3.5.5.9, CFAR spectrum extension](#) for a full description.

**Note:** *The CFARCTRL.CFAREN bitfield should not be set to LCLMAXI, LCLMAXO or LCLMAXN without using setting LCLMAX.LMODE or LCLMAX.TMODE to a value other than “OFF” as this will affect performance and cause the Bin Rejection Unit to behave in an unpredictable manner.*

<sup>1)</sup> If double pass mode is enabled then the process of identifying datapoint of interest is repeated for the first FFT of the measurement cycle for each pass and both sets of information are stored. The appropriate set of data will then be used for processing all further FFTs of the relevant pass.

## Signal Processing Unit (SPU)

**Table 613 Local Maximum Configuration Parameters**

Parameter	Definition	Comments
local max enable	enable / disable	Combined with the control for the CFAR module as these are mutually exclusive <b>CFARCTRL.CFAREN</b>
Radar Memory Address	Base address to be used for writing the threshold results to the Radar Memory	<b>CFARCTRL.BASE</b>
Local Max Mode <sup>1)</sup>	Off, Reject if not local max, reject if local max	<b>LCLMAX.LMODE</b>
Local Max Check Combining	Logical Operation used to combine check results when both checks are active	<b>LCLMAX.CMBN</b>
Spectrum Extension Mode	Off, Range or Velocity	<b>CFARCTRL.EXTN</b>
Window Width <sup>1)</sup>	Window size to be used for local max calculation	<b>LCLMAX.WIDTH</b>
Threshold Mode	Off, Above, Under	<b>LCLMAX.TMODE</b>
Threshold Value	user defined value	<b>LCLMAX.TSHLD</b>
Threshold Extension Mode	Left or Right Justification of the TSHLD value in the 32 bit comparison value	<b>LCLMAX.LJUST</b>

1) LMODE must be set to a value of  $1_D$  or  $2_D$  and WIDTH to a value of  $1_D$  or  $2_D$  for the Local MAX Unit to flag any bins

The Unit can be configured to flag bins where the magnitude is local max or where the magnitude is not a local max. The unit can simultaneously be configured to check against a threshold value and flag a bin if the magnitude is above the threshold or if the magnitude is below the threshold.

If both checks are enabled, the results are combined as defined using the LCLMAX.CMBN bit. Both logical AND and logical OR operations can be selected. i.e. flag a bin on both checks triggering a reject or flag a bin on either check triggering a reject.

This is a 32 bit comparison. The 24 bit LCLMAX.TSHLD is extended to 32 bits before being used. This extension can either be right or left justified. If the LCLMAX.LJUST bitfield is set to  $0_B$ , the extension is right justified and 8 MSBs of value  $0_B$  are added. If LCLMAX.LJUST is set to  $1_B$ , the extension is left justified and 8 LSBs of value  $0_B$  are added.

**Note:** The Spectrum Extension function ([Section 19.3.5.5.9](#)) is used to provide the extra window data needed for the Local Max Unit window if LMODE is not equal to  $00_B$ . CFARCTRL.SEWIN must be set to a value matching the LCLMAX.WIDTH value. If LCLMAX.WIDTH= $01_B$ , then SEWIN= $000001_B$  and if LCLMX.WIDTH= $10_B$ , then SEWIN= $000010_B$ .

### 19.3.5.3 FFT Data Output Path

This is the output path for the FFT results.

The base address for the FFT results data written to Radar Memory is stored in the ODP\_CONF.BASE bitfield. The format of the data is controlled by the ODP\_CONF.MODE, ODP\_CONF.FTR, ODP\_CONF.SCALE, ODP\_CONF.EXPNT and ODP\_CONF FORMAT bitfields.

## Signal Processing Unit (SPU)

**Table 614 Output Data Processor Format Options**

Parameter	Definition	Comments
Enable FFT results output	On/Off switch to enable writing of the post-processed FFT results to memory	<b>ODP_CONF.MODE</b>
Results Compression	Enable Compression of the FFT results to 16 bit precision with a common exponent	<b>ODP_CONF.SCALE</b>
Results compression scaling factor	The scaling factor to be used if results compression is enabled. The 32 bit data will be shifted right by this number of bits before truncation to the 16 LSBs	<b>ODP_CONF.EXPNT</b>
Real Results	Force the complex component of the FFT results to 0 as it is read from the buffer memory. The complex component is written to memory but has a value of 0.	<b>ODP_CONF.FTR</b>
In Place Writing of Results	Configure the Output Data Processor to Compute Write addresses in the same order as the Input DMA so that results are written to the addresses cleared by reading input data	<b>ODP_CONF.IPF</b>
Write results as real only data	The FFT results written to memory do not have an imaginary component but consist only of packed, real values	<b>ODP_CONF.ROF</b>
Post-processing option for the FFT results	The FFT results can be converted to half precision floating point format (as defined in IEEE 754) before being written to memory.	<b>ODP_CONF.HPFP</b>

Operation of the HPFP bitfield is described in [Section 19.3.5.3.4, “Half Precision Floating Point Format” on Page 65](#).

### 19.3.5.3.1 Scalar Addition

The pre-processing unit can add a complex offset to each data value. This value is a constant stored in the SCALARADD.OPERAND bitfield and the function will be activated if a non-zero value is written to this field.

### 19.3.5.3.2 Complex Rescaling

The pre-processing unit can multiply the data value by a scaling factor. This value is a constant stored in the SCALARMULT.OPERAND bitfield which allows the value to be rescaled but does not affect the phase. The function will be activated when a non-zero value is written to this field.

### 19.3.5.3.3 Bin Rejection Unit

This units post-processes the data to be written to Radar Memory using the contents of the bin rejection register and the output from either the CFAR unit or the Local Maximum Unit.<sup>1)</sup>

The bin rejection register contains one bit for each “bin” (datapoint) in the FFT results. It is accessed through 64, 32 bit registers in the register space of the SPU. If the bit is set to 0, then the relevant bin will either be removed from the output dataset written to the Radar Memory or set to a value of  $0_B$ .

This feature can be used in conjunction with either the CFAR module or Local Maximum Unit output although here support is limited to a maximum FFT size of 1024 bits. This linking of functionality is controlled by setting the CFARCTRL.CFAREN bitfield to one of the inline operating modes. The options are Inline CFAR or Inline Local Maximum.

1) The CFAR unit will flag bins that are to be kept. The Local Max Unit will flag bins if they are to be rejected or set to  $0_B$ .

## Signal Processing Unit (SPU)

In this case, the bin rejection register and the results from the CFAR or Local Maximum Unit must both permit the bin to be written. If either function requires the bin to be removed (or set to zero), then it will be removed (or set to zero)

e.g. If the bin rejection function requires the bin to be set to  $0_D$ , then it will be set to  $0_D$  even if the CFAR has identified it as a bin to be kept.

This can be viewed as the logical ANDing of an bin acceptance mask from the CFAR/Local Max unit with the acceptance mask programmed in the Bin Rejection register. Bins corresponding to bits set to  $1_B$  in the resulting, combined mask will be retained unchanged while bins corresponding to bits set to  $0_B$  in the resulting mask will be either removed from the output or set to a value of  $0_D$  depending on the mode of the bin rejection unit

**Table 615 Bin Rejection Unit Configuration Options**

Signal	Definition	Comments
operating mode	$00_B$ = Off $01_B$ = BIN rejection, remove bins from output $10_B$ = Set BIN value to 0 $11_B$ = Reserved	<b>BINREJCTRL.RMODE</b>
BIN list to be removed	2048 bit register that defined which BIN is to be removed or zeroed (1 means BIN to be retained or passed unchanged)	<b>BINx_REJ.B</b> <b>x=0-63</b>

## Threshold Detection

The threshold detection function is integrated into the Bin Rejection Unit. The function checks to see if the bin being checked exceeds a programmed threshold. If the threshold is exceeded, then the bin is set to zero. The threshold comparison is based on the magnitude of the bin.

This is a 32 bit comparison. The 24 bit BINREJCTRL.VALUE is extended to 32 bits before being used. This extension can either be right or left justified. If the BINREJCTRL.LJUST bitfield is set to  $0_B$ , the extension is right justified and 8 MSBs of value  $0_B$  are added. If BINREJCTRL.LJUST is set to  $1_B$ , the extension is left justified and 8 LSBs of value  $0_B$  are added.

**Table 616 Thresholding Configuration Parameters**

Parameter	Definition	Comments
thresholding enable	enable / disable. If enabled, set a bin to zero if it exceeds the magnitude defined in BINREJCTRL.VALUE	Function is Combined into the Bin Rejection Unit <b>BINREJCTRL.ZMODE</b>
threshold value	user defined value	<b>BINREJCTRL.VALUE</b>
Threshold Extension Mode	Left or Right Justification of the VALUE value in the 32 bit comparison value	<b>BINREJCTRL.LJUST</b>

## Status Information

Registers are available which provide information on the behaviour of the bin rejection unit for the last FFT processed. This information is only guaranteed to be valid while the SPU is idle (i.e. at the end of each processing operation) as the data is not buffered. When the SPU is busy the information may be in the process of being updated when read. If it is desired to read the data between linked list operations, then the linked list should be configured to stop and interrupt the processor. Once the processor has read the data, SPU operation can be restarted by a write to the CTRL register.

## Signal Processing Unit (SPU)

**Note:** Any changes in the static mask set by the BINx\_BINREJ register are not buffered but are reflected immediately in the values read from the MASK\_ACCEPT registers. This happens even when the SPU is idle. The values in the MASK\_ACCEPT registers should therefore be read before any update is made to the configuration

**Table 617 Bin Rejection Unit Status**

Parameter	Definition	Comments
Rejection Count	The number of bins set to zero or rejected based on the static mask and input from the CFAR or Local Max Units	<b>BINCOUNT.REJCNT</b>
Threshold Count	The number of bins set to zero based on the threshold function of the Bin Rejection Unit	<b>BINCOUNT.THSLDCNT</b>
Acceptance Mask	The bins set to zero or rejected based on the static mask registers and input from the CFAR or Local Max Units	<b>MASK_ACCEPT.Bn</b>

**Note:** The rejection count and threshold count are calculated separately based on the bin values at the input to the unit i.e. before any processing has been applied, e.g. a bin can increment the threshold counter even if it is then rejected.

### 19.3.5.3.4 Half Precision Floating Point Format

The FFT results can be reformatted in IEEE 754 binary16 (half precision) floating point format. This is enabled by setting the bit **BEx\_ODP\_CONF (x=0-1).HPFP** to 1<sub>B</sub>

The half precision floating point format has:

- a sign bit
- 5 bits of exponent encoding a value between -14 and 15
- 11 bits of significand precision<sup>1)</sup>

With this format, the magnitude which can be encoded ranges from a minimum of  $1 \times 2^{-14}$  (neglecting subnormal numbers<sup>2)</sup>) to a maximum of  $(2-2^{-10}) \times 2^{15}$  which is equivalent to  $2^{16}-2^5 = 65504$ .

The maximum range of a 32 bit integer is from -2147483648 (0-2<sup>31</sup>) to 2147483647 (2<sup>31</sup>-1). To best fit this into the range of the half precision floating point format, the 32 bit precision number is first divided by 2<sup>15</sup> to give a range of -65536 (0-2<sup>16</sup>) to (neglecting the fractional component<sup>3)</sup> 65535 (2<sup>16</sup>-1). This is then converted to the half precision floating point format with values less than -65504 or greater than 65504 saturating at the relevant limit.

The rounding used during this conversion is “round to nearest, ties to even”.

1) 10 bits are stored to specify the fractional part of the significand, with an implicit lead bit. The lead bit value is 1 unless the exponent field is stored with all zeros  
 2) Support for subnormal numbers is not implemented. Any conversion result which would require representation using a subnormal number is instead represented as 0.  
 3) With fractional component 65535.99997

## Signal Processing Unit (SPU)

### 19.3.5.4 Non-Coherent Integration

The non-Coherent Integration<sup>1)</sup> (NCI) Module combines the data from multiple antennae into a single output. It achieves this by combining the equivalent linear power values from each antenna stored in the Buffer RAM using a scalar multiplication of the sample point followed by an addition. Each antenna can have its own multiplication constant. The multiplication constants are a 16 bit, unsigned, scalar quantity. The summed result can then be scaled to prevent overflow. The scaling operation is configured using the NCICTRL.SCALE bitfield.

The format of the output data is controlled by the NCICTRL.FORMAT bitfield. Data can be written as 16 bit or 32 bit precision real values. Additionally, an option is reserved to allow 16 bit precision complex format to be written for later reprocessing by the bin rejection unit.

This mode expects that the Input DMA Engine has been configured in Integration Mode so that the buffer RAM contains one FFT result from each connected antenna. If the data in the buffer memory is complex, then a 32 bit linear power value is calculated. If the data in the buffer memory is already a power value, this will be used directly.

Note that, if the NCI module is enabled, the CFAR module can only be used to process the NCI output, as reading data for direct input to the CFAR and the NCI require different addressing modes for the Buffer RAM.

This operation assumes that the linear power is a 32 bit, unsigned quantity. This is multiplied by the 16 bit weighting constant to give a 48 bit result which is then added into a 51 bit accumulator. Once the power values derived from the equivalent bins of all FFT results in the buffer RAM are added into the accumulator, the accumulator result can then be right shifted by 0, 1, 2 or 3 bits depending on the NCICTRL.SCALE setting.

The 32 bit output value will be taken from bits [47:16] of the accumulator value. The operation is equivalent to dividing by  $2^{16}$  and then rounding down to the nearest integer.

If a 16 bit precision result is configured this will be derived from bits [47:32] of the accumulator. The operation is equivalent to dividing the accumulator by  $2^{32}$  and rounding to the nearest integer.

For either output format, If any of bits [50:48] of the accumulator result are set, then an overflow condition is detected and all of bits of the output will be set to saturate the output value.

**Table 618 Vector Add/Sum Configuration Parameters**

Parameter	Definition	Comments
enable / disable	enable or disable the Vector add/sum <sup>1)</sup>	<b>NCICTRL.EN</b>
operand output format	16 or 32bits	<b>NCICTRL FORMAT</b>
weights	individual weights per antenna	16bit precision <b>NCISCALARx.ANTy</b> <b>x=0-3, y=0-7</b>
number of active antenna	per SPU	derived from the configuration of the Input DMA Engine and passed via Streaming Processor 1 and the FFT accelerator
result rescaling	optional result division by 1 or by 2 or by 4 or by 8.implemented using shift BUT sign extension is maintained.	to avoid saturation when having multiple antenna <b>NCICTRL.SCALE</b>

- 1) If the integrated data will neither be used by other processing units nor written to Radar Memory then enabling this bit will have no effect on processing flow i.e. the extra read pass through the buffer memory will not take place.

1) Power Domain Vector Addition

## Signal Processing Unit (SPU)

### 19.3.5.5 Constant False Alarm Rate Module

The CFAR module is used to identify interesting points in the data and then filter the data so that only these points are written to Radar Memory. It can operate in two modes as detailed in the following sections

#### 19.3.5.5.1 Inline Mode

In inline mode, the first FFT result of the measurement cycle<sup>1)</sup> is read from RAM and used to identify which datapoints are of interest. This information is then stored and used, in combination with the bin rejection register value, to filter the first and all subsequent datasets. This mode therefore requires additional time and buffer RAM read accesses to read the first FFT data for processing by the CFAR or Local Maximum Unit. The number of extra reads and therefore the delay will be dependent on the size of the CFAR window and whether or not spectrum extension is enabled.

In-line mode cannot be used if NCI is enabled.

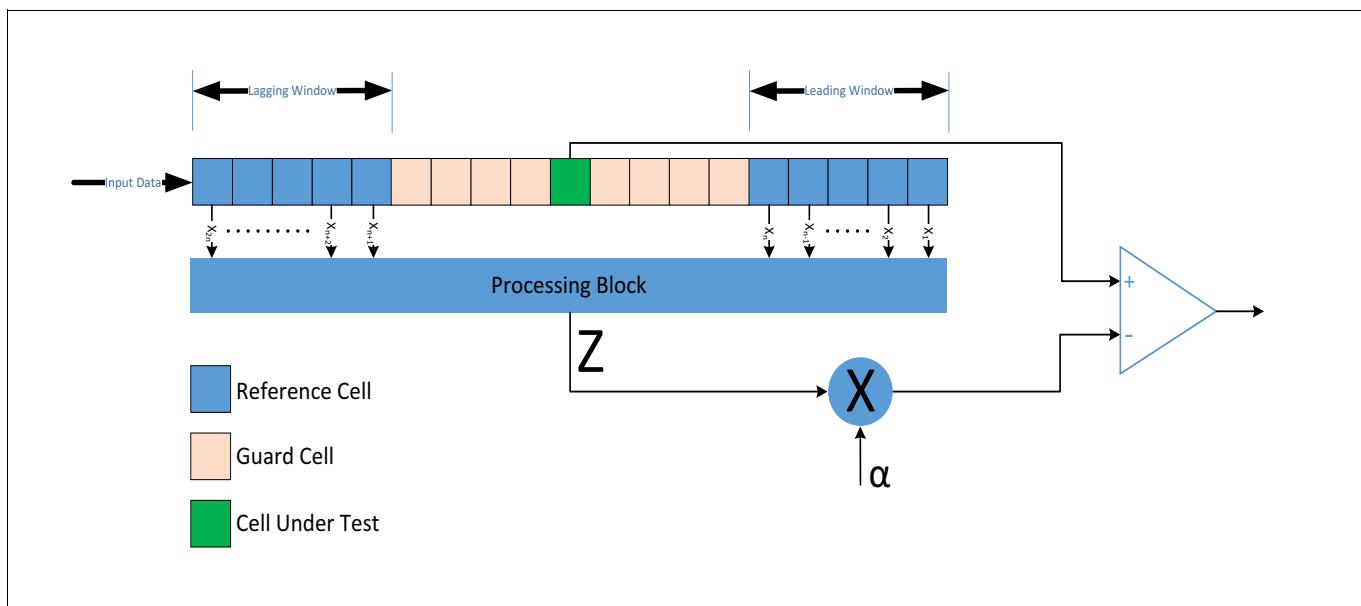

#### 19.3.5.5.2 Off-line Mode

In this mode, each ramp from each antennae is used to generate a set of data. This data is then written to Radar Memory as a table. No information is fed to the bin rejection unit.

In off-line mode, the Non-Coherent Integration Unit can be used as a pre-processor. As the data is read from the memory, it is routed through the NCI Unit to produce a composite sample value. This is then used for the CFAR input.

#### 19.3.5.5.3 CFAR Engine Architecture

The following diagram shows the top level architecture of the CFAR engine

**Figure 252 CFAR Engine Architecture**

Input power samples are shifted through the processing window, which consists of windows of reference cells on either side of the Cell Under Test (CUT). Each window is separated from the Cell Under Test by a configurable

1) If double pass mode is enabled then the process of identifying datapoint of interest is repeated for the first FFT of the measurement cycle for each pass and both sets of information are stored. The appropriate set of data will then be used for processing all further FFTs of the relevant pass.

## Signal Processing Unit (SPU)

number of guard cells. The windows cells are processed to generate a threshold value (Z). This is then scaled for comparison with the CUT value. Note that in this diagram, the threshold is shown as Z multiplied by a constant "alpha". The actual implementation outputs Z as  $\log_2$  power, not linear power so the actual implementation is  $\log_2(Z) + \text{"beta"}$ , where beta is  $\log_2(\text{alpha})$ . The parameter beta is available as a register bitfield for both engines.

### 19.3.5.4 CFAR Engine Data Format

The CFAR engine uses a 64 bit linear power value internally. This is obtained from the 32 bit values computed by the SPU logic by multiplying by  $2^{31}$  to generate a maximum possible value of  $7FFF\_FFF\_8000\_0000_H$ . Where the CFAR engine uses  $\log_2$  power for internal calculations or comparison, this is computed as a 16 bit log2 value with 7 integer and 9 fractional bits from the 64 bit linear power value.

### 19.3.5.5 CFAR Module Configuration

The CFAR module contains two, independent engines. One engine implements the CA-CFAR algorithm and some derivatives (including CASH-CFAR). The other implements the GOS-CFAR algorithm and some derivatives. Both engines can be independently enabled and configured. The exception is when the spectrum extension is enabled. In this case both engines must use an identical window size, if both are enabled.

In off-line mode, the engines are controlled by the CFARCTRL.CFAR\_CAE bitfield for the CA engine and the CFARCTRL.CFAR\_GOSE bitfield for the GOS engine. When the appropriate bitfield is set the related engine will output data to Radar Memory. Both engines will write results to Radar Memory if enabled.

The CFAR results can also be used to configure the bin rejection unit (inline mode). This is enabled by setting the CFARCTRL.CFAREN bitfield to CFARI and using the CFARCFG.CFARSEL bitfield to select an engine. If an engine is enabled, it will write its results to Radar Memory even if not selected by the CFARCTRL.CFARSEL bitfield. In in-line mode, the CFAR results are only calculated for the first FFT of the measurement cycle so a maximum of two values will be written.

#### Notes

1. *CFARCTRL.CFAREN bitfield should not be set to CFARI, CFARO or CFARN without using either CFARCTRL.CFAR\_CAE or CFARCTRL.CFAR\_GOSE to enable a CFAR engine as this will affect performance and cause the Bin Rejection Unit to behave in an unpredictable manner.*
2. *If double pass is enabled the in-line bin rejection mask will be calculated for the first FFT of both passes. The independent bin rejection masks will then be used for all further FFTs of each relevant pass*

The results data will be written to Radar Memory at incrementing contiguous addresses starting from the programmed base address. Results will be in ascending bin order with bin 0 stored at the LSB of the word at the lowest address. Results of less than 256 bits in length will be aligned on a power of 2 bit address boundary i.e.

- results of more than 8 bits size and less than 17 bits size will be aligned on 16 bit boundaries (one result in every 2 bytes of memory) results of more than 16 bits size and less than 33 bits size will be aligned on 32 bit boundaries (one result in every 4 bytes of memory)
- results of more than 32 bits size and less than 65 bits size will be aligned on 64 bit boundaries (one result in every 8 bytes of memory)
- results of more than 64 bits size and less than 128 bits size will be aligned on 128 bit boundaries (one result in every 16 bytes of memory)
- results of more than 128 bits size and less than 257 bits size will be aligned on 256 bit boundaries (one result in every 32 bytes of memory)
- Results of more than 256 bits will be rounded up in size to the next 256 bit (32 byte) address boundary.
  - e.g. a result with 734 bits of data will be fitted into 768 bits (96 bytes) of memory

## Signal Processing Unit (SPU)

If both engines are enabled, the data from the two engines can be separated with the results from the CA-CFAR written to memory starting at the base address (CFARTCTRL.BASE) and the results from the GOS-CFAR written to memory starting at the base address plus offset<sup>1)</sup> (CFARCFG3.CHAN5OFFSET). If only the GOS-CFAR engine is enabled, then the offset address can be set to 0000<sub>H</sub>.

**Table 619 1D-CFAR engines Common configuration parameters**

Parameter	Definition	Comments
Base Address	Starting address for writing CA-CFAR results to memory.	<b>CFARCTRL.BASE</b> Byte Address. must be 256 bit (32 byte) aligned
Offset Address	Word address offset added to base address to generate the starting address for writing GOS-CFAR results to memory	<b>CFARCFG3.CHAN5OFFST</b> 32 byte word Address.
number of bins	from FFT8 to FFT2048. any intermediate power of 2 value supported	FFT size is passed from the loader configuration <sup>1)</sup> <b>LDR_CONF.SIZE</b>
CFAR input selection	select input from FFT engine or from non coherent integration.	note that when input from FFT engine is used, signal power will be computed on each received BIN. <b>CFARCTRL.CFAREN</b>
Spectrum extension mode	2 extension modes depending if CFAR is run on range or on dopplermode1 = spectrum extension for rangemode2 = spectrum extension for doppler	<b>CFARCTRL.EXNSN</b>
Spectrum Extension Window	number of extra cells to be added on each end of the CFAR data	<b>CFARCTRL.SEWIN</b>
CFAR enable	CFAR enabling / disabling	<b>CFARCTRL.CFAREN,</b> <b>CFARCFG.CFAR_CAE</b> and <b>CFARCFG.CFAR_GOSE</b>

- 1) If the FFT accelerator is bypassed, the size of the input data is derived from the bin loop repeat value (ID\_RM\_BLR.BLR) if data is sourced from Radar Memory or sample count (ID\_CONF.SMPLCNT) if the data is sourced from the RIF

### 19.3.5.5.6 GOS-CFAR Engine

Configuration Parameters for the GOS-CFAR Engine are detailed in the following table

**Table 620 GOS-CFAR engine SW configuration parameters**

Parameter	Definition	Comments
GOS-CFAR algorithm	selects between GO	<b>CFARCFG.GOSALGO</b>
number of cells in leading and lagging windows for GOS-CFAR	can be set to any value from 1 to 32 cells either side of the cell under test	leading and lagging window <b>CFARCFG2.GOSWINCELL</b>

1) 2048 off, 2048 bin CFAR results will occupy 512 KiB of memory. A 16 bit offset field with byte addressing allows for 128 KiB. For this reason, the offset is specified as a 32 byte aligned, word address.

## Signal Processing Unit (SPU)

**Table 620 GOS-CFAR engine SW configuration parameters (cont'd)**

Parameter	Definition	Comments
number of guard cells	can be set to any value from 0 to 31	any value from 0 to 30 permitted <b>CFARCFG.GOSGUARD</b>
GOS-CFAR Beta parameter	16 bit, unsigned number with 7 integer bits and 9 fractional bits. Used to adjust the threshold i.e. Cell Under Test must exceed the trigger value by more than this parameter. The parameter represents $\log_2$ power	<b>CFARCFG3.GOSBETA</b>
GOS-CFAR Lead Index	Index of sorted statistic in leading window in GOS-CFAR	<b>CFARCFG2.IDXLD</b> min value 0, max value GOSWINCELL-1
GOS-CFAR Trailing Index	Index of sorted statistic in lagging window in GOS-CFAR	<b>CFARCFG2.IDXLG</b> min value 0, max value GOSWINCELL-1

In the GOS-CFAR algorithms, the samples within the leading/lagging windows are processed through a non-linear sorting operation and selected ordered statistics:  $Y_1$ ,  $Y_2$  are extracted from the two sub-windows, respectively. The GOSCA, GOSGO, and GOSSO algorithms differ in the manner  $Y_1$ ,  $Y_2$  are combined:

- GOSCA:  $Z = Y_1 + Y_2$
- GOSGO:  $Z = \max\{Y_1, Y_2\}$
- GOSSO:  $Z = \min\{Y_1, Y_2\}$

The resulting statistic  $Z$  is finally scaled by the “beta” scaling factor in order to determine the threshold value. The value of the “beta” parameter determines the probabilities of False Alarm (FA) and Missed Detection (MD). For the GOSGO and GOSSO algorithms the  $\log_2$ -domain input power sample implementation is directly equivalent to the linear one, since both the sorting and max/min operations produce equivalent ( $\log_2$ -domain) values for  $Z$ . The only difference is that the threshold value is produced by scaling  $Z$  additively with “beta”. On the other hand a direct  $\log_2$ -domain implementation of the GOSCA algorithm is not normally equivalent to the linear-domain implementation, since  $\log_2(Y_1 + Y_2)$  is not equal to  $(\log_2(Y_1) + \log_2(Y_2))$ . However in the CFAR module an equivalent  $\log_2$ -domain result to the linear domain one is obtained by post processing.

### 19.3.5.5.7 CA-CFAR Engine

The CA-CFAR engine supports the CA-CFAR, CAGO-CFAR, CASO-CFAR and CASH-CFAR algorithms. The configuration Parameters for the CA-CFAR Engine are detailed in the following table:

**Table 621 CA-CFAR engine configuration parameters**

Parameter	Definition	Comments
CA-CFAR algorithm	selects between CA, CAGO,CASO and CASH	<b>CFARCFG.CAALGO</b>
CA-CFAR Beta parameter	16 bit, unsigned number with 7 integer bits and 9 fractional bits. Used to adjust the threshold i.e. Cell Under Test must exceed the trigger value by more than this parameter. The parameter represents $\log_2$ power	<b>CFARCFG.CABETA</b>
number of guard cells	can be set to any value from 0 to 16 <sup>1)</sup>	any value from 0 to 16 permitted <b>CFARCFG.CAGUARD</b>

## Signal Processing Unit (SPU)

**Table 621 CA-CFAR engine configuration parameters (cont'd)**

Parameter	Definition	Comments
number of cells in leading and lagging windows for CA-CFAR	This defines the window size for comparison. The window size used is $2^n$ , where n is the value in the register bitfield	leading and lagging window <b>CFARCFG.CAWINCELL</b> min value 1, max value 5
active cells in window to be used for averaging for CA-CFAR/CASH-CFAR	This defines the window size for averaging within the leading and lagging windows. The window size used is $2^n$ , where n is the value in the register bitfield	<b>CFARCFG2.CASHWIN</b> min value 0, max value 5. Must be less than or equal to CAWINCELL value when CASH algorithm is selected. Otherwise must be equal to CAWINCELL

1) Values greater than 16 will cause undefined operation and incorrect results

In the CASH and CA-CFAR algorithms, the samples within the leading/lagging windows are processed through sample averaging to produce  $Y_1$ ,  $Y_2$  statistics for the leading and lagging windows respectively. Averaging is performed in the linear power domain and conversion into the  $\log_2$ -domain is performed prior to the application of the non-linear/linear operation in the processing block as shown in [Figure 252 “CFAR Engine Architecture” on Page 67](#).

In CASH-CFAR, the  $\log_2$ -converted averaged power samples are processed through MAX and MIN operations, as described in “F. X. Hofele, An Innovative CFAR Algorithm, CIE Intern. Conf. on Radar, 2001” and associated patents.

In CA/CAGO/CASO-CFAR the  $\log_2$ -domain processing is similar to the GOS-CFAR.

Threshold scaling in CASH/CA-CFAR is performed additively using the “beta” parameter in a similar manner to that used by GOS-CFAR.

### 19.3.5.8 CFAR Engine Configuration Restrictions

The CFAR engine requires some constraints on configuration to avoid undefined results

- The value of two times the sum of the number of guard cells and the number of cell in the window must not exceed the FFT size minus one.
- If spectrum extension is enabled, the spectrum extension window must be greater than or equal to the sum of the number of guard cells and the number of window cells. If both CFAR engines are enabled, this number must be calculated for both engines and the larger value must be used.
- The achievable maximum value for the  $\log_2$  power representation of the linear power is  $7E00_H$  (for a linear power of  $FFFF\_FFFF\_FFFF\_FFFF_H$ ) If the Beta parameter exceeds this value, it is impossible for any detection to occur.

### 19.3.5.9 CFAR spectrum extension

2 extension modes need to be considered: range extension and velocity extension.

Range and Velocity extension is supported by shifting additional data points into the CFAR unit at the beginning and end of the FFT to preload the window cells with the correct data. This requires the equivalent number of output data points from the CFAR to be ignored. This will be handled transparently by the supporting logic if this mode is enabled

Spectrum extension is always done per FFT dataset by adding additional bins to the dataset. The content replicating the value of some of the existing bins into the new bins. Data is fed into the CFAR unit on a “per antenna” basis. Spectrum Extension never uses data from more than one antenna. The bins to be replicated depend on the spectrum extension mode.

---

## Signal Processing Unit (SPU)

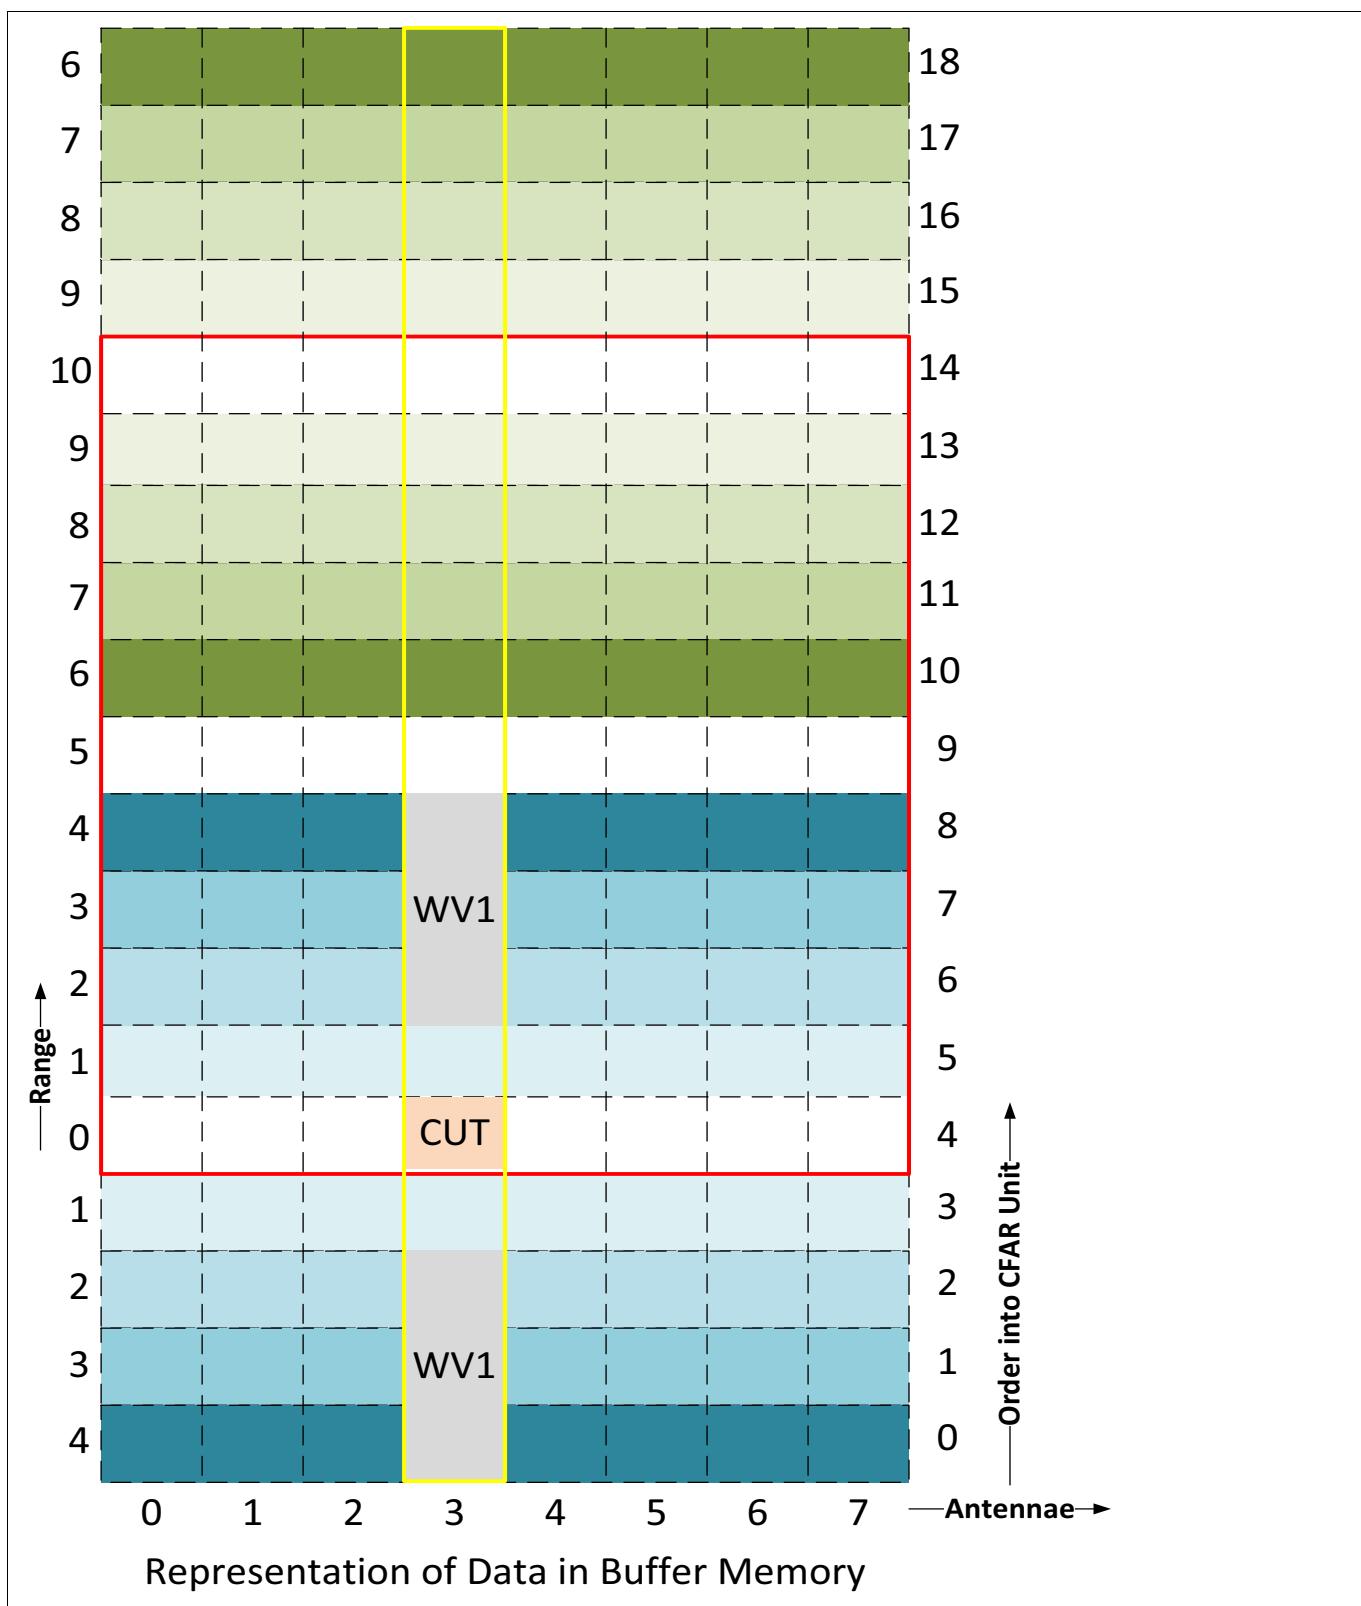

Spectrum extension will cause some data to be read twice from the buffer memory. The amount of extra reads will be directly linked to the size of the extension defined by CFARCTRL.SEWIN

**Note:** *Spectrum Extension is used in conjunction with the CFAR or Local MAX functions and should not be enabled if neither of these functions is enabled. Enabling the Spectrum Extension in the absence of enabling either CFAR or Local Max is not supported and will result in abnormal operation of the SPU.*

### Spectrum Extension for CFAR in Range

In range spectrum extension, the spectrum is extended by mirroring across the border as illustrated in the figure below. In this figure, the y-axis is along the FFT dataset (bin number ascending from the bottom of the figure).

### Signal Processing Unit (SPU)

**Figure 253 Diagram of Range Spectrum Extension**

Please note that the figure is only showing the principle as real extension needs to be done according to the window size for range and for velocity directions. The extent of the “real” data is shown by the red rectangle. The effective size of the dataset and the mirroring used to achieve it is shown by the colour coding. The extended

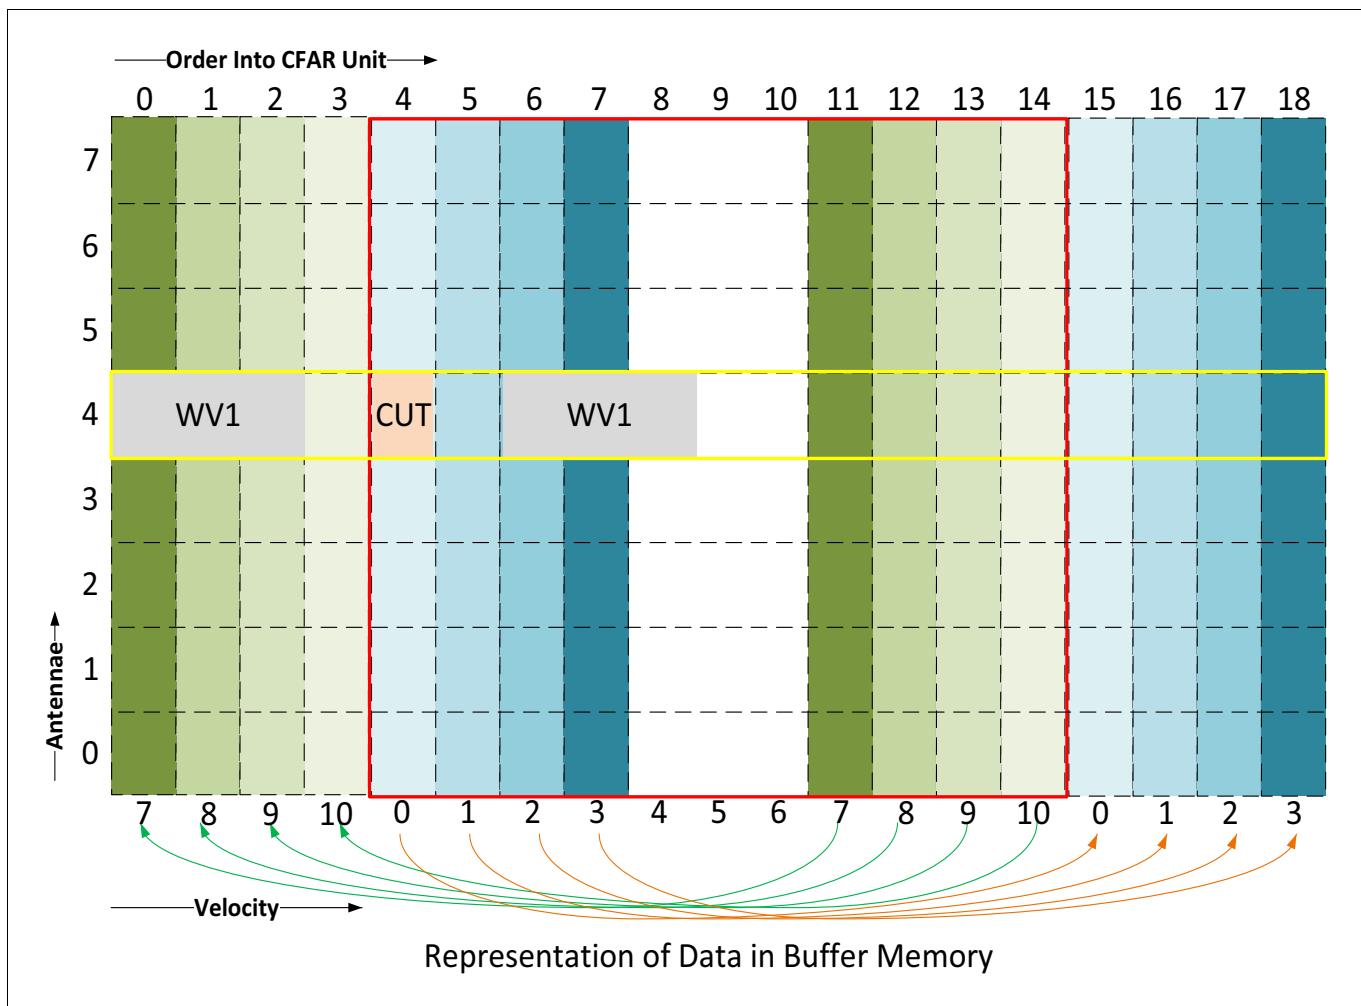

## Signal Processing Unit (SPU)

dataset fed to the CFAR units is shown as the yellow rectangle. CUT is “Cell Under Test” and WV1 represents an example window with guard band.

The behaviour if the window size exceeds the size of the dataset is not defined.

### Spectrum Extension for CFAR in Velocity

In velocity / Doppler direction, the spectrum is extended by implementing cyclic repetition. The colour coding in the diagram below shows how the repetition is implemented. The extent of the “real” data is shown by the red rectangle. Please note that the figure is only showing the principle as real extension needs to be done according to the window size for range and for velocity directions.

**Figure 254 Diagram of Velocity Spectrum Extension**

The extent of the “real” data is shown by the red rectangle. The effective size of the dataset and the mirroring used to achieve it is shown by the colour coding. The extended dataset fed to the CFAR units is shown as the yellow rectangle. CUT is “Cell Under Test” and WV1 represents an example window with guard band.

The behaviour if the window size exceeds the size of the dataset is not defined.

## Signal Processing Unit (SPU)

### Spectrum Extension on NCI Unit Output

Spectrum extension is always a one-dimensional operation which affects the input to the CFAR unit. When using spectrum extension with NCI, the integration is performed first and the spectrum extension is then applied to the resulting one-dimensional vector as if dealing with a single antenna system.

#### 19.3.5.5.10 Operation of Spectrum Extension

The spectrum extension modes work by adding extrapolated bins to each end of the FFT results. The number of bins added depend on the window size in use. For a window of e.g. 7 bins on each side of the bin under evaluation and additional 7 extrapolated bins will be added to each end of the FFT data to ensure that the first and last real bins are evaluated against a full set of window data.

Operation of the spectrum extension modes is controlled by the bitfield CFARCTRL.EXTNSN

For range spectrum extension, the extrapolated bins are mirrored. This means that when bin 0 is under comparison, real bins 1 to n are used for the values of extrapolated bins -1 to -n respectively (where n is determined by the comparison window size). For a 256 point FFT real bins 254 to 254-n are used for the values of extrapolated bins 256 to 256+n when evaluating bin 255.

For velocity spectrum extension, the extrapolated bins are determined by cyclic repetition. Again, using a 256 bin FFT as an example, when evaluating bin 0, extrapolated bins -n to -1 will be the values of real bins 255-n to 255. When evaluating bin 255, extrapolated bins 256 to 256+n will be the values of real bins 0 to n.

#### 19.3.5.6 Summation Sideband Operations

The Output Data Processor can generate several types of sideband data related to the FFT results being processed. These operations can either use log<sub>2</sub> power, linear power or approximate magnitude and can be subdivided into two types:

- Complex Arithmetic Operations
  - SUMCTRL.SUMMODE=SUMANT. Calculate the complex sum across FFT results in buffer memory (sum-antenna). The result is a 1D vector, with the same length as the FFT. Data format is defined by PWRSUM.PRECISION and can either be 16 bit precision complex or 32 bit precision complex. The result will be normalised as configured by PWRSUM.SCALE.
  - FFT. SUMCTRL.SUMMODE=SUM. Calculate the complex sum of all datapoints of an FFT. Data in this mode is always 32 bit precision. One value is stored in the output data for each FFT processed. The output value will always be normalised by dividing by the number of datapoints in the FFT<sup>1)</sup>.
  - FFT. SUMCTRL.SUMMODE=SUMLINP. Calculate the sum of the linear power of all datapoints in an FFT. Data in this mode is always 32 bit precision. One value is stored in the output data for each FFT processed. No complex part will be stored. The output value will always be normalised by dividing by the number of datapoints in the FFT<sup>1)</sup>.
- log<sub>2</sub> Power Operations
  - the sum of the log<sub>2</sub> power of all the datapoints in an FFT. SUMCTRL.PWRMODE=SUM. This will always be 16 bit precision<sup>2)</sup>. No complex part will be stored. The output value will always be normalised by dividing by the number of datapoints in the FFT<sup>1)</sup>.

Data will be written as follows

---

1) If the FFT bypass is enabled, then the number of data points in the data may not be a power of two. In this case, the dataset will be padded with zero values up to the next power of two and normalisation will divide by the power of two.  
 2) When normalising the output value to 16 bit precision, the result will be rounded down to the nearest integer. This is an exception to the general usage of “round to nearest integer”

## Signal Processing Unit (SPU)

- The output from the Complex Arithmetic Operation, if enabled, will be packed and written to ascending, contiguous addresses starting from SUMCTRL.BASE
- The output from the  $\log_2$  power operation, if enabled, will be packed and written to ascending, contiguous addresses starting from PWRSUM.BASE

The results of the Complex Arithmetic Operations (SUMMODE=SUMANT or SUMMODE=SUM) can be forced to have a zero imaginary component by setting SUMCTRL.REAL to  $1_B$ .

**Table 622 Sum Configuration Options**

Parameter	Definition	Comments
Address	Base Address for starting the writing of results	<b>SUMCTRL.BASE</b>
sum type selection	select between "off", "sum", "sum-linp" and "Sum-antenna"	<b>SUMCTRL.SUMMODE</b>
sum type selection (power data)	select between "off" and "sum" (on)	<b>SUMCTRL.PWRMODE</b>
real or complex data	select which part of the data to take as input	when real is selected, even is complex data is provided, only the real part will be taken for the sum <b>SUMCTRL.REAL</b>
Antennae	which antennae to include in Sum-antenna mode	Bitmask containing one bit per antenna <b>SUMCTRL.USEANT</b>
Address for $\log_2$ power	Base Address for starting the writing of results	<b>PWRSUM.BASE</b>

### 19.3.5.6.1 Organisation

The implementation of this function is split into three separate units in the MATH2 unit. One of these units operates on  $\log_2$  power information, one on complex data or linear power and the final unit performs the complex addition of FFT results across antenna. This is shown on the MATH2 unit block diagram. These units are

- Summation Unit (Power Sum)
- Summation Unit (Complex Sum)
- Complex Vector Add (sum-antenna or Coherent Integration Output)

### 19.3.5.7 Statistical Information

The output of Statistical data is enabled by setting SBCTRL.EN to  $1_B$ .

The mean value computed by the Unloader Unit is queued for writing to the Radar Memory. Additionally, the mean value is used to compute the variance (standard deviation squared) for each FFT. While the FFT data is being parsed to compute the variance, the minimum and maximum power values will be captured

Along with the minimum and maximum power values, the index of the FFT bin at which the minimum and maximum occurred will also be captured.

In the event of multiple bins having the same minimum or maximum, only the index of the first bin to have the value will be captured.

The base address for the writes to start is defined in SBCTRL.BASE. and configuring either of the enable conditions will result in the statistical information output channel being enabled. However, only the requested data will be written. When SBCTRL.EN is 1 then the statistical information will be written in packets of 32 bytes

## Signal Processing Unit (SPU)

per FFT (256 bit aligned) with 20 bytes of data and 12 spare bytes of indeterminate value. See [Table 623 “Statistical Information Written” on Page 77](#) for the data format used.

**Table 623 Statistical Information Written**

Parameter	Size (bytes)	Address Offset
Minimum Power	4 <sub>D</sub>	0 <sub>D</sub>
Maximum Power	4 <sub>D</sub>	4 <sub>D</sub>
Mean Power	4 <sub>D</sub>	8 <sub>D</sub>
Variance	4 <sub>D</sub>	12 <sub>D</sub>
FFT Bin Index for Minimum Power	2 <sub>D</sub>	16 <sub>D</sub>
FFT Bin Index for Maximum Power	2 <sub>D</sub>	18 <sub>D</sub>

The configuration parameters affecting the statistical data output are shown in [Table 624 “Statistical Unit Configuration Parameters” on Page 77](#)

**Table 624 Statistical Unit Configuration Parameters**

Parameter	Definition	Comments
statistical data enable	enable / disable	<b>SBCTRL.EN</b>
FFT Output Channel Enable	enable/disable FFT Result output	ODP_CONF.MODE
FFT Output Channel Post-Processing	Enable FFT Result Post-processing	ODP_CONF FORMAT

### 19.3.6 Output DMA Engine

This section describes the operation of the DMA engine that the SPU uses to write results to memory.

#### 19.3.6.1 Output DMA Engine Channels

As described in [Table 612 “Output DMA Engine Data Streams” on Page 58](#), the Output DMA Engine has eight independent data channels. These are configured using the following parameters:

**Table 625 Output DMA Engine Configuration Parameters**

Parameter	Definition	Comments <sup>1)</sup>
DMA base address for port1	DMA base address when starting a new FFT sequence from Radar memory	FFT results only <b>ODP_CONF.BASE</b>
DMA inner loop address offset	offset address to be added to base address	FFT results only
DMA outer loop address offset	offset address to be added to base address	These parameters are used only for in-place FFT and therefore have to match the Input Data Engine Configuration. Consequently these parameters are inherited from the Input DMA Engine
DMA inner loop repeat value	number of times of inner loop execution	
DMA outer loop repeat value	number of times of outer loop execution	
effective DMA transfer counter	dedicated counter to count effective number of Radar memory writes	FFT results only safety function

## Signal Processing Unit (SPU)

**Table 625 Output DMA Engine Configuration Parameters (cont'd)**

Parameter	Definition	Comments <sup>1)</sup>
DMA base address for port2	signal power	PWRCTRL.BASE
DMA base address for port3	min, Max, average	SBCTRL.BASE
DMA base address for port4	thresholding with local max or CFAR CA	CFARCTRL.BASE
DMA base address for port5	thresholding with CFAR GOS	CFARCTRL.BASE + CFARCFG3. CHAN5OFFST
DMA base address for port6	Vector add /sum	NCICTRL.BASE
DMA base address for port7	sum, sum-linp, sum-antenna	SUMCTRL.BASE
DMA Base Address for port8	sum of $\log_2$ power over FFT	PWRSUM.BASE
signed FFT BIN casting/rescaling	defines how many bits are kept from the LSB (of the 32bit internal precision) note that the sign, located on the MSB, is maintained.	ODP_CONF.EXPNT
output FIFO flush <sup>2)</sup>	FIFOs are flushed upon each configuration change. Required for the last computation step	This is an implicit parameter triggered internally when the processing of the last FFT in the measurement cycle is completed

1) All Registers here (except CFARCFG3) are duplicated to allow Double Pass Mode not to overwrite data

2) Automatic Operation, no specific control bit planned for this

Each of the BASE fields defines the start address for the output channel. The write address will be incremented automatically so that the results of each channel are stored as an array in memory starting from the defined base address.

The exception is the “In Place FFT” mode for writing the FFT results. Here the ODP\_CONF.BASE field is used as the start address but the address sequence is calculated using the Input DMA Engine Loop Count and Loop Offset parameters.

The output data stream is pushed to Radar Memory without any possibility of delay or wait states. The Radar Memory is required to keep pace with the output data rate. This is achieved by giving writes absolute priority in arbitration and arranging separate arbitration for each 256 KiB Radar Memory tile.

**Note:** *In systems with two active SPUs or with ID\_CONF2.BYPASS enabled, it is mandatory to ensure that the output from each SPU is directed to different tiles of the Radar Memory. In the event of arbitration being required between two SPU writes, then the write which loses arbitration will be lost.*

**Note:** *The SPU is specified to cope with Radar Memory sizes up to 16 MiB. Any MSBs of address bitfields not needed to address the Radar Memory available in the product will be silently ignored and set to 0<sub>B</sub> by the Output DMA Engine when initialising the output addresses. If incrementing addresses during operation causes the Output DMA Engine to generate an address outside the range of the available Radar Memory in the product, an error will be generated.*

### 19.3.6.2 Data Cube Organisation and Size after processing ADC data

The FFT results of processing ADC sample sets (ramp data) are always kept together in memory.

## Signal Processing Unit (SPU)

Each FFT result always starts at a 256 bit (32 byte) aligned address. This is mandatory if the data is to be read back into the SPU as the read operations controlled by the Input Data Manager require the start address of each dataset to be 256 bit aligned.

The ramp data are then grouped by antennae so the ramp  $n^1)$  data for all antennae (inner loop output) is grouped together in memory. The size of the data cube is variable and depends on the following factors

- data format, real or complex
- data precision 16 bit or 32 bit (DPR)
- samples per ramp or FFT output (maximum bin loop count, BLC)
- number of antennae (NA)
- number of ramps in measurement cycle (maximum outer loop count, OLC)

The size of each data point (SDP) is as follows

- 16 bit real: 2 bytes (DPR = 16 bit)
- 32 bit real: 4 bytes (DPR = 32bit)
- 16 bit complex: 4 bytes (DPR = 16 bit)
- 32 bit complex: 8 bytes (DPR = 32bit)

The size in bytes of the data generated for each configured antennae per ramp (ADS) is

(19.2)

$$\text{ADS(bytes)} = \text{BLC} \times \text{SDP}$$

The value for ADS will always be rounded up to the next 32 bytes (ADSR).

The overall dataset size (DS) is then

(19.3)

$$\text{DS(bytes)} = (\text{ADSR}) \times \text{NA} \times \text{OLC}$$

As the maximum amount of data that can fit into the Buffer RAM is 32 kBytes, this gives a hard limit for the amount of data per inner loop (the ADS value).

### 19.3.7 Radar sequencer

The Radar sequencer is the main control sequencer of the SPU. It manages the configuration/reconfiguration of each unit and controls the sequencing of operations. It also monitors each unit for correct operation and generates suitable signalling to the application software via the Interrupt system and the Safety Management Unit.

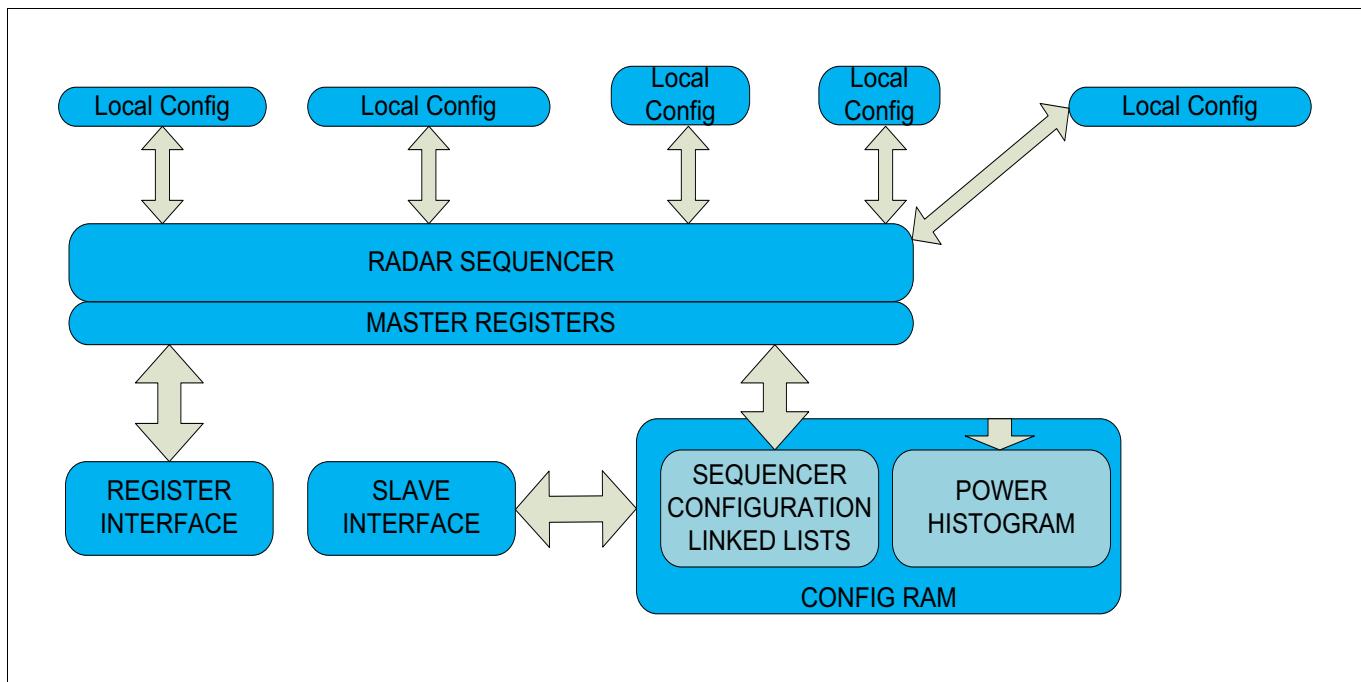

General principles of operation are:

- Configurations can be written directly to the registers of the SPU by application software
- However, configurations can also be stored in the configuration memory, which is a RAM accessible by the application software (this RAM is also used to store the histogram)
- Configurations are organized in linked lists.

This following sections describe the features and behaviour controlled by the Radar Sequencer.

1) where n is the ramp number and also the outer loop count

## Signal Processing Unit (SPU)

**Figure 255 Radar Sequencer Overview**

### 19.3.7.1 General Configuration

The Radar sequencer has several configuration options that define the overall configuration of the SPU.

**Table 626 General Configuration Options**

Function	Register	Bitfield	Comment
Clocking Mode	CTRL	DIV	FFT Operating Mode. Configures the rate at which the LOADER outputs data. 1, 2, 4 or 8 clocks/bin are possible. 2 clks/bin is considered “normal” operating speed
	CLC	DISR	Clock Disable. Switch off the SPU’s internal clock
Linked List Base Address	CTRL	NXT_CONF	Base address for the next set of configuration information in the linked list
Start	CTRL	TRIG	Starts the Radar Sequencer
Operating Mode	CTRL	MODE	Defines when the SPU will start processing input data
Attention	CTRL	ATTN	Trigger a service request interrupt when execution of the current configuration is completed
Cross Trigger	CTRL	XTRIG	Trigger a “DONE” event when execution of the current configuration is completed.
Last Configuration	CTRL	LAST	Current Configuration is the last configuration to be executed. Do not load a further configuration from the address defined by NXT_CONF

## Signal Processing Unit (SPU)

### 19.3.7.2 Radar sequencer start / stop

CTRL.MODE is used to define the conditions under which the SPU will start processing data.

The register space is organised so that the CTRL register should be the last register read during configuration by linked list. This ensures that a software trigger always starts with a valid data set. Starting processing of a linked list can be started either by writing a full set of register values directly into the register site finishing with a valid write to the CTRL register or by writing a MODE value of “RELOAD” and a valid NXT\_CONT value to the CTRL register

Writing a 1<sub>B</sub> to the CTRL.TRIG bit starts the radar sequencer provided that the CTRL.MODE bitfield is set to “SW” (software).

The SPU will stop processing a linked list when processing completes on a configuration which has the CTRL.LAST bit set or if the configuration just loaded contains “OFF” or “STOP” in the CTRL.MODE field.

**Note:** *The only difference between setting CTRL.LAST and loading a configuration set with CTRL.MODE set to OFF is that using CTRL.LAST eliminates an unnecessary configuration load. CTRL.MODE=STOP should only be used if it is required to abort processing off a linked list. If it is loaded from configuration memory then it will behave in the same way as setting CTRL.MODE to OFF.*

The CTRL.BUSY bitfield shows if the SPU is running or is stopped. Loading a configuration which has a CTRL.MODE field not set to OFF or STOP will cause the SPU to transition to the running state even if it is then just waiting for a trigger event. Once in the running state, software can only stop the SPU by writing “STOP” to CTRL.MODE. Any other value will have no effect.

**Note:** *Only the CTRL register should be written while the SPU is busy. Writing any other register will have immediate effects on the SPU configuration and may lead to undesirable consequences including a lock up of the SPU.*

**Table 627 CTRL.MODE Value Definitions**

Value	Function
OFF	SPU will do nothing. This is used to terminate a linked list operation when loaded from a configuration set in config RAM. Software writing OFF to the CTRL register once the SPU has been configured has no effect.
INT	SPU will pause waiting for data on the RIF input. Valid data on the RIF input will trigger operation. This can be qualified by the Partial Acquisition counter LIMIT value if the PACTR.TRIG bit is set
EXT	SPU will pause waiting for a trigger from an external source. This is used to trigger the SPU from the SPU Lockstep module if present on the product. Valid data on the RIF input will be ignored until the trigger event occurs. Valid data on the RIF data after the configured measurement cycle has completed will be ignored. If the Radar memory is configured as the data source, processing will commence immediately.
SPU0	SPU will trigger on an “DONE” event from SPU0 <sup>1)</sup>
SPU1	SPU will trigger on an “DONE” event from SPU1 <sup>1)</sup>
RELOAD	SPU will trigger an immediate configuration load from the value in the CTRL.NXTCONF field

## Signal Processing Unit (SPU)

**Table 627 CTRL.MODE Value Definitions (cont'd)**

Value	Function
SW	SPU will immediately start processing when a $1_B$ is detected in the CTRL.TRIG bitfield. The trigger event may occur simultaneously with "SW" being written to CTRL.MODE
STOP	This value should be written to the MODE bitfield if it is required to stop the SPU in the middle of linked list processing. If written while the SPU is processing data, the SPU will stop when the current processing operation is completed rather than loading the next configuration set. This value should not be loaded from a configuration set in RAM. In this case OFF should be used instead

1) Note that the SPU will only generate the "DONE" event when explicitly configured using the CTRL.XTRIG bitfield

The values INT and EXT are intended to be used when data is being read from one or more RIF instances (or, in the case of EXT, if the SPUs are lockstepped).

The value EXT can also be used when reading data from Radar Memory when the SPUs are lockstepped.

SPU0, SPU1 and SW are intended to be used when reading data from Radar Memory. These options cannot be used when the SPU s are lockstepped.

As soon as any of the values: INT, EXT, SPU0, SPU1 or SW are written to the CTRL.MODE bitfield, the SPU will report its state as "BUSY" when CTRL.BUSY is read.

### 19.3.7.3 Synchronized Radar sequencer Start

The synchronised start function allows the 2 SPUs to be started at the same time. When using synchronised start, there will be no skew between the start point of the two SPUs as this mode is used to start processing in lockstep mode when reading data from the Radar Memory. Synchronised start is configured setting the CTRL.MODE bitfield to EXT and using the SPU Lockstep module to simultaneously trigger both SPUs.

### 19.3.7.4 Configuration / Reconfiguration

During linked lists of computations, the Radar SPU supports full reconfiguration of the computation units of the SPU by reading the full register set from configuration memory. Partial reconfiguration is supported by making a copy of the previous configuration into the configuration memory and changing only the register fields affecting the functionality requiring reconfiguration before reloading it directly into the SPU registers using the linked list function.

### 19.3.7.5 Linked Lists Organization

A linked list is a set of configuration sets stored in Configuration Memory defining a sequence of computations that are run without CPU intervention. The linked list is stores in memory as an image of the registers, starting from IDM\_CONF and ending at CTRL. The image of IDM\_CONF is stored at the base address of the linked list entry and all the other registers are at the same relative offset as their address in the system memory map.

The Transaction Counter registers, CRC registers, CLC, MODID, STAT, MONITOR, OCS, ODA, USROTC, ACCEN, KRST0, KRST1 and KRSTCLR registers cannot be reconfigured by the linked list function.

### 19.3.7.6 CPU monitoring during run time

The CPU(s) can read configuration registers during run time to check or wait for the radar sequencer to complete a computation sequence. The CPU can also read status registers to monitor the proper execution of the sequence. The following status registers can be monitored (read only) during run time

- ramp counter (derived from Input Data Manager)

## Signal Processing Unit (SPU)

- sample counter
- 1 busy flag per sub block
- 1 busy flag for SPU
- linked list sequence completed

### 19.3.7.7 Interrupts

The Radar SPU has a high degree of autonomy. As such, it generates few interrupts. Each interrupt source can be masked but for safety reasons, its flag can be read by application software.

Each SPU instance has two physical interrupt requests.

- Attention Request: asserted on one or more of events occurring during normal operation when intervention by the application software is needed
- Error Flag: asserted on an error condition when accurate completion of the calculation is compromised

The table below is showing the different interrupt sources

**Table 628 Interrupt Trigger Definition**

Event	Definition	Comments
end of execution	A configuration with the CTRL.ATTN bit set has completed execution	Attention Request <b>STAT.INTMSK(0)</b>
Arithmetic Overflow During iFFT	The FFT accelerator has reported that an output number will not fit into the supported format	Attention Request <b>STAT.INTMSK(1)</b>
Input DMA Unit	To be defined.	Attention Request <b>STAT.INTMSK(2)</b>
end of linked list	set after confirmed write of the last result of the outer loop.	Attention Request <b>STAT.INTMSK(3)</b>
Partial Acquisition Counter Trigger	Partial Acquisition counter has reached programmed limit with PACTR.ATTN bit set	Attention Request <b>STAT.INTMSK(4)</b>
any status event (to be defined)		<b>STAT.INTMSK(5)</b>
Radar Memory Read Error	Address Overflow on Radar Memory read or Radar Memory has reported an error on read	Error Flag <b>STAT.ERRMSK(0)</b>
Input DMA Unit write error	Address Overflow on Buffer Memory write	Error Flag <b>STAT.ERRMSK(1)</b>
Radar Memory Write error	Address Overflow on Radar Memory Write or the Radar Memory has reported an error on write. This covers both the Output DMA and the Bypass Channel for RIF1 data	Error Flag <b>STAT.ERRMSK(2)</b>
FIFO overrun	One or more of the SPU internal FIFOs has overflowed	Error Flag <b>STAT.ERRMSK(3)</b>

## Signal Processing Unit (SPU)

**Table 628 Interrupt Trigger Definition (cont'd)**

Event	Definition	Comments
Partial Acquisition Counter Error	Partial Acquisition Counter has reached limit with PACTR.ERR bit set	Error Flag <b>STAT.ERRMSK(4)</b>
Input Data Overrun	The LOADER/FFT/MATH2 pipeline has not completed processing when the next set of FFTs have been fully written to buffer memory and the RIF has more data to be written for the following ramp. A ramp has (or ramps have) been skipped.	Error Flag <b>STAT.ERRMSK(5)</b>

### 19.3.8 Streaming Processor 1, Buffer RAM Switching Behaviour

When the Input DMA Engine has finished writing a data block to the Buffer RAM, it will enable the switching of the Buffer RAMs to present the new data to the Loader module. If the Loader module is still reading the previous data block, the switch will not take place until the Loader module has finished.

The behaviour then varies depending on whether the data source is the Radar Interface or Radar Memory

#### 19.3.8.1 Data Source is Radar Interface

In the event that new data is presented at the Input DMA Engine inputs before the Loader has finished, the data will be written to the RAM and the switch of the buffer RAMs will not take place. This will be flagged as an "Input Data Overrun" error and can be used to trigger an SPU error interrupt (STAT.INTMSK(5) and STAT.ERRMSK(5)). As some applications may find controlled skipping of ramps useful, the maximum number of ramps skipped between buffer RAM switches occurring in a measurement cycle will be stored in the OVRRN field of the STAT register.

#### 19.3.8.2 Data Source is Radar Memory

Reading of further data from the Radar Memory will be stalled until the Loader has finished reading the previous data and the buffer RAM can be switched.

### 19.3.9 Configuration Memory

The configuration memory is used for several functions

- Storing complete or partial sets of configuration register settings for use by the linked list function of the SPU
- Storing Window Parameters for use by the FFT.
- Storing the working data for the power histogram calculation

The Configuration Memory is mapped into the system address space so that the application software can:

- write configuration register settings.
- write window parameters.
- read power histogram information.

Note that the operation of the histogram function requires all the available bandwidth of the RAM.

If the SPU is busy, then accesses to the configuration memory will be errored to prevent the bus access stalling for an extended period.

---

## Signal Processing Unit (SPU)

### 19.3.9.1 Safety/Security

As the configuration memory is primarily used for storing configuration settings, it is protected by the Access Enable mechanism used to prevent unauthorised modification of the SPU registers.

### 19.3.9.2 Configuration Register Data Format

The configuration register settings are stored in the configuration memory in the same organisation as they exist in the register space. Registers that can be updated from the configuration memory are in the address range ID\_CONF to CTRL. The ID\_CONF value will be stored at an address of  $0_H$  relative to the start address for the configuration set. The relative addresses of the data values for the other registers remain unchanged from their address map in system memory.

### 19.3.9.2.1 Loading Configuration Settings

The loading of configuration settings into the registers can be triggered either manually or automatically by one of the following events:

- Software Trigger
- Trigger on SPU idle
  - This will trigger a complete register load when the last write is flushed to Radar Memory

### 19.3.9.3 Window Data Format

The window data is stored linearly in the configuration memory with the address offset corresponding to the data point that the window value should be used for. The address offset size is affected by the format of the window data set in LDR\_CONF2 and will vary between 2 and 8 bytes per coefficient. For complex window coefficients, the real component is stored at the lower address. An independent address offset can be defined for each antenna.

### 19.3.9.4 Configuration Memory Usage Restrictions

The configuration information is stored in a memory that is independent from the Radar memory. This memory is also used to store the results from the histogram unit and the window parameters.

The histogram unit needs all the available bandwidth of this memory. The configuration memory is therefore organised as two independent banks and, if the histogram is enabled, the window information and configuration linked lists must be stored in the other bank

The TriCore subsystem should not attempt to access this memory during SPU run time. If a processor does attempt to access the memory while the SPU is utilising it the SPU will generate an error to the TriCore subsystem. This is to avoid stalling the processor execution for an excessive period of time.

The configuration memory is organised in 8 byte words. All register fields used to store configuration memory addresses must contain 8 byte aligned values. Any non-zero value written to bits[2:0] of these register fields will be ignored.

The configuration memory does not support byte or half-word (16 bit) write accesses

### 19.4.1 Register Description

#### Clock Control

**CLC**  
**Clock Control** (00000<sub>H</sub>) Reset Value: [Table 631](#)

Field	Bits	Type	Description
<b>DISR</b>	0	rw	<b>Disable Request</b> 0 <sub>B</sub> <b>Enable</b> , Request that the SPU clock tree be switched on 1 <sub>B</sub> <b>Disable</b> , Request that the SPU clock tree be switched off
<b>DISS</b>	1	rh	<b>Disable Status</b> This bit will be set to 1 if the SPU kernel clock is disabled 0 <sub>B</sub> <b>Enable</b> , The SPU clock tree is switched on 1 <sub>B</sub> <b>Disabled</b> , The SPU clock tree is switched off
<b>FDIS</b>	2	rw	<b>Freeze Disable</b> This bit controls the freeze function for this module. The freeze function is not implemented for the SPU so this bit will have no effect. This bit can be set to 0 <sub>B</sub> 0 <sub>B</sub> <b>Disabled</b> , Module Operates on corrected clock with reduced modulation jitter. No effect for SPU 1 <sub>B</sub> <b>Enable</b> , Module operates on uncorrected clock, with full modulation jitter.
<b>EDIS</b>	3	rw	<b>Sleep Mode Enable Control</b> Reserved. This bit currently has no effect on the SPU. It should be kept at 0 <sub>B</sub> for future compatibility 0 <sub>B</sub> <b>Disabled</b> , Sleep Mode is Off 1 <sub>B</sub> <b>Enable</b> , Sleep Mode is On (no effect)
<b>RES</b>	31:4	r	<b>Reserved</b>

## Signal Processing Unit (SPU)

**Table 630 Access Mode Restrictions of CLC sorted by descending priority**

Mode Name	Access Mode		Description
ENDINIT and Master enabled in ACCEN	r	EDIS, FDIS, RES	Write Accesses Permitted during Initialisation
	rh	DISS	
	rw	DISR	
Otherwise (default)	r	DISR, EDIS, FDIS, RES	Default Access Mode (Bus Error on Write)
	rh	DISS	

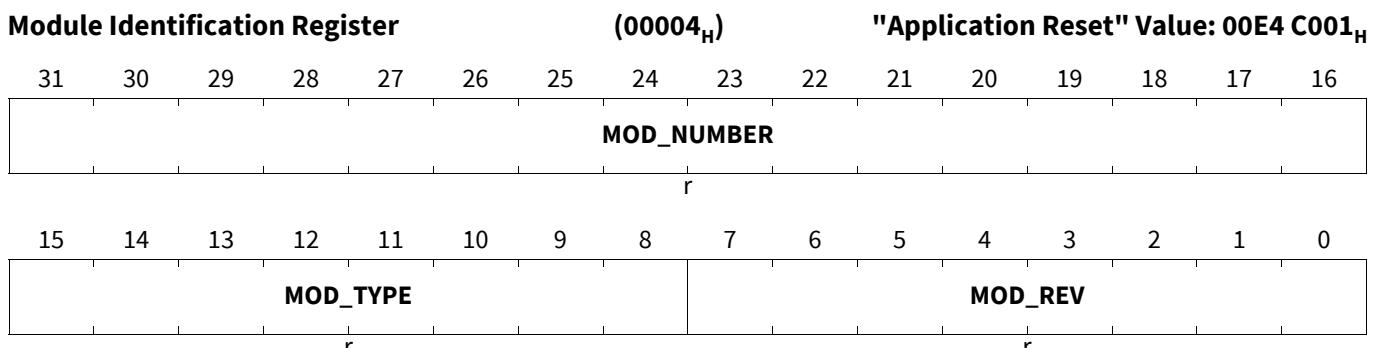

**Table 631 Reset Values of CLC**

Reset Type	Reset Value	Note
Application Reset	0000 0003 <sub>H</sub>	Application Reset

### Module Identification Register

This register contains information intended to enable identification of the module and the version of the module. The Revision Number (MOD\_REV) of the SPU is 01<sub>H</sub>.

#### MODID

Field	Bits	Type	Description
<b>MOD_REV</b>	7:0	r	<b>Module Revision Number</b> This bit field defines the module revision number. The value of a module revision starts with 01H (first revision)
<b>MOD_TYPE</b>	15:8	r	<b>Module Type</b> Set to 0xC0 to indicate a 32 bit module
<b>MOD_NUMBE R</b>	31:16	r	<b>Module Number Value</b> Set to 0x00E4. This number is unique to the SPU.

**Table 632 Access Mode Restrictions of MODID sorted by descending priority**

Mode Name	Access Mode		Description
Write Accesses	r	MOD_NUMBER, MOD_REV, MOD_TYPE	Any write access will cause bus error
Otherwise (default)	r	MOD_NUMBER, MOD_REV, MOD_TYPE	Default Access Mode (Bus Error on Write)

## Signal Processing Unit (SPU)

### Status and Reporting

This register allows the interrupt trigger masks to be set and the triggers causing interrupts to be read. See [Section 19.3.7.7, Interrupts](#) for bit allocation in the ERRMSK, INTMSK, ERRTRG and INTTRG fields

#### STAT

### Input DMA Configuration

This register configures the base operating mode for the Input DMA and also provides the configuration parameters specific to accepting data from the RIF(s). The ANT, SMPLCNT, RAMPS and FORMAT fields are only used if the data source in the SRC field is specified as one or more RIFs. These fields will be ignored if the SRC field specifies that data is to be read from Radar Memory

### ID\_CONF

### Input DMA Configuration 2

The Input DMA can bypass data from RIF1 if the incoming data for each ramp exceeds the capacity of the buffer memory. This register configures the bypass mode and also allows the bypassed data to be reloaded into the buffer memory by the Input DMA. Note that, when reloading bypassed data, the data source is still considered to be a RIF for configuration purposes.

#### ID\_CONF2

**Input DMA Configuration 2** (00034<sub>H</sub>) Reset Value: Table 638

## Signal Processing Unit (SPU)

Field	Bits	Type	Description
BPADDR	18:0	rw	<p><b>Bypass Address</b>            This is the base address to be used when reading or writing bypass data. It is a 256 bit (32 byte) aligned address and needs to have five LSBs added to convert to a system address. It allows for a maximum addressable range of 16 MiB. Bypass data is written as a raw data stream as generated by the Radar Interface. No processing is performed by the SPU until the data is read back from the Radar Memory.</p> <p>This field is sized to address a 16 MiB Radar Memory. Any MSBs not needed to address the memory in the product will be ignored. An overflow error (if configured) will be generated when the generated address exceeds the amount of physical Radar Memory available.</p>
RES	23:19, 31:26	r	<b>Reserved</b>
BYPASS	24	rw	<p><b>SPU Bypass Mode</b>            If enabled, and RIF0 and RIF1 are both configured as data sources, then the RIF1 data is written to EMEM directly without processing and can then be reloaded later. Switching between write and read operations is controlled by the BPRLD bitfield. Only the RIF0 data is processed. This mode is only effective for SPU instance 0 and should only be used in a two SPU system if the SPUs are lockstepped so that the data written from SPU1 is ignored.</p>
BPRLD	25	rw	<p><b>Bypass Reload</b>            If set, BYPASS will cause data to be reloaded from Radar Memory starting from BPADDR. If cleared, BYPASS will cause data to be written to Radar Memory starting from BPADDR.</p>

Table 637 Access Mode Restrictions of ID\_CONF2 sorted by descending priority

Field	Bits	Type	Description
<b>BASE</b>	18:0	rw	<b>Radar Memory Base Address</b> Base Address of the data to be read from Radar Memory. This is a 32 byte (256 bit) aligned address relative to the start address of the Radar Memory. Five LSBs need to be added to convert to a system address. This field is sized to address a 16 MiB Radar Memory. Any MSBs not needed to address the memory in the product will be ignored. An overflow error (if configured) will be generated when the generated address exceeds the amount of physical Radar Memory available.
<b>FORMAT</b>	21:19	rw	<b>Input Data Format</b> The format of the Input Data to be read from the Radar Memory. Note that the REAL16BIT format must not be used if the TRNSPS bit is also set. 000 <sub>B</sub> <b>CMPLX16BIT</b> , 16 Bit Precision Complex Data 001 <sub>B</sub> <b>CMPLX32BIT</b> , 32 Bit Precision Complex Data 010 <sub>B</sub> <b>PWR32BIT</b> , 32 Bit Precision Power Data 011 <sub>B</sub> <b>RES3</b> , Reserved 100 <sub>B</sub> <b>REAL16BIT</b> , 16 Bit Precision Real Data The format cannot be used if ID_RM_CONF.TRNSPS=1 101 <sub>B</sub> <b>REAL32BIT</b> , 32 Bit Precision Real Data 110 <sub>B</sub> <b>REAL16FP</b> , Half Precision Floating Point, real data The format cannot be used if ID_RM_CONF.TRNSPS=1 111 <sub>B</sub> <b>CMPLX16FP</b> , Half Precision Floating Point, complex data

## Signal Processing Unit (SPU)

Field	Bits	Type	Description
TRNSPS	22	rw	<p><b>Transpose Addressing</b>  This bit should be set when the bins or samples used to construct an FFT input set in the Buffer memory do not occupy contiguous addresses in the Radar Memory. If set, it switches the operating mode of the Input DMA so that each of the bins in the 256 bit word read from radar Memory are treated as bins of different input FFT datasets when being written to buffer memory</p> <p><math>0_B</math> <b>LIN</b>, Linear Mode  Bins stored in contiguous addresses of Radar Memory will be loaded directly into Buffer Memory as an input for an FFT dataset.</p> <p><math>1_B</math> <b>TRN</b>, Transpose  Bins stored in contiguous addresses of Radar Memory will be treated as belonging to different FFT input datasets</p>
RES	23, 27	r	<b>Reserved</b>
AM	26:24	rw	<p><b>Antenna Mapping</b>  Several processing elements of the SPU need to identify each FFT dataset with a particular antenna. This field, in conjunction with the PM field, defines how this should be done. This field applies when PM is set to <math>0_B</math>. Setting PM to <math>1_B</math> is equivalent to setting this field to IDX.</p> <p><math>000_B</math> <b>OFF</b>, Default  Antenna ID passed to processing chain is permanently <math>0_D</math></p> <p><math>001_B</math> <b>IDX</b>, Index Mode  Antenna ID is derived from the dataset index</p> <p><math>010_B</math> <b>ILR</b>, Inner Loop Repeat  Antenna ID is derived from the Inner Loop Repeat Counter Value</p> <p><math>011_B</math> <b>OLR</b>, Outer Loop Repeat  Antenna ID is derived from the Outer Loop Repeat Counter Value</p> <p><math>100_B</math> <b>BLR</b>, Bin Loop Repeat  Antenna ID is derived from the Bin Loop Repeat Counter Value</p> <p><math>101_B</math> <b>RES</b>, Reserved</p> <p>...</p> <p><math>111_B</math> <b>RES</b>, Reserved</p>
BLOCKS	30:28	rw	<p><b>Number of Datablocks</b>  In Integration mode, the number of datablocks to be simultaneously constructed in the buffer memory. Normally when reading across antenna, most of the data read is discarded. If this field is non-zero, the Input DMA Engine will attempt to build multiple datablocks in memory using the additional data. The value of this field is then used to control the maximum number of datablocks that will fit into the physical limit of the buffer memory. The number of datablocks is the field value plus one. The maximum permissible value for this field is 3 for 64 bit data (32 bit precision complex) and 7 for 32 bit data (16 bit precision complex or 32 bit power)</p>

## Signal Processing Unit (SPU)

Field	Bits	Type	Description
PM	31	rw	<p><b>Processing Mode</b></p> <p>This bit is set when the Input DMA is required to build datasets comprising one FFT from each attached antennae. This would be necessary when it is intended to use the coherent or non-coherent integration functions of the MATH2 unit.</p> <p>0<sub>B</sub> <b>DM</b>, Default Mode This is the optimal mode for in-place FFT calculation. All the datapoints read from memory can be directly used to construct a single datablock in the buffer memory. This means that the 32<sub>D</sub> or 64<sub>D</sub> bit data read in each 256<sub>D</sub> bit word will be used by incrementing either the bin loop or inner loop</p> <p>1<sub>B</sub> <b>IM</b>, Integration Mode In Integration Mode, it is assumed that the buffer memory must contain one FFT input dataset for each antenna. Setting this bit forces the buffer memory to be switched only after the completion of a complete pass through the inner loop. If this bit is set, then the Input DMA Engine is allowed to construct multiple datablocks in memory if this is needed to maximise utilisation of the Radar Memory bandwidth. This function is controlled by the ID_RM_CONF.BLOCKS bitfield.</p>

### Partial-Acquisition Counter

This counter is used to monitor and control partial-acquisition. If enabled, it will monitor the input data stream from the RIF and increment at the end of each ramp as determined by the sample count and number of antennae captured from the IDM configuration when the counter was last reset. As the counter increments at the end of the ramp, the first ramp of the measurement cycle will be considered as ramp 0.

Note: LDMST should be used only with bit mask enabled for the 'rh' bits in this register. Hardware updates occurring between the read and write phases of an RMW may be overwritten.

### PACTR

Application Reset	0000 0000 <sub>H</sub>	Application Reset
Kernel Reset (software controlled by KRST0-1 registers)	0000 0000 <sub>H</sub>	Kernel Reset (software controlled by KRST0-1 registers)

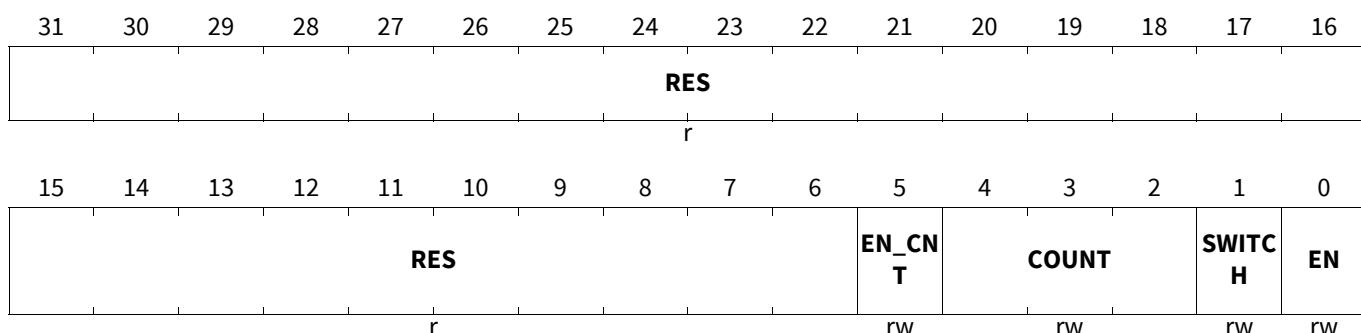

### Double Pass Configuration

Double Pass Mode allows the configuration of the MATH1 unit to be changed during processing of ADC data. The selected configuration can be alternated on a ramp-by ramp basis or both programmed configurations can be applied to all ramps.

## Signal Processing Unit (SPU)

### DPASS\_CONF

#### Double Pass Configuration

(0005C<sub>H</sub>)Reset Value: [Table 658](#)

Field	Bits	Type	Description
<b>EN</b>	0	rw	<b>Enable</b> The SPU allows all processing operations to be run twice per data block or different processing parameters to be used on sequences of data blocks. This mode is enabled using the DPASS_CONF.EN bitfield. This results in two sets of results being written to Radar Memory
<b>SWITCH</b>	1	rw	<b>Buffer Memory Switch</b> If set to 0 <sub>B</sub> , both configurations of the MATH1 and MATH2 units will be applied to all data blocks and two full sets of output data will be written to the Radar Memory. If set to 1 <sub>B</sub> , the two configurations for MATH1 and MATH2 will be applied to alternate data blocks. Each set of output data written to Radar memory will contain half the data.
<b>COUNT</b>	4:2	rw	<b>Switch Count</b> If DPASS_CONF.EN_CNT is set, this field determines the number of data blocks to be processed before the alternate sets of window parameters are switched. The number of data blocks processed by the Loader between parameter switches is COUNT+1. i.e. if COUNT=0 then the window parameters will be switched for every data block processed, if COUNT=7, then the parameters will be switched after every eight data blocks processed.
<b>EN_CNT</b>	5	rw	<b>Enable Count</b> This bit enables switching the two sets of window parameters based on the DPASS_CONF.COUNT bitfield rather than the "Double Pass" settings. When set, the window parameters are switched every time a counter counting the number of data blocks processed reached the terminal count stored in the COUNT field + 1. The DPASS_CONF.EN and DPASS_CONF.SWITCH settings have no effect on the window parameters when this bit is set.
<b>RES</b>	31:6	r	<b>Reserved</b>

<b>DRPF</b>								<b>DRPL</b>							
rw								rw							

Field	Bits	Type	Description
<b>DRPL</b>	7:0	rw	<b>Drop Last</b> Stores a number "m". The last m samples of the input data will be ignored
<b>DRPF</b>	15:8	rw	<b>Drop First</b> Stores a number "n". The first n samples of the input data will be ignored

## Signal Processing Unit (SPU)

Field	Bits	Type	Description
<b>EXPNT</b>	21:16	rw	<b>Common Exponent</b> For $16_D$ bit data, this indicates the alignment correction to be applied when reformatting to 32 bit. It should be set to $0_D$ if no adjustment of magnitude is needed. Otherwise the $16_D$ bit data will be shifted left by the number of bits set in this field and sign extended to $32_D$ bits. Empty bits at the right end of the $32_D$ bit value will be set to $0_B$ . The maximum expected value for this field is $16_D$ when using data read from Radar Memory as this is the largest value that will be generated using the compression function in the output data manager. Larger values can be used to create some gain in the input signal. Overflows in the shift operation will cause saturation of the output.
<b>PHSHFT</b>	23:22	rw	<b>Fast Phase Shift</b> This bitfield can set a fast phase shift of 0, 90, 180 or 270 degrees $00_B$ <b>ZERO</b> , No Phase Shift $01_B$ <b>NINETY</b> , 90 degree phase shift $10_B$ <b>ONEEIGHTY</b> , 180 degree phase shift $11_B$ <b>TWOSEVENTY</b> , 270 degree phase shift
<b>SIZE</b>	27:24	rw	<b>FFT Size</b> Number of samples for the FFT. Must be a power of two between 8 and 2048. Unspecified values are reserved and must not be written. $0_H$ <b>8</b> , FFT is eight data samples $1_H$ <b>16</b> , FFT is sixteen data samples $2_H$ <b>32</b> , FFT is thirty-two data samples $3_H$ <b>64</b> , FFT is sixty-four data samples $4_H$ <b>128</b> , FFT is one hundred and twenty-eight data samples $5_H$ <b>256</b> , FFT is two hundred and fifty-six data samples $6_H$ <b>512</b> , FFT is five hundred and twelve data samples $7_H$ <b>1024</b> , FFT is one thousand and twenty-four data samples $8_H$ <b>2048</b> , FFT is two thousand and forty-eight data samples
<b>FORMAT</b>	29:28	rw	<b>Window Data Format</b> Format of the Window Function Data stored in the configuration memory. If a complex format is selected, the real component of each value is always stored at the lower address in memory. $00_B$ <b>REAL16</b> , 16 Bit Real Window Data $01_B$ <b>REAL32</b> , 32 Bit Real Window Data $10_B$ <b>CMPLX16</b> , 16 Bit Complex Window Data $11_B$ <b>CMPLX32</b> , 32 Bit Complex Window Data
<b>FFTBYPS</b>	30	rw	<b>FFT Bypass</b> Bypass the FFT Module
<b>IFFT</b>	31	rw	<b>Inverse FFT Enable</b> If set, the accelerator will perform an IFFT operation instead of an FFT. In IFFT mode, the automatic descaling of the FFT output is disabled

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
<b>BASE</b>															
rw															

Field	Bits	Type	Description
<b>BASE</b>	18:0	rw	<b>Radar Memory Base Address</b> The base address to be used when writing data to Radar Memory. This is a word (256 bit) address relative to the Radar Memory base address. All writes will be 32 byte words. Data will be buffered internally until 32 bytes are available. The generated address will automatically increment after each write. If a partial word remains at the end of processing an FFT, the data will be padded to 32 bytes and flushed to Radar Memory. This field is sized to address a 16 MiB Radar Memory. Any MSBs not needed to address the memory in the product will be ignored. An overflow error (if configured) will be generated when the generated address exceeds the amount of physical Radar Memory available.
<b>MODE</b>	19	rw	<b>ODP Mode</b> Major Operating Mode for the ODP 0 <sub>B</sub> <b>OFF</b> , FFT Output Disable The FFT output path is disabled. 1 <sub>B</sub> <b>ON</b> , FFT On The FFT data output path is enabled
<b>FTR</b>	20	rw	<b>Force to Real</b> The complex component of the FFT output data will be set to zero when it is read from the buffer memory. This will affect all processing operations of the MATH2 unit.
<b>SCALE</b>	21	rw	<b>Scale Results to 16 bit</b> If set, the results will be scaled to 16 bit precision before writing to EMEM. The scaling factor used will be from the ODP_CONF.EXPNT bitfield 0 <sub>B</sub> <b>32BIT</b> , Output is written with 32 bit precision 1 <sub>B</sub> <b>16BIT</b> , Output is written with 16 bit precision
<b>EXPNT</b>	26:22	rw	<b>Common Exponent</b> When writing 16 bit precision data to the Radar Memory, this field indicates the number of LSBs to be removed. i.e. the 32 bit data will be shifted right by this number of bit positions before truncating to the 16 least significant bits. The remaining bits will be set to maximum or minimum value if overflow or underflow has occurred

## Signal Processing Unit (SPU)

Field	Bits	Type	Description
IPF	27	rw	<b>In Place FFT</b> When set, the Output Data Processor will attempt to write FFT results to the memory locations freed up by the reading of the input data.
ROF	28	rw	<b>Real Only Format</b> When set, the Output Data Processor will write FFT output data in a real only format. The imaginary component of the results will not be written. This mode differs from the function of "Force to Real" (FTR) because any other calculations performed using the FFT data will use the imaginary component. If consistency is required between the real only data written and the results of the other channels, then FTR should also be set.
HPFP	29	rw	<b>Half Precision Floating Point</b> When set, the Output Data Processor will write FFT output data in half precision floating point format. If this bit is set then SCALE is redundant and will be ignored. FTR and ROF can still be used.
RES	31:30	r	<b>Reserved</b>

## Signal Processing Unit (SPU)

### Bin Rejection Unit Control

Control Parameters for the Bin Rejection Unit. The Bin Rejection Unit takes inputs from a 2048 set of registers (one bit per FFT data point) and a 1024 register from the CFAR and Threshold Unit. These bits are used to zero bins or remove them from the outputs data stream. Additionally bins can be compared to a threshold value and set to zero if the threshold is exceeded. The threshold value is set as a magnitude. The Magnitude Approximation of the complex data bins is used for the comparison

#### BINREJCTRL

**Bin Rejection Unit Control** **(00208<sub>H</sub>)** **Reset Value: Table 708**

### Dataset Metadata

This register is duplicated so that the stored information is available for each set of configuration options used in "Double Pass" mode.

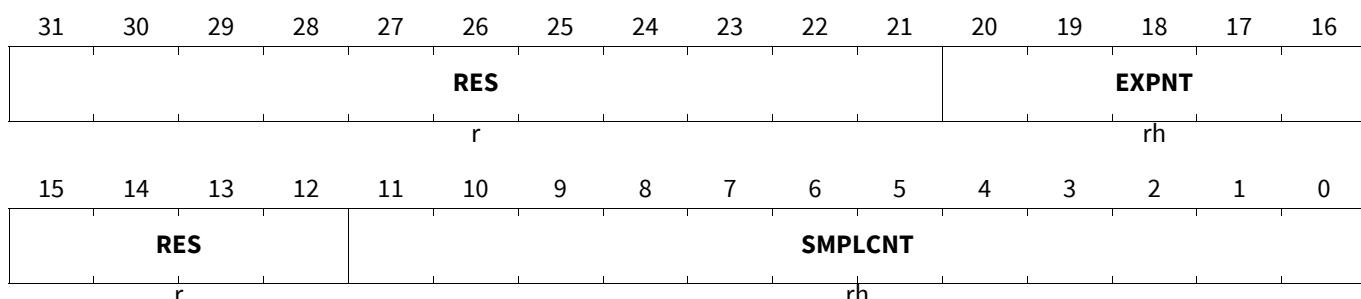

Secondary Information describing the data that has just been processed

#### MDq\_METADATA (q=0-1)

##### Dataset Metadata

(00220<sub>H</sub>+q\*88<sub>H</sub>)

Reset Value: [Table 718](#)

## Signal Processing Unit (SPU)

Field	Bits	Type	Description
SMPLCNT	11:0	rh	<b>Sample Count</b> Number of samples per FFT written to memory. This is useful when using the CFAR inline as the number of bins in the FFT result that will pass the threshold test is not known ahead of processing. The field contains the actual number of samples written to the Radar Memory
RES	15:12, 31:21	r	<b>Reserved</b>
EXPNT	20:16	rh	<b>Common Exponent</b> This indicates the optimum alignment correction that could have been applied if reformatting to 16 bit precision. If "n" is the minimum number of redundant sign bits present in the data at the FFT output, it will be set to $(16_D - n)$ . This can then be used as the value of UNLDR_CONF.EXPNT to be programmed for the next measurement cycle if it is intended to use 16 bit precision data. The maximum permissible value for this field is $16_D$

Table 717 Access Mode Restrictions of MDq\_METADATA (q=0-1) sorted by descending priority

Mode Name	Access Mode		Description
Write Accesses	r	RES	Any write access will cause bus error
	rh	EXPNT, SMPLCNT	
Otherwise (default)	r	RES	Default Access Mode (Bus Error on Write)

**Bin Rejection Unit Tracking**

This register is duplicated so that the stored information is available for each set of configuration options used in "Double Pass" mode.

This register provides information about the bin rejection unit behaviour for the data that has just been processed. The value read is dynamically updated while the SPU is processing data and is only stable when the SPU has completed processing and has written all data to memory.

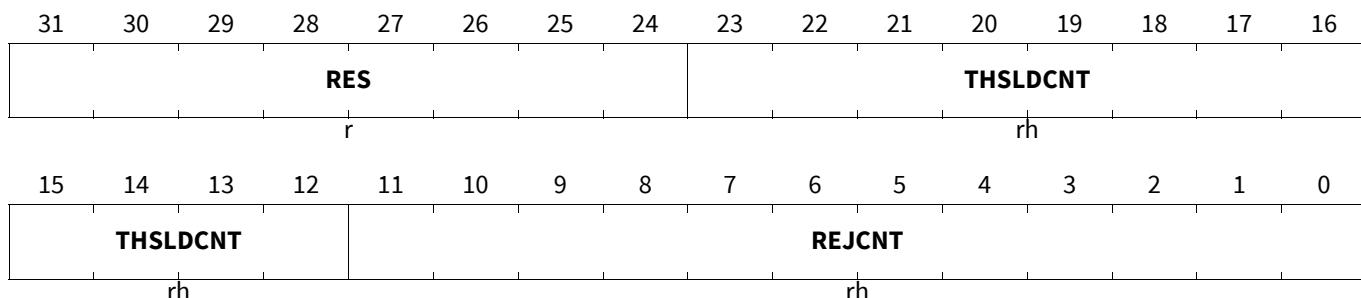

## Signal Processing Unit (SPU)

### MDq\_BINCOUNT (q=0-1)

Bin Rejection Unit Tracking

(00224<sub>H</sub>+q\*88<sub>H</sub>)

Reset Value: [Table 720](#)

Field	Bits	Type	Description
REJCNT	11:0	rh	<b>Rejection Count</b> Number of samples rejected or set to zero by the bin rejection unit based on the inputs from the CFAR or Local Max functions combined with the static mask registers, BINm_REJ. Always contains the value for the last FFT processed
THSLDCNT	23:12	rh	<b>Threshold Function Count</b> Number of samples set to zero by the bin rejection unit threshold function. Always contains the value for the last FFT processed
RES	31:24	r	<b>Reserved</b>

### Bin Acceptance Mask

Every bit in these registers corresponds to an FFT sample point. If the bit is cleared, then Bin Rejection Unit has either removed the corresponding sample point from the data written to EMEM or set it to a zero value. This register set supports a maximum FFT result size of 1024 sample points and excludes data on points set to zero by the bin rejection unit threshold function. The data contained in the register set is guaranteed to be valid only when the SPU is idle and is relevant for the last FFT processed.

## Signal Processing Unit (SPU)

Each register contains part of the bin acceptance mask. Each bit corresponds to a bin of the FFT output. If the bit is cleared, then the corresponding bin has been filtered from the output or set to zero by either the Local Max Unit, the CFAR Unit or the static mask configuration.

### MDq\_MASKm\_ACCEPT (m=0-31;q=0-1)

Bin Acceptance Mask

( $00228_H + q*88_H + m*4$ )

### Safety Mechanism Control Functions (User)

This register provides access to the control functions for safety mechanisms not used as part of the normal configuration of the SPU. The various test bitfields defined in this register are used to test that the safety mechanisms can generate alarms as intended as a connectivity test only. It is therefore not necessary (or desirable) for the SPU to be running while these tests are run.

### Access Enable Register 0

The Access Enable Register 0 controls access for writes to registers and configuration memory using the on chip bus master TAG ID 000000B to 011111B (see On Chip Bus chapter for the products TAG ID <> master peripheral mapping). The SPU is prepared for a 6 bit TAG ID. The registers ACCEN0 / ACCEN1 are providing one enable bit for each possible 6 bit TAG ID encoding.

Mapping of TAG IDs to ACCEN0.ENx: EN0 -> TAG ID 000000B, EN1 -> TAG ID 000001B, ..., EN31 -> TAG ID 011111B.

## Signal Processing Unit (SPU)

### 19.5 Debug

For debugging purposes, it is possible to stop execution of a linked list. To avoid additional complexity, this can be done by software only before activating the next entry. However the debugger can stop execution using the system wide OCDS suspend functionality.

For availability reasons, the command to stop execution requires to write 3 bits,  $111_B$ , defined as STOP, to the CTRL.MODE bitfield

To reduce complexity, the Radar sequencer can only be stopped by the debugger. It is not possible to resume it. Once the OCDS suspend has been removed, the SPU should be initialised using kernel reset.

Two types of suspend are available

- Hard Suspend: this stops the kernel clock of the SPU immediately. Registers can still be read but should not be written. Config RAM cannot be accessed<sup>1)</sup>. EMEM control signals may suspend in the active state<sup>2)</sup>.
- Soft Suspend: The “GO” signals for the processing modules of the SPU are suppressed. The modules will complete, as far as possible<sup>3)</sup>, processing of the current dataset. Suspend will be acknowledged as soon as the Output Data Manager has completed all outstanding writes to Radar Memory<sup>4)</sup>.

#### 19.5.1 Trace Format

The SPU has a trace connection to the MCDS. The intention of the trace data is to allow synchronisation of SPU output events with CPU activity in the microcontroller. The MCDS has insufficient bandwidth to allow full trace of all FFT results written to EMEM so the data which can be traced simultaneously is limited. The trace logic contains sufficient buffering to allow any four<sup>5)</sup> of the eight available channels to be monitored. The following information can be output to the trace port.

**Table 773 SPU Trace Data**

Output DMA Channel	Function	Trace Data
1	FFT Results Output	Address and the first 256 bit word written for each FFT processed
2	Signal Power	Address and the first 256 bit word written for each FFT processed
3	Statistical Data	Address and data trace of all values written.
4	CFAR CA Engine Data/Local Maximum Unit Output	Address and data trace of all values written.
5	CFAR Go Engine Data	Address and data trace of all values written.

- 1) The hard suspend function operates by stopping the kernel clock of the SPU. As the config RAM arbitration logic also runs off the kernel clock, the config RAM is not accessible during hard suspend.
- 2) In this case, the EMEM tile control can be used to error the stuck access and permit debugger access to the affected EMEM tile
- 3) In some cases, data will remain in the FFT accelerator pipeline. In these circumstances the UNLOADER module will be unable to complete processing and.
- 4) If the histogram function is enabled, accesses to config RAM by the SPU may continue after soft suspend is acknowledged. This is because the FFT pipeline cannot be guaranteed to complete processing during soft suspend and is therefore not used to gate suspend acknowledgement.
- 5) For very short datasets, the bandwidth requirements for DMA channels 3 to 8 increase significantly and the number of simultaneous channels that can be traced drops. Each packet traced requires four clock cycles of the SPU clock. If the number of cycles to output the trace data exceeds the number of clock cycles required for the MATH2 unit to process the dataset, then trace data will be lost

## Signal Processing Unit (SPU)

**Table 773 SPU Trace Data (cont'd)**

Output DMA Channel	Function	Trace Data
6	Vector Add/Sum	Address and the first 256 bit word written for each FFT processed
7	sum. sum-linp, sum-antenna	Address and data trace of all values written.
8	sum of log2 power	Address and data trace of all values written.

Trace Data output is controlled by the USROTC.TRSCTRL bitfield. The eight bits in the field correspond to the eight Output DMA channels in ascending order.

### 19.5.2 Debugger events

The following event triggers are available as hardware events for the debugger via the configuration options in the OCS register.

**Table 774 OTGB Hardware Triggers (Set A)**

0	SPU Processing Starts -Trigger event defined in CTRL register has been detected

1) This check occurs even if compression is disabled. In this case the flag will be set if data would have been lost if compression had been enabled

## 19.6 Safety Measures

The SPU has the following safety mechanisms to assist in its use in safety related applications

### 19.6.1 Hardware Safety Mechanisms

The SPU has the following autonomous hardware safety mechanisms which report failures via SMU alarms

#### 19.6.1.1 Lockstep

In products with two SPUs instantiated, there is a capability to lockstep the SPUs by writing an identical configuration set and using the same hardware trigger event to start the processing cycle. The hardware trigger could either be:

- ADC data being written from the RIF or RIF(s)
- A trigger event from the radar state machine
- A trigger event from the SPU Lockstep Module

With identical configurations and a simultaneous trigger. The SPUs will perform the same operations in the same clock cycle. This allows the address and control outputs from the SPUs to the buffer RAMS to be compared. A full description of the SPU Lockstep functionality is available in the dedicated chapter of the specification.

#### 19.6.1.1.1 Data Comparison Lockstep

To improve coverage when the same data is sent to both SPUs, a second lockstep unit also allows the data outputs to the buffer RAMs and Radar Memory to be compared. Note that this mode can only be used if both SPU instances are processing exactly the same input data and are configured to write to exactly the same Radar Memory address range.

If data is being read from Radar Memory, then the SPU1 RAM control signals will be ignored and the read data and valid signal associated with the SPU0 reads from Radar Memory will be used as the SPU1 inputs.

Data written from SPU1 will be ignored.

#### 19.6.1.2 Register CRC

The register CRC uses a 32 bit ethernet polynomial which assumes that the register contents are converted to an LSB first sequential data stream. The data stream will be generated using the registers from ID\_CONF to CTRL

## Signal Processing Unit (SPU)

inclusive. Unused register addresses, and the address of the REGCRC register, itself shall be replaced by 0000 0000<sub>H</sub> in the datastream. Additionally, the CTRL.TRIG bit and CTRL.BUSY bit should be assumed to be 0<sub>B</sub> (value when read) and the value of the PACTR.COUNT bitfield should be assumed to be 0<sub>D</sub> for calculating the reference CRC.

The polynomial shall run periodically once enabled and the CRC generated from the register contents compared with the value stored in the REGCRC.CRC bitfield. If the comparison fails, then an SMU alarm will be generated.

The Register CRC is enabled by writing 10<sub>B</sub> to the **SMCTRL**.REGCRCEN bitfield and disabled by writing 01<sub>B</sub>.

Control and comparison logic of the safety mechanism is replicated using negated logic. Any difference in behaviour between the two sets of logic will result in setting of the SMSTAT.SMCTRLSTS bit.

The alarm can be tested by writing an invalid CRC to REGCRC.CRC.

If this condition has triggered an alarm, bit 1 of the SMSTAT.SMSTAT bitfield will be set to 1<sub>B</sub>.

### 19.6.1.3 RIF Interface CRC Check

The data path between the RIF and the SPU is protected by a CRC. The CRC is checked once per ramp. The ramp size is determined from the settings of the ID\_CONF register. The check will take place when the data is written into the internal assembly buffer of the Input Data Manager. A CRC failure will result in an SMU alarm. This mechanism is controlled by the **SMCTRL**.RIFCRC bitfield.

The CRC check enabled by writing 10<sub>B</sub> to the **SMCTRL**.RIFCRC bitfield and disabled by writing 01<sub>B</sub>. Writing either of the other two possible values will result in the **SMSTAT**.SMCTRLSTS bit being set

If this condition has triggered an alarm, bit 0 of the **SMSTAT**.SMSTAT bitfield will be set to 1<sub>B</sub>.

This alarm condition can be tested by writing 10<sub>B</sub> to the **SMUSER**.RIFCRCTST bitfield.

### 19.6.1.4 Bypass Data CRC Check

The data stored by the SPU in Radar memory when bypass is enabled is protected by a CRC. The CRC is generated at the end of the measurement cycle using the same ethernet polynomial used elsewhere in the SPU and written at the next consecutive address after the last data word written. The end of the measurement cycle is determined from the settings of the ID\_CONF register. The CRC will be checked by the Input Data Manager when the read back during the bypass reload operation. A CRC failure will result in an SMU alarm.

The CRC check enabled by writing 10<sub>B</sub> to the **SMCTRL**.BPCRC bitfield and disabled by writing 01<sub>B</sub>. Writing either of the other two possible values will result in the **SMSTAT**.SMCTRLSTS bit being set.

If this condition has triggered an alarm, bit 2 of the **SMSTAT**.SMSTAT bitfield will be set to 1<sub>B</sub>.

This alarm condition can be tested by writing 10<sub>B</sub> to the **SMUSER**.BPCRCTST bitfield.

This safety mechanism can be tested by writing a short dataset with a known, bad CRC to Radar memory and triggering a bypass reload operation.

### 19.6.1.5 Radar Memory Control Signal Redundancy

All control signals controlling accesses to Radar Memory are duplicated. The duplicate signals are set to the negated value of the primary control signal. In the event of the two signals becoming inconsistent, it can be assumed that an error has occurred. An inconsistent state is detected by comparators and will cause an SMU alarm.

This check is permanently enabled. If this condition has triggered an alarm<sup>1)</sup>, bit 4 of the **SMSTAT**.SMSTAT bitfield will be set to 1<sub>B</sub>.

<sup>1)</sup> The Error flag returned by the EMEM for an access address error is also a redundant signal but, as this is already a monitor rather than a control, an inconsistency in this pair causes the **SMSTAT**.SMCTRLSTS bit to set and does not generate an alarm

## Signal Processing Unit (SPU)

### 19.6.1.6 Radar Memory Tile Access Error

Radar Memory tiles are enabled for SPU accesses by configuring the tile control mechanism in the EMEM. An SPU access can be directed to a blocked tile either by a configuration error or a fault in the SPU logic. In the event of the EMEM reporting that an access has failed because it has been mapped to a blocked tile, this mechanism can be used to trigger an SMU alarm.

The alarm is enabled by writing  $10_B$  to the **SMCTRL.RMTAERR** bitfield and disabled by writing  $01_B$ . Writing either of the other two possible values will result in the **SMSTAT.SMCTRLSTS** bit being set.

If this condition has triggered an alarm, bit 5 of the **SMSTAT.SMSTAT** bitfield will be set to  $1_B$ .

This alarm condition can be tested by writing  $10_B$  to the **SMUSER.RMTAERRTST** bitfield.

### 19.6.1.7 Radar Memory Read Data ECC

Read data returned for a Radar Memory access by the SPU is protected by an ECC computed in the EMEM from the address presented to the RAM and the data output from the RAM. This is checked by the SPU to ensure that the data is correct and has been read from the expected RAM location. A failed check will be signalled via an SMU alarm

The alarm is always enabled.

If this condition has triggered an alarm, bit 3 of the **SMSTAT.SMSTAT** bitfield will be set to  $1_B$ .

This alarm condition can be tested by writing  $10_B$  to the **SMUSER.RDECCTST** bitfield.

### 19.6.1.8 RAM ECC

RAM contents are protected by ECC. Corrupted locations will be corrected if a single bit is in error or detected if two bits are in error. Detected failures will be signalled via an SMU alarm

### 19.6.1.9 RAM Address Signature ROM

The RAM address decode is checked by a signature ROM. Failures in the address decode will be signalled via an SMU alarm

### 19.6.1.10 Access Enable

Write accesses to the registers and configuration memory<sup>1)</sup> are controlled by the Access Enable mechanism. This is configured using the **ACCEN0/ACCEN1** registers and uses the master tag used to identify the originating master of each write transaction to permit or deny access to modify the contents of the register or memory.

## 19.6.2 Software Based Safety Mechanisms

The SPU supports the following safety mechanisms which require support from software. Failures are to be reported by the software rather than via the SMU

### 19.6.2.1 Software Based Self Test

A gap occurring between application processing operations can be used to run self test patterns through the SPU to detect faults in the SPU hardware and the interfaces between the SPU and the Radar Memory.

<sup>1)</sup> The configuration memory is treated as module configuration information rather than system memory and it is therefore appropriate to apply the same protection as for the registers.

## Signal Processing Unit (SPU)

### 19.6.2.2 SPU Execution Time Check

A class of faults exist in the SPU hardware which could cause a deadlock of the SPU control hardware. A software check should be provided which does a “sanity check” on the time needed for the SPU to complete execution and flags an error if execution does not complete within the expected time. This check would also detect faults in the MMIC or MMIC<->uC interface which cause an interruption in the data stream and therefore a stall in the SPU processing.

### 19.6.2.3 Configuration Memory Content Check

The contents of the configuration memory should be checked once written to ensure that all data has been transferred to the memory correctly

## 19.6.3 Hardware Functionality Supporting Software Safety Mechanisms

The following hardware functionality exists within the SPU to increase the effectiveness of the Software Based Safety Mechanisms

### 19.6.3.1 Monitor Counters

The SPU contains counters which allow the correct operation of critical operations to be checked. These track events such as reads and writes from the Radar Memory and load and unload operations from the FFT accelerator. The monitor counters can be checked by software to ensure that the correct number of operations have been performed.

The Monitor Counters are mapped into the SPU register space as read only registers.

The Monitor Counters have an associated control register which allows the Monitor Counters to be initialised. This register can be used for fault injection. The register provides an address field (CNTCLR.SELECT) to select one of the Monitor Counters and a control field (CNTCLR.CNTTST) used to enable fault injection. When fault injection is enabled, the next read to the selected Monitor Counter register will return data with one or more bits flipped. The value of CNTCLR.CNTTST will return to OFF once the selected register has been read. Writing OFF before the selected register has been read will disable the error injection.

Writing any value other than ON or OFF is invalid and will set the SMSTAT.SMCTRLSTS bitfield.

### 19.6.3.2 Monitor CRC Units

The SPU contains CRC units used to provide a method of checking the activity on key internal interfaces. These include:

- The internal RAM interfaces of the FFT accelerator
- Buffer Ram Interfaces
- Input Data Manager EMEM Interfaces
- Output Data Manager EMEM Interface
- Configuration RAM Interfaces

The CRCs shall be separated into two blocks in the registers space.

- CRCs which are independent of the data being processed. These are enabled using **SMCTRL**.CTRLCRCEN
- CRCS which are dependent on the data being processed. These are enabled using **SMCTRL**.DATACRCEN

The first can be used for providing some detection of soft errors occurring during execution as well as during software based self test. The second can only be used while processing known data during software based self test.

The CRC units are mapped into the SPU register space as read only registers.

## Signal Processing Unit (SPU)

The CRC Units have an associated control field (**SMUSER.CINIT**). The CRC units are initialised to the reset value by writing 10<sub>B</sub> to **SMUSER.CINIT**.

**Note:** *Enabling in-line CFAR or local maximum based bin rejection will change the address sequence at the ODM output. This affects the CRC accessed via the CTRL2\_CRC register. If the control based CRC is being used then either the CTRL2\_CRC register must be excluded from the CRC checks or dynamic bin rejection based on the data being processed must not be used.*

**Note:** *Using the CRCs associated with the RAM interfaces of the FFT accelerator requires that the SPU be reset before CRC calculation starts. This is necessary because the address generators of the FFT accelerator are only initialised by reset. Otherwise they retain the state they reached at the end of the previous processing operation. A kernel reset before starting CRC calculation is recommended.*

### 19.6.3.3 Redundant Control Logic

All control and status state bits (flip-flops) implementing safety mechanism functionality are duplicated. The duplicate flip-flops are used to store the negated value of the bit. This can be observed directly in the SMCTRL and SMUSER registers. In the event of the state of these bits becoming inconsistent, it can be assumed that either a programming or soft error has occurred. An inconsistent state is detected by comparators and can be observed by polling the SMSTAT.SMCTRLSTS bit.

### 19.6.4 SMU events

The following table lists the events that can trigger an SMU alarm. See [Section 19.6.1](#) for a description of the hardware safety mechanisms.

**Table 776 SMU Events**

Event	Definition	Source	Comments
uncorrectable ECC error in Radar memory	Read data from a Radar Memory RAM has been corrupted	MTU	One of Multiple alarms will be generated based on MTU configuration
uncorrectable ECC error in a RAM internal to the SPU	Read data from an SPU RAM has been corrupted		
compare error	when using lock step, an external comparator is comparing the outputs of the 2 Radar SPU.	SPU Lockstep	

## Signal Processing Unit (SPU)

**Table 776 SMU Events (cont'd)**

Event	Definition	Source	Comments
Register CRC check	Computed Register CRC does not match pre-programmed value	SPU	Alarm Mapping is defined in the SMU Specification
Bypass Data CRC check	Computed bypass data CRC does not match the value read from memory		
Radar Memory Control Logic Failure	The control signals for accessing Radar Memory are implemented as redundant logic. This alarm condition indicates that the SPU has detected an inconsistency in the redundant logic		
RIF Data CRC Check	CRC computed from RIF data stream does not match expected value tagged onto the end of the ramp data		
Radar Memory Access Address Error	An access to the Radar Memory has been mapped to a tile that has not been enabled for SPU accesses by writing to the EMEM tile control registers		
Radar Memory Read Data ECC Check	The read data for Radar Memory accesses is returned with an ECC computed from the access address and data. This is checked and an alarm set if the check fails		

Note: *the SMU allows the user to define the action that will be taken as a result of these events (see SMU specification).*

### 19.6.5 Safety assumptions

The safety assumptions for the Radar signal processing unit are described here.

#### 19.6.5.1 Safety assumptions and safety goals

There are 2 safety cases

- Radar with 1 Radar SPU only for low end applications
- Radar with 2 x Radar SPUs for mid range and high performance radar

##### 19.6.5.1.1 Case1 = Radar with 1 Radar SPU only for low end applications

In the worse case, the Radar/ECU is involved in decision making for emergency brake or active lane assist, where at system level, customers may find it appropriate to use 2 different sensors to confirm the decision.

The other application use case considered would be where the results from the Radar/ECU application are used only to provide advisory information to the driver.

## Signal Processing Unit (SPU)

### 19.6.5.1.2 Case2 = Radar with 2 Radar SPUs only for mid to high end Radar

The radar/AURIX™ here is involved at least in decisions for directly implementing emergency braking or active lane steering without driver intervention. Again, the application may be required to use sensor redundancy at the system level.

### 19.6.5.1.3 Case3 = Radar + sensor fusion with 2 Radar SPUs only for mid to high end Radar

From the Radar/AURIX™ perspective, this case is the same as above.

In addition to this, the TriCores in the Radar/AURIX™ will be involved in doing sensor fusion in order to support high integrity decisions based on data coming from the radar/SPU and independent data coming from an external sensor. From the AURIX™ perspective, this use case is similar to the sensor fusion explained separately.

## 19.6.5.2 Radar Application assumptions

The following constraints can be used in an application in order to implement application oriented safety mechanisms.

### 19.6.5.2.1 Case 1: A decision is never taken on single ADC acquisition

This is the basic principle of FFTs for Radar: the FFT is integrating the noise measured by Radar where random variations are filtered out and where only consistent signal variations are kept.

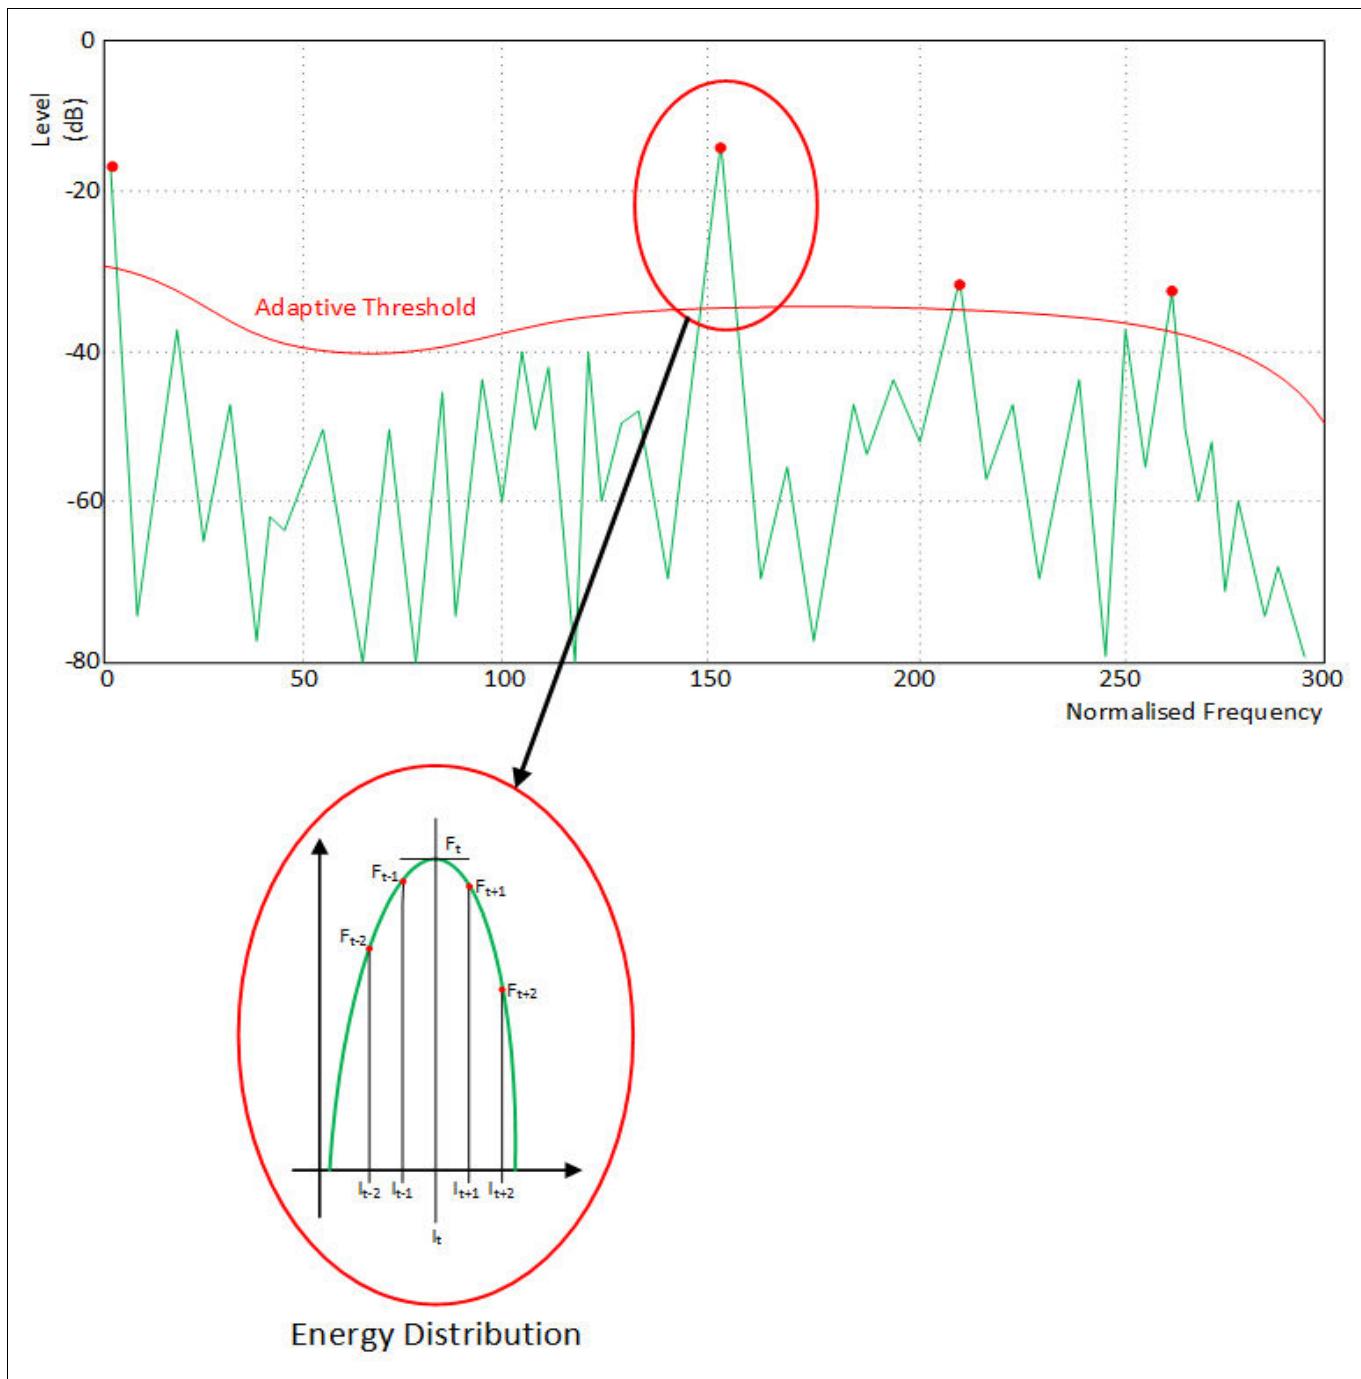

### 19.6.5.2.2 Case 2: A decision is never taken on a single FFT computation (1st stage and 2nd stage FFTs)

- Automotive Radar are now based on multiple antenna organized in phase array. So,
  - Antenna are separated by a distance
  - each antenna has same receiving lobe as the others
  - the difference between antenna is the phase of the signals: this phase difference allows the application to derive the angle of the object from the antenna.

### 19.6.5.2.3 Case 3: FFT peaks are never isolated

The figure below is showing that in fact, energy is distributed to adjacent FFT BINs so that a FFT peak is never isolated

## Signal Processing Unit (SPU)

**Figure 256 Example of FFT Result Energy Distribution**

A safety mechanism can be implemented to check if an FFT BIN is isolated to reject any isolated FFT BIN (where isolated means that the signal power on adjacent BINs is not high enough and where high enough is defined by application criteria).

Target acquisition is never taken from single acquisition

- this is definitely true for low end (see safety case1)
- this is not true for high performance radar.

Still, even if decision is taken from single acquisition, if we are allowed to assume that the RF device that is doing all preprocessing until the Analog to Digital Conversion is working fine, then, as we have a radar based on multiple

## Signal Processing Unit (SPU)

antenna with phase difference, an FFT peak leading to target decision is based on valid signal detected by multiple antenna. So

- there should be peaks detected on more than 1 antenna
- each peak on each antenna should meet the energy distribution criteria explained before

### 19.7 Use Cases

This section details assumed use case restrictions for the use of the SPU

#### 19.7.1 Use of FFT Clock Division (CTRL.DIV)

This bitfield is used to control the data throughput through the FFT engine. It is intended to be used to ensure that the FFT data is not passed to the ODP faster than it can be processed by the MATH2 unit. Although the MATH unit can exert back pressure on the UNLOADER to prevent overruns, this back pressure is then fed back to the LOADER and IDM. This is not an issue if data is being read from the Radar Memory but could potentially cause unpredictable slipping of input ramps if the data source is the RIF interface.

If data is being read from the RIF and ramp skipping is either intended or expected to be possible, the recommendation is that the CTRL.DIV bitfield should be set so that the FFT always takes longer to process the data than the MATH2 unit.

#### 19.7.2 In Place FFT

One of the key requirements for using in place FFT is that the amount of data written should not exceed the amount of data read. If this requirement is not met, then the write address generator will overtake the read address generator and start to write to locations that have not yet been read. Some particular things to watch out for

- Padding in the loader, this can increase the size of each FFT
- Bin Loop Repeat Values when using transpose mode. The output will be padded to a multiple of 32 bytes. If the bin loop repeat value and sample size result in an amount of data being read that is not a multiple of 32 bytes, then the padding will result in an increase in data size. This is not an issue when not using transpose mode as each dataset in the input data is required to be 32 byte aligned. This will result in enough free space to allow for the padding.
- Double Pass Mode is almost certain to increase if not double the data size if the FFT results are written on both passes

It is also a requirement that the Input Data Manager be configured such that each RADAR memory location is only read once in the measurement cycle. i.e. bandwidth optimisation is configured that all data samples in the 32 byte RADAR memory word are used.

#### 19.7.3 In Place FFT with ADC Data

The “In Place FFT” can be used even if the data source for the SPU is set to RIF. The Output Data Manager will use the register values in ID\_RM\_\* to compute the write addresses for the FFT results as if the SPU data was being read from EMEM. However, there are important exceptions which have to be taken into consideration

- The value of ID\_RM\_CONF.PM is not respected. The address is always generated as if this bit is set to 0<sub>B</sub>. This means that any addressing scheme which requires “Integration Mode” is not available
- If the BLR is programmed with greater value than the number of samples per line, the minimum difference between two consecutive emem write addresses will be equal to BLO/sample\_size (from ID\_RM\_CONF.FORMAT). In some cases this will mean that the addressing jumps/is not consecutive.

## Signal Processing Unit (SPU)

- For example, if BLR > 4 for COMPLEX 32 format (8 bytes) – that is 4 samples per line – and BLO is 32 bytes (256bits – 1 EMEM line), address will jump 4 lines.(BLO/No.of bytes per sample).
- It is recommended that the ID\_RM\_CONF.TRNSPS bitfield be constrained to 0<sub>B</sub>.

### 19.7.4 ODM/MATH2 Dataset Sizes

The MATH2 unit is implemented to process a minimum dataset size of eight samples. Units such as CFAR and Local Max require a larger minimum number of samples to function. Use the padding function in the LOADER module to maintain an optimum dataset size.

**Note:** *As the data block size decreases, the time needed for setup and configuration of the MATH2 unit becomes significant compared to the processing time. Performance may therefore decrease as the data block size becomes very small. For trivial dataset sizes (e.g. single samples), the SPU may not function as intended. It has been assumed that operations on datasets this small would be more efficiently performed by the CPU(s).*

### 19.7.5 In-line CFAR

There is a restriction on in-line CFAR operation for the TC39x A-step. When using double pass mode, only a single CFAR result is available for the Bin Rejection Unit. This is calculated from the first FFT of the first pass. The SPU cannot store a separate CFAR result for the first FFT of the second pass. Any configuration option related to the second pass in-line FFT result will only apply to data written to RADAR memory. This restriction does not apply to any other devices than the TC39x A-step. In the other devices, a second results register is available for the CFAR (and Local Max Unit) results which allows a different mask to be applied in both passes when double pass mode is enabled.

### 19.7.6 CFAR Configuration

Valid values should always be used to initialise the CFAR configuration registers even if it is not intended to use the CFAR engine affected by the register. This is intended to eliminate the possibility of an unexpected, invalid register setting causing an unintended output from the CFAR module.

### 19.7.7 Non-Coherent Integration

A path should always be enabled for the NCI output if the NCI function is enabled. i.e. either the CFAR or Local MAX units should be configured to use the NCI output (CFARCTRL.CFAR\_EN set to CFARN or LCLMAXN) or the direct output of NCI data to Radar memory should be enabled (NCICTRL.FORMAT=ON).

### 19.7.8 FFT Data Output Path

Do not enable in-line mode for the CFAR or Local MAX units without setting ODP\_CONF.MODE to ON

### 19.7.9 Using SUMCTRL.SUMMODE=SUMANT with unconstrained ILR value

SUMCTRL.SUMMODE=SUMANT will cause the MATH2 unit to sum across the FFTs in the output buffer memory to produce a combined FFT output (coherent integration). The use case for this is when the output buffer memory contains one FFT result per antennae. This requires an alignment between the maximum number of antennae (8) and the maximum number of FFTs which can be stored in the output buffer memory (8).

Setting up a datablock with one FFT per antennae requires that the inner loop offset of the IDM is used to step across antennae data. There are multiple IDM configurations where this isn't the case but there is no hardware lock to ensure that coherent integration is not used for these configurations. In these cases, setting

## Signal Processing Unit (SPU)

SUMMODE=SUMANT will still cause one result to be calculated per datablock even though the datablock does not contain one full iteration of the inner loop.

The behaviour of the Simulink model differs from the hardware in that the model will produce a calculation result which uses all results from the inner loop iteration, however large the inner loop repeat value. This is not possible for the RTL as it does not contain the storage needed for the intermediate results generated after the processing of each dataset.

### 19.7.10 Kernel Reset and Lockstep

In the event that it is required to perform a kernel reset of the SPU while lockstep is enabled, the SPU lockstep must be disabled before triggering the kernel reset to prevent spurious alarms being generated. This is because it is impossible to simultaneously trigger the kernel reset in both SPUs so a comparator mismatch is unavoidable.

A kernel reset must be performed before enabling lockstep if either of the SPUs has been used for data processing. This is needed to initialise the address generators in the FFT accelerator to a known state.

### 19.7.11 Supported Clocking Modes

The ADAS subsystem has the following operating restrictions

- $f_{\text{BBB}}$  must be half the SPU operating frequency  $f_{\text{ADAS}}$
- $f_{\text{SRI}}$  must be constrained relative to  $f_{\text{BBB}}$ . Ratios of 1:1 and 1:2 are supported by the EMEM.  $f_{\text{BBB}}$  cannot run faster than  $f_{\text{SRI}}$ .
- Trace will not be possible unless  $f_{\text{SRI}}$  is equal to  $f_{\text{ADAS}}$  however normal operation of the SPU will still be possible.

Assuming that the SPU is run as fast as possible (300 MHz for the TC39x), this gives two primary use cases.

- Use Case 1
  - ADAS Clock: 300 MHz
  - SRI Clock: 300 MHz
  - BBB Clock: 150 MHz
  - SPB Clock: 100 MHz
- Use Case 2
  - ADAS Clock: 300 MHz
  - SRI Clock: 150 MHz
  - BBB Clock: 150 MHz
  - SPB Clock: 75 MHz

*Note: It is unlikely that it will be possible to configure a supported clock setup until the PLL is locked. It is recommended that it is not attempted to use the SPU until a stable PLL lock is confirmed.*

### 19.7.12 RAM Initialization

The **FFT Accelerator** uses RAM instances to implement much of its internal storage requirements. Due to details in the implementation, some of the locations in these RAM instances can be read before being written with valid data. While this does not affect the results of the FFT calculation as the data is discarded, it can trigger some of the safety mechanisms in the RAM support hardware causing spurious SMU alarms.

In order to prevent this, if the alarms are enabled for the application, the RAMs should be initialised via the MTU interface before first use of the SPU.

## Signal Processing Unit (SPU)

### 19.7.13 Two SPU Instances Writing to the Same Radar Memory Tile

For TC39x derived devices, the two SPU instances must be configured to write to different tiles in the Radar Memory otherwise writes occurring in the same clock cycle will result in the SPU1 access being terminated with an error. The exception is if the device is configured for full lockstep of the SPU instances. In this case the SPU1 write is ignored and the Radar Memory is updated with the data from the SPU0 write.

For TC35x derived devices, this constraint is partially removed and the SPUs can be configured so that the FFT results from both SPU instances can be written to the same tile in the Radar Memory.

In the TC35x derived devices a single FIFO stage for SPU1 writes has been introduced. This FIFO allows SPU1 writes to be delayed by a single clock cycle so that writes occurring in the same clock cycle no longer collide. This requires that both SPU0 and SPU1 accesses to the tile use at most 50% of the available memory bandwidth and that writes from each SPU instance never occur in consecutive clock cycles. These constraints describe the writing of FFT results (PORT1 of the Output DMA Engine Data Streams as described in [Section 19.3.5, “MATH2 Unit” on Page 57](#)). When written as 32 bit precision, complex data, four FFT result bins can be fitted into each 256 bit, Radar Memory word. This means that highest throughput requirement is that one word of FFT results is written every four SPU clock cycles or every two Radar Memory clock cycles and that there is always at least one Radar Memory clock cycle before the next word of results is available to be written.

In the event of an overflow in the single stage FIFO, the affected SPU1 access will be errored.

Writing FFT results from both SPU instances to the same memory tile is the only supported use case.

### 19.7.14 Performance of the SPU

SPU performance for any given configuration is complicated by the number of configuration settings that can affect the number of clock cycles needed for each operation to complete. Generally, for simple configurations such as generating FFT results and writing them to memory, the SPU performance can approach 1 clock per bin for large datacubes. For smaller datacubes, the latency and configuration overheads for each stage in the processing pipeline become more significant. Also enabling multiple processing pipelines in the MATH2 unit or double pass processing mode can also significantly limit performance.

**Note:** *This section describes the main features of the SPU, as implemented, that can impact performance. Due to the complexity of the SPU not all configuration options that will impact performance are fully described.*

For the purposes of estimation, the SPU can be considered as three, independent pipeline stages

- The Input Data Manager (IDM)
- The LOADER/FFT/UNLOADER stage
- The MATH2 Units and Output Data Manager

The overall time to execute the configuration can also be split into three parts

- Pipeline Load Latency: The time taken to load the initial buffer RAM and trigger the FFT
- Data Processing Time: The time taken for all the data to be processed by the SPU
- Pipeline Unload Latency: the time taken to flush the MATH2 and ODM after the final FFT is processed

The total execution time for the configuration is derived by adding together all three times.

The SPU pipeline stages can sustain a processing rate in terms of clocks per bin but also incur a setup overhead for each time the buffer RAMs at the input or output of the pipeline stage are switched. In order to calculate the overall processing speed of the SPU, the time taken for each pipeline stage to process the data in the buffer RAM between each switching event needs to be calculated to determine which processing element is the slowest and therefore determines the achievable performance.

## Signal Processing Unit (SPU)

Generally, the number of times each stage of the pipeline is executed is aligned. So one IDM execution leads to one LOADER/FFT/UNLOADER execution leads to one MATH2/ODM execution. The exceptions are:

- when  $ID\_RM\_CONF.TRNSPS = 1_B$  and  $ID\_RM\_CONF.PM = 1_B$ . In this case, the  $ID\_RM\_CONF.BLOCKS$  parameter will cause the IDM to load multiple datablocks in a single execution. The second and third stage elements of the processing pipeline will therefore execute  $ID\_RM\_CONF.BLOCKS$  times for each execution of the IDM.
- When “Double Pass” is enabled ( $DPASS\_CONF.EN = 1_B$  and  $DPASS\_CONF.SWITCH = 0_B$ ). See [Section 19.7.14.5](#) for more information.

### 19.7.14.1 Input Data Manager Performance, RIF Data

The IDM operates either with the RIF as data source or the RADAR Memory (EMEM). If data is sourced from the RIF, the performance is likely to be limited by the sample rate of the internal ADCs or external RF front end, provided that the ADAS clock is set to the maximum possible frequency of 300 MHz.

The IDM itself can write up to 128 bits per clock cycle to the buffer memory. This is enough for 8 bins per clock of ADC data as a maximum data size of 16 bits is supported by the RIF interface.

Each RIF interface is 32 bits wide so can transfer 2 bins per clock. When configuring the ADAS clock used to clock the SPU and RIF, a frequency must be chosen so that the bandwidth available on the interface between each RIF and the SPU is sufficient to transfer all data received on the LVDS interface within the 2 bin per clock limit.

### 19.7.14.2 Input Data Manager Performance, EMEM Data

The IDM operates either with the RIF as data source or the RADAR Memory (EMEM). If the data is sourced from EMEM, then the IDM can read 256 bits of data every two clock cycles. As the maximum supported data size is 64 bits (32 bit precision, complex data), the IDM can maintain 2 bins per clock read performance. This is matched by the write performance which is 128 bits per clock or 2 bins per clock.

This holds as long as

- access to the EMEM is not contended
- IDM bandwidth optimisation is functioning optimally for performance

#### Notes on conditions affecting performance

1. Access contention applies when multiple SPU I/O channels are attempting to access the same tile in EMEM. For the specific case of in-place FFT, it is assumed that the SPU instance will be reading and writing from the same memory tile for at least some of the time. In this case, writing the FFT results will require 50% of the available EMEM bandwidth. The IDM can achieve 1 clock per bin performance using the other 50% available EMEM bandwidth. Consequently, the SPU can be configured for in-place FFT without affecting performance provided that tiles used for FFT results are not used for other SPU output channels.
2. The second condition will not be the case if  $ID\_RM\_CONF.TRNSPS = 1_B$  and  $ID\_RM\_CONF.PM = 1_B$ . In this case, the  $ID\_RM\_CONF.BLOCKS$  will need to be set to the correct value to ensure that all data read from EMEM is used for performance to be maintained. Even in this case, if the overall data size is small (e.g. zero or one buffer RAM switches needed to process all the data), the fact that so much of the data has to be read by the IDM to load the pipeline may mean that the pipeline load latency will be sufficiently large to degrade performance below 2 clocks per bin for executing the configuration
3. For configurations where the SPU is taking data from the RIF interface, the SPU performance can be limited by the rate at which data is fed via the RIF interface rather than the SPU configuration options. “Bypass Reload” uses the RIF interface so this consideration also applies when data is being read from EMEM when  $ID\_CONF2.BYPASS = 1_B$  and  $ID\_CONF2.BPRLD = 1_B$
4. if  $ID\_RM\_CONF.TRNSPS = 1_B$  and  $ID\_RM\_CONF.PM = 1_B$ , then performance of 2 clocks per bin may not be achieved if the IDM bandwidth optimisation is not possible. If all the data read from EMEM is not used, the excess data read and discarded still consumes EMEM bandwidth and can push the usable data fetched to less than one bin every

## Signal Processing Unit (SPU)

*two clocks.*

*e.g. The SPU can read one EMEM word every two SPU clocks. If only one usable sample can be retrieved from the fetched word the IDM performance can never be better than 1 bin per 2 clocks.*

### 19.7.14.3 LOADER/FFT/UNLOADER Performance

The performance of the LOADER/FFT/UNLOADER is primarily defined by the setting of the CTRL.DIV bitfield which sets the rate at which the LOADER pushes data into the FFT accelerator. There are also some secondary considerations which affect the overall time to process a datablock

- At the start of each datablock, the LOADER pipeline will take 9 clock cycles to initialise
- The latency through the FFT is  $2 * (\text{FFT size}) - 1$  clock cycles
- The UNLOADER latency is approximately 3 clock cycles
- The FFT is only flushed at the end of the run. This means that the first data of datablock n+1 is needed to flush the last of the data from datablock n from the accelerator. The amount of data required is related to the FFT size programmed. This can effect the latency of datablock n through the second stage of the pipeline and delay the buffer RAM switch which makes datablock n available to the MATH2 unit. This is of particular interest for the first datablock of the configuration as the start of MATH2/ODM processing will be delayed until the datablock 0 data is flushed from the FFT accelerator.

### 19.7.14.4 MATH2/ODM Performance

The performance of the MATH2 and ODM will be defined by the fetch rate from buffer memory. This is fixed at one bin every clock cycle. The following provisos apply

- The MATH2 runs a set up task every buffer RAM switch which takes approximately 12 clock cycles
- There are two classes of processing path through the MATH2 which require the data to be read from buffer RAM in two incompatible ways. Operations such as the FFT data output path through the bin rejection unit require the data to be read as consecutive points from each FFT result. The operations using the data integrated across antenna requires equivalent data points to be read consecutively from each FFT result stored in the buffer memory so the integrated value can be calculated. If both types of path are enabled, then this conflict is addressed by reading the data from the buffer memory twice. The first fetch will be used for the operations requiring linear addressing by FFT result. The second fetch will be performed for operations requiring the integrated result across antennae. The number of fetches required is evaluated and executed independently for each pass if double pass mode is enabled.
- Spectrum extension increases the effective size of each FFT by the twice the value of the CFARCTRL.SEWIN parameter.
- If in-line CFAR mode is specified, the first FFT of the configuration run will be fetched an additional time to establish the CFAR results bitmask. This is a one-off overhead occurred
- The MATH2 processing latency will be include between each of the data fetch operations (sequential and NCI/DBF) if both passes are enabled as the control logic will wait for the results of the first pass to complete before starting the second pass
  - The latency through the NCI module is approximately 2 clocks
  - The propagation delay through the CFAR module is approximately 10 clocks plus the window size (defined by CFARCFG2.GOSWINCELL, CFARCFG2.CASHWIN or CFARCFG.CAWINCELL)
  - The ODM will take approximately 8 clocks to flush the output buffers

## Signal Processing Unit (SPU)

### 19.7.14.5 Effect of “Double Pass” on Performance

If DPASS\_CONF.EN\_CNT = 0 and DPASS\_CONF.SWITCH = 0 then setting DPASS\_CONF.EN = 1 will cause the second and third stages of the processing pipeline to run twice for every one execution of the IDM stage<sup>1)</sup>.

If DPASS\_CONF.SWITCH = 1 and DPASS\_CONF.EN = 1, then the only effect is to switch parameter sets for every second datablock processed.

If DPASS\_CONF.EN\_CNT = 1 then the parameter sets will switch every DPASS\_CONF.COUNT datablocks.

Note: *Because of the pipelining, the MATH2/ODM stage of the pipeline will be executing the configuration defined by the BE0\_\* registers while the LOADER/FFT/UNLOADER is executing the configuration defined by the BE1\_\* registers and vice-versa*

## 19.8 I/O Interfaces

**Table 777 List of SPU Interface Signals**

Interface Signals	I/O	Description

<a href="#">Page 191</a>	<a href="#">Section 19.7.14.1</a> , New section added to clarify dependency between LVDS data rate at RIF and required ADAS clock frequency	

## Signal Processing Unit 2 (SPU2)

### 20 Signal Processing Unit 2 (SPU2)

The Signal Processing Unit 2 (SPU2) is the second generation of the SPU, a semi-autonomous accelerator for performing Fast Fourier Transforms (FFTs) on data from one or more dedicated ADC interfaces. For the rest of this chapter this functional block will be referred to as “TC3Ax SPU”.

The TC3Ax SPU uses a three stage, streaming architecture to provide data pre-processing, FFT, and data post-processing operations. The TC3Ax SPU uses the Radar Memory to store datasets and has internal buffer memories which are used to store the data currently progressing through the processing pipeline.

**Figure 257 TC3Ax SPU Architecture**

#### 20.1 Feature List

The TC3Ax SPU has the following top level features

- Up to 2 concurrent TC3Ax SPU instances active concurrently
- A maximum achievable performance can approach 1 clock per sample processed for large data cubes. (See [Section 20.7](#) of this document for a more detailed explanation of factors affecting TC3Ax SPU throughput.)
- A 256bit bus connection to Radar memory with 2 clocks per read or write access
- Radar sequencer to manage the automatic execution of linked list where execution units are reconfigured between computation steps
- Internal configuration memory for linked lists
- 2 selectable input data flows (ADC interface or main RAM)

## Signal Processing Unit 2 (SPU2)

- The ADC Interface supports real or complex data
- Input / output precision selectable: 16bits, 32bits, half precision floating point or compressed
- Input DMA with HW transpose unit and data padding
- Multiple execution units
  - Time domain interference detection and removal
  - Windowing with complex windowing and HW support for phase demodulation
  - FFT from 8 to 2048 points
  - 2 x 1D-CFAR, thresholding units implementing 4 CA and 3 GOS algorithms
  - 1 x BIN rejection unit
  - Non coherent integration over 2 TC3Ax SPU instances
  - Digital beam forming over 2 TC3Ax SPU instances
  - Antenna signal integration for elevation
  - Basic thresholding (local maximum detection)
- RAM size optimisation by using configurable FFT strategy (in place, out of place, partially shifted)
- Output DMA with output FIFOs so that each data flow has its own FIFO and configurable DMA parameters
- A min/max/averaging unit.
- A histogram unit up to 4096 elements
- Support for up to 8 data lanes @ 600Mbit/s
- Low speed 60 Mb/s single ended IF

### 20.2 Overview

See Overview of the SPU chapter for an overview.

### 20.3 Functional Description

This section describes programming and using the TC3Ax SPU. It deals with each of the major functional blocks of the TC3Ax SPU in the order data flows through the processing pipeline.

#### 20.3.1 Input DMA Engine

The Input DMA Engine can either passively accept data pushed by the ADC interfaces (RIF or Radar Interface) or actively load part or all of an existing data cube from the Radar Memory. Its function is to structure the data in the Buffer RAM into FFT data sets. To do this, it uses the following general control data as well as control information specific to the data source used.

**Table 779 Input DMA Unit General Parameters for all Input Sources**

Parameter	Definition	Comments
Data Source	ADC (RIF), Bypassed data or Radar Memory data	<b>ID_CONF2.SRC</b>
Source RIF	Select which ADC interface (RIF) data are processed	<b>ID_CONF2.SRCRIFm</b> Note: If SRC==RIF and SRCRIFm are all zero the behaviour is undefined
start mode	trigger mode for the TC3Ax SPU ( <b>CTRL.MODE</b> ). Options are defined in <a href="#">Table 822, CTRL.MODE Value Definitions</a>	

## Signal Processing Unit 2 (SPU2)

### 20.3.1.1 Load ADC data from the RIF

When loading data from the RIF or RIFs, processing mode is always default and the input data format and number of antennae must be aligned with the RIF configuration settings. In addition the following operating modes can be configured

**Table 780 Input DMA Unit Specific Parameters for ADC Data**

Parameter	Definition	Comments
Ramps per Measurement Cycle	Number of ramps to be acquired after trigger.	Excess ramps will be ignored unless the TC3Ax SPU is retriggered <b>ID_CONF.RAMPS</b>
Number of active antenna	Number of physical antennae connected to the ADC interfaces of the microcontroller	<b>ID_CONF2.ANT</b>
Input format	Signed or unsigned	<b>ID_CONF2.SIGNED</b>
Samples per Ramp or Bins per FFT	The number of sample points to be used in the input datasets for the FFT <sup>1)</sup>	<b>ID_CONF.SMPLCNT</b>
Input format	Real or complex	<b>ID_CONF2 FORMAT</b>

1) Although one is the minimum number of samples the MATH0 unit cannot function correctly with less than eight.

### 20.3.1.1.1 Principles of Operation (ADC IF)

There are some restrictions imposed on the physical configuration of the overall system by the Input DMA. The most significant of these are that, if both ADC IF<sup>1)</sup> instances are being processed by a single TC3Ax SPU:

- the configuration of the ADC IFs must be identical so that the quantity of data being fed to the TC3Ax SPU by each ADC IF is the same.
- The data sources providing data to the ADC IFs must be synchronised. This is for two reasons
  - To enable meaningful integration (or other calculations) across the antennae, the sampling time for each antenna must be aligned and kept consistent to within very small limits
  - The ADC IFs contain buffers to ensure that the data fed to the TC3Ax SPU is aligned in the same clock cycle for equivalent antenna. The alignment of data is triggered by setting a configuration option in the RIF module registers. The data provided to the ADC IFs must be sufficiently aligned to prevent these buffers overflowing. The buffering is sufficient to allow for one complete sample misalignment at the serial inputs to the ADC IFs.

When configured for internal or software trigger mode, the TC3Ax SPU will accept all data from the ADC IFs. The ADC IF in this case must maintain synchronisation to the ramps and only pass valid data to the TC3Ax SPU (although there is a limited facility to remove undesired data by truncating the dataset in the MATH1 unit).

#### Antennae (ID\_CONF2.ANT)

The number of active antennae is the number of physical antennae attached to the configured data source (ADC IF0, ADC IF1 or both). This can be up to four antennae per ADC IF (RIF).

1) The ADC IF function is implemented in the RADAR Interface (RIF) module

## Signal Processing Unit 2 (SPU2)

### 20.3.1.1.2 Bypass Function

The Bypass function of the Input DMA allows ADC (RIF) data to be both written to Radar Memory and processed in the TC3Ax SPU at the same time. The Bypass function operates independently from the Input DMA Load from Radar Memory function allowing RIF data to be bypassed at the same time as the TC3Ax SPU processes data read from Radar Memory. A single TC3Ax SPU configuration can only have ID\_CONF2.SRC set to either RIF or RM but the Bypass function requires the source to be set to RIF. To get the TC3Ax SPU to process data from Radar Memory and bypass RIF data at the same time requires two different configurations. The RELOAD MODE in the CTRL register can be used to trigger the Bypass function and the next configuration can be used to trigger the TC3Ax SPU to process data from the Radar Memory.

The RIF interfaces for which data shall be processed are identified by setting the corresponding ID\_CONF2.SRCRIFm bits. The ID\_CONF2.SRC bitfield must also be set to RIF. If CTRL.BPTRIG bit is set to a 1<sub>B</sub> and at least one of the ID\_CONF2.SRCRIFm bits is set to a 1<sub>B</sub> when the SPU is triggered the bypass function shall be triggered. The Bypass function may be triggered alone by using the RELOAD MODE in the CTRL register. The base address for writing bypassed data is defined by BYPASS\_CTRL.BPADDR. Data is written to memory in the order as it is received from a RIF. When more than one RIF is bypassed then data is written in the order it is received from the RIF interfaces and data from RIF0 shall be added to the Radar Memory word first. In this case the resulting memory word will have 32 bits from RIF0 then 32 bits from RIF1 followed by 32 bits from RIF0 and so on.

Once triggered, the Bypass function will operate until it has written the amount of data as defined by ID\_CONF.SMPCNT, ID\_CONF.RAMPS, ID\_CONF2.ANT from all RIFs selected by BYPASS\_CTRL.SRCRIFm. The Bypass function takes a copy of the values of these registers when it is triggered. If STAT.INTMSK(2) is set, then the Bypass function will trigger an ATTN interrupt when the last data has been written to Radar Memory. The Bypass function will always run to completion, independent of the state of the TC3Ax SPU, and cannot be stopped except by resetting the TC3Ax SPU. Triggering Bypass when Bypass is busy, as indicated by the MONITOR.BP\_BUSY bit, has no effect.

Data that has been written to Radar Memory using the Bypass function may be read back for processing. To do this ID\_CONF2.SRC must be set to BPRLD and ID\_CONF2.SRCRIFm must be set the same values as BYPASS\_CTRL.SRCRIFm were when the data was written. Attempting to reload data by setting ID\_CONF2.SRC==BPRLD after the Bypass function has been triggered with the same setting of BYPASS\_CTRL.BPADDR is not recommended as such a configuration would cause a race condition between reading and writing data at the same location in Radar Memory.

**Table 781 Bypass Configuration**

Parameter	Definition	Comments
Bypass trigger	When CTRL.BPTRIG is set any trigger of the SPU will trigger Bypass. In addition, Bypass can be triggered alone by CTRL.MODE==RELOAD	<b>CTRL.BPTRIG CTRL.MODE</b>
Bypass address	Base address for writing bypass data	<b>BYPASS_CTRL.BPADDR</b>
Bypass source enable	Select which ADC (RIF) data source are bypassed. At least one of SRCRIFm must be set for Bypass to be triggered	<b>BYPASS_CTRL.SRCRIFm</b>

## Signal Processing Unit 2 (SPU2)

**Table 781 Bypass Configuration (cont'd)**

Parameter	Definition	Comments
Bypass read-back	Enable reading of bypassed data	<b>ID_CONF2.SRC</b> Set to BPRLD
Bypass read-back source	Should the set the same as BYPASS_CTRL.SRCRIFm when data was written. At least one of SRCRIFm must be set. A configuration with SRC==BPRLD and these bits all zero will result in undefined behaviour.	<b>ID_CONF2.SRCRIFm</b>

### Split Processing

Bypass may be used in systems with 2 RIF instances when there is too much data from the ADCs to be handled by the SPUs in a single pass. ID\_CONF2.SRC should be set to RIF and the antennae must be distributed symmetrically between the two RIF instances.

The ID\_CONF2.SRCRIFm should be set to select one RIF (RIF0, say) so that data from RIF0 is processed. BYPASS\_CTRL.SRCRIFm should be set to select the other RIF (RIF1, say) so that the data from RIF1 is written directly to Radar Memory for later processing. The base address is stored in the BYPASS\_CTRL.BPADDR field. The first pass is configured by setting BYPASS\_CTRL.BYPASS. This will process the RIF0 data and bypass the RIF1 data. The second pass is configured by setting ID\_CONF2.SRC to BPRLD and setting ID\_CONF2.SRCRIFm to the same setting of BYPASS\_CTRL.SRXCRIFm (RIF1, say) as was used in the first pass. This will read the data from the address in the BPADDR field rather than the RIF interface so BPADDR should be left at the same value as in the first pass.

All other register settings, apart from the ODP\_BASE.BASE should be the same. In Bypass Mode, the reloaded data is treated as an ADC IF (RIF) data stream rather than a datacube in Radar Memory. So the same parameters apply as when loading ADC data directly from a RIF. The parameters used when loading from Radar Memory are not applicable.

#### 20.3.1.2 Load from Radar Memory

The following options are specific to loading data from Radar Memory:

**Table 782 Input DMA Unit Parameters for Reading Data from Radar Memory**

Parameter	Definition	Comments
Input format	16bit or 32bit precision complex data, 16bit or 32bit precision real data, IEEE 754 half precision floating point real data, IEEE 754 half precision floating point complex data, compressed complex data, 32 bit power, IEEE 754 half precision floating point power data,	<b>ID_RM_CONF2.FORMAT</b>
DMA base address	DMA base address when starting a new FFT sequence from Radar memory	Word (256 bit) address relative to start of Radar Memory <b>ID_RM_CONF.BASE</b>

## Signal Processing Unit 2 (SPU2)

**Table 782 Input DMA Unit Parameters for Reading Data from Radar Memory (cont'd)**

Parameter	Definition	Comments
DMA outer loop address offset	Offset address to be added to base address (Radar Memory address calculation)	Byte offset <b>ID_RM_OLO.OLO</b>
DMA outer loop repeat value (parameter “m”)	Number of times of outer loop execution	e.g. for 2nd stage FFT, this would be the number of antennae to process in default mode. <b>ID_RM_IOLR.OLR</b>
DMA inner loop address offset	Offset to be added to base address (Radar Memory address calculation)	Byte offset <b>ID_RM_ILO.ILO</b>
DMA inner loop repeat value (parameter “n”)	Number of times of inner loop execution	Inner loop count is incremented by one every time a complete FFT is read from memory <b>IDM_RM_IOLR.ILR</b>
Bin offset	Radar Memory address offset between adjacent bins in an input dataset	Byte offset. When reading a linear FFT from memory, this would be set to the size of one data element <b>IDM_RM_BLO.BLO</b>
Bin Offset Loop Repeat (parameter “p”)	Number of reads needed to traverse one input FFT. (number of bins in an input dataset)	The number of samples in each FFT input (dataset) being constructed <b>IDM_RM_BLR.BLR</b>
Addressing Mode	Linear or Transpose Addressing	<b>ID_RM_CONF2.TRNSPS</b>
Processing Mode	Default Mode or Integration Mode for bandwidth optimisation.	Integration Mode should be used when constructing input datasets for use with the coherent or non-coherent integration functions in the MATH2 units <b>IDM_RM_CONF2.PM</b>
Number of simultaneous data blocks from RAM	For integration mode, defines the number of concurrent information sets (data blocks) that are fetched from memory. Depends on memory organization. Number from 1 to 8.(1,2 4 and 8 supported).	Number of data blocks that will fit into the buffer memory. <b>IDM_RM_CONF2.BLOCKS</b> Add one to this field to get the number of data blocks. Supported values are therefore: 0, 1, 3, and 7.

## Signal Processing Unit 2 (SPU2)

**Table 782 Input DMA Unit Parameters for Reading Data from Radar Memory (cont'd)**

Parameter	Definition	Comments
Mapping of FFT datasets to antenna	Defines how each dataset in the buffer memory is linked to an antenna ID for windowing and other antenna specific operations	<b>ID_RM_CONF2.AM</b>
Incremental Processing Mode?	Allows one TC3Ax SPU instance to trigger another on a ramp-by-ramp basis providing a ramp fits into the buffer RAM. The IDM waits for the Incremental Trigger input from the other TC3Ax SPU before first loading the buffer RAM and after each buffer RAM switch.	<b>ID_RM_CONF2.IMODE</b>

All address fields in registers are specified in words (256 bits or 32 bytes).

At any time the byte address that the Input DMA is reading from is defined as:

```
(base address<<5) + ((outer loop offset)*m) + ((inner loop offset)*n) + ((bin loop offset)*p)
```

where **n** and **m** are as defined above and **p** is the bin being read. This will be used to generate a word address for Radar Memory by truncating bits [4:0] of the generated address. Bits [4:0] will be used to select within the 256 bit word retrieved from radar Memory.

The input DMA engine will read (at least) one complete set of FFT input data per inner loop using the Bin Offset field to increment the byte address between sample reads.

A more detailed description of the operating modes is given in the following sub-sections.

### 20.3.1.2.1 Principles of Operation (Radar Memory)

The Input DMA is designed to allow autonomous processing of a three dimensional data array stored in the Radar memory. Typically the three axes of the array would be representing FFT sample number, ramp or acquisition count and antenna. The intention is to allow assembling input sets for the FFT accelerator by stepping across the axes in any arbitrary order.

This is accomplished by constructing the read address for the Input DMA from a base address and three independent address offsets (“bin loop address”, “inner loop address” and “outer loop address”).

The term “bin loop” is used as the bin loop repeat value maps directly to the number of bins in each FFT dataset constructed in the buffer RAM. The bin loop repeat value defines the size of the input dataset.

**Note:** *The maximum number of bins supported in an FFT dataset is 2048. Setting a Bin Loop Repeat value for an FFT size greater than this (i.e. ID\_RM\_BLR.BLR > 2047) is not supported and should be avoided.*

Some assumptions are made about the organisation of the data. Specifically that:

- Each dataset in memory starts at a 32 byte aligned address. This allows the bandwidth optimisation hardware to function and is enforced by the Output Data Manager. This restriction has to be observed when using software to build data arrays in memory for reading by the Input Data Manager
- The second assumption follows from the first. If all datasets are 32 byte aligned, it follows that 2 co-ordinate axes of the data array must be multiples of 32 byte. These axes will be used to step along datasets. Only a single co-ordinate axis, the one used to step along data samples stored in adjacent memory locations, can be less than a multiple of 32 bytes and this can be set to the data sample size. However, bandwidth optimisation

## Signal Processing Unit 2 (SPU2)

will enforce the reading of data in 32 byte words, so this axis will increment by 32 bytes and the IDM will behave in an identical manner whether the increment is set to sample size or 32 bytes. Note that this axis can also be set in the IDM to be a multiple of 32 bytes but, in this case, the data read for this axis will be non-contiguous and will “jump” after every 4, 8 or 16 samples depending on the sample size.

**Note:** *The TC3Ax SPU is specified to cope with Radar Memory sizes up to 16 MiB. If programming causes it to generate an address outside the range of the available Radar Memory in the product, an error will be generated by the Radar Memory*

Each counter has an associated offset and a repeat count. Operation (neglecting the effect of bandwidth optimisation) is then as follows:

**Table 783 Input DMA Execution Flow**

1	initialise the “bin loop address”, the “inner loop address” and the “outer loop address”.
2	loop
3	The read address is computed by adding the “base address”, the “bin loop address”, the “inner loop address” and the “outer loop address”.
4	An input value is then read from the address
5	“bin loop count” is incremented
6	If { the bin loop count has reached the “bin offset loop repeat” value } then
7	“bin loop count” is reset
8	“bin loop address” is reset
9	“inner loop count” is incremented
10	If { the “inner loop count” has reached the “inner offset loop repeat” value } then
11	“inner loop count” is reset
12	“inner loop address” is reset
13	“outer loop count” is incremented
14	If { the “outer loop count” has reached the “outer offset loop repeat” value } then
15	execution has completed, exit loop
16	else
17	“outer loop address” is set to “outer loop address” plus “outer loop offset”
18	end if
19	else
20	“inner loop address” is set to “inner loop address” plus “inner loop offset”
21	end if
22	else
23	“bin loop address” is set to “bin loop address” plus “bin loop offset”
24	end if
25	end loop
26	stop

The flow above is the basic operation flow without considering bandwidth optimisation. As the Radar Memory is organised as 256 bit words and the data element occupy either 32 or 64 bits depending on precision and format, then bandwidth usage can be optimised by using as much as possible of the 256 bit word<sup>1)</sup>. The Input DMA will

## Signal Processing Unit 2 (SPU2)

attempt to do this based on register settings by “collapsing” one or more of the loops i.e. effectively performing multiple iterations of one of the loops in a single pass as described in the following sections.

**Table 784 Input DMA Loop Mapping**

Mode	Co-ordinate Mapping <sup>1)</sup>			Notes	ID_RM_CONF2 Register Settings <sup>2)</sup>
	Bin Loop Address Iteration	Inner Loop Address Iteration	Outer Loop Address Iteration		
1	<b>Sample</b>	FFT	Antenna	Linear (Default) Addressing Mode. Each Radar Memory Read fetches multiple samples for the same FFT. Integration mode can be used to build a datablock for NCI or DBF <sup>3)</sup> . Blocks must be 0 <sub>B</sub> See <a href="#">Chapter 20.3.1.2.2</a>	<b>TRNSPS=0</b> PM=0,1 <b>BLOCKS=0</b>
2	<b>Sample</b>	Antenna	FFT	Linear (Default) Addressing Mode. Each Radar Memory Read fetches multiple samples for the same FFT. Integration mode can be used to build a datablock for NCI or DBF. Blocks must be 0 <sub>B</sub> See <a href="#">Chapter 20.3.1.2.2</a>	<b>TRNSPS=0</b> PM=0,1 <b>BLOCKS=0</b>
3	FFT	<b>Sample</b>	Antenna	Transpose Addressing Mode. Each Radar Memory Read fetches samples for multiple FFT datasets. Integration mode is not supported. Blocks must be 0 <sub>D</sub> See <a href="#">Chapter 20.3.1.2.3</a> . ID_RM_CONF2.FORMAT=REAL16BIT not supported. ID_RM_CONF2.FORMAT=REAL16FP not supported.	<b>TRNSPS=1</b> PM=0 <b>BLOCKS=0</b>
4	FFT	Antenna	<b>Sample</b>	Transpose Addressing Mode. Each Radar Memory Read fetches samples for multiple data blocks. Integration mode must be set. Blocks can be set to a value other than 0 <sub>D</sub> for bandwidth optimisation See <a href="#">Chapter 20.3.1.2.4</a> ID_RM_CONF2.FORMAT=REAL16BIT not supported. ID_RM_CONF2.FORMAT=REAL16FP not supported.	<b>TRNSPS=1</b> PM=1 <b>BLOCKS=0,1,3,7</b>

1) The exceptions to this are the 16 bit precision, real only formats, REAL16BIT and REAL16FP. These formats can only be used if TRNSPS=0. If the TC3Ax SPU is configured with (FORMAT=REAL16BIT or FORMAT=REAL16FP) and TRNSPS=1, the resulting datasets will be corrupted.

## Signal Processing Unit 2 (SPU2)

**Table 784 Input DMA Loop Mapping (cont'd)**

Mode	Co-ordinate Mapping <sup>1)</sup>			Notes	ID_RM_CONF2 Register Settings <sup>2)</sup>
	Bin Loop Address Iteration	Inner Loop Address Iteration	Outer Loop Address Iteration		
5	Antenna	<b>Sample</b>	FFT	Transpose Addressing Mode. Each Radar Memory Read fetches samples for multiple FFT datasets. Integration mode is not supported. Blocks must be $0_D$ . See <a href="#">Chapter 20.3.1.2.3</a> ID_RM_CONF2.FORMAT=REAL16BIT not supported. ID_RM_CONF2.FORMAT=REAL16FP not supported.	<b>TRNSPS=1</b> PM=0 <b>BLOCKS=0</b>
6	Antenna	FFT	<b>Sample</b>	Transpose Addressing Mode. Each Radar Memory Read fetches samples for multiple data blocks. Integration mode must be set. Blocks can be set to a value other than $0_D$ for bandwidth optimisation. See <a href="#">Chapter 20.3.1.2.4</a> ID_RM_CONF2.FORMAT=REAL16BIT not supported. ID_RM_CONF2.FORMAT=REAL16FP not supported.	<b>TRNSPS=1</b> PM=1 BLOCKS=0,1,3,7

- 1) Incrementing the Offset counter increments address to next sample bin, next FFT dataset or next antenna. When iterating across samples, data is still read as 256 bit words so the address will increment by at least one, 256 bit word as long as bandwidth optimisation is operating.
- 2) Mandatory settings are shown in bold. Options where multiple values are possible are shown as a commas separated list
- 3) Provided that ID\_RM\_IOLR.ILR is less than or equal to  $7_D$ .

### Incremental Trigger

When ID\_RM\_CONF2.IMODE is set, the IDM will wait for an Incremental Trigger from another TC3Ax SPU before first loading the Buffer RAM with data and after each Buffer RAM switch. The other TC3Ax SPU must be configured with CTRL.ITRIG set to generate the Incremental Trigger when it has finished processing the contents of its Buffer RAM and has written all data to the Radar Memory. The TC3Ax SPU will keep track of the number of outstanding incremental trigger events if the other SPU is processing data faster than the SPU. Configuring two TC3Ax SPUs both with ID\_RM\_CONF2.IMODE set is not supported as they would both wait for a trigger from the other causing a deadlock.

### 20.3.1.2.2 Case 1: “Bin Offset” is used to Iterate Across Adjacent Samples

In this case, the bins in Radar Memory to be used as consecutive inputs bins for each FFT dataset are stored in consecutive addresses in Radar Memory so each 256 bit read will load four, eight or sixteen bins depending on the precision of the data. The input DMA will therefore execute four, eight or sixteen iterations of the “bin offset” loop simultaneously. As this does not require address transposition, the ID\_RM\_CONF2.TRNSPS bit must be set to  $0_B$  (LIN).

Bandwidth optimisation is not needed in this mode as all data fetched in a 256 bit read is used in the same FFT dataset.

### Buffer Memory Switching

If the ID\_RM\_CONF2.PM bit is set to IM, this signals that the data block should contain one dataset for each antenna (i.e. the Inner Loop Offset is set to step across antennae) and the Buffer Memory will be switched when

## Signal Processing Unit 2 (SPU2)

the Inner Loop Repeat Count is reached. Otherwise, the Input Buffer Memory will be switched every four (for 64 bit data) or eight (for 32 bit data) iterations of the Inner Loop or when all data has been read whichever occurs first.

**Note:** *Setting ID\_RM\_CONF2.BLOCKS to a non-zero value with ID\_RM\_CONF2.TRNSPS set to 0<sub>B</sub> is not supported and will result in undefined operation of the input DMA.*

### 20.3.1.2.3 Case 2: “Inner Loop Offset” is set to Iterate Across Adjacent Samples

This is the first of the co-ordinate transposition cases, so the ID\_RM\_CONF2.TRNSPS bit must also be set to explicitly signal the intent to use co-ordinate transposition to the logic of the TC3Ax SPU. The Bin Loop offset can be set to step either across antennae or across FFT result datasets.

The ID\_RM\_CONF2.TRNSPS bit signals that the data from each 256 bit read will be used in different FFT input datasets and should therefore be written to different areas of the buffer memory (“scattered”).

As stated, the bins in Radar Memory to be used as consecutive input bins in each FFT dataset are stored in non-consecutive addresses in Radar Memory so each 256 bit read will load four or eight bins depending on the precision of the data<sup>1)</sup> but these samples will be from different FFT input sets. The input DMA will therefore execute four or eight iterations of the “inner loop” simultaneously. This bandwidth optimisation is described in [Section 20.3.1.2.5, “Bandwidth Optimisation for Default Processing Mode” on Page 12](#).

ID\_RM\_CONF2.PM must be set to DM for this operating case as the data from each 256 bit read is all needed for a single datablock.

#### Buffer Memory Switching

The Input Buffer Memory will be switched either when the Inner Loop Count is updated. i.e. every four (for 64 bit data) or eight (for 32 bit data) iterations of the Inner Loop or when all data has been read.

### 20.3.1.2.4 Case 3: “Outer Loop Offset” is set to Iterate Across Adjacent Samples

This is the second of the co-ordinate transposition cases, so the ID\_RM\_CONF2.TRNSPS bit must also be set to explicitly signal the intent to use co-ordinate transposition to the logic to the logic of the TC3Ax SPU. Either the Bin Loop Offset or Inner Loop Offset will be set to step across the FFT datasets stored in the Radar Memory. However in both of these cases, consecutive samples to be used as inputs to the FFT are stored in non-consecutive addresses in Radar Memory so, while each 256 bit read will load four or eight bins<sup>1)</sup> depending on the precision of the data, these samples will be from different FFT input sets. This differs from case 2 in that using the remaining data from the 256 bit read requires an increment of the outer loop. This is signalled to the logic by setting ID\_RM\_CONF2.PM to IM (1<sub>B</sub>).

In this case, to avoid discarding data and wasting bandwidth, multiple data blocks can be built in memory by setting the ID\_RM\_CONF2.BLOCKS bitfield to a value other than 0<sub>D</sub>. This bandwidth optimisation is described in [Section 20.3.1.2.6, “Bandwidth Optimisation Integration Processing Mode.” on Page 12](#). This has the effect of collapsing the outer loop as well as the inner loop resulting in a three-dimensional array of input data in the buffer memory.

#### Buffer Memory Switching

If the ID\_RM\_CONF2.PM bit is set to IM, this signals that the data block should contain one dataset for each antenna (i.e. the Inner Loop Offset is set to step across antennae) and the Buffer Memory will be switched when the Inner Loop Repeat Count is reached. Note that in this case, the FFT accelerator will run

<sup>1)</sup> 16 bit precision real data (FORMAT=REAL16BIT) and 16 bit half precision floating point real data (FORMAT=REAL16FP) are not supported with TRNSPS=1.

## Signal Processing Unit 2 (SPU2)

ID\_RM\_CONF2.BLOCKS+1 processing operations for each switch of the buffer memory. Otherwise, the Input Buffer Memory will be switched every four (for 64 bit data) or eight (for 32 bit data) iterations of the Inner Loop or when the Outer Loop Count is updated or all data has been read whichever occurs first.

### 20.3.1.2.5 Bandwidth Optimisation for Default Processing Mode

The memory mapping used to store data after the TC3Ax SPU processes ADC samples means that consecutive addresses in memory contain adjacent samples from the same FFT and that the same FFT result points from different antennae are always separated in the address space. Default mode is designed to work with this memory organisation to optimally construct multiple input datasets from each set of 256 bit reads. Each of the samples in a single data read will be allocated to different input datasets in the buffer memory.

The mode is enabled by setting ID\_RM\_CONF2.TRNSPS=TRN and ID\_RM\_CONF2.PM=DM

To work in default mode either the **ID\_RM\_BLO**.BLO or **ID\_RM\_ILO**.ILO bitfields must be used to iterate across samples in adjacent memory locations.

**Note:** *It is supported that one of the three fields, **ID\_RM\_OLO**.OLO, **ID\_RM\_ILO**.ILO and **ID\_RM\_BLO**.BLO can be set to the sample size as this can be a useful reminder of the expected IDM behaviour. However this is not mandatory. Setting the relevant field to increment by a 256 bit word (32 bytes) will cause the TC3Ax SPU to operate in exactly the same way. Setting the field to an integer multiple of 32 bytes is also supported.*

### 20.3.1.2.6 Bandwidth Optimisation Integration Processing Mode.

Integration Mode Bandwidth Optimisation is intended for the use case where the MATH2 unit is required to integrate results across antennae while the input data manager is using transposed addressing. In this mode, the Input DMA Engine must load data into the Input Buffer Memory so that each constructed data block contains one dataset from each antenna.

The mode is enabled by setting ID\_RM\_CONF2.TRNSPS=TRN and ID\_RM\_CONF2.PM=IM.

In this case, the data block being constructed in memory would use only one sample point from each 256 bit read, as the first dimension of traversing the data cube (Bin Loop Offset) is across FFT results and the second (Inner Loop Offset) is across antennae (i.e. the data blocks constructed are suitable for use by the coherent or non-coherent integration functions of the MATH2 unit). This compares to the default transpose addressing mode, where the first dimension is still across FFT results but the second is across sample points and each read fetches several contiguous sample points which can be used to construct datasets that can be processed as a single data block.

To mitigate the inefficient use of Radar Memory bandwidth, an optimisation submode of Integration Mode controlled by the ID\_RM\_CONF2.BLOCKS bitfield is available.

Enabling this submode allows multiple data blocks to be constructed in the buffer memory. Then, instead of switching the buffer memory between every data block, the base address the Loader Module uses for reads is adjusted instead. When IDM\_RM\_CONF2.PM is set to 1 and a non-zero value is written to ID\_RM\_CONF2.BLOCKS, the Input DMA Engine will try and use some of the excess data read to construct the additional data blocks in the buffer memory.

To support this, the Buffer RAM will be logically sub-divided into multiple segments based on the most significant address bits, one for each data block. The number of data blocks being equal to the value of the ID\_RM\_CONF2.BLOCKS bitfield plus one. BLOCKS can be set to values between  $0_D$ ,  $1_D$ ,  $3_D$ , and  $7_D$ .

The Data Loader Unit will then read each data block sequentially rather than switching the buffer memory and only switch the buffer memory when all the data blocks have been processed. All units downstream of the FFT still process each data block discretely.

Application software must ensure that the data will fit into the sub-divided buffer memory.

## Signal Processing Unit 2 (SPU2)

**Note:** If the number of data blocks built in the buffer memory does not use all of the 256 bits read from Radar Memory, then the same 256 bits will be read on successive passes until all the data is consumed. e.g. if the data in radar memory is 64 bit and BLOCKS is set to  $1_D$ , then the Input DMA will make two passes through the data in Radar Memory. Each pass will create two data blocks in the Buffer Memory.

### 20.3.1.3 Partial-acquisition Counter

The partial-acquisition counter is used to count ramps and hence to determine the absolute position in the measurement cycle. It is reset by software and will then use the configuration information (samples per ramp and number of antennae) valid at the point of reset to count ramps until the next time it is reset by software.

The intended use case of the counter is to allow the TC3Ax SPU to be triggered multiple times during a single measurement cycle while still retaining synchronisation with the input data stream from the Radar Interface(s). This allows the first few ramps of a measurement cycle to be processed to determine useful information about the input data. The TC3Ax SPU can then be reprogrammed to make most effective use of the input data and retriggered at a known ramp count to process the remaining data from the measurement cycle.

The counter can be configured to generate an error or attention interrupt if any particular value is reached with the counter still enabled.

The TC3Ax SPU can be configured to delay start of processing until a particular value is reached.

The operation of functions related to this counter are controlled by the bitfields of the PACTR register.

**Table 785 Partial-acquisition Counter Specific Parameters for ADC Data**

Parameter	Definition	Comments
Initialise the Counter	Reset the value of the partial-acquisition counter to $0_D$ .	<b>PACTR.RST</b>
Enable the Counter	Counter will increment every time the IDM requests a switch of the input buffers.	<b>PACTR.EN</b>
Limit Value for the counter	Comparison value for triggering a pre-programmed event Note that for comparison purposes, the first ramp of a measurement cycle is considered to be ramp 0.	<b>PACTR.LIMIT</b>
Trigger	Trigger TC3Ax SPU data processing on a limit event	<b>PACTR.TRIG</b>
Error	Trigger an error interrupt on a limit event (unless TRIG bit is set and TC3Ax SPU is configured and waiting for data i.e. CTRL register written with MODE=INT)	<b>PACTR.ERR</b>
Attention	Trigger an attention request interrupt on a limit event	<b>PACTR.ATTN</b>
Counter Value	Current state of the Partial Acquisition Counter	<b>PACTR.COUNT</b>

## Signal Processing Unit 2 (SPU2)

Example use case for a measurement cycle with 1024 ramps of 256 samples and 4 antennae with the intention to process the first four ramps, skip two ramps while reprogramming the TC3Ax SPU and then process the remaining 1018 ramps:

- Program TC3Ax SPU for data from RIF, 256 samples and 4 antennae and four ramps, reset the partial-acquisition counter. Set the PACTR Error Interrupt and configure the limit field to 6 (as we expect to have reprogrammed the TC3Ax SPU by the start of the seventh ramp). Trigger the TC3Ax SPU by either internal (CTRL.MODE=INT) or external mode (CTRL.MODE=EXT).
  - This will initialise the Partial-acquisition counter with the correct information to keep track of the ramps
  - The TC3Ax SPU will process 4 ramps and then stop. The TC3Ax SPU DONE interrupt will then trigger the CPU to process the data. The CPU can then take decisions on how to best configure the TC3Ax SPU for the remainder of the measurement cycle
  - The Partial-acquisition counter will continue to track ramps. If the ramp counter reaches six (i.e. the seventh ramp has started) without the PACTR register being updated by the CPU, then the error interrupt will be asserted. This would indicate that the expected reconfiguration time has been exceeded.
- The CPU reprograms the TC3Ax SPU for the remainder of the measurement cycle<sup>1)</sup>. The partial-acquisition counter trigger bit is set and the error bit is set. The CTRL.MODE bitfield must be set to INT or EXT<sup>2)</sup>. The partial-acquisition counter is not reset.
  - The TC3Ax SPU is triggered at the start of ramp seven and the data from the seventh ramp to the one thousand and twenty-fourth ramp is acquired and processed. This trigger must be an internal trigger.
  - Setting the error bit eliminates the race condition of the start of the seventh ramp occurring between the write to the PACTR register and the write to the CTRL register. The error interrupt will be gated if TRIG is set and the CTRL register has been written with MODE=INT or with MODE=EXT and an external trigger has occurred.

The partial-acquisition counter can only be used to monitor input data sourced from the Radar Interface. It cannot be used to track data loaded from Radar Memory.

### Notes

1. *The TC3Ax SPU can process data from the Radar Memory without impacting the operation of the Partial Acquisition Counter once it is configured and running*
2. *Setting the partial acquisition trigger (PACTR.TRIG = 1) without enabling the counter (PACTR.EN = 0) will still enable the trigger logic. Incoming Data will be filtered indefinitely waiting for a limit event which will not occur*

### 20.3.1.4 FFT Data to Antenna Mapping

Some processing units (e.g. the complex windowing function) require that each set of FFT data be associated with an antenna. This is done using the information stored in the ID\_RM\_CONF2.PM and ID\_RM\_CONF2.AM bitfields.

If ID\_RM\_CONF2.PM is set to 1<sub>B</sub>, then the buffer memory datablock will contain one dataset from each antenna. The processing units will therefore use the dataset index to identify the antenna.

If ID\_RM\_CONF2.PM is set to 0<sub>B</sub>, then the data block is assumed to contain data from a single antenna. In this case, the setting of ID\_RM\_CONF2.AM is used to define which of the loop repeat counters (Inner Loop Repeat or Outer Loop Repeat) is used to generate the antenna ID. Alternatively, the antenna ID can be forced to either 0<sub>D</sub> or

---

1) The reconfiguration of the TC3Ax SPU is not expected to change any setting in the ID\_CONF or ID\_CONF2 registers except the ID\_CONF.RAMPS field as the RIF(s) are still running the same measurement cycle and the format of the data input should not have changed. This restriction means that, although BYPASS could be used, reloading bypassed data before the end of the measurement cycle (i.e. in the gaps between partial acquisitions) is not supported.

2) If the partial-acquisition Counter trigger condition is reached before the CTRL register is programmed to enable the TC3Ax SPU, then an error interrupt will always be generated.

## Signal Processing Unit 2 (SPU2)

“dataset index” (equivalent to ID\_RM\_CONF2.PM=1<sub>B</sub>). If the antenna ID is derived from one of the loop counters, only the three LSBs of the counter will be used to keep the antenna ID within the permitted range of 0<sub>D</sub> to 7<sub>D</sub>.

The loop repeat counter value used is chosen at the point the buffer memory is filled and before the counter is incremented for reading the next data, This leads to the following effects:

- If ID\_RM\_CONF2.AM is set to BLR, the antenna ID will always be the three LSBs of the BLR value in the RM\_BLR register.
- If ID\_RM\_CONF2.AM is set to ILR, the antenna ID will be as follows
  - for the final data block before incrementing the Outer Loop Counter, the antenna ID will be the 3 LSBs of the ILR value in RM\_IOLR
  - for other data blocks, the antenna ID will alternate between 3<sub>D</sub> and 7<sub>D</sub> for 32 bit precision complex data and will always be 7<sub>D</sub> for 16 bit precision data (real or complex format) or power data.
- If ID\_RM\_CONF2.AM is set to OLR, the antenna ID will start at 0<sub>D</sub> and will then increment every time the Outer Loop Counter is incremented. If ID\_RM\_CONF2.BLOCKS is not equal to zero, the value will be the final value of the Outer Loop Counter when the IDM completes loading of the buffer memory

### 20.3.1.5 Reading Power Data From Radar Memory

The Input DMA will normally read complex data from the Radar Memory as this is the expected format of FFT results. However, in some cases, further analysis of linear power data stored by a previous processing pass of the TC3Ax SPU may be desirable. This data may be stored as 32 bit unsigned integer or 16 bit IEEE 754 Half Precision Floating Point format and ID\_RM\_CONF2.FORMAT has options for reading these data.

These settings are intended to allow power data to be processed by the MATH2 units and must only be used with the FFT accelerator and MATH1 complex data specific functions bypassed or disabled.

### 20.3.1.6 Reading 16 bit Real Data From Radar Memory

The Input DMA will normally read complex data from the Radar Memory as this is the expected format of FFT results. However, in some case, memory restrictions may require data to be stored as 16 bit precision, real only data. Reading 16 bit precision, real data can be done by setting ID\_RM\_CONF2.FORMAT to REAL16BIT for integer data or REAL16FP for half precision floating point. If either of these options is used, then address transpose mode is not available and ID\_RM\_CONF2.TRNSPS must be set to 0<sub>B</sub>.

#### 20.3.1.6.1 Buffer Memory Switching for 16 bit real data

If the ID\_RM\_CONF2.PM bit is set to IM, this signals that the data block should contain one dataset for each antenna (i.e. the Inner Loop Offset is set to step across antennae) and the Buffer Memory will be switched when the Inner Loop Repeat Count is reached. Otherwise, the Input Buffer Memory will be switched every eight iterations of the Inner Loop or when all data has been read whichever occurs first.

### 20.3.1.7 Reading Half Precision Floating Point Data From Radar Memory

For half precision floating point, denormalised numbers, Infinities and NaNs should be avoided in the input data. Denormalised numbers will be treated as zero. Infinities and NaNs will be set to either maximum negative or maximum positive values depending on the sign bit to allow processing to continue and will not propagate. The TC3Ax SPU has no capability to process signalling NaNs.

### 20.3.1.8 Reading Compressed Complex Data From Radar Memory

Data written to Radar Memory by the TC3Ax SPU in compressed format using ODP\_CONF.COMPRESS==1 may be read by the TC3Ax SPU by setting RM\_CONF2.FORMAT to COMPRESS. The data is unpacked such that each bin

## Signal Processing Unit 2 (SPU2)

uses the same number of bits as 16-bit complex data in the Buffer Memory. The Data Loader Unit converts the unpacked data into 32-bit complex. See “[Data Loader Unit](#)” on Page 17 for details.

### 20.3.1.9 Data Storage in Buffer Memory

The datasets will be stored linearly in the buffer memory in the order they should be processed. This allows the Data Loader module to progress sequentially through the buffer memory address space.

### 20.3.2 Streaming Processor 1

Streaming Processor 1 retrieves data from the buffer memory loaded by the Input DMA Engine and processes the information for use by the FFT accelerator

#### 20.3.2.1 Double Pass Mode

The TC3Ax SPU allows all processing operations to be run twice per data block. This mode is enabled using the DPASS\_CONF.EN bitfield. Once the data has been loaded to Buffer RAM by the Input DMA Engine, the subsequent modules in the processing pipeline have the option to

- read the data twice and apply different processing options. This is the default “double pass” mode
- independently apply the different parameter sets defined for the window function to successive sequences of data blocks. See [Section 20.3.2.1.2](#) below.

This results in two sets of results being written to Radar Memory.

**Table 786 Parameters Specific to Double Pass Mode**

Parameter	Definition	Comments
Enable Mode	Configure TC3Ax SPU to process each data block twice.	<b>DPASS_CONF.EN</b>
Switch Mode	Configure TC3Ax SPU to process successive data blocks with different parameter sets. Number of data blocks between parameter switches configured by DPASS_CONF.COUNT	<b>DPASS_CONF.SWITCH</b>
Window Parameter Switch Count	Switch the window parameters when this many data blocks have been processed	<b>DPASS_CONF.COUNT</b>
Window Parameter Switch Count Enable	Enable the Window Parameter switch count	<b>DPASS_CONF.EN_CNT</b>

The values to be used in the second processing pass are stored in the BE1\_<REGNAME> registers.

The following register fields should not be changed between processing passes. A write to these fields in either copy of the register will be reflected in both registers.

## Signal Processing Unit 2 (SPU2)

**Table 787 Mirrored Register Fields**

Register	Field
LDR_CONF	DRPL
	DRPF
	EXPNT
	SIZE
	FFTBYPS
	IFFT
LDR_CONF2	PADF
	PADDIS
UNLDR_CONF	FORMAT
	EXPNT

**Note:** Note that the mode of the FFT module (FFT or IFFT) cannot be varied between passes so the LDR\_CONF.IFFT bit is mirrored.

### 20.3.2.1.1 Double Pass Switch Mode

The behaviour of Double Pass Mode can be modified by setting the DPASS\_CONF.SWITCH bitfield. In this case, each data block is only processed once and the different parameter settings are applied to consecutive data blocks.

### 20.3.2.1.2 Window Parameter Switch

The switch of the two possible sets of parameters for the window function can be made independent of the double pass functionality by setting the DPASS\_CONF.EN\_CNT. When this bit is set, the window parameters are selected independently of the double pass function and applied to sequences of data blocks. The number of data blocks per sequence is configured by the DPASS\_CONF.COUNT bitfield and is set to COUNT+1. If COUNT=0, then the different parameter settings are applied to alternate data blocks. If COUNT=7, then the different parameter settings are applied to sequences of 8 data blocks.

### 20.3.2.2 Data Loader Unit

The Data Loader will read data from memory and reformat it before pushing it into the MATH0 and MATH1 unit pipelines.

#### 20.3.2.2.1 Data Reformatting for MATH0

As only ADC data is sent to MATH0, the only reformatting is conversion from unsigned to 2's complement format when the Input DMA configuration has ID\_CONF2.SIGNED == UNSIGNED. In this case the DC Offset Removal function handles the reformatting (see “DC Offset Removal” on Page 21 for details). When the input is complex this conversion is done separately for both the real and imaginary components.

#### 20.3.2.2.2 Data Reformatting for MATH1

The format of the input data can reformat input data by resizing it from 16 to 32 bit precision and by converting it from real to complex format. Operations will occur in the following order

## Signal Processing Unit 2 (SPU2)

- 16 to 32 bit precision
- real to complex conversion

**Table 788 Loader Configuration Parameters**

Parameter	Definition	Comments
Number of samples	Number of samples per FFT currently in the buffer RAM	Passed from the Input DMA Engine
Number of data sets	Number of FFTs to run	Passed from the Input DMA Engine
Data precision	16 or 32 bits	Passed from the Input DMA Engine
Data type	Real or complex	Passed from the Input DMA Engine
Data format	Integer, floating point or compressed	Applicable to Radar Memory data only. Passed from the Input DMA Engine
Integration Mode Bandwidth Optimisation	Buffer Memory Configuration. Number of Datablocks in the buffer memory	Passed from the Input DMA Engine
Signed or Unsigned	Input Data is unsigned or 2's complement format	Applicable to ADC data only, passed from the Input DMA Engine

### Data Reformatting

The format of the data in the buffer memory is known as it is programmed into the Input DMA Engine configuration. All data to be processed by the FFT accelerator must be in 32 bit complex format.<sup>1)</sup> Real data is converted to complex data with a zero imaginary component. 16 bit data is extended to 32 bit using the method specified by the LDR\_CONF.EXPNT bitfield. This controls how the 16 bit data is justified within the 32 bit output field. The type of data (signed or unsigned) is passed from the Input DMA Engine and is derived from the ID\_CONF2.SIGNED bitfield. This determines whether a signed or unsigned extension to 32 bits is used. When MATH0 is enabled and not bypassed the data is always sign extended because the DC Offset Removal function converts to signed data.

When using data from Radar Memory, LDR\_CONF.EXPNT has a maximum permissible value of  $16_D$  and aligns 16 bit fixed exponent format data. When using data from the Radar Interface, the number of significant bits can be less than  $16_D$  so the maximum permissible value of LDR\_CONF.EXPNT can be increased to allow for 10 bit data right aligned in the 16 bit field.

If the shift operation causes a loss of significant data bits, then the output of the shift operation will saturate at full scale.

If the input data format is complex, then both real and imaginary components are treated in the same manner.

If the input data format is compressed (ID\_RM\_CONF2.FORMAT=COMPRESS) then the LDR\_CONF.EXPNT field has no effect. The unpacked compressed data in the Buffer RAM is expanded to 32-bit complex data.

### Integration Mode Bandwidth Optimisation

This is described in [Chapter 20.3.1.2.6, “Bandwidth Optimisation Integration Processing Mode.” on Page 12.](#)

1) The FFT accelerator itself operates on 24-bit data internally but the rest of the FFT data path is 32-bits.

## Signal Processing Unit 2 (SPU2)

The Integration Mode Bandwidth Optimisation of the Input DMA Engine results in multiple datablocks being present in the buffer memory. The Buffer memory would normally be switched between datablocks. When this mode is enabled, instead of switching the buffer memory, the buffer memory address is offset to point to the next datablock. The MATH1, FFT and all units downstream of this point therefore see separate datablocks as normal.

### 20.3.2.3 MATH0 Unit

The MATH0 unit handles processing of ADC data<sup>1)</sup> before it is passed to the MATH1 unit. It has time-domain interference detection and removal functions as well as a DC offset removal function. The interference is assumed to occur in one or more bursts within a ramp. The unit may be bypassed by setting M0CTRL.BYPASS bitfield. When bypassed, the unit may still process data, writing it to Radar Memory. It may also detect interference bursts, recording their locations in registers without writing any data to Memory. The MATH0 unit processes data on a ramp-by-ramp and antenna-by-antenna basis as it comes out of the Buffer RAM. This means, at any one stage in the processing, only samples from one antenna are available in the unit.

The MATH0 unit has a double buffer with two banks, called the Ramp Buffer, and each bank has capacity to hold two copies of a whole ramp from one antenna. The buffer has two write channels and two read channels with one read and one write per bank. Data flows along two paths in MATH0: forwards and backwards as shown in “[MATH0 Unit Architecture](#)” on Page 20. This enables the signal to be filtered in both directions from the start and end of each interference burst.

When MATH0 is active data is read from the Buffer RAM starting with the last sample in a ramp in reverse order. Otherwise data is read starting with the first sample in natural order. The DC Offset and Transient Removal functions operate on a sample-by-sample basis and have no state so they not affected by the order of the data. One copy of data is loaded into Ramp Buffer after optional processing by these units. The same data is also fed to the Detector and Backwards Filter and the filtered output is written into Ramp Buffer.

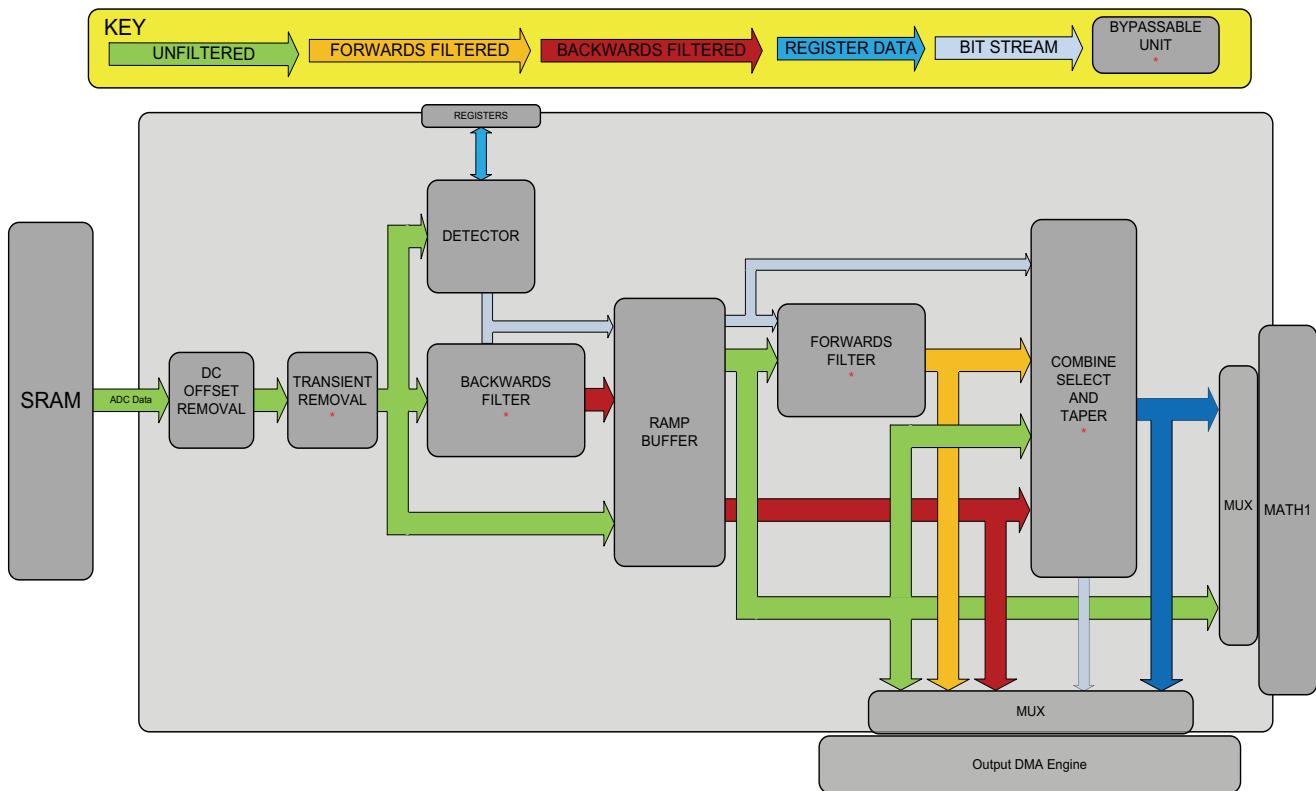

The data is read out of the Ramp Buffer in two streams, filtered and unfiltered such that the data samples are in their original order and aligned to each other. The unfiltered data is filtered by the Forwards Filter. The forwards and backwards filtered data are fed along with the unfiltered data to the Combine Select and Taper (CST) unit.

The Detector unit operates on backwards data so that it is able to control the backwards filter directly. The location of any detected interference is recorded in a set of registers and presented as a bit stream to the filter and the Ramp Buffer. The Detector results are then read in the correct order to be used by the subsequent units that operate in a forwards direction.

All of the units marked with a star (\*) in [Figure 258 “MATH0 Unit Architecture” on Page 20](#) are bypassable. When MATH0 is bypassed by setting M0CTRL.BYPASS data will still be processed by the DC Offset and Transient Removal units if they are enabled. MATH0 functions are not supported when ID\_CONF2.SRC==RM and the unit should be disabled by clearing M0CTRL.EN.

<sup>1)</sup> MATH0 can only process data when ID\_CONF2.SRC==RIF or BYPASS. Enabling MATH0 when ID\_CONF2.SRC==RM MATH0 is not supported.

## Signal Processing Unit 2 (SPU2)

**Figure 258 MATH0 Unit Architecture**

**Table 789 MATH0 General Configuration**

Parameter	Definition	Comments
Operating mode	Select the type of data being processed: real or complex	<b>ID_CONF2.FORMAT</b> Controlled by the IDM FORMAT
Operating mode	Select the type of data being processed: unsigned or signed	<b>ID_CONF2.SIGNED</b> Controlled by the IDM FORMAT NB This setting only affects sign/zero extension for DC offset removal
Enable	Enable the unit.	<b>MOCTRL.EN</b> Enabling MATH0 with ID_CONF2.SRC==RM is not supported
Bypass	Bypass MATH0 and send data directly to MATH1 after DC Offset and Transient Removal. Data is still processed by MATH0 and available for writing to Radar Memory	<b>MOCTRL.BYPASS</b>
Output base address	Address in the Radar Memory where MATH0 will write data if enabled by RPLCTRL.OSEL	<b>MOCTRL.BASE</b>

## Signal Processing Unit 2 (SPU2)

**Table 789 MATH0 General Configuration (cont'd)**

Parameter	Definition	Comments
Output data enable and selection	Selects what data is written to Radar Memory. See “ <a href="#">Output to Radar Memory</a> ” on Page 27 for details.	RPLCTRL.OSEL
Number of samples per ramp	The number of samples per ramp is defined by the Input DMA configuration. When the MATH0 unit is enabled, the minimum number of samples allowed is 128.	ID_CONF.SMPLCNT

### 20.3.2.3.1 DC Offset Removal

This unit subtracts the mean value, calculated over a complete ramp, from each sample giving a resulting data stream that is free of any DC offset. The mean value is calculated as the data is written to the Buffer RAM so that it is available when the first sample is read from the Buffer RAM. For complex data, a separate mean is calculated for the real and imaginary components and these are subtracted from the relevant component in each sample.

When ID\_CONF2.SIGNED=UNSIGNED the data input to DC Offset Removal is zero extended to 17 bits to convert to a signed value without loss of precision. The output from DC offset is saturated to a signed 16-bit value. The rest of MATH0 operates on signed ADC data. The calculation of the DC offset shall be performed to a precision of plus or minus one LSB of the 16-bit value provided the correct reciprocal value is configured in the SCRECIP register.

The operation of Data Reformatting is affected when MATH1 receives data from MATH0 (see “[Data Reformatting for MATH1](#)” on Page 17 for details).

**Table 790 DC Offset Removal Configuration**

Parameter	Definition	Comments
Enable	DC offset removal is always enabled if MATH0 is enabled	M0CTRL.EN
Sample Count Reciprocal	DC offset calculates the mean value using a reciprocal of the number of samples programmed in this register	SCRECIP.EXP SCRECIP.MANT

### 20.3.2.3.2 Transient Removal

This unit compares each sample magnitude with a threshold magnitude and replaces any sample that exceeds that threshold with a new value depending on the mode controlled by M0CTRL.TRRM. The function of this unit is described by the following equation:

(20.1)

$$f(x) = \begin{cases} \text{VALUE, if } |x| > \text{THRESH} \\ x, \text{ otherwise} \end{cases}$$

where VALUE is either zero or  $\text{sgn}(x) \times \text{THRESH}$  depending on the value of M0CTRL.TRRM. Also the  $\text{sgn}()$  function takes the sign of its argument.

## Signal Processing Unit 2 (SPU2)

**Table 791 Transient Removal Configuration**

Parameter	Definition	Comments
Enable	Remove transients if set otherwise pass input unchanged	<b>M0CTRL.TREN</b>
Mode	When a sample exceeds the threshold, set to zero value (ZERO) or the threshold value (THRESHOLD)	<b>M0CTRL.TRRM</b>
Threshold	The magnitude threshold value to compare with the magnitude of the sample value	<b>TRTHRESH.THRESH</b>

### 20.3.2.3.3 Interference Detection

The Interference Detector function identifies any parts of the ADC input stream where the difference in power level from one sample to the next exceeds a configurable threshold, DETCFG.THRESH. It includes an optional high-pass filter before linear power and difference calculation. The power difference is compared with the configurable threshold and the result is feed to a delay line with a configurable number of bits. Each bit that is a one represents a sample where the power difference threshold is exceeded. The number of bits that are one in the delay line is counted and this population count is compared to another configurable threshold, DETCTRL.PCTHRESH.

The Detector operates on sample data stream read from the Buffer Memory so that it may control the backwards filter. The output from the Detector is also used by the forwards filter and the Combine Select and Taper (CST) unit. The detection information is re-ordered as necessary before being passed to these units or being output to Memory.

The Detector may be configured to write the detection results to Memory using DETCTRL.OE. The output consists of a stream of bits, one per input sample in the forwards direction. A given bit is set if interference has been detected according to the algorithm, otherwise the bit shall be zero. The bit stream is packed into 256 bit words before being written to memory. Any remaining data at the end of a measurement cycle shall be padded with zeros to 256 and flushed to Memory. When double pass is active two sets of data shall be written to Radar Memory.

Any interference bursts that are detected are also recorded in a set of status registers MDM0\_CNT and MDM0\_BURSTb. This data is also stored in order in a forwards direction. These registers are written by hardware and may only be read by software. The CST unit also uses this data to locate any bursts. If there are more than  $16_D$  bursts in a ramp, only the last  $16_D$  will be seen by the unit. A flag is set in MDM0\_CNT when the CST unit gets inconsistent burst data.

The high-pass filter is a discrete realization of a first order RC filter where each output  $y$  is given by:

(20.2)

$$y_i = \alpha \times (y_{i-1} + x_i - x_{i-1})$$

Where  $x_i$  and  $x_{i-1}$  are the current and previous input samples. The real fractional coefficient, alpha, is configured by an 8-bit unsigned bit-field called DETCTRL.ALPHA. The output of the filter is saturated to 16 bits. The feedback term  $y_{i-1}$ , begin the previous filter output, is represented as a signed 18-bit value. The 8 LSBs of the product are

## Signal Processing Unit 2 (SPU2)

dropped and the result of the sum, inside the parentheses are saturated to 18 bits. When in complex mode each component, real and imaginary, is filtered separately.

### Detector Configuration and Status

**Table 792 Interference Detection Configuration**

Parameter	Definition	Comments
Enable	Enable the detector	<b>DETCTRL.EN</b>
Output enable	If set when EN set, write a bit mask to Radar Memory starting at the location defined in DETBASE.BASE.  Note: <i>When EN is not set this bit is ignored.</i>	<b>DETCTRL.OE</b>
High-pass filter enable	When set to OFF, the filter will be bypassed.	<b>DETCTRL.HPFEN</b>
High-pass filter coefficient	Defines the cut-off frequency of the filter. Setting to zero will disable the detector function.	<b>DETCTRL.ALPHA</b>
Detection power difference threshold	When the power difference is greater than this value a one is feed into the detection window delay line.	<b>DETCFG.THRESH</b>
Detection window size	The number of samples either-side of the current sample. The total number of samples in the window is 1+2xWINSIZE.	<b>DETCTRL.WINSIZE</b>
Population count threshold	The threshold applied to the population count. When set to zero only one sample needs to exceed the power difference threshold.	<b>DETCTRL.PCTHRESH</b>

**Table 793 Detector Status**

Parameter	Definition	Comments
Burst count	Incremented each time an interference burst is detected and a MDM0_BURSTb register is set by the hardware. Reset at the start of a measurement cycle.	<b>MDM0_CNT.CNT</b>
Burst count overflow	Set if the count overflows. Stays set and only gets reset when the SPU is triggered.	<b>MDM0_CNT.OV</b>

## Signal Processing Unit 2 (SPU2)

**Table 793 Detector Status (cont'd)**

Parameter	Definition	Comments
Excess bursts detected	Set if CST gets inconsistent burst data. Stays set and only gets reset when the SPU is triggered.	<b>MDM0_CNT.XS</b>
Burst descriptor	A set of sixteen registers that describe a burst by its ramp number, location in that ramp and its length. The START and LENGTH fields are set according to the detection on first antenna/channel of the ramp number given in the NUM field. A zero value of LENGTH equates to a burst with one sample in it.	<b>MDM0_BURSTb (b=0-15)</b>

**Note:** *The detector burst descriptor metadata is collected on a ramp-by-ramp basis because it is assumed that any interference will affect all antennae in a similar way. Given that the ADC sample rate is of the order of one thousandth of the Radar frequency this assumption can be seen to hold for all use cases.*

### 20.3.2.3.4 Ramp Buffer

The ramp buffer allows each ramp to be filtered from the beginning forwards and from the end backwards for each detected burst. The data is read once from the Buffer RAM and stored twice in the ramp buffer, once before backwards filtering and once after. The filter buffer has two banks so that a second ramp may be written while the first is being read. This double buffering is necessary because the whole ramp must be stored to be able to access it in both directions.

Each ramp buffer memory bank is large enough to hold two complete 2048 sample ramps where each sample is a 16 bit real value. For complex ADC data, the maximum number of samples that can be stored per ramp is halved.

### 20.3.2.3.5 Filtering

There are two identical filter units both configured by the same set of registers, with the exception of the FILTCTRL.CONJ bitfield. Each implements an Infinite Impulse Response (IIR) filter which includes a recursive section and a non-recursive section. The only difference between the two units is that each operates on data samples in opposite orders, forwards and backwards. The input and output data are treated as signed fixed point data with one integer bit and 15 fractional bits. The coefficients are treated as signed fixed point data with three integer bits and 13 fractional bits. The output of each filter is saturated to the minimum and maximum representable values while the internal feedback path for the recursive section is not saturated.

The filters are enabled by FILTCTRL.EN. When not enabled they are bypassed and data flows directly to the next stage: the Ramp Buffer for the backwards filter and the Combine Select and Taper unit for the forwards filter. When the filters are enabled and there is no interference detected the filters are transparent with their output being equal to their input but they maintain their state by shifting the input sample values into the delay line.

The filter unit has a configurable delay line allowing the taps to be allocated between a recursive section and non-recursive section. The non-recursive section holds delayed input samples and the recursive section holds delayed output samples. The delay line has a total of 16 16-bit elements. These elements may be allocated to the recursive section by setting the number of recursive coefficients in FILTCTRL.NCOEFR. The remaining 16 - NCOEFR coefficients are available to the non-recursive section. The number of non-recursive coefficients that are active is defined by FILTCTRL.NCOEFNR. By setting FILTCTRL.NCOEFR to zero, the filter becomes entirely non-

## Signal Processing Unit 2 (SPU2)

recursive, in other words, it shall be a Finite Impulse Response filter (FIR). By setting FILTCTRL.NCOEFR to zero, the filter becomes a resonator as the input signal has no effect on the output. Setting both FILTCTRL.NCOEFR and FILTCTRL.NCOEFNR to zero shall result in the output from the filter being zero always.

When ID\_CONF2.FORMAT==COMPLEX and the unit is operating on complex data, two delay elements are used for each sample and the coefficients are used pairs. In this mode the LSB of NCOEFR shall be ignored and the number of complex coefficients shall be the value in the MSBs of that field.

The values in the FILTCOEFc registers shall be used in the recursive section starting with the lowest numbered register field first. So, FILTCOEF0.C0 shall be the factor used to multiply the filter output delayed by one sample, FILTCOEF0.C1 for the filter output delayed by two samples and so on. The coefficient values shall be used in the non-recursive section starting with the highest numbered register field first. So FILTCOEF8.C1 shall be the factor used to multiply the filter input, FILTCOEF8.C0 shall be the factor for the filter input delayed by one sample and so on.

When ID\_CONF2.FORMAT==COMPLEX one complex coefficient is held in each register with C0 holding the real part and C1 holding the imaginary part.

The initial filter state at the start of a burst is set to the last N input samples. The samples are loaded into the filter delay lines and moved along as if the filter were operating normally except that, when no interference is detected, the filter output is kept equal to its input. The value of N in this case is notional given the number of taps in the relevant filter section, recursive or non-recursive, may be different to each other. Each section of the filter shall be initialised with the appropriate number of data samples. If an interference burst occurs at the start or end of a ramp and less than N samples have been loaded into the filters, the un-initialized filter taps shall have zero values.

**Table 794 Filter Configuration**

Parameter	Definition	Comments
Enable	Enable filtering, bypass	FILTCTRL.EN
Number of recursive coefficients	Allocate this many of the available coefficients to the recursive section. The rest are available to the non-recursive section.	FILTCTRL.NCOEFR
Number of non-recursive coefficients	Allocate this many of the available coefficients to the non-recursive section. NCOEFR takes priority so the maximum value of non-recursive real coefficients can never be more than 16 - NCOEFR (8 - NCOEFR for complex)	FILTCTRL.NCOEFNR
Coefficient conjugation	Enable conjugation of complex coefficients in the backwards filter. Has no effect on the forwards filter. Has no effect when ID_CONF2.FORMAT==REAL	FILTCTRL.CONJ
Filter coefficients	A set of 8 registers containing 16 16-bit values used for coefficients.	FILTCOEFc (c=0-7)

### 20.3.2.3.6 Combine Select and Taper

This Combine Select and Taper (CST) unit has three sample data inputs and one control input from the Detector unit. It outputs data to MATH1 and, optionally, to Radar Memory. The unit has two operating modes called SOFT

## Signal Processing Unit 2 (SPU2)

and HARD, selected by the RPLCTRL.MODE field. In SOFT mode the unit is controlled by a set of BURSTb registers while in HARD mode the Detector output is the control. For each sample the unit selects between the unfiltered input and a replacement sample value. The replacement value is control by the RPLCTRL.SRC field and may be one of the following:

- ZERO - if tapering is enabled the last sample before the burst is held at the filter inputs otherwise the combined output of CST unit shall be zero for all samples in a burst
- FILTER - the mean of the forward and backward filter outputs with optional tapering
- FORWARD - the output of the Forward filter

**Table 795 Combine Select and Taper Configuration**

Parameter	Definition	Comments
Enable	Enable replacement of samples.	RPLCTRL.EN
Source	Select the source of replacement samples.	RPLCTRL.SRC
Mode	Select what determines the replacement. SOFT mode uses BURSTb registers, HARD uses the output of the Detector	RPLCTRL.MODE SOFT or HARD
Number of Bursts	Used when MODE==SOFT, defines how many bursts are to be replaced	RPLCTRL.NBURSTS
Burst Descriptors	Used when MODE==SOFT. Each register describes a burst in terms of the ramp number (NUM) and sample number (START) and its length (LENGTH). The burst length is LENGTH+1 so the minimum length is 1.	BURSTb These registers are programmed by software. The MDM0_BURSTb registers are written by the Detector Function.
Tapering enable	Enable tapering of the replacement samples.	RPLCTRL.TPREN

### Soft Mode

When RPLCTRL.MODE==SOFT the CST function uses the BURSTb registers to determine where to replace samples. The fields of BURSTb are defined in the same way as the metadata MDM0\_BURSTb. The RPLCTRL.NBURSTS field defines how many of the BURSTb registers shall be used. The BURSTb registers shall be used in numerical order from BURST0 to BURST{NBURSTS}. If NBURSTS==0<sub>D</sub> then no samples shall be replaced. Longer burst lengths may be programmed than would be possible with the LENGTH field size of 10 because abutting or overlapping bursts shall be treated as a single burst.

### Tapering when FILTER is Replacement Source

The tapering function for the filter source is calculated by finding the 16-bit reciprocal of the burst length (DELTA) and using this to decrement a tapering value  $t_i$  that starts at 1.0, represented as an unsigned 16 bit value FFFF<sub>H</sub>. When the burst length is one, and the LENGTH field of the burst descriptor is zero DELTA shall be zero. When the burst length is two DELTA shall be FFFF<sub>H</sub>. For all other burst lengths the DELTA value shall be calculated such that the tapering value always reaches zero, with a tolerance of 1 LSB, by the last sample in the burst. The tapering value must never wrap past zero. The tapering value shall decrease monotonically over the whole burst and be correct to within plus or minus one LSB.

## Signal Processing Unit 2 (SPU2)

The tapering operation used for the filter replacement source (SRC==FILTER) is calculated by first subtracting the forwards filter output sample from the backwards filter sample to yield a 17 bit value. This is multiplied by the current 16-bit unsigned taper function value producing a signed 33 bit value. That maximum negative value this product can take is  $\text{FFFF}_{\text{H}}$  because the maximal operands are  $\text{FFFF}_{\text{H}}$  and  $10001_{\text{H}}$  (max negative - max positive). The signed 16 bit value taken from bits 31:15 of this result is then subtracted from the signed 17-bit value of the sign-extended current backward filter output. The 17-bit result of this subtraction operation can never overflow 16 bits because the calculation always gives a value in the inclusive range between the values of the forwards and backwards filter outputs. The output is taken from bits 15:0 of the subtraction result. This calculation is shown the following equation:

(20.3)

$$\text{out}_i = \text{backward}_i - t_i \times (\text{backward}_i - \text{forward}_i)$$

If RPLCTRL.TPREN is not set when RPLCTRL.SRC==FILTER then the output of the tapering unit shall be the mean of the forwards and backwards filter outputs. This is calculated by adding the sample values and shifting right by one place, truncating to 16 bits.

### Tapering when ZERO is Replacement Source

When tapering is enabled the inputs to the filters are held at the last sample value before the burst for the duration of an interference burst. The combined output shall be calculated in the same way as when RPLCTRL.SRC==FILTER and tapering is disabled giving the mean of the two filter outputs.

When tapering is disabled the samples between START and START+LENGTH-1 of a burst shall be all replaced with zero in the combined output.

### Bursts at the Start or End of a Ramp

When a burst is at the start or end of a ramp there is no data before or after the burst to use in the replacement functions. In these cases zero sample values shall be used in place of the missing data.

#### 20.3.2.3.7 Output to Radar Memory

The MATH0 unit has two output channels, one for the detector bit stream and the other for sample data.

The detector bit stream is only available as an output if the CST function is in HARD mode. The bit stream output is packed into 256-bit words with any unused bits in the last word of a measurement cycle being set to zero.

The sample data output may come from one of the following sources in the MATH0 unit:

- The output of the Combine Select and Taper unit
- The output of the filters - both filter outputs are interleaved
- The output of the Transient Removal unit - this output is still available if the unit is bypassed

The format of this output data is defined by ID\_CONF2.FORMAT being either 16-bit real or 16-bit complex and shall be capable of being read by the IDM with suitable parameter settings. Specifically, data shall be padded with zeros to fill the last 256-bit word at the end of each FFT data set to ensure the next data starts at a 256-bit word boundary.

## Signal Processing Unit 2 (SPU2)

**Table 796 Output Configuration**

Parameter	Definition	Comments
MATH0 Output select	Select which, if any, data is output for Radar Memory	<b>RPLCTRL.OSEL</b>
MATH0 Output Base Address	Base address of where in Radar Memory data shall be written	<b>M0CTRL.BASE</b>
Detector Output enable	Enable output of detector bit stream to Memory	<b>DETCTRL.OE</b>
Detector Output Base Address	Base address of where in Radar Memory data shall be written	<b>DETBASE.BASE</b>

### 20.3.2.4 MATH1 Unit

The MATH1 unit handles transforms applied to the data before the FFT processor. The operations will be applied in the following order:

- Zero Insertion
- Truncation
- Windowing
- Phase Shift
- Padding

**Note:** All of these operations except Zero Insertion are available even if the FFT Engine is bypassed by setting the LDR\_CONF.FFTBYP bit.

**Table 797 MATH1 Configuration Parameters**

Parameter	Definition	Comments
Number of samples	Number of samples per FFT to be loaded into the FFT accelerator	<b>LDR_CONF.SIZE</b>
Number of data sets	Number of FFTs to run	passed from the Loader Unit
Zero insertion enable	Enable zero insertion function Function not available when LDR_CONF.FFTBYP is set.	<b>LDR_CONF2.ZI</b>
Zero insertion mask	A set of registers defining a mask of up to 256 bits	<b>ZI_MASKn</b>
Window base address	Base address in Config Memory where the windowing functions are stored	<b>LDR_CONF2.WBASE</b>
Antenna window offset address	Offset from the Window base address of the window function for a particular antenna	<b>Ax_ANTFOST.ADROFSTy</b> <b>where x=0-3,y=0-1</b>
Padding activation	Padding enable / disable	implicit activation when the FFT size from the loader does not match the FFT size for the FFT accelerator

## Signal Processing Unit 2 (SPU2)

**Table 797 MATH1 Configuration Parameters (cont'd)**

Parameter	Definition	Comments
Leading padding	Position of the 1st operand in the FFT (others being zeroed).	<b>LDR_CONF2.PADF</b>
Padding disable	Disable padding if LDR_CONF.FFTBYPSET	<b>LDR_CONF2.PADDIS</b>
Fast phase shift	Does a 0/90/180/270 phase shift without using the windowing memory	<b>LDR_CONF.PHSHFT</b>

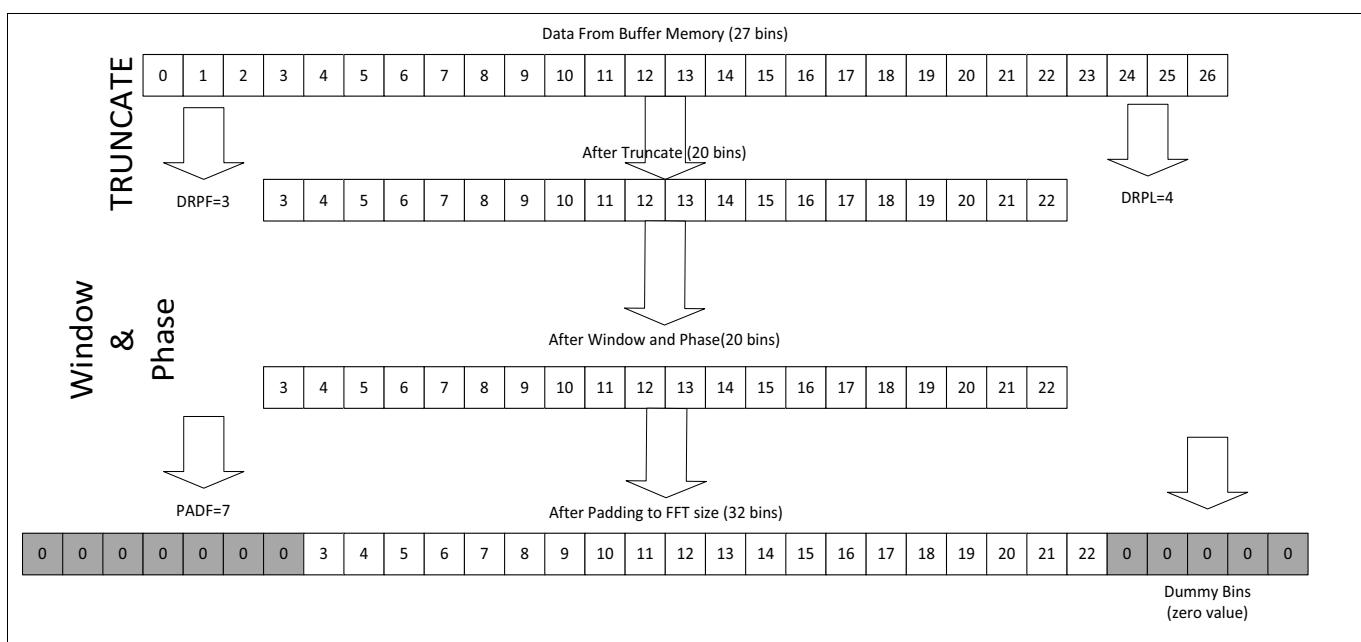

### 20.3.2.4.1 Zero Insertion

The Zero Insertion function is enabled by the LDR\_CONF2.ZI bit. When enabled no truncation nor leading padding shall be performed (LDR\_CONF2.PADF shall be ignored). The input data is read from the Buffer Memory according to the bit mask held in the ZI\_MASKn registers and the FFT size defined by LDR\_CONF.SIZE. For each integer K from zero up to LDR\_CONF.SIZE-1 the corresponding bit b in ZI\_MASKn, where n = K DIV 32 and b = K MOD 32, is tested. If the bit is 1<sub>B</sub>, the next data sample is read from the Buffer Memory and passed to the windowing function, otherwise a zero value is passed. If the number of ones in the bit mask is not equal to the number of samples defined by the Input DMA Engine configuration, the behaviour of Zero Insertion is not defined. If LDR\_CONF.SIZE is more than 5<sub>H</sub>, meaning the FFT size is more than 256 samples, then the FFT input samples beyond the 256th shall be set to zero when Zero Insertion is enabled.

*Note:* The Zero Insertion function is only supported when ID\_CONF2.SRC==RM

### 20.3.2.4.2 Overview of Data Truncation and Padding

The diagram below gives a functional overview of how the operations described below affect the bins of the data loaded from the buffer memory

**Figure 259 MATH1 Operation Overview**

*Note:* No truncation or padding is done if Zero Insertion is enabled.

## Signal Processing Unit 2 (SPU2)

### 20.3.2.4.3 Truncation

Truncation is performed by two register fields, LDR\_CONF.DRPF and LDR\_CONF.DRPL. The reference for the dataset size is taken from the Input DMA Engine Configuration, ID\_CONF.SMPLCNT field. DRPF is used to truncate from the beginning of the dataset and DRPL to truncate from the end of the dataset.

### 20.3.2.4.4 Windowing

Windowing is enable using the LDR\_CONF2.WINEN bit. The coefficients for the windowing function are stored in the configuration memory. The output of the windowing unit is scaled so that the maximum value of the window coefficients is  $+(2^{31}-1)/2^{31}$  and the minimum value is -1.

To retain precision, any needed truncation will be done at the output of arithmetic operations rather than the input. Where a result needs to be scaled down to fit into an output, the result will be rounded down to nearest integer after division.

The base address of the window coefficients is stored in LDR\_CONF2.WBASE. Additionally an address offset can be defined for each antenna. The offset is defined in bytes. If the address offsets are set to zero, the same window will be used for all antennae. Offsets are stored in the ANTOFST fields of the A[0|1]\_ANTOFST registers in the following order:

**Table 798 Antenna to Offset Register Mapping**

Antenna	Register	Bitfield
0	A0_ANTOFST	ADROFST0_ANT
1	A0_ANTOFST	ADROFST1_ANT
2	A1_ANTOFST	ADROFST0_ANT
3	A1_ANTOFST	ADROFST1_ANT
4	A2_ANTOFST	ADROFST0_ANT
5	A2_ANTOFST	ADROFST1_ANT
6	A3_ANTOFST	ADROFST0_ANT
7	A3_ANTOFST	ADROFST1_ANT

Antenna number selection is controlled by the ID\_RM\_CONF.AM and ID\_RM\_CONF.PM bitfields.

The window size must be the same as the truncated data set (i.e. before the padding operation).

The window data can be stored in several formats to save memory. Maximum precision is achieved using 32 bit complex window coefficients. However the data can also be stored in 32 bit real format, in which case the windowing function can affect magnitude but not phase. Further compression can be achieved by using 16 bit formats. Format is set using the LDR\_CONF.FRMT bitfield.

Window coefficients stored as 16 bit are extended to 32 bit by extending with 16 LSBs set to  $0_B$  so that the stored coefficient is left justified in the 32 bit value.

### 20.3.2.4.5 Phase Shift

The phase shift is achieved by sign manipulation of the real and imaginary components of the complex data values as described in the following table.

## Signal Processing Unit 2 (SPU2)

**Table 799 Phase Shift Operation**

Shift (degrees)	LDR_CONF.PHSHFT	Output to Input Mapping	
		Real OP	Imaginary OP
0	00	(Real IP) * 1	(Imag IP) * 1
90	01	(Imag IP) * -1	(Real IP) * 1
180	10	(Real IP) * -1	(Imag IP) * -1
270	11	(Imag IP) * 1	(Real IP) * -1

### 20.3.2.4.6 Padding

The truncated dataset is then padded to the FFT size set by the LDR\_CONF.SIZE bitfield. The LDR\_CONF2.PADF bitfield is used to determine how many zero data points are added to the front of the dataset. The remainder are added at the end.

Note that the dataset size cannot exceed the size set in the LDR\_CONF.SIZE bitfield. If the programmed value of LDR\_CONF2.PADF would violate this limit, then the behaviour of the loader is undefined but correct results will not be obtained. Similarly, LDR\_CONF.SIZE must not be set to a smaller number than the number of data points left after the Truncate operation.

When the FFT Accelerator is disabled by setting LDR\_CONF.FFTBYPS padding will still be performed unless LDR\_CONF2.PADDIS is also set. This allows data sets with non-power-of-two sizes to be passed to MATH2.

### 20.3.2.5 FFT Accelerator

The FFT accelerator uses a pipelined architecture to implement the efficient radix  $2^2$  architecture. It performs internal operations on 24-bit data. The 32-bit input data is reduced to 24-bit using the top bits (31:7) and rounding to 24 bits using the round to nearest, ties to even method. The output of the FFT accelerator is extended to 32 bits by appending 8 zero bits as LSBs.

The FFT accelerator can be completely bypassed using the LDR\_CONF.FFTBYPS bit.

When performing an FFT, the accelerator will divide the output by the number of data points in the FFT to ensure that the output data does not overflow the integer output format.

An inverse FFT can be performed by setting the LDR\_CONF.IFFT bit. Setting the mode to IFFT will disable the descaling function of the FFT accelerator IP and the output will not be divided.

**Note:** *The inverse FFT function is intended to be used to post-process FFT results to recreate the original input data. If arbitrary input data is used or windowing or scaling is applied to the FFT results before attempting an inverse FFT, an overflow may occur at the output of the FFT accelerator which would normally be compensated for by the descaling operation. This overflow will be signalled to the processor by interrupt if the STAT.INTMSK[1] bit is set.*

Note that the dataset size cannot exceed the size set in the LDR\_CONF.SIZE bitfield. The number of datapoints read from the Buffer RAM is determined by the Input DMA configuration. If the programmed values of LDR\_CONF.DRPF, LDR\_CONF.DRPL and LDR\_CONF2.PADF results in a number of datapoints that violate this limit, then the behaviour of the loader is undefined but correct results will not be obtained.

## Signal Processing Unit 2 (SPU2)

**Table 800 FFT Engine Configuration Parameters**

Parameter	Definition	Comments
FFT length	defined in the global registers as the number of operands for the inner loop	<b>LDR_CONF.SIZE</b>
FFT enable	FFT enabling / disabling	logically the same as “not FFT bypass” <b>LDR_CONF.FFTBYP</b>
Inverse FFT Mode	Configure the FFT accelerator to perform and Inverse FFT operation instead of the normal FFT	<b>LDR_CONF.IFFT</b>

### 20.3.3 Data Unloader

The Data Unloader writes the data from the FFT accelerator module into the output buffer RAM. All user programmable options are associated with the sideband processing of signal power to generate a histogram. By default, the Data Unloader writes 32 bit precision complex data to the Buffer RAM. As a space saving measure, the UNLDR\_CONF.FORMAT bitfield can be set to 16BIT and the UNLDR\_CONF.EXPNT bitfield used to set a common exponent value for the written data. The 32 bit values will then be shifted right by the number of bit positions programmed in the UNLDR\_CONF.EXPNT field before a saturating truncation to the 16 LSBs is performed (see “[Saturating Truncation” on Page 41](#) for further details). When using this mode, the value of the EXPNT should be restricted to values between 0 and 16. The behaviour of the Data Unloader with values outside this range is undefined.

If writing of 32 bit precision data is configured, then setting the EXPNT field to a non-zero value will cause the FFT output data to be shifted left by the number of bits set in the EXPNT field (preserving sign). If this causes the data value to overflow, then the data will be set to full scale minimum or maximum value depending on the sign.

*Note:* *If the data being processed is 32 bit precision linear power (ID\_RM\_CONF FORMAT=PWR32BIT or PWR16FP, then compression is not supported and the data format (UNLDR\_CONF FORMAT) should always be set to 32BIT.*

The Data Unloader also tracks the number of sign bits (i.e. leading ones and zeros) in the FFT output data for use by the application software.

**Table 801 Unloader Configuration Parameters**

Parameter	Definition	Comments
Common Exponent	The 32 bit data will be shifted right by this number of bits before truncation to the 16 LSBs if the FORMAT selected is 16 bit and left if the format is 32 bit	<b>UNLDR_CONF.EXPNT</b>
Format	Select the format of the data to be written to the buffer memory. Options are 16 or 32 bit precision complex.	<b>UNLDR_CONF FORMAT</b>

---

## Signal Processing Unit 2 (SPU2)

### 20.3.3.1 Power Histogram

The power histogram module stores a histogram of the FFT output power distribution into the configuration RAM. The method used derives the histogram bin index from the  $\log_2$  of the power. This method first requires the linear power to be calculated.

The linear power value used is derived in two possible ways:

- If the data format is complex, it will be calculated to 32 bit precision using the method described in “[Pre-Processing Units](#)” on Page 40. This method ensures that all 32 bits of the calculated power value contain useful data (i.e. all bits will toggle, no bits will be at a constant value over the full range of inputs)
- If the data format is 32 bit power, the data will be used directly.

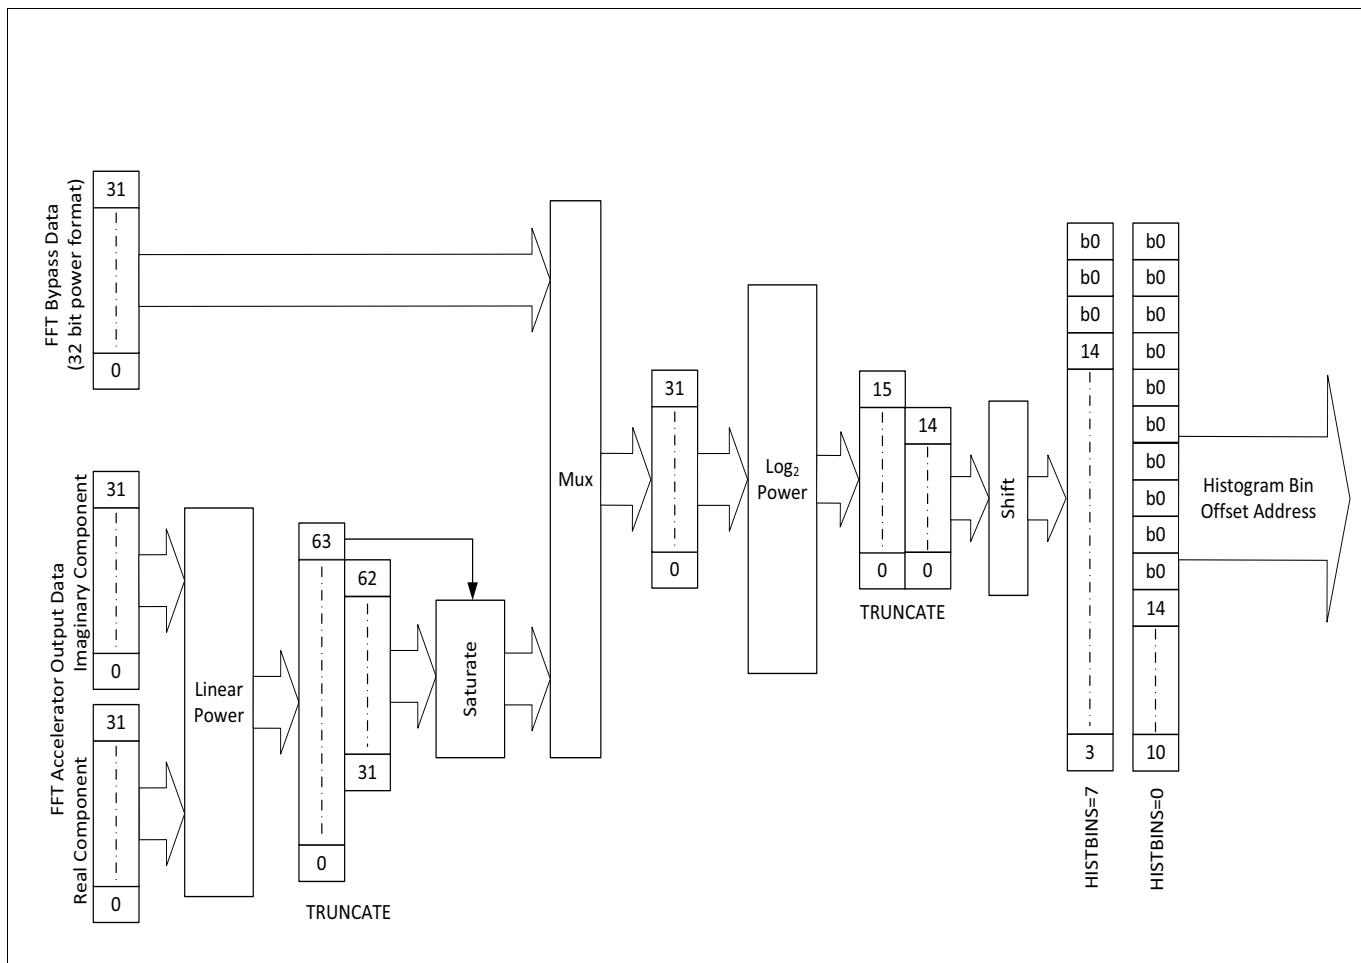

**Note:** *The value of the ODP\_CONF.FTR bitfield is considered when calculating the power values used for the histogram. If ODP\_CONF.FTR is set, then the imaginary component of the FFT output data will be set to  $0_D$ .*

This 32 bit linear power value is used to derive a 16 bit  $\log_2$  power value. The  $\log_2$  power value is formatted as:

- bit 15: sign bit, always 0 (inputs of less than  $2^0$  are mapped to a result of 0)
- bits 14 downto 10: integer part
- bits 9 downto 0: fractional part

The  $\log_2$  power value is then right shifted by a programmable number of bits and used as a word address offset from the histogram base address in the configuration memory. The 64 bit word stored at this address is incremented. As bit 15 is always zero, it is specifically excluded from the address

## Signal Processing Unit 2 (SPU2)

**Figure 260 Diagrammatic Representation of Histogram Bin Offset Generation**

The histogram is enabled by writing an  $1_B$  to UNLDR\_CONF.HIST\_EN, the base address is stored in UNLDR\_CONF.HISTBASE. The number of bins is configured by the value in UNLDR\_CONF.HISTBINS. A minimum of 32 bins and a maximum of 4096 bins are supported. The number of bins must always be a power of 2 and is given by  $2^{(\text{HISTBINS}+5)}$ . The size of the right shift referred to in the previous paragraph is therefore (10-HISTBINS).

The byte address of any given bin is UNLDR\_CONF.HISTBASE + ((BIN NR.) \* 8).

The power histogram will be calculated for the number of FFTs controlled by the values in the UNLDR\_CONF2.START and UNLDR\_CONF2.END fields. The FFTs of the measurement cycle are counted with the first FFT being FFT 0. If the count is greater than or equal to UNLDR\_CONF2.START and less than or equal to UNLDR\_CONF2.END, then the FFT is used to compute the histogram. If UNLDR\_CONF2.END is set to all 1, then accumulation of histogram data will run continuously from when the count reaches the UNLDR\_CONF2.START value until the end of the measurement cycle.

For every FFT included in the histogram, only those bins in the range defined by UNLDR\_CONF3.STARTBIN and UNLDR\_CONF3.ENDBIN are included in the calculation. The range is inclusive with the first bin being number 0 and setting UNLDR\_CONF3.ENDBIN to any value greater than the last bin number has the same effect as setting it to include the last bin.

The calculation of the power histogram can be further filtered by considering antenna ID. This mode is enabled by setting UNLDR\_CONF.HAFE. If set, only FFT results associated with the antenna ID stored in the UNLDR\_CONF.AVF will contribute to the power histogram or update the FFT count used for checks against UNLDR\_CONF2.START and UNLDR\_CONF2.END values.

## Signal Processing Unit 2 (SPU2)

The histogram needs two clock cycles to process each bin as it needs to read the current value from the configuration memory and then write it back after updating. Consequently, the histogram must only be enabled if the FFT clock rate is less than one half, that is AUXCTRL.DIVF is set to something greater than or equal to  $8_D$ .

**Note:** *The histogram and the windowing function in the LOADER both require full bandwidth access to the Configuration RAM while the TC3Ax SPU is running. To prevent conflict, the Configuration Memory is split into four towers. See “[Configuration Memory Usage Restrictions](#)” on Page 68 for details. The memory used for histogram and the memory used for the window functions must not be in the same tower if both functions are active at the same time. The memory allocated for the histogram must not be split between towers under any circumstances as this is not supported by the hardware implementation.*

**Table 802 Histogram Configuration Parameters**

Parameter	Definition	Comments
Histogram enable	enable / disable for histogram	<b>UNLDR_CONF.HISTEN</b>
Number of classes	from 32 to 4096 classes	<b>UNLDR_CONF.HISTBINS</b>
Base address of the histogram in the RAM		note that we may have a modulo here to avoid too high complexity in address computations <b>UNLDR_CONF.HISTBASE</b>
Start Delay	FFTs to count before starting histogram calculation	<b>UNLDR_CONF2.STRT</b>
End Delay	FFTs to count before ending histogram calculation	<b>UNLDR_CONF2.END</b>
Start Bin	Number of the first bin to include	<b>UNLDR_CONF3.STRTBIN</b>
End Bin	Number of last bin to include	<b>UNLDR_CONF3.ENDBIN</b>
Filter by Antennae	Enable histogram data to be accumulated only for a single antenna	<b>UNLDR_CONF.HAFE</b>
Antenna Number to use for filtering	Index of Antenna to be used for histogram data accumulation	<b>UNLDR_CONF.AVF</b>
Real Data Format	Ignore imaginary component when computing power	<b>ODP_CONF.FTR</b>

### 20.3.3.2 Statistical Information

The Data Unloader can calculate the mean value of the power for each FFT while processing the data. The information will be stored in a FIFO for later use by the Output Data Processor. Calculation and storage of this information is enabled using the SBCTRL.EN bitfield.

The mean is always calculated from 32 bit data. If 16 bit complex format is selected by UNLDR\_CONF.FORMAT, the mean calculation will use the 32 bit data before the shift defined by UNLDR\_CONF.EXPNT is applied. If 32 bit complex format is selected, the mean calculation will use the 32 bit data after the shift defined in UNLDR\_CONF.EXPNT is applied. This ensures that the mean is calculated using the same data as used by the Output Data Processor.

The linear power value used is calculated using the method described in “[Pre-Processing Units](#)” on Page 40.

## Signal Processing Unit 2 (SPU2)

This gives half the information needed to compute the variance (square of standard deviation). To complete the variance calculation, a second pass through the data is needed. This is done when the data is read by the Output Data Processor.

Statistical information for the measurement cycle can be stored in the Radar Memory. One set each of minimum power, maximum power, mean power and standard variance will be stored for each FFT processed.

The division used to complete the variance<sup>1)</sup> calculation is a “shift right” operation rather than a full hardware division. This causes some inaccuracies when the number of samples is not a power of two. This does not affect the statistical information computed from FFT results but the calculation of the statistical information uses a mean value based on the number of samples being rounded up to the next power of two when the FFT engine is bypassed ( $LDR\_CONF.FFTBYP = 1_B$ ) and padding is disabled ( $LDR\_CONF.PDDIS = 1_B$ ).

These operations are described in more detail in the relevant section in the Output Data Processor section.

**Note:** *To ensure that the data used for the statistical calculations is consistent the value of the ODP\_CONF.FTR bitfield is considered when calculating the power values used for the computing the mean. If ODP\_CONF.FTR is set, then the imaginary component of the FFT output data will be set to 0\_D.*

### 20.3.4 Streaming Processor 2, The Output Data Processor

The Output Data Processor module formats and writes the results datasets to the Radar Memory. It can also route the data through multiple processing modules working on complex data and power. The Output Data Processor is split into two submodules, the MATH2 Unit and the Output DMA Engine. When reading data from the Buffer RAM, the Processor uses the UNLDR\_CONF.FORMAT and UNLDR\_CONF.EXPNT to determine whether the stored data is in native 32 bit precision format or has been compressed to 16 bit precision and requires reformatting.

The ODP has a processing path for manipulating the base data and bin rejection working in parallel with multiple analysis units (CFAR, integration (NCI/DBF), statistics and arithmetic).

#### 20.3.4.1 Streaming Processor 2 Data Fetch from Buffer Memory

There are two classes of processing path through the MATH2 which require the data to be read from Buffer RAM in two incompatible ways.

- Operations such as the FFT data output path through the bin rejection unit require the data to be read as consecutive points from each FFT result.
- Operations using the data integrated across antenna requires equivalent data points to be read consecutively from each FFT result stored in the buffer memory so the integrated value can be calculated.

If both types of path are enabled by the programmed configuration options, then this conflict is addressed by reading the data from the buffer memory twice. The first fetch will be used for the operations requiring linear addressing by FFT result. The second fetch will be performed for operations requiring the integrated result across antennae. The number of fetches required is evaluated and executed independently for each pass if double pass mode is enabled.

#### 20.3.4.2 In Place FFT

Setting ODP\_CONF.IPF configures the Output Data Processor to generate addresses using the same base and offset scheme used by the input DMA. To support this registers are available to allow the offsets and loop repeat counts to be configured. The intention is that the output data can be written to the memory locations cleared by the reading of the input data.

1) The variance calculated is the population variance rather than a sample variance. The sum of the squares is divided by the number of samples rather than the number of samples minus one.

## Signal Processing Unit 2 (SPU2)

To do this the Output DMA uses an equivalent set of counter and offset registers to those instantiated in the Input DMA engine. The parameters used to configure this duplicate register set are derived from the Input DMA configuration registers and the values should be calculated so that the Output DMA addresses follow the same sequence as the Input DMA addresses.

There are some differences in the way the ODM register values are used to generate addresses:

- All offset fields are EMEM word addresses
- There are no equivalents to the IDM\_RM\_CONF.TRNSPS and ID\_RM\_CONF.PM bitfields. Dependent on the settings of these bitfields, one of the loop repeat registers will be incremented by more than one. As no equivalent for these bitfields exist in the equivalent ODM registers, the equivalent loop repeat value will have to be divided to compensate. The increment value is the number of samples in a 256 bit EMEM word, the equivalent ODM value will be the IDM bitfield value divided by the number of samples in a 256 bit word.

The Output DMA will always assemble enough results to completely fill each 256 bit word before moving to the next address in the sequence. This will result in fewer words being written than read if the output data size is smaller than the input data size. Conversely, if the output data requires more memory than the input data, results will be unpredictable and, consequently, use of in place FFT in these cases is not supported.

In Place FFT addressing only applies to the writing of the FFT results.

It is strongly recommended that bin rejection is not used with in place FFT when using transposed addressing as no additional memory saving will be possible (data will be written as a sparse array in memory) and addressing of the resultant data will be extremely complex.

### 20.3.4.2.1 Restrictions

Correct operation of this mode requires that the Input DMA reads and uses all 32 bytes of each word in Radar Memory in a single pass. If only part of the word is used, it is probable that the Output Data Processor will overwrite the location before a further pass through the data cube by the Input DMA uses the rest of the word.

This mode cannot be used if Double Pass mode is used to write two sets of FFT results.

### 20.3.5 MATH2 Unit

The MATH2 Unit implements multiple parallel processing units as shown in [Figure 261](#) below. These processing units are grouped into two data flows, one working on the raw complex data and the other on linear or  $\log_2$  power. The following table shows the operating domain and concurrency of the various functions:

**Table 803 MATH2 Unit Functional Concurrency**

	Function - Only one function can be active for each O/P Channel								
	Stats	Local Max/ Logical Func	CFAR CA	CFAR GOS	FFT Data <sup>1)</sup>	Log <sub>2</sub> Signal Power	ND0 <sup>2)</sup>	ND1 <sup>2)</sup>	Label list
Power Domain <sup>3)</sup>	Yes	Yes	Yes	Yes	No	Yes	Yes	Yes	Yes
Complex Domain <sup>4)</sup>	No	No	No	No	Yes	No	Yes	Yes	No
O/P Channel	PORT3	PORT8	PORT4	PORT5	PORT1	PORT2	PORT6	PORT7	PORT9

1) Incorporates any or all of scalar add, scalar multiply and bin rejection.

2) ND0 and ND1 are the dual integration units that operate in power/complex domain depending on their configuration

3) Function is possible using power as input

## Signal Processing Unit 2 (SPU2)

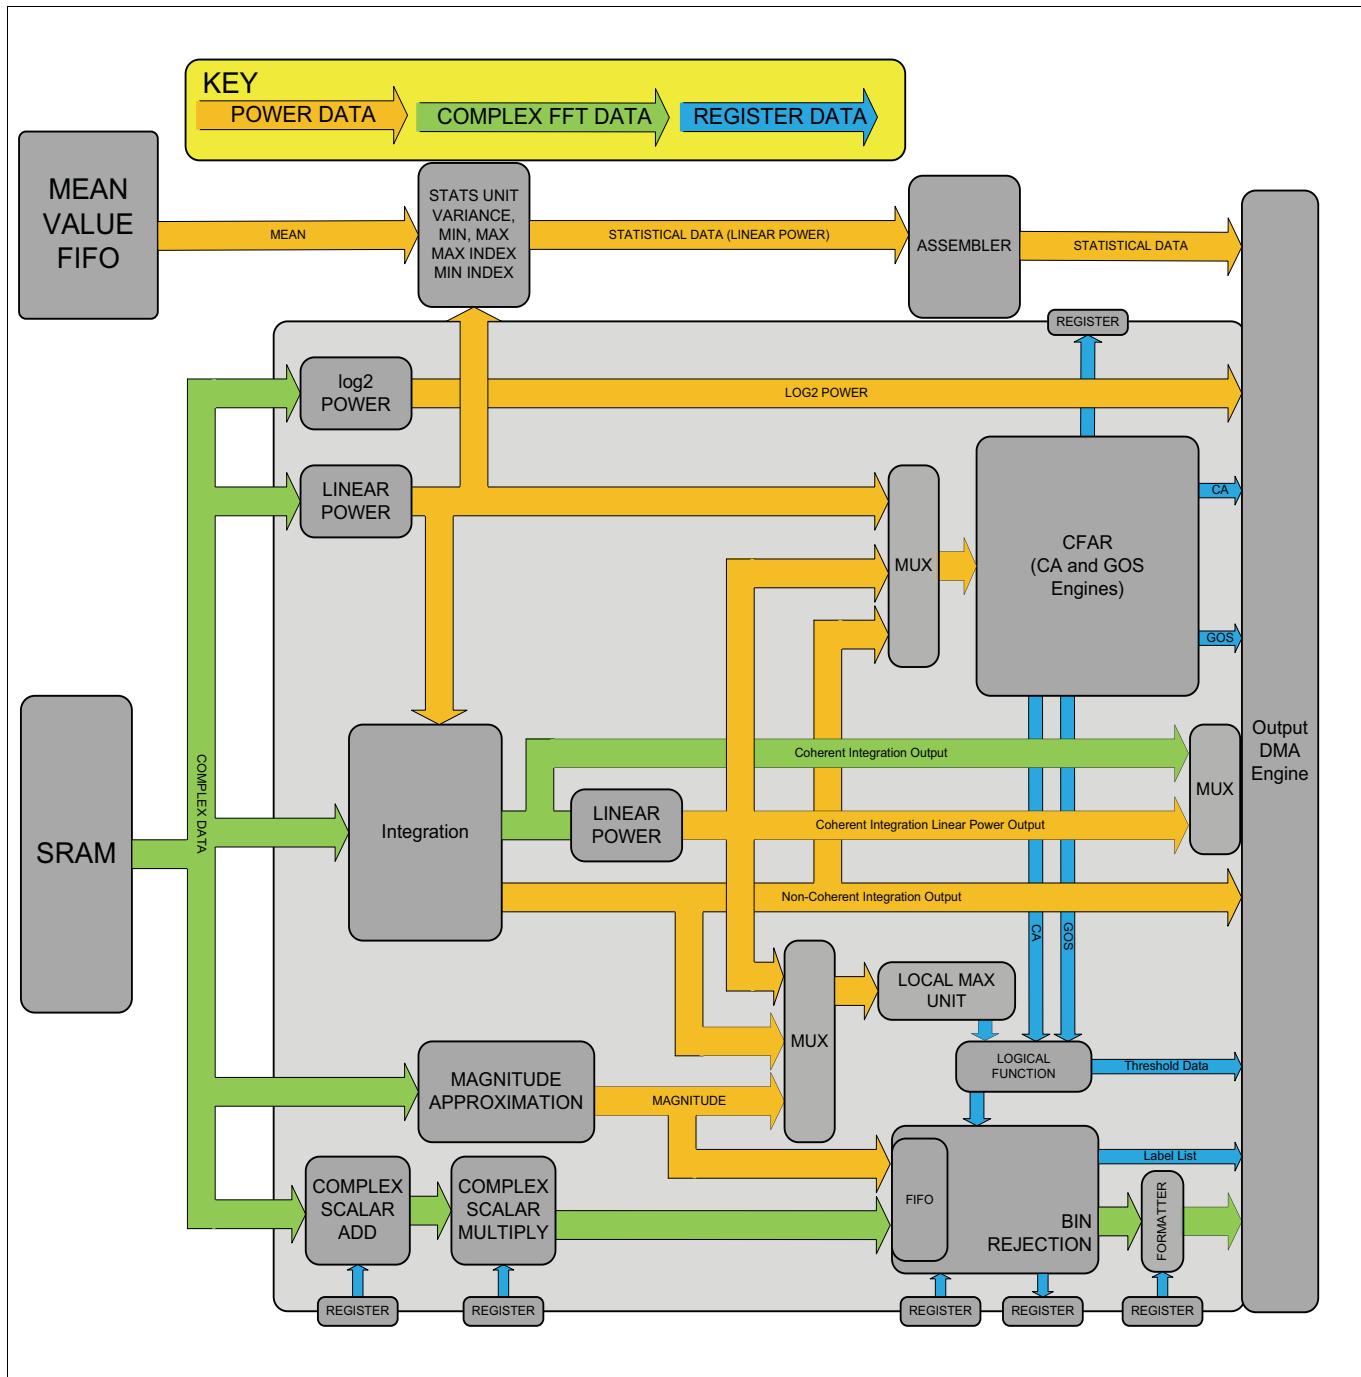

- 4) Function is possible with Complex Values as input

**Table 804 Output DMA Engine Data Streams**

Output port	Definition	Comments	Precision (Bits)	Padding <sup>1)</sup> per FFT or measurement cycle
Port1	3 sources of informationFFT unitFFT BIN rejection and zeroingadd scalar or complex to vector		16 or 32 bit precision, complex or real formats	FFT
Port2	$\log_2$ signal power		16 bits	FFT
Port3	min, max, average, (standard deviation) <sup>2)</sup>		32 bits	FFT
	index of min, index of max	12 bits of data, padded to 16 bits with leading zeroes	16 bit	
Port4	CFAR (CA Engine)		1 bit per FFT bin	cycle
Port5	CFAR (GOS Engine)		1 bit per FFT bin	cycle
Port6	Vector weighted sum, complex or power domain	typically: coherent or non coherent integration <sup>2)</sup>	16 or 32 bit complex 16 or 32 bit power	FFT
Port7	Vector weighted sum, complex or power domain	typically: coherent or non coherent integration <sup>2)</sup>	16 or 32 bit complex 16 or 32 bit power	FFT
Port8	local max or logical function		1 bit per FFT bin	cycle
Port9	Label list output	Amount of data depends on CFARCFG3.	64 bits max per label	cycle

- 1) Padding is used to ensure that the next set of data written starts on a 256 bit aligned address. Data intended to be read back into the TC3Ax SPU will have one element per FFT bin processed and each dataset must start on a 256 bit aligned address. These data streams will be padded per FFT. Other data streams will be padded per measurement cycle to optimise memory usage
- 2) Output from this operation is a 1D vector of the same length as the input FFTs

## Signal Processing Unit 2 (SPU2)

**Figure 261 MATH2 Unit Architecture**

The MATH2 unit will always expand the data read from the buffer memory to 32 bit precision before using it in any functions. The expansion function is the inverse of the compression operation used in the Unloader with any additional LSBs being padded with  $0_B$  and the MSBs being sign extended. See [Section 20.3.3, “Data Unloader” on Page 32](#).

Where 32 bit precision values are multiplied to generate a result at 32 bit precision, rescaling of the result will take place after the multiplication operation. Rescaling will always remove the least significant bits of the result.

When multiplying two signed 32 bit numbers, the result will be a 64 bit signed value and this will be scaled to 32 bits by dividing by  $2^{31}$  and rounding down to the nearest integer while discarding the MSB. As multiplying two full scale negative numbers will result in an overflow using this algorithm, this corner case will generate a full scale, positive result.

## Signal Processing Unit 2 (SPU2)

When multiplying two unsigned 32 bit numbers, the result will be a 64 bit unsigned value and this will be scaled to 32 bits by dividing by  $2^{32}$  and rounding down to the nearest integer.

If any calculation result is scaled to 16 bits, then the result will be rounded to the nearest integer after division. Results which fall exactly midway between two integers will be rounded away from zero.

Scaling of the results of 32 bit addition operations to produce a 32 bit output are handled in a similar manner. The intermediate result is always sized so that overflow does not occur and then this is scaled down to 32 bits by dividing and rounding down towards -Infinity to the nearest integer. The scaling to 32 bits will, in most cases, occur automatically unless the number of operands is configurable, in which case, a configurable scaling factor has been provided.

### 20.3.5.1 Pre-Processing Units

The pre-processing units convert the raw FFT data to  $\log_2$  power, linear power or magnitude or change the precision of the data.

#### 20.3.5.1.1 Linear Power Calculation

Linear power is calculated to 32 bit precision by

- squaring the real and imaginary components and scaling by dividing by  $2^{31}$ .
  - For full scale positive data, this gives a value of  $7FFF\_FFFE_H$
  - For full scale negative data, this gives a value of  $8000\_0000_H$
- adding the truncated squares of the real and imaginary components and saturating the results
  - $7FFF\_FFFE_H$  for both real and imaginary complex components gives  $FFFF\_FFFC_H$  when the squares are added and saturation does not take place
  - $8000\_0000_H$  for both real and imaginary complex components gives  $1\_0000\_0000_H$  when the squares are added and  $FFFF\_FFFF_H$  after saturation.

#### 20.3.5.1.2 $\log_2$ Power Calculation

$\log_2$  power is computed to a precision of 16 bits and will be stored as an unsigned integer value with 7 integer bits and 9 fractional bits. This is a representation of the 32 bit precision linear power value scaled to 64 bits by multiplying by  $2^{31}$ . This is done to be compatible with the  $\log_2$  power calculation used inside the CFAR module which uses a 64 bit linear power input. An input linear power value of  $2^{31}$  scales to a 64 bit value of  $2^{62}$ . A 64 bit value of  $2^{62}$  corresponds to a  $\log_2$  value of  $7C00_H$ . The MSB of the 16 bit value is always zero.

The algorithm used is as follows:

- In the first stage, the location of the first bit set in the 64 bit input value is used to determine the integer component of the output.
- In the second phase of the algorithm, the most significant eight bits of the residual from the first phase is used as the index into a 256 entry look up table used to apply an appropriate fractional correction to the integer value

The maximum granularity of the look up table output is 0.006. An input value of  $0000\_0000_H$  is mapped to an output value of  $0000_H$ .

## Signal Processing Unit 2 (SPU2)

### 20.3.5.1.3 Magnitude Approximation

For magnitude, the approximation:

(20.4)

$$\text{MAGNITUDE} = \alpha \times (\text{MAX}(\text{ABS}(I), \text{ABS}(Q))) + \beta \times \text{MIN}(\text{ABS}(I), \text{ABS}(Q))$$

is used. The two multiplication constants are stored in the ALPHA and BETA bitfields of the MAGAPPROX register. The magnitude value is calculated at 32 bit precision. ALPHA and BETA are unsigned constants scaled to have a value range of between 0 and 1 approximately (actually 0.99998 to five significant digits). The output is a 32 bit value scaled to have an overall gain of 1.

**Note:** *The ABS function used in the magnitude approximation maps a full scale negative number  $8000\_0000_H$  to a magnitude of  $7FFF\_FFFF_H$*

Later operations then use the magnitude value. Operations which use magnitude data are:

- Threshold Detection, [Section 20.3.5.3.3](#)
- Local Maximum, [Section 20.3.5.2](#)

### 20.3.5.1.4 Saturating Truncation

The saturating truncation operation will remove the 16 MSBs of a 32 bit quantity to leave a 16 bit result. The intention is that the 32 bit quantity is scaled such that no significant information is lost when doing this (i.e. the 17 MSBs contain only sign information). However if this not the case and one or more of the MSBs contain  $1_B$  for positive quantities or  $0_B$  for negative quantities, then the 16 bit result will be set to full scale positive in the first case and full scale negative in the second case.

### 20.3.5.2 Local Maximum Detection Unit

The module checks to see if the bin being checked is a local maximum by comparing against adjacent bins. If it is, then the bin will be flagged. The module can also simultaneously check the bin against a threshold value. The output information can be written to Radar Memory and used by the Bin Rejection Unit.

This module can be used concurrently with the CFAR engines. The Local Maximum Detection Unit has the same options for range and velocity spectrum extension as the CFAR engines. See [Section 20.3.5.5.8, CFAR spectrum extension](#) for a full description. It has the same control for its data source as the CFAR engines, see [Section 20.3.5.5.4, CFAR Module Configuration](#), except that the FFT input for Local Maximum comes from the Magnitude Approximation unit.

The Output DMA channel for output to memory is shared between Local Maximum and the [Logical Function](#) unit (see [Section 20.3.5.3.3](#)) so writing Local Maximum to memory requires CFARCTRL.LFOSEL to be set to LCLMAX.

**Table 805 Local Maximum Configuration Parameters**

Parameter	Definition	Comments
local max enable	enable / disable	<b>CFARCTRL.LCLMAX</b>
Radar Memory Address	Base address to be used for writing the threshold results to the Radar Memory	<b>LCLMAXBASE.BASE</b>
Output enable	Write data to Radar Memory	<b>LCLMAXBASE.EN</b>
Output select	Select whether LCLMAX is output or Logical Function	<b>CFARCTRL.LFOSEL</b>

## Signal Processing Unit 2 (SPU2)

**Table 805 Local Maximum Configuration Parameters (cont'd)**

Parameter	Definition	Comments
Mode	Select whether threshold, local maximum or both checks shall be active	<b>LCLMAX.MODE</b>
Local Max Check Combining	Logical Operation used to combine check results when both checks are active	<b>LCLMAX.CMBN</b>
Spectrum Extension Mode	Off, Range or Velocity	<b>CFARCTRL.EXTNSN</b>
Window Width <sup>1)</sup>	Window size to be used for local max calculation	<b>LCLMAX.WIDTH</b>
Threshold Value	user defined value	<b>LCLMAX.TSHLD</b>
Threshold Extension Mode	Left or Right Justification of the TSHLD value in the 32 bit comparison value	<b>LCLMAX.LJUST</b>
Input selection	select input from FFT engine, INT0 or INT1. Selecting INT0 or INT1 when that unit is not active is not supported and will produce undefined results.	note that when input from FFT engine is used, the approximate magnitude will be computed on each received BIN. <b>CFARCTRL.SRCSEL</b>

1) WIDTH must be set to  $1_B$  or  $2_B$  to flag any bins when MODE only has Local Max enabled

The Unit can be configured to flag bins where the magnitude is local max or where the magnitude is not a local max. The unit can simultaneously be configured to check against a threshold value and flag a bin if the magnitude is above the threshold or if the magnitude is below the threshold.

If both checks are enabled, the results are combined as defined using the LCLMAX.CMBN bit. Both logical AND and logical OR operations can be selected: for example flag a bin on both checks triggering a reject or flag a bin on either check triggering a reject.

The comparison is done with 32 bit values and the 24 bit LCLMAX.TSHLD is extended to 32 bits before being used. This extension can either be right or left justified. If the LCLMAX.LJUST bitfield is set to  $0_B$ , the extension is right justified and 8 MSBs of value  $0_B$  are appended. If LCLMAX.LJUST is set to  $1_B$ , the extension is left justified and 8 LSBs of value  $0_B$  are appended.

**Note:** The Spectrum Extension function ([Section 20.3.5.5.8](#)) is used to provide the extra window data needed for the Local Max Unit window if CFARCTRL.LCLMAX is set and LCLMAX.MODE is not equal to  $10_B$  or  $11_B$  meaning the local max function is active. CFARCTRL.SEWIN must be set to a value at least the LCLMAX.WIDTH value. If LCLMAX.WIDTH= $01_B$ , then SEWIN= $=000001_B$  and if LCLMX.WIDTH= $10_B$ , then SEWIN= $=000010_B$ .

### 20.3.5.3 FFT Data Output Path

This is the output path for the FFT results.

The base address for the FFT results data written to Radar Memory is stored in the ODP\_BASE register. The format of the data is controlled by the ODP\_CONF.MODE, ODP\_CONF.FTR, ODP\_CONF.SCALE, ODP\_CONF.EXPNT, ODP\_CONF.HPFP and ODP\_CONF.COMPRESS bitfields.

## Signal Processing Unit 2 (SPU2)

**Table 806 Output Data Processor Format Options**

Parameter	Definition	Comments
Enable FFT results output	On/Off switch to enable writing of the post-processed FFT results to memory	<b>ODP_CONF.MODE</b>
Results Compression	Enable Compression of the FFT results to 16 bit precision with a common exponent	<b>ODP_CONF.SCALE</b>
Results compression scaling factor	The scaling factor to be used if results compression is enabled. The 32 bit data will be shifted right by this number of bits before truncation to the 16 LSBs	<b>ODP_CONF.EXPNT</b>
Real Results	Force the complex component of the FFT results to 0 as it is read from the buffer memory. The complex component is written to memory but has a value of 0.	<b>ODP_CONF.FTR</b>
In Place Writing of Results	Configure the Output Data Processor to Compute Write addresses in the same order as the Input DMA so that results are written to the addresses cleared by reading input data	<b>ODP_CONF.IPF</b>
Write results as real only data	The FFT results written to memory do not have an imaginary component but consist only of packed, real values	<b>ODP_CONF.ROF</b>
Post-processing option for the FFT results	The FFT results can be converted to half precision floating point format (as defined in IEEE 754) before being written to memory.	<b>ODP_CONF.HPFP</b>
Compression of half precision floating point data	The FFT results in HPFP format can be compressed by packing 16 complex values into 256 bits.	<b>ODP_CONF.COMPRESS</b>

Operation of the HPFP bitfield is described in [Section 20.3.5.3.4, “Half Precision Floating Point Format” on Page 48](#). The compression is described in [Section 20.3.5.3.5, “FFT Data Compression” on Page 48](#).

### 20.3.5.3.1 Scalar Addition

The pre-processing unit can add a offset to each complex data value. The offset is added to each component, real and imaginary, of the data value. The value of the offset is a constant stored in the SCALARADD.OPERAND bitfield and the function will be activated if a non-zero value is written to this field.

### 20.3.5.3.2 Complex Rescaling

The pre-processing unit can multiply each data value by a scaling factor. This value is a 32 bit real constant stored in the SCALARMULT.OPERAND bitfield which allows the value to be rescaled but does not affect the phase. The function will be activated when a non-zero value is written to this field.

### 20.3.5.3.3 Bin Rejection Unit

This unit post-processes the data to be written to Radar Memory using the contents of the bin rejection register and the outputs from the CFAR engines and the Local Maximum Unit. The outputs of these units are combined in a logical function before being used for bin rejection.

The bin rejection register contains one bit for each “bin” (datapoint) in the FFT results. It is accessed through 64, 32 bit registers in the register space of the TC3Ax SPU. If the bit is set to 0, then the relevant bin will either be removed from the output dataset written to the Radar Memory or set to a value of  $0_D$ .

## Signal Processing Unit 2 (SPU2)

This feature can be used in conjunction with the logical function of the outputs of the CFAR engines and the Local Maximum Unit output<sup>1)</sup>. In this mode, the bin rejection register and the output from the Logical Function must both permit the bin to be written. If either function requires the bin to be removed (or set to zero), then it will be removed (or set to zero). For example, if the bin acceptance mask requires the bin to be set to  $0_D$ , then it will be set to  $0_D$  even if the Logical Function has identified it as a bin to be kept.

This can be viewed as the logical ANDing of a bin acceptance mask from the Logical Function with the acceptance mask programmed in the Bin Rejection register. Bins corresponding to bits set to  $1_B$  in the resulting, combined mask will be retained unchanged while bins corresponding to bits set to  $0_B$  in the resulting mask will be either removed from the output or set to a value of  $0_D$  depending on the mode of the bin rejection unit.

**Table 807 Bin Rejection Unit Configuration Options**

Signal	Definition	Comments
operating mode	$00_B$ = Off $01_B$ = BIN rejection, remove bins from output $10_B$ = Set BIN value to 0 $11_B$ = Reserved	<b>BINREJCTRL.RMODE</b>
BIN list to be removed	2048 bit register that defines which BIN is to be removed or zeroed (1 means BIN to be retained or passed unchanged)	<b>BINx.REJ.B</b> <b>x=0-63</b>

### Logical Function

The logical function unit combines the 3 logical outputs of the CA CFAR, GOS CFAR and Local Max<sup>2)</sup> units into a single bit that controls bin rejection along with the bin rejection register. The function uses the three input bits, where  $1_B$  means keep bin and  $0_B$  means reject bin, as an address composed of Local Max as the LSB, GOS as the middle bit and CA as the MSB. This address is used to select a bit from the binary LFUNC register field value. Some examples of how the Logical Function may be configured are given in the table below:

**Table 808 Configuring the LFUNC Parameter**

Operation	L FUNC Value	Comments
Always zero	$00000000_B$	Any input value selects $0_B$
<b>GOS OR CA OR LMAX<sup>1)</sup></b>	$11111110_B$	Output is $0_B$ only when all three inputs are $0_B$
<b>GOS AND CA AND LMAX</b>	$10000000_B$	Output is $1_B$ only when all three inputs are $1_B$
<b>GOS</b>	$11001100_B$	Output only depends on the value of GOS
<b>CA</b>	$11110000_B$	CA is the MSB of the address
<b>CA AND (GOS OR LMAX)</b>	$11100000_B$	As above but when both GOS and LMAX are $0_B$ the output is $0_B$
<b>GOS XOR LMAX</b>	$01100110_B$	The output is independent of CA so the bit pattern is duplicated in the LS 4 bits and MS 4 bits. When GOS and LMAX are both $1_B$ the output is $0_B$
Always one	$11111111_B$	Any input value selects $1_B$

1) LMAX represents the Local Maximum output

1) If INT0 or INT1 are selected as the source for CFAR and Local Maximum then Bin Rejection will ignore the Logical Function value in this case.  
2) As Local Max flags bins to be rejected, while CFAR flags bins to be kept, the Local Maximum logical value is inverted before input to the Logical Function.

## Signal Processing Unit 2 (SPU2)

Note: If a unit, CA CFAR, GOS CFAR or LCLMAX, is not enabled LFUNC should be configured such that its value has no effect on the Logical Function output. Failure to do this will result in undefined behaviour.

Note: If none of the units CA CFAR, GOS CFAR nor LCLMAX are enabled LFUNC should be set to  $1111111_B$ . Configuring to  $0000000_B$  will result in all bins being rejected.

The Output DMA channel for output of the bit stream to memory is shared between Logical Function and the **Local Maximum Detection Unit** (see [Section 20.3.5.2](#)) so writing the Logical Function output to memory requires CFARCTRL.LFOSEL to be set to LFUNC. The Logical Function output also feeds into the Label List output function (see below).

**Table 809 Logical Function Configuration Parameter**

Parameter	Definition	Comments
Logical Function	An 8 bit field representing a 3 bit input 1 bit output lookup table. The inputs are Local Max, CA CFAR and GOS CFAR. Setting the field to all ones makes the output of the Bin Rejection unit independent of any of the CFAR or Local Max units.	Function acts on the output of the CFAR and Local Max units <b>CFARCTRL.LFUNC</b>
Radar Memory Address	Base address to be used for writing the results to the Radar Memory. This is the address where the start of bit stream is.	<b>LCLMAXBASE.BASE</b>
Output enable	Enable output of data to Radar Memory. Note, if LFOSEL==LCLMAX and CFARCTRL.LCLMAX==OFF no data shall be written to memory. Likewise, if LFOSEL==LFUNC and none of CA CFAR, GOS CFAR nor LCLMAX are enabled.	<b>LCLMAXBASE.EN</b>
Output select	Select whether LCLMAX is output or Logical Function	<b>CFARCTRL.LFOSEL</b>

### Label List Output

The Label List function operates on Label Events. A Label Event is defined based on the task being executed by MATH2. For an integration task (ND\_CTRL.MODE is not OFF and CFARCTRL.SRCSEL==INT0 or INT1) a Label Event is defined as the output of the Logical Function being a one. For a linear fetch task (CFARCTRL.SRCSEL==FFT) a Label Event is defined as the combination of the Logical Function being one and the Bin-Rejection mask set to accept a bin. As these two cases are mutually exclusive, given CFARCTRL.SRCSEL can either be FFT or not FFT, the Label List function will only operate in one of the tasks if two fetch modes are needed to fulfil the requirements of a configuration.

A record of Label Events may be written to Radar Memory as a list of labels by enabling Label List output. Each label has two possible parts: the system address and a 2D index. Either or both may be enabled by CFARTRLLBLCON. When both are enabled the system address is written first.

The system address and index (x,y) is calculated as shown in the pseudocode below.

```

x := 0
y := 0
address := LBLCALC.BASE<<5
FOREACH bin
    IF Label_Event

```

## Signal Processing Unit 2 (SPU2)

```

        write(address)
END
IF x < LBL.XRPT
    x := x + 1
    address := address + LBLX.MUL
ELSIF y < LBL.YRPT
    x := 0
    y := y + 1
    address := address + LBLY.MUL
ELSE
    x := 0
    y := 0
    address := address + LBLZ.MUL
END
END

```

The value of LBLCALC.BASE is shifted left 5 places to convert from a 256-bit word address to a system byte address. The first data point in the 3D data cube is usually located at this address. The address calculations are done in 32-bit arithmetic to produce a system byte address that can be written to Radar Memory.

The 2D index (x,y) is formatted as a 32 bit word with the x value in bits 12:0 and the y value in bits 25:13. Bits 31:26 of the word are always zero. The index output is only useful when CFARCTRL.SRCSEL==INT0 or CFARCTRL.SRCSEL==INT1. In this case the FOREACH iterates over the single results produced by integrating over multiple antenna so there are only two dimensions. If CFARCTRL.SRCSEL==FFT the 2D index (x,y) may not, depending on the settings of LBL.XRPT and LBL.YRPT, contain enough information to uniquely identify the bin of interest.

For each sample when there is a Label Event, this function appends one or two 32 bit words, depending on the value of CFARCTRL.LBLCON, to the data to be written to memory. The data is written starting at the location defined by the base address, LBLBASE.BASE. A count of labels written is maintained in two counters MD0\_LBLCNT and MD1\_LBLCNT to go with the two passes available in Double Pass Mode (see “[Double Pass Mode](#)” on Page 16).

The labelling function is enabled when CFARCTRL.LBLMODE is set to one of three active values:

- COUNT: just count Label Events
- NOINT: just write data
- INT: write data and generate interrupts in both of the following cases:
  - MDq\_LBLCNT.CNT reaches half the value stored in CFARCFG3.LBLOLM
  - MDq\_LBLCNT.CNT reaches the value stored in CFARCFG3.LBLOLM

The count is cleared by writing 1<sub>B</sub> to the MDq\_LBLCNT.CLR bitfield. The count should only be cleared when the SPU is idle.

The behaviour for modes other than COUNT after the count reaches CFARCFG3.LBLOLM is controlled by CFARCFG3LBLWRAP. If this bit is set the next Label Event after the count reaches CFARCFG3.LBLOLM will cause the following actions:

- any pending data is padded with zeros to width of the memory interface and written to Radar Memory at the current location
- MDq\_LBLCNT.CNT is reset to zero
- writing address is set to LBLBASE.BASE

before any more words are added to the data to be written.

When data output is enabled and CFARCFG3LBLWRAP is set, CFARCFG3.LBLOLM must be set such that:

## Signal Processing Unit 2 (SPU2)

$(\text{LBLLOLM} + 1) \bmod 8 = 0$

This is to ensure that the write address only wraps at a complete Radar Memory words boundary.

If CFARCFG3.LBLWRAP is not set no data shall be appended to the data to be written after the word that corresponds to the case: MDq\_LBLCNT.CNT==CFARCFG3.LBLLOLM.

At the end of processing a measurement cycle, in any case when data writing is enabled, any remaining data to be written to memory shall be padded with zeros to width of the memory interface and flushed to Radar Memory.

**Table 810 Label List Output Configuration Parameters**

Parameter	Definition	Comments
Label mode	Selects if the unit is enabled and what effect it has	Function labels CFAR and Local Max results <b>CFARCTRL.LBLMODE</b>
Label content select	Selects what is written as the label data. This may be the system address of the peak, the 3D index or both	Function labels CFAR and Local Max results <b>CFARCTRL.LBLCON</b>
Base address	Base address for data in Memory	<b>LBLBASE.BASE</b>
Label Calculation Base address	Value used as the base for label address calculation	<b>LBLCALC.BASE</b>
Label Calculation X multiplier	Value used as an address increment for the X dimension	<b>LBLX.MUL</b>
Label Calculation Y multiplier	Value used as an address increment for the Y dimension	<b>LBLY.MUL</b>
Label Calculation Z multiplier	Value used as an address increment for the Z dimension	<b>LBLZ.MUL</b>
Label Calculation X repeat	The number of elements in the X direction	<b>LBL.XRPT</b>
Label Calculation Y repeat	The number of elements in the Y direction	<b>LBL.YRPT</b>
Counter	Count of accepted bins	<b>MDq_LBLCNT.CNT</b>
Counter clear	Write a $1_B$ to clear the count	<b>MDq_LBLCNT.CLR</b>
Count limit	The maximum number of flagged bins to output as labels. The maximum number output is the value of this field plus one.	<b>CFARCFG3.LBLLOLM</b>
Wrap enable	Wrap the count to zero and address to LBLBASE.BASE	<b>CFARCFG3.LBLWRAP</b>

### Threshold Detection

The threshold detection function is integrated into the Bin Rejection Unit. The function checks to see if the bin being checked exceeds a programmed threshold. If the threshold is exceeded, then the bin is set to zero. The threshold comparison is based on the magnitude of the bin.

This is a 32 bit comparison. The 24 bit BINREJCTRL.VALUE is extended to 32 bits before being used. This extension can either be right or left justified. If the BINREJCTRL.LJUST bitfield is set to  $0_B$ , the extension is right justified and 8 MSBs of value  $0_B$  are added. If BINREJCTRL.LJUST is set to  $1_B$ , the extension is left justified and 8 LSBs of value  $0_B$  are added.

## Signal Processing Unit 2 (SPU2)

**Table 811 Thresholding Configuration Parameters**

Parameter	Definition	Comments
thresholding enable	enable / disable. If enabled, set a bin to zero if it exceeds the magnitude defined in BINREJCTRL.VALUE	Function is Combined into the Bin Rejection Unit <b>BINREJCTRL.ZMODE</b>
threshold value	user defined value	<b>BINREJCTRL.VALUE</b>
Threshold Extension Mode	Left or Right Justification of the VALUE value in the 32 bit comparison value	<b>BINREJCTRL.LJUST</b>

### 20.3.5.3.4 Half Precision Floating Point Format

The FFT results can be reformatted in IEEE 754 binary16 (half precision) floating point format. This is enabled by setting the bit **BEx\_ODP\_CONF (x=0-1).HPFP** to  $1_B$ . The outputs from Non-Coherent Integration and Digital Beam Forming also support this format.

The half precision floating point format has:

- a sign bit
- 5 bits of exponent encoding a value between -14 and 15
- 11 bits of significand precision<sup>1)</sup>

With this format, the magnitude which can be encoded ranges from a minimum of  $1 \times 2^{-14}$  (neglecting subnormal numbers<sup>2)</sup>) to a maximum of  $(2-2^{-10}) \times 2^{15}$  which is equivalent to  $2^{16}-2^5 = 65504$ .

The maximum range of a 32 bit signed integer is from  $-2147483648$  ( $0-2^{31}$ ) to  $2147483647$  ( $2^{31}-1$ ). To best fit this into the range of the half precision floating point format, the 32 bit precision number is first divided by  $2^{15}$  to give a range of  $-65536$  ( $0-2^{16}$ ) to (neglecting the fractional component<sup>3)</sup>  $65535$  ( $2^{16}-1$ ). This is then converted to the half precision floating point format with values less than -65504 or greater than 65504 saturating at the relevant limit.

For unsigned 32-bit power data the number is first divided by  $2^{16}$  and then treated the same as signed data.

The rounding used during these conversions is “round to nearest, ties to even”.

### 20.3.5.3.5 FFT Data Compression

The FFT data in half precision floating point format may be compressed so that 16 complex values fit into one 256 bit word in memory. This is enabled by setting the bit **BEx\_ODP\_CONF (x=0-1).COMPRESS** to  $1_B$ . The ODP\_CONF.ROF, ODP\_CONF.SCALE and ODP\_CONF.EXPNT bitfields have no effect if this mode is enabled. If this mode is enabled the ODP\_CONF.IPF field may only be set to  $1_B$  if RM\_CONF2.FORMAT==COMPRESS otherwise the behavior is undefined. The compressed format only applies to complex FFT data. The compression is lossy.

### 20.3.5.4 Dual Integration Units

The two Integration units are both capable of performing Non-Coherent Integration (NCI) or Digital Beam Forming (DBF), also known as Coherent Integration (CI). Each unit combines the data from multiple antennae into a single output in the complex domain or power domain, depending on how it is configured. When an Integration unit is enabled the Input DMA Engine should also be configured in Integration Mode (RM\_CONF2.PM=IM) so that the buffer RAM contains one FFT result from each connected antenna.

- 
- 1) 10 bits are stored to specify the fractional part of the significand with an implicit lead bit. The lead bit value is 1 unless the exponent field is stored with all zeros
  - 2) Support for subnormal numbers is not implemented. Any conversion result which would require representation using a subnormal number is instead represented as 0.
  - 3) With fractional component 65535.99997

## Signal Processing Unit 2 (SPU2)

The units are enabled and their operation configured by setting NDCTRL.MODE while writing of the output to Radar Memory is enabled by ND\_BASEb.EN. If a unit is not enabled then its related ND\_BASEb.EN has no effect. The antennae included in the sum of products are selected by a bit mask in NDCTRL.USEANTI and each selected antenna has its own multiplication constant. The summed result can be scaled to prevent overflow. The scaling operation is configured using the NDCTRL.SCALEi bitfield. The format of the output data is controlled by the NDCTRL.FORMATi bitfield. Data can be written as 16 bit, 32 bit integer or half precision floating point real or complex values. For the real-only data output modes when the Unit is in DBF mode, the power ( $|•|^2$ ) of the complex value is calculated before output to memory. The output that connects to the CFAR engines is always the power value.

Note that, if either Integration module is enabled, the CFAR module can only be used to process output from one of the Integration units, as reading data for direct input to the CFAR and Integration require different addressing modes for the Buffer RAM. The CFARCTRL.SRCSEL field should be set to INT0 or INT1 when the Input DMA Engine is configured in Integration Mode.

**Table 812 Integration Unit Configuration Parameters**

Parameter	Definition	Comments
Unit operation mode	enable or disable each unit and set its operation mode <sup>1)</sup>	<b>NDCTRL.MODE</b>
operand output format	16 or 32bits, half precision floating point	<b>NDCTRL.FORMATi</b>
weights	individual weights per antenna stored in configuration memory	32bit precision <b>NDCBASE.NDCBASEi</b>
antennae	which antennae to include	<b>NDCTRL.USEANTI</b>
result rescaling	optional result division by 1 or by 2 or by 4 or by 8.implemented using shift where sign extension is maintained.	to avoid saturation when having multiple antenna <b>NDCTRL.SCALEi</b>
output base address	starting point in memory where data shall be written	<b>ND_BASEi.BASE</b>
output enable	enable output to Radar Memory	<b>ND_BASEi.EN</b>

- 1) If the integrated data will neither be used by other processing units nor written to Radar Memory then enabling this bit will have no effect on processing flow i.e. the extra read pass through the buffer memory will not take place.

**Table 813 Integration Unit Modes**

Parameter Value	Unit 0 Operating Mode	Unit 1 Operating Mode
<b>OFF</b>	Disabled	Disabled
<b>NCI_OFF</b>	NCI	Disabled
<b>NCI_NCI</b>	NCI	NCI
<b>NCI_DBF</b>	NCI	DBF
<b>DBF_OFF</b>	DBF	Disabled
<b>DBF_DBF</b>	DBF	DBF

### 20.3.5.4.1 Digital Beam Forming

A unit performs DBF by combining the equivalent values from each antenna stored in the Buffer RAM using a complex multiplication of the sample point followed an addition. Each antenna can have its own multiplication constant. The multiplication weights are 16 bit, signed, complex numbers.

## Signal Processing Unit 2 (SPU2)

The input to DBF is 32 bit signed complex data. This is multiplied by the 16 bit complex weighting constant to give a 48 bit result. The resulting value is added into two 51 bit accumulators, one for each component of the complex data. Once the values derived from the equivalent bins of all FFT results in the buffer RAM are added into the accumulators, the accumulator results can then be right shifted by 0, 1, 2 or 3 bits depending on the NDCTRL.SCALEi setting.

The 32 bit output value for each component will be taken from bits [47:16] of the relevant accumulator value. The operation is equivalent to dividing by  $2^{15}$  and then rounding down to the nearest integer.

For power format output, the power of the complex result is calculated using the method described in [Section 20.3.5.1.1, “Linear Power Calculation” on Page 40](#).

If a 16 bit precision result output is configured, each component will be derived from bits [47:32] of the relevant accumulator. The operation is equivalent to dividing the accumulator by  $2^{31}$  and rounding to the nearest integer.

For half precision floating point output the value will be taken from bits [47:16] as for the 32-bit value and then treated the same way as FFT data as described in [Section 20.3.5.3.4, “Half Precision Floating Point Format” on Page 48](#).

If any of bits [49:47] of the accumulator value are different to the sign bit (bit 50), then an overflow condition is detected and the output shall be saturated according to the value of the sign bit. For integer formats this is maximum positive and maximum negative. For half precision floating point formats the output value is set to the IEEE 754 Infinity value of  $7C00_H$  for positive sign and  $FC00_H$  for negative sign. This saturation is also reflected in the result of the power calculation except the saturated value is always positive.

Normally the NDCTRL.DBFREAL should be set to COMPLEX. Setting the NDCTRL.DBFREAL field to REAL will result in only the real part of the weights and FFT bin value being used in the multiplication and real result being fed directly to the addition. When NDCTRL.DBFREAL==REAL and a complex output format is selected the imaginary part shall be set to zero.

**Table 814 Digital Beam Forming Configuration Parameter**

Parameter	Definition	Comments
real mode	real-only calculation: ignore imaginary part, zero imaginary part of output	<b>NDCTRL.DBFREAL</b>

### 20.3.5.4.2 Non-Coherent Integration

The input to NCI is unsigned 32 bit linear power. If the data in the buffer memory is already a power value, due to the setting of RM\_CONF2.FORMAT, then the power calculation is bypassed. The input is multiplied by the 16 bit real part<sup>1)</sup> of the weighting constant to give a 48 bit result. This weight is unsigned. The weighted power value is added into a 51 bit accumulator. Once the power values derived from the equivalent bins of the selected FFT results in the buffer RAM are added into the accumulator, the accumulator result can then be right shifted by 0, 1, 2 or 3 bits depending on the NDCTRL.SCALEi setting. If the data in the buffer memory is complex then a 32 bit linear power value is calculated before the multiplication.

The 32 bit output value will be taken from bits [47:16] of the accumulator value. The operation is equivalent to dividing by  $2^{16}$  and then rounding down to the nearest integer.

If a 16 bit precision result is configured this will be derived from bits [47:32] of the accumulator. The operation is equivalent to dividing the accumulator by  $2^{32}$  and rounding to the nearest integer.

The half precision floating point value will be taken from bits [47:16], the same as for the 32-bit output value, and then treated the same way as FFT data as described in [Section 20.3.5.3.4, “Half Precision Floating Point Format” on Page 48](#).

1) The coefficients in configuration memory are still 16-bit complex values but the imaginary part is ignored when in NCI mode.

## Signal Processing Unit 2 (SPU2)

For the integer output formats, if any of bits [50:48] of the accumulator result are set, then an overflow condition is detected and all of bits of the output will be set to saturate the output value. For half precision floating point formats the output value is set to the IEEE 754 +Infinity value  $7c00_{H}$ .

### 20.3.5.5 Constant False Alarm Rate Module

The CFAR module is used to identify interesting points in the data and then filter the data so that only these points are written to Radar Memory. There are 2 engines that may operate at the same time.

For each engine, if output is enabled, the results are written to Radar Memory as a table. The same information is also always fed to the Bin Rejection unit via the Logical Function. The output of that Logical Function may also be written to Memory as a list of labels that locate each point of interest in the 3D space formed of the bin number, FFT number and antenna number.

#### 20.3.5.5.1 CFAR Input Sources

There are 3 selectable sources of data for the CFAR module input as described below. The data source is selected by the CFARCTRL.SRCSEL field. The same input data goes to both engines.

##### FFT Data

Each ramp from each antennae is used to generate a set of sample power values taken from the unit described in [Section 20.3.5.1.1, “Linear Power Calculation” on Page 40](#).

##### Data from Integration Unit 0

As the data is read from the memory, it is routed through the first Integration Unit to produce a composite sample power value. This is then used for the CFAR input.

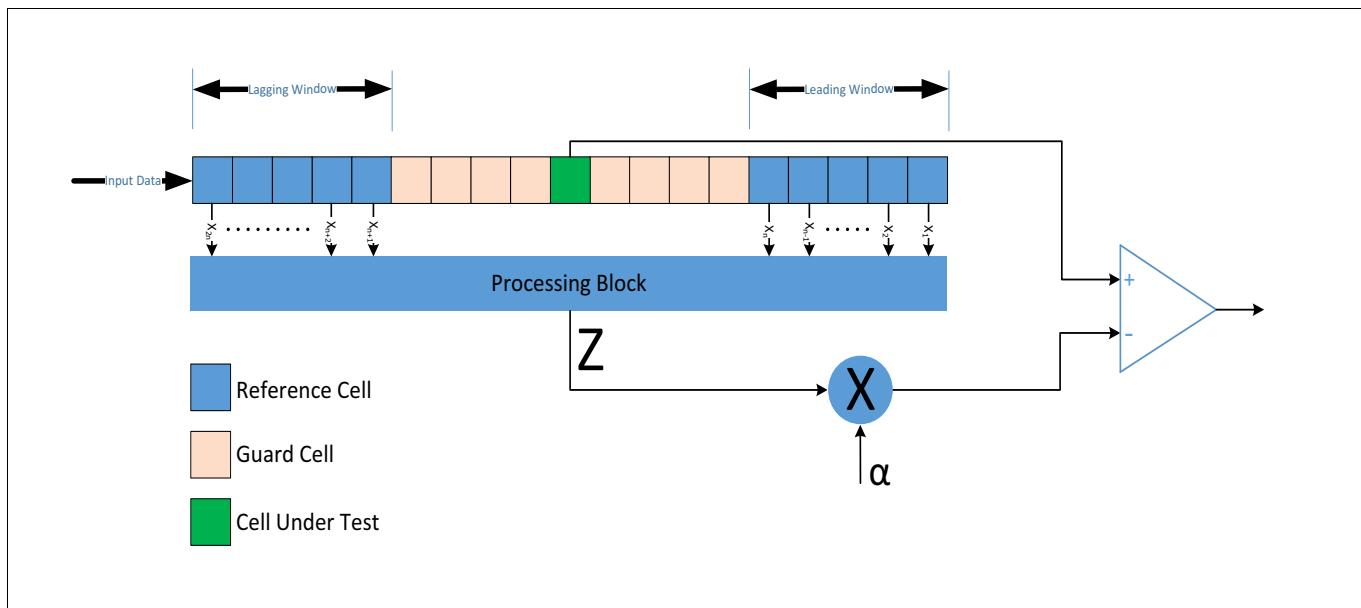

##### Data from Integration Unit 1

As the data is read from the memory, it is routed through the second Integration Unit to produce a composite sample power value. This is then used for the CFAR input.

#### 20.3.5.5.2 CFAR Engine Architecture

The following diagram shows the top level architecture of the CFAR engine

## Signal Processing Unit 2 (SPU2)

**Figure 262 CFAR Engine Architecture**

Input power samples are shifted through the processing window, which consists of windows of reference cells on either side of the Cell Under Test (CUT). Each window is separated from the Cell Under Test by a configurable number of guard cells. The windows cells are processed to generate a threshold value ( $Z$ ). This is then scaled for comparison with the CUT value. Note that in this diagram, the threshold is shown as  $Z$  multiplied by a constant "alpha". The actual implementation outputs  $Z$  as  $\log_2$  power, not linear power so the actual implementation is  $\log_2(Z) + \text{beta}$ , where beta is  $\log_2(\alpha)$ . The parameter beta is available as a register bitfield for both engines.

### 20.3.5.5.3 CFAR Engine Data Format

The CFAR engine uses a 64 bit linear power value internally. This is obtained from the 32 bit values computed by the TC3Ax SPU logic by multiplying by  $2^{31}$  to generate a maximum possible value of  $7FFF\_FFF\_8000\_0000_H$ . Where the CFAR engine uses  $\log_2$  power for internal calculations or comparison, this is computed as a 16 bit log2 value with 7 integer and 9 fractional bits from the 64 bit linear power value.

### 20.3.5.5.4 CFAR Module Configuration

The CFAR module contains two, independent engines. One engine implements the CA-CFAR algorithm and some derivatives (including CASH-CFAR). The other implements the GOS-CFAR algorithm and some derivatives. Both engines can be independently enabled and configured.

The engines are controlled by the CFARCTRL.CFAR\_CAE bitfield for the CA engine and the CFARCTRL.CFAR\_GOSE bitfield for the GOS engine. The results from one or both engines may be written to Radar Memory by setting the CABASE.EN or GOSBASE.EN bitfields. Separate base addresses for output are defined by the CABASE.BASE and GOSBASE.BASE bitfields. If an engine is not enabled then its output enable (EN) bitfield has no effect and no data will be written to Memory.

The CFAR results can also be used to control the Bin Rejection unit. This is enabled by setting the CFARCTRL.LFUNC bitfield to a value that results in the output of the Logical Function being influenced by one or both engines. When an engine is not enabled its output to the Bin Rejection unit is fixed to zero.

The results data will be written to Radar Memory at incrementing contiguous addresses starting from the programmed base address for each engine. Results will be in ascending bin order with bin 0 stored at the LSB of the word at the lowest address. Results of less than 256 bits in length will be aligned on a power of 2 bit address boundary i.e.

## Signal Processing Unit 2 (SPU2)

- results of more than 8 bits size and less than 17 bits size will be aligned on 16 bit boundaries (one result in every 2 bytes of memory) results of more than 16 bits size and less than 33 bits size will be aligned on 32 bit boundaries (one result in every 4 bytes of memory)
- results of more than 32 bits size and less than 65 bits size will be aligned on 64 bit boundaries (one result in every 8 bytes of memory)
- results of more than 64 bits size and less than 128 bits size will be aligned on 128 bit boundaries (one result in every 16 bytes of memory)
- results of more than 128 bits size and less than 257 bits size will be aligned on 256 bit boundaries (one result in every 32 bytes of memory)
- Results of more than 256 bits will be rounded up in size to the next 256 bit (32 byte) address boundary.
  - e.g. a result with 734 bits of data will be fitted into 768 bits (96 bytes) of memory

**Table 815 1D-CFAR Engines Common Configuration Parameters**

Parameter	Definition	Comments
CA Base Address	Starting address for writing CA-CFAR results to memory	<b>CABASE.BASE</b> Word Address, must be 256 bit (32 byte) aligned
GOS Base Address	Starting address for writing GOS-CFAR results to memory	<b>GOSBASE.BASE</b> Word Address, must be 256 bit (32 byte) aligned
Number of bins	From FFT8 to FFT2048. Any intermediate power of 2 value supported	FFT size is passed from the loader configuration <sup>1)</sup> <b>LDR_CONF.SIZE</b>
CFAR input selection	Select input from FFT engine, INT0 or INT1	Note that when input from FFT engine is used, signal power will be computed on each received BIN. <b>CFARCTRL.SRCSEL</b>
Spectrum extension mode	Select one of two extension modes depending on whether CFAR is run on range or doppler: mode1 = spectrum extension for range mode2 = spectrum extension for doppler	<b>CFARCTRL.EXTNSEN</b>
Spectrum Extension Window	Number of extra cells to be added on each end of the CFAR data	<b>CFARCTRL.SEWIN</b>
CFAR enable	CFAR enabling / disabling	<b>CFARCTRL.CFAR_CAE and CFARCTRL.CFAR_GOSE</b>
Label mode select	Enable and select label list output mode	<b>CFARCTRLLBLMODE</b>

1) If the FFT accelerator is bypassed, the size of the input data is derived from the bin loop repeat value (ID\_RM\_BLR.BLR) if data is sourced from Radar Memory or sample count (ID\_CONF.SMPLCNT) if the data is sourced from the RIF

### 20.3.5.5.5 GOS-CFAR Engine

Configuration Parameters for the GOS-CFAR Engine are detailed in the following table

## Signal Processing Unit 2 (SPU2)

**Table 816 GOS-CFAR engine SW configuration parameters**

Parameter	Definition	Comments
GOS-CFAR algorithm	Selects between CA, GO and SO	<b>CFARCFG1.GOSALGO</b>
number of cells in leading and lagging windows for GOS-CFAR	Can be set to any value from 1 to 32 cells either side of the cell under test	leading and lagging window <b>CFARCFG2.GOSWINCELL</b>
number of guard cells	This field has a possible value range of 0-63 but only values from 0 o 30 are permitted.	<b>CFARCFG2.GOSGUARD</b>
GOS-CFAR Beta parameter	16 bit, unsigned number with 7 integer bits and 9 fractional bits. Used to adjust the threshold i.e. Cell Under Test must exceed the trigger value by more than this parameter. The parameter represents $\log_2$ power	<b>CFARCFG3.GOSBETA</b>
GOS-CFAR Lead Index	Index of sorted statistic in leading window in GOS-CFAR	<b>CFARCFG2.IDXL0</b> min value 0, max value GOSWINCELL-1
GOS-CFAR Trailing Index	Index of sorted statistic in lagging window in GOS-CFAR	<b>CFARCFG2.IDXLG</b> min value 0, max value GOSWINCELL-1

In the GOS-CFAR algorithms, the samples within the leading/lagging windows are processed through a non-linear sorting operation and selected ordered statistics:  $Y_1$ ,  $Y_2$  are extracted from the two sub-windows, respectively. The GOSCA, GOSGO, and GOSSO algorithms differ in the manner  $Y_1$ ,  $Y_2$  are combined:

- GOSCA:  $Z = Y_1 + Y_2$
- GOSGO:  $Z = \max\{Y_1, Y_2\}$
- GOSSO:  $Z = \min\{Y_1, Y_2\}$

The resulting statistic  $Z$  is finally scaled by the “beta” scaling factor in order to determine the threshold value. The value of the “beta” parameter determines the probabilities of False Alarm (FA) and Missed Detection (MD). For the GOSGO and GOSSO algorithms the  $\log_2$ -domain input power sample implementation is directly equivalent to the linear one, since both the sorting and max/min operations produce equivalent ( $\log_2$ -domain) values for  $Z$ . The only difference is that the threshold value is produced by scaling  $Z$  additively with “beta”. On the other hand a direct  $\log_2$ -domain implementation of the GOSCA algorithm is not normally equivalent to the linear-domain implementation, since  $\log_2(Y_1 + Y_2)$  is not equal to  $(\log_2(Y_1) + \log_2(Y_2))$ . However in the CFAR module an equivalent  $\log_2$ -domain result to the linear domain one is obtained by post processing.

### 20.3.5.6 CA-CFAR Engine

The CA-CFAR engine supports the CA-CFAR, CAGO-CFAR, CASO-CFAR and CASH-CFAR algorithms. The configuration Parameters for the CA-CFAR Engine are detailed in the following table:

## Signal Processing Unit 2 (SPU2)

**Table 817 CA-CFAR engine configuration parameters**

Parameter	Definition	Comments
CA-CFAR algorithm	selects between CA, CAGO,CASO and CASH	<b>CFARCFG1.CAALGO</b>
CA-CFAR Beta parameter	16 bit, unsigned number with 7 integer bits and 9 fractional bits. Used to adjust the threshold i.e. Cell Under Test must exceed the trigger value by more than this parameter. The parameter represents $\log_2$ power	<b>CFARCFG1.CABETA</b>
number of guard cells	can be set to any value from 0 to 16 <sup>1)</sup>	any value from 0 to 16 permitted <b>CFARCFG1.CAGUARD</b>
number of cells in leading and lagging windows for CA-CFAR	This defines the window size for comparison. The window size used is $2^n$ , where n is the value in the register bitfield	leading and lagging window <b>CFARCFG1.CAWINCELL</b> min value 1, max value 5
active cells in window to be used for averaging for CA-CFAR/CASH-CFAR	This defines the window size for averaging within the leading and lagging windows. The window size used is $2^n$ , where n is the value in the register bitfield	<b>CFARCFG2.CASHWIN</b> min value 0, max value 5. Must be less than or equal to CAWINCELL value when CASH algorithm is selected. Otherwise must be equal to CAWINCELL

1) Values greater than 16 will cause undefined operation and incorrect results

In the CASH and CA-CFAR algorithms, the samples within the leading/lagging windows are processed through sample averaging to produce  $Y_1$ ,  $Y_2$  statistics for the leading and lagging windows respectively. Averaging is performed in the linear power domain and conversion into the  $\log_2$ -domain is performed prior to the application of the non-linear/linear operation in the processing block as shown in [Figure 262 “CFAR Engine Architecture” on Page 52](#).

In CASH-CFAR, the  $\log_2$ -converted averaged power samples are processed through MAX and MIN operations, as described in “F. X. Hofele, An Innovative CFAR Algorithm, CIE Intern. Conf. on Radar, 2001” and associated patents.

In CA/CAGO/CASO-CFAR the  $\log_2$ -domain processing is similar to the GOS-CFAR.

Threshold scaling in CASH/CA-CFAR is performed additively using the “beta” parameter in a similar manner to that used by GOS-CFAR.

### 20.3.5.5.7 CFAR Engine Configuration Restrictions

The CFAR engine requires some constraints on configuration to avoid undefined results

- The value of two times the sum of the number of guard cells and the number of cell in the window must not exceed the FFT size minus one.
- If spectrum extension is enabled, the spectrum extension window size, CFARCTRL.SEWIN, must equal to the largest sum of the number of guard cells and the number of window cells for all CFAR engines that are enabled. The sum must be calculated for each engine and the largest value must be used.
- The achievable maximum value for the  $\log_2$  power representation of the linear power is  $7DFF_H$  (for a linear power of  $7FFF\_FFFF\_8000\_0000_H$ ) If the Beta parameter exceeds this value, it is impossible for any detection to occur.

---

## Signal Processing Unit 2 (SPU2)

### 20.3.5.5.8 CFAR spectrum extension

Two extension modes need to be considered: range extension and velocity extension.

Range and Velocity extension is supported by shifting additional data points into the CFAR unit at the beginning and end of the FFT to preload the window cells with the correct data. This requires the equivalent number of output data points from the CFAR to be ignored. This will be handled transparently by the supporting logic if this mode is enabled

Spectrum extension is always done per FFT dataset by adding additional bins to the dataset. The content replicating the value of some of the existing bins into the new bins. Data is fed into the CFAR unit on a “per antenna” basis. Spectrum Extension never uses data from more than one antenna. The bins to be replicated depend on the spectrum extension mode.

Spectrum extension will cause some data to be read twice from the buffer memory. The amount of extra reads will be directly linked to the size of the extension defined by CFARCTRL.SEWIN. SEWIN should be set to be no larger than the largest window as required according to the settings of the active units: CA CFAR, GOS CFAR and LCLMAX.

**Note:** *Spectrum Extension is used in conjunction with the CFAR or Local MAX functions and should not be enabled if neither of these functions is enabled. Enabling the Spectrum Extension in the absence of enabling either CFAR or Local Max is not supported and will result in abnormal operation of the TC3Ax SPU.*

#### Spectrum Extension for CFAR in Range

In range spectrum extension, the spectrum is extended by mirroring across the border as illustrated in the figure below. In this figure, the y-axis is along the FFT dataset (bin number ascending from the bottom of the figure).

## Signal Processing Unit 2 (SPU2)

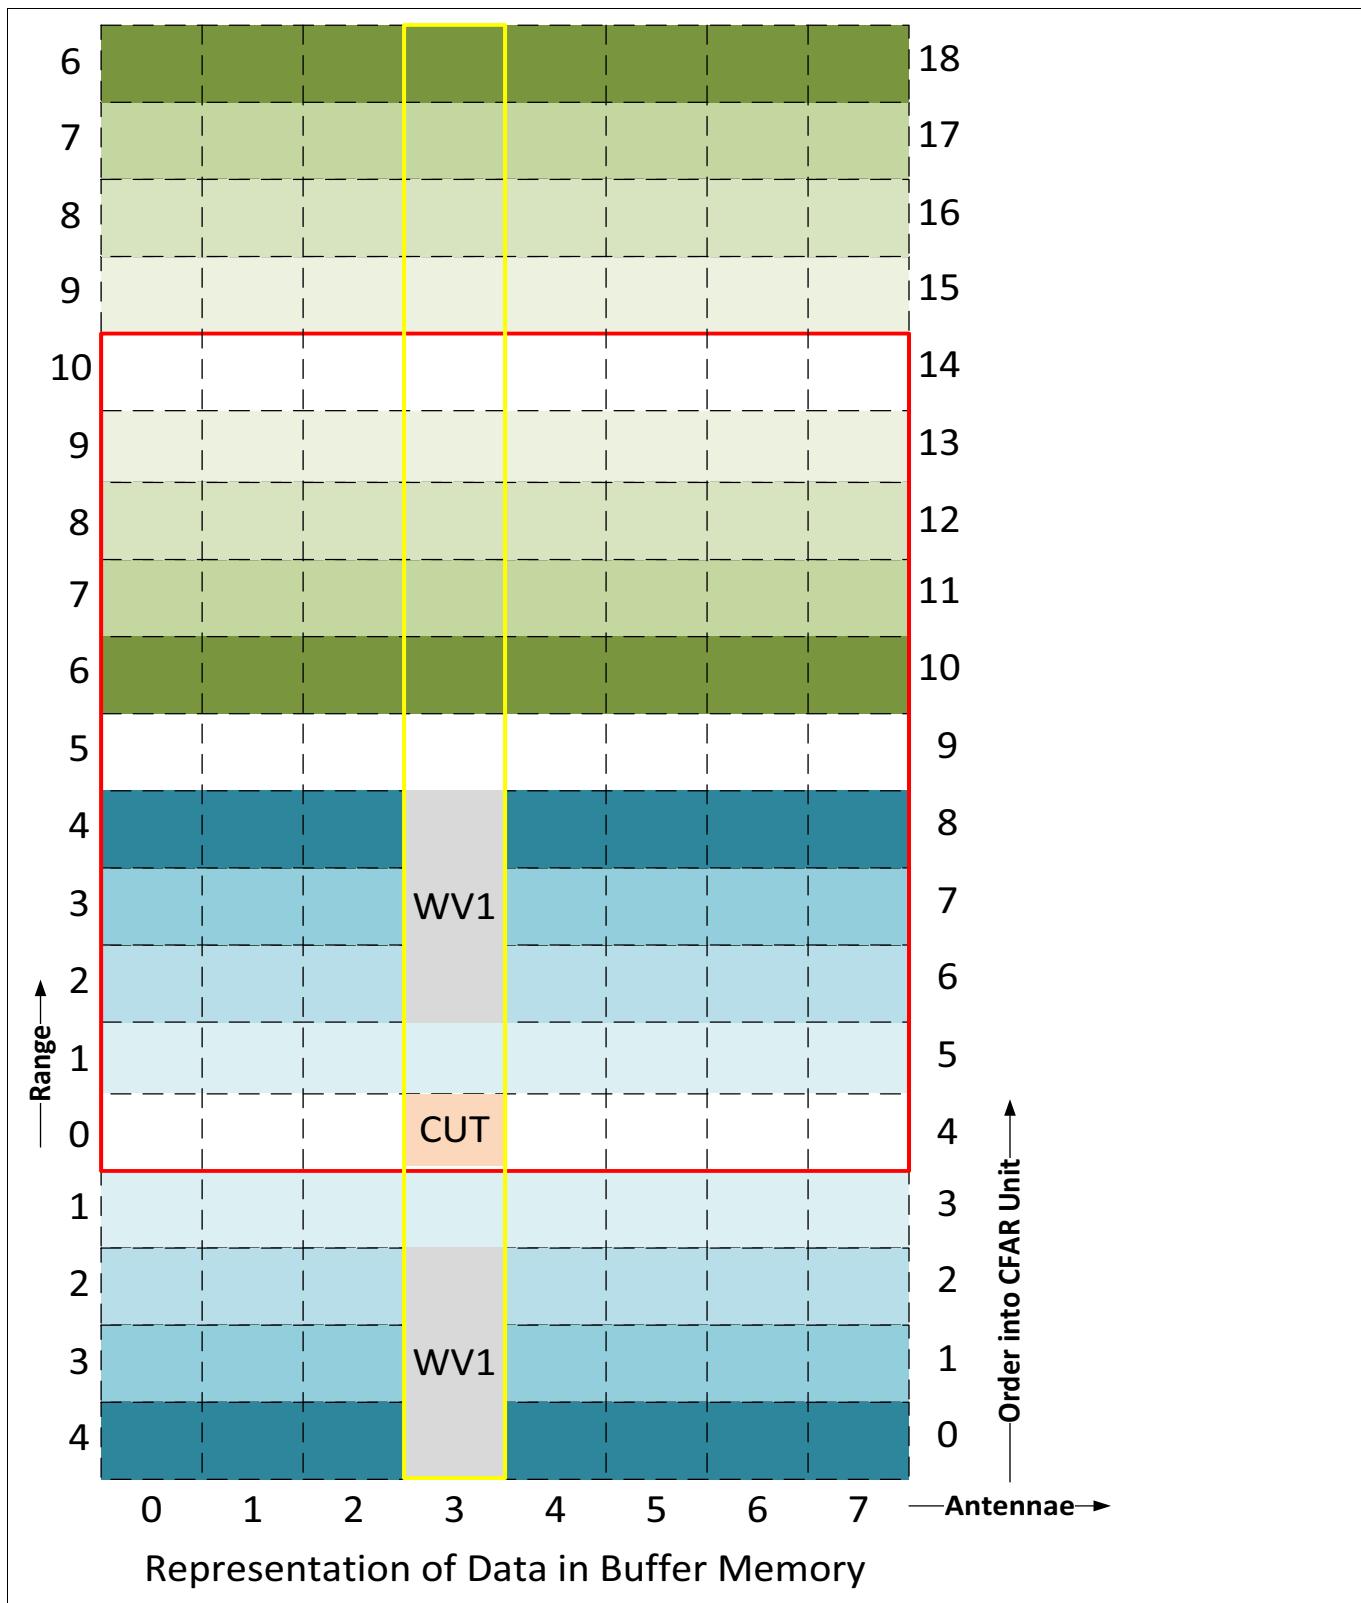

Figure 263 Diagram of Range Spectrum Extension

Please note that the figure is only showing the principle as real extension needs to be done according to the window size for range and for velocity directions. The extent of the “real” data is shown by the red rectangle. The effective size of the dataset and the mirroring used to achieve it is shown by the color coding. The extended

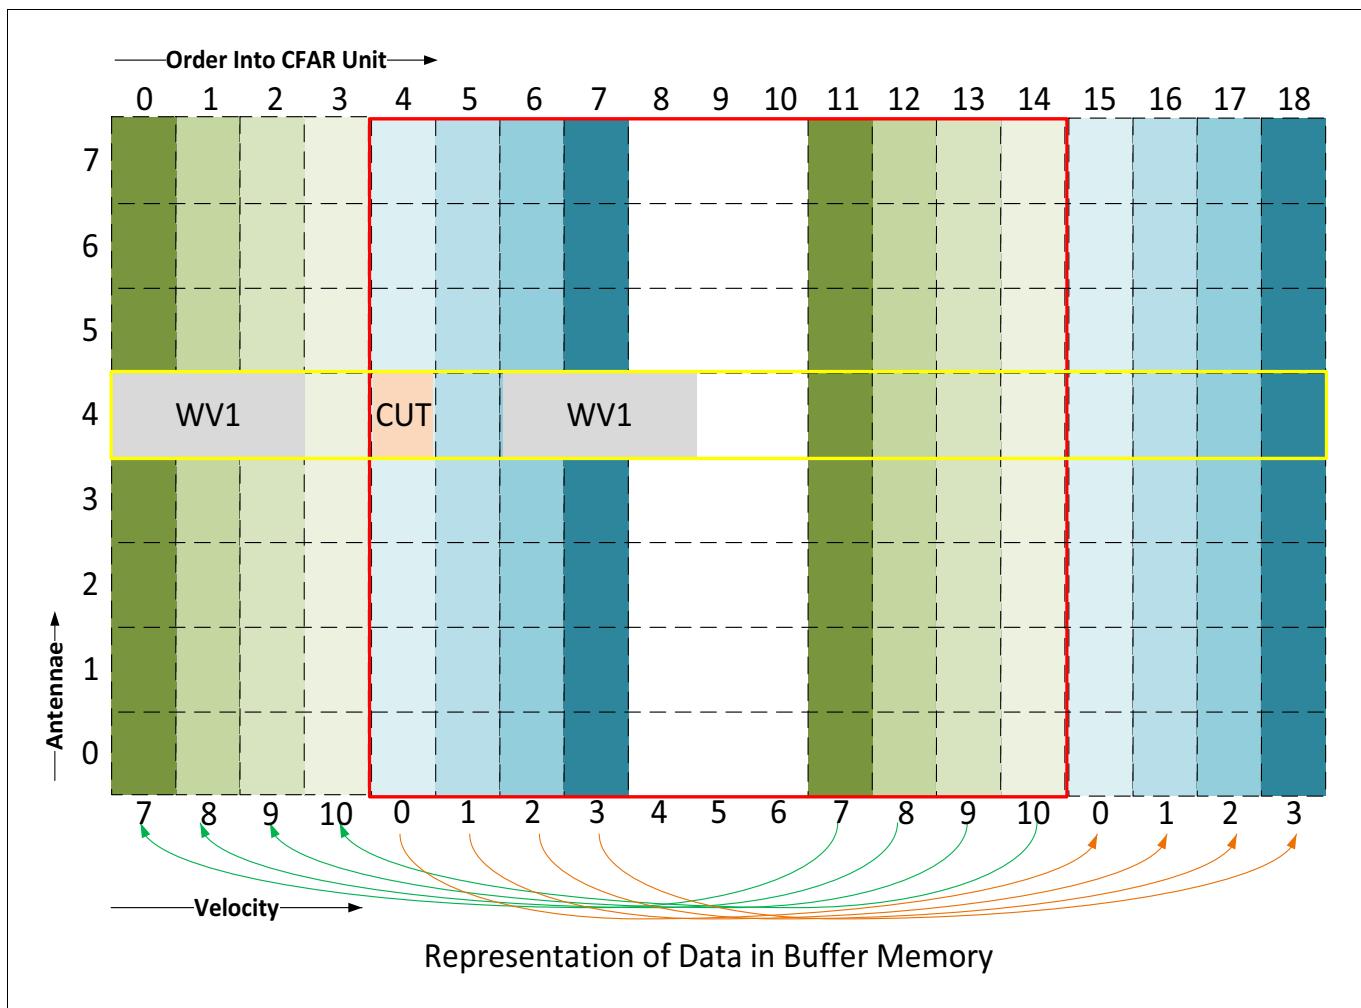

## Signal Processing Unit 2 (SPU2)

dataset fed to the CFAR units is shown as the yellow rectangle. CUT is “Cell Under Test” and WV1 represents an example window with guard band.

The behaviour if the window size exceeds the size of the dataset is not defined.

### Spectrum Extension for CFAR in Velocity

In velocity / Doppler direction, the spectrum is extended by implementing cyclic repetition. The color coding in the diagram below shows how the repetition is implemented. The extent of the “real” data is shown by the red rectangle. Please note that the figure is only showing the principle as real extension needs to be done according to the window size for range and for velocity directions.

**Figure 264 Diagram of Velocity Spectrum Extension**

The extent of the “real” data is shown by the red rectangle. The effective size of the dataset and the mirroring used to achieve it is shown by the color coding. The extended dataset fed to the CFAR units is shown as the yellow rectangle. CUT is “Cell Under Test” and WV1 represents an example window with guard band.

The behaviour if the window size exceeds the size of the dataset is not defined.

## Signal Processing Unit 2 (SPU2)

### Spectrum Extension on Outputs from Integration (NCI/DBF)

Spectrum extension is always a one-dimensional operation which affects the input to the CFAR unit. When using spectrum extension with input from the integration units, the integration is performed first and the spectrum extension is then applied to the resulting one-dimensional vector as if dealing with a single antenna system.

### Spectrum Extension for Local Maximum

Spectrum extension for the Local Maximum function operates in the same way as for CFAR. When both Local Maximum and CFAR are enabled then the extension window should be set to suit the largest of the values need by the CFAR and Local Maximum units.

#### 20.3.5.5.9 Operation of Spectrum Extension

The spectrum extension modes work by adding extrapolated bins to each end of the FFT results. The number of pins added depend on the window size in use. For a window of e.g. 7 bins on each side of the bin under evaluation and additional 7 extrapolated bins will be added to each end of the FFT data to ensure that the first and last real bins are evaluated against a full set of window data.

Operation of the spectrum extension modes is controlled by the bitfield CFARCTRL.EXTNSN

For range spectrum extension, the extrapolated bins are mirrored. This means that when bin 0 is under comparison, real bins 1 to n are used for the values of extrapolated bins -1 to -n respectively (where n is determined by the comparison window size). For a 256 point FFT real bins 254 to 254-n are used for the values of extrapolated bins 256 to 256+n when evaluating bin 255.

For velocity spectrum extension, the extrapolated bins are determined by cyclic repetition. Again, using a 256 bin FFT as an example, when evaluating bin 0, extrapolated bins -n to -1 will be the values of real bins 255-n to 255. When evaluating bin 255, extrapolated bins 256 to 256+n will be the values of real bins 0 to n.

#### 20.3.5.6 Statistical Information

The output of Statistical data is enabled by setting SBCTRL.EN to 1<sub>B</sub>.

The mean value computed by the Unloader Unit is queued for writing to the Radar Memory. Additionally, the mean value is used to compute the variance (standard deviation squared) for each FFT. While the FFT data is being parsed to compute the variance, the minimum and maximum power values will be captured

Along with the minimum and maximum power values, the index of the FFT bin at which the minimum and maximum occurred will also be captured.

In the event of multiple bins having the same minimum or maximum, only the index of the first bin to have the value will be captured.

The base address for the writes to start is defined in SBCTRL.BASE. and configuring either of the enable conditions will result in the statistical information output channel being enabled. However, only the requested data will be written. When SBCTRL.EN is 1 then the statistical information will be written in packets of 32 bytes per FFT (256 bit aligned) with 20 bytes of data and 12 spare bytes of indeterminate value. See [Table 818 "Statistical Information Written" on Page 59](#) for the data format used.

**Table 818 Statistical Information Written**

Parameter	Size (bytes)	Address Offset
Minimum Power	4 <sub>D</sub>	0 <sub>D</sub>
Maximum Power	4 <sub>D</sub>	4 <sub>D</sub>
Mean Power	4 <sub>D</sub>	8 <sub>D</sub>

## Signal Processing Unit 2 (SPU2)

**Table 818 Statistical Information Written (cont'd)**

Parameter	Size (bytes)	Address Offset
Variance	4 <sub>D</sub>	12 <sub>D</sub>
FFT Bin Index for Minimum Power	2 <sub>D</sub>	16 <sub>D</sub>
FFT Bin Index for Maximum Power	2 <sub>D</sub>	18 <sub>D</sub>

The configuration parameters affecting the statistical data output are shown in [Table 819 “Statistical Unit Configuration Parameters” on Page 60](#)

**Table 819 Statistical Unit Configuration Parameters**

Parameter	Definition	Comments
statistical data enable	enable / disable	<b>SBCTRL.EN</b>

### 20.3.6 Output DMA Engine

This section describes the operation of the DMA engine that the TC3Ax SPU uses to write results to memory.

#### 20.3.6.1 Output DMA Engine Channels

As described in [Table 804 “Output DMA Engine Data Streams” on Page 38](#), the Output DMA Engine has nine independent data channels. These are configured using the following parameters:

**Table 820 Output DMA Engine Configuration Parameters**

Parameter	Definition	Comments
DMA base address for port1	DMA base address when starting a new FFT sequence from Radar memory	FFT results only <b>ODP_BASE.BASE</b>
DMA inner loop address offset	Offset address to be added to base address	FFT results only
DMA outer loop address offset	Offset address to be added to base address	These parameters are used for in-place FFT
DMA inner loop repeat value	Number of times of inner loop execution	
DMA outer loop repeat value	Number of times of butter loop execution	
DMA base address for port2	Signal power	<b>PWRCTRL.BASE</b>
DMA base address for port3	Statistics: min, max, mean, variance	<b>SBCTRL.BASE</b>
DMA base address for port4	Thresholding with CFAR CA	<b>CABASE.BASE</b>
DMA base address for port5	Thresholding with CFAR GOS	<b>GOSBASE.BASE</b>
DMA base address for port6	Non-Coherent Integration or Digital Beam Forming	<b>NDBASE0.BASE</b>
DMA base address for port7	Non-Coherent Integration or Digital Beam Forming	<b>NDBASE1.BASE</b>
DMA Base Address for port8	Thresholding with Local Maximum or Logical Function	<b>LCLMAXBASE.BASE</b> Output selected with CFARCTRL.LFOSEL
DMA Base Address for port9	Label list output	<b>LBLBASE.BASE</b>

## Signal Processing Unit 2 (SPU2)

**Table 820 Output DMA Engine Configuration Parameters (cont'd)**

Parameter	Definition	Comments
signed FFT BIN casting/rescaling	defines how many bits are kept from the LSB (of the 32bit internal precision) note that the sign, located on the MSB, is maintained.	<b>ODP_CONF.EXPNT</b>
output FIFO flush <sup>1)</sup>	FIFOs are flushed upon each configuration change. Required for the last computation step	This is an implicit parameter triggered internally when the processing of the last FFT in the measurement cycle is completed

1) Automatic Operation, no specific control bit included for this

Each of the BASE fields defines the start address for the output channel. The write address will be incremented automatically so that the results of each channel are stored as an array in memory starting from the defined base address.

The exception is the “In Place FFT” mode for writing the FFT results. Here the ODP\_BASE register is used as the start address and the address sequence is calculated using the Output DMA Engine Loop Count and Loop Offset parameters in the ODP\_ILO, ODP\_OLO, ODP\_BLO and ODP\_IOLR registers which behave in the same way as the equivalent registers in the Input DMA (see “[In Place FFT](#) on Page 36 and “[Load from Radar Memory](#) on Page 5).

The output data stream is pushed to Radar Memory without any possibility of delay or wait states. The Radar Memory is required to keep pace with the output data rate. This is achieved by giving writes absolute priority in arbitration and arranging separate arbitration for each 256 KiB Radar Memory tile.

**Note:** *In systems with two active SPUs or with BYPASS\_CTRL.BYPASS enabled, it is mandatory to ensure that the output from each TC3Ax SPU is directed to different tiles of the Radar Memory. In the event of arbitration being required between two TC3Ax SPU writes, then the write which loses arbitration will be lost.*

**Note:** *The TC3Ax SPU is specified to cope with Radar Memory sizes up to 16 MiB. Any accesses outside the range of the Radar Memory on the device will result in an error being generated by the Radar Memory module.*

### 20.3.6.2 Data Cube Organisation and Size after processing ADC data

The FFT results of processing ADC sample sets (ramp data) are always kept together in memory.

Each FFT result always starts at a 256 bit (32 byte) aligned address. This is mandatory if the data is to be read back into the TC3Ax SPU as the read operations controlled by the Input Data Manager require the start address of each dataset to be 256 bit aligned.

The ramp data are then grouped by antennae so the ramp n<sup>1)</sup> data for all antennae (inner loop output) is grouped together in memory. The size of the data cube is variable and depends on the following factors

- data format, real or complex
- data precision 16 bit or 32 bit (DPR)
- samples per ramp or FFT output (maximum bin loop count, BLC)

1) where n is the ramp number and also the outer loop count

## Signal Processing Unit 2 (SPU2)

- number of antennae (NA)
- number of ramps in measurement cycle (maximum outer loop count, OLC)

The size of each data point (SDP) is as follows

- 16 bit real: 2 bytes (DPR = 16 bit)
- 32 bit real: 4 bytes (DPR = 32bit)
- 16 bit complex: 4 bytes (DPR = 16 bit)
- 32 bit complex: 8 bytes (DPR = 32bit)

The size in bytes of the data generated for each configured antennae per ramp (ADS) is

$$\text{ADS(bytes)} = \text{BLC} \times \text{SDP} \quad (20.5)$$

The value for ADS will always be rounded up to the next 32 bytes (ADSR).

The overall dataset size (DS) is then

$$\text{DS(bytes)} = (\text{ADSR}) \times \text{NA} \times \text{OLC} \quad (20.6)$$

As the maximum amount of data that can fit into the Buffer RAM is 64kBytes, this gives a hard limit for the amount of data per inner loop (the ADS value).

### 20.3.7 Radar sequencer

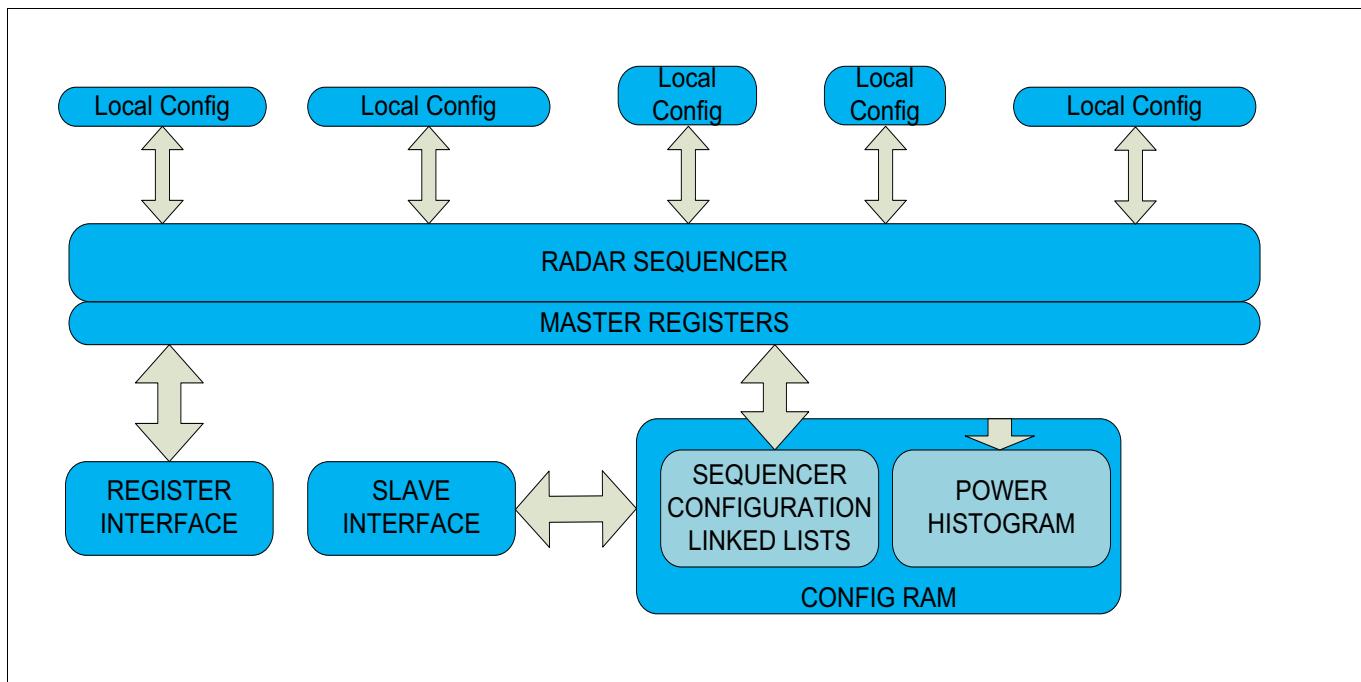

The Radar sequencer is the main control sequencer of the TC3Ax SPU. It manages the configuration/reconfiguration of each unit and controls the sequencing of operations. It also monitors each unit for correct operation and generates suitable signalling to the application software via the Interrupt system and the Safety Management Unit.

General principles of operation are:

- Configurations can be written directly to the registers of the TC3Ax SPU by application software
- However, configurations can also be stored in the configuration memory, which is a RAM accessible by the application software (this RAM is also used to store the histogram)
- Configurations may be organized in linked lists.

This following sections describe the features and behaviour controlled by the Radar Sequencer.

## Signal Processing Unit 2 (SPU2)

**Figure 265 Radar Sequencer Overview**

### 20.3.7.1 General Configuration

The Radar sequencer has several configuration options that define the overall configuration of the TC3Ax SPU.

**Table 821 General Configuration Options**

Function	Register	Bitfield	Comment
Clocking Mode	AUXCTRL	DIVF	Fractional clock division ratio for the LOADER/MATH0/MATH1/FFT/UNLOADER pipeline. The ratio is given by the formula $1 - DIVF/16$
	AUXCTRL	CLKRAMP	If enabled, the first and last input Buffer Memory of the configuration shall be processed at 50% of the TC3Ax SPU clock frequency
	CLC	DISR	Clock Disable. Switch off the TC3Ax SPU's internal clock
Linked List Base Address	CTRL	NXT_CONF	Base address for the next set of configuration information in the linked list
Start	CTRL	TRIG	Starts the Radar Sequencer if MODE==SW
Operating Mode	CTRL	MODE	Defines when the TC3Ax SPU will start processing input data
Attention	CTRL	ATTN	Trigger a service request interrupt when execution of the current configuration is completed
Cross Trigger	CTRL	XTRIG	Trigger a "DONE" event when execution of the current configuration is completed.

## Signal Processing Unit 2 (SPU2)

**Table 821 General Configuration Options (cont'd)**

Function	Register	Bitfield	Comment
Incremental Trigger	CTRL	ITRIG	Generate a pulse on the incremental trigger output after MATH2 has completed processing Buffer Memory contents and ODM has written all data to Memory.
Bypass Trigger	CTRL	BPTRIG	If set the Bypass function shall be triggered depending on the MODE setting
Last Configuration	CTRL	LAST	Current Configuration is the last configuration to be executed. Do not load a further configuration from the address defined by NXT_CONF

### 20.3.7.2 Radar sequencer start / stop

CTRL.MODE is used to define the conditions under which the TC3Ax SPU will start processing data.

The register space is organised so that the CTRL register should be the last register read during configuration by linked list. This ensures that a software trigger always starts with a valid data set. Starting processing of a linked list can be started either by writing a full set of register values directly into the register site finishing with a valid write to the CTRL register or by writing a MODE value of “RELOAD” and a valid NXT\_CONT value to the CTRL register

Writing a 1<sub>B</sub> to the CTRL.TRIG bit starts the radar sequencer provided that the CTRL.MODE bitfield is set to “SW” (software).

The TC3Ax SPU will stop processing a linked list when processing completes on a configuration which has the CTRL.LAST bit set or if the configuration just loaded contains “OFF” or “STOP” in the CTRL.MODE field.

**Note:** *The only difference between setting CTRL.LAST and loading a configuration set with CTRL.MODE set to OFF is that using CTRL.LAST eliminates an unnecessary configuration load. CTRL.MODE=STOP should only be used if it is required to abort processing of a linked list. If it is loaded from configuration memory then it will behave in the same way as setting CTRL.MODE to OFF.*

The CTRL.BUSY bitfield shows if the TC3Ax SPU is running or is stopped. Loading a configuration which has a CTRL.MODE field not set to OFF or STOP will cause the TC3Ax SPU to transition to the running state even if it is then just waiting for a trigger event. Once in the running state, software can only stop the TC3Ax SPU by writing “STOP” to CTRL.MODE. Any other value will have no effect.

**Note:** *Only the CTRL register should be written while the TC3Ax SPU is busy. Writing any other register will have immediate effects on the TC3Ax SPU configuration and may lead to undesirable consequences including a lock up of the TC3Ax SPU.*

**Table 822 CTRL.MODE Value Definitions**

Value	Function
OFF	TC3Ax SPU will do nothing. This is used to terminate a linked list operation when loaded from a configuration set in config RAM. Software writing OFF to the CTRL register once the TC3Ax SPU has been configured has no effect.
INT	TC3Ax SPU will pause waiting for data on the RIF input. Valid data on the RIF input will trigger operation. This can be qualified by the Partial Acquisition counter LIMIT value if the PACTR.TRIG bit is set

## Signal Processing Unit 2 (SPU2)

**Table 822 CTRL.MODE Value Definitions (cont'd)**

Value	Function
EXT	TC3Ax SPU will pause waiting for a trigger from an external source. Valid data on the RIF input will be ignored until the trigger event occurs. Valid data on the RIF data after the configured measurement cycle has completed will be ignored. If the Radar memory is configured as the data source, processing will commence immediately.
SPU0	TC3Ax SPU will trigger on an “DONE” event from SPU0 <sup>1)</sup>
SPU1	TC3Ax SPU will trigger on an “DONE” event from SPU1 <sup>1)</sup>
RELOAD	TC3Ax SPU will trigger an immediate configuration load from the value in the CTRL.NXTCONF field. Bypass will be triggered if CTRL.BPTRIG is set
SW	TC3Ax SPU will immediately start processing when a $1_B$ is detected in the CTRL.TRIG bitfield. The trigger event may occur simultaneously with “SW” being written to CTRL.MODE
STOP	This value should be written to the MODE bitfield if it is required to stop the TC3Ax SPU in the middle of linked list processing. If written while the TC3Ax SPU is processing data, the TC3Ax SPU will stop when the current processing operation is completed rather than loading the next configuration set. This value should not be loaded from a configuration set in RAM. In this case OFF should be used instead

1) Note that the TC3Ax SPU will only generate the “DONE” event when explicitly configured using the CTRL.XTRIG bitfield

The values INT and EXT are intended to be used when data is being read from one or more RIF instances.

The value EXT can also be used when reading data from Radar Memory.

SPU0, SPU1 and SW are intended to be used when reading data from Radar Memory.

As soon as any of the values: INT, EXT, SPU0, SPU1 or SW are written to the CTRL.MODE bitfield, the TC3Ax SPU will report its state as “BUSY” when CTRL.BUSY is read.

### 20.3.7.3 Synchronized Radar sequencer Start

The synchronised start function allows the 2 SPUs to be started at the same time. When using synchronised start, there will be no skew between the start point of the two SPUs. Synchronised start is configured setting the CTRL.MODE bitfield to EXT and triggering the start with an external source.

### 20.3.7.4 Configuration / Reconfiguration

During linked lists of computations, the Radar TC3Ax SPU supports full reconfiguration of the computation units of the TC3Ax SPU by reading the full register set from configuration memory. Partial reconfiguration is supported by making a copy of the previous configuration into the configuration memory and changing only the register fields affecting the functionality requiring reconfiguration before reloading it directly into the TC3Ax SPU registers using the linked list function.

### 20.3.7.5 Linked Lists Organization

A linked list is a set of configuration sets stored in Configuration Memory defining a sequence of computations that are run without CPU intervention. The linked list is stored in memory as an image of the registers, starting from ID\_CONF and ending at CTRL. The image of ID\_CONF is stored at the base address of the linked list entry and all the other registers are at the same relative offset as their address in the system memory map.

## Signal Processing Unit 2 (SPU2)

The registers outside the range from ID\_CONF to CTRL (including the CRC registers, CLC, MODID, STAT, MONITOR, OCS, ODA, USROTC, ACCEN, KRST0, KRST1 and KRSTCLR registers) cannot be reconfigured by the linked list function.

### 20.3.7.6 CPU monitoring during run time

The CPU(s) can read configuration registers during run time to check or wait for the radar sequencer to complete a computation sequence. The CPU can also read status registers to monitor the proper execution of the sequence. The following status registers can be monitored (read only) during run time

- ramp counter (derived from Input Data Manager)
- sample counter
- 1 busy flag per sub block
- 1 busy flag for TC3Ax SPU
- linked list sequence completed

### 20.3.7.7 Interrupts

The Radar TC3Ax SPU has a high degree of autonomy. As such, it generates few interrupts. Each interrupt source can be masked but for safety reasons, its flag can be read by application software.

Each TC3Ax SPU instance has two physical interrupt requests.

- Attention Request: asserted on one or more of events occurring during normal operation when intervention by the application software is needed
- Error Flag: asserted on an error condition when accurate completion of the calculation is compromised

The table below shows the different interrupt sources.

**Table 823 Interrupt Trigger Definition**

Event	Definition	Comments
End of execution	A configuration with the CTRL.ATTN bit set has completed execution	Attention Request <b>STATCTRL.INTMSK(0)</b>
Arithmetic Overflow During iFFT	The FFT accelerator has reported that an output number will not fit into the supported format	Attention Request <b>STATCTRL.INTMSK(1)</b>
Bypass Trigger	Set after the write of the last sample of the last ramp by Bypass function is confirmed.	<b>STATCTRL.INTMSK(2)</b>
End of linked list	Set after confirmed write of the last result of the outer loop.	Attention Request <b>STATCTRL.INTMSK(3)</b>
Partial Acquisition Counter Trigger	Partial Acquisition counter has reached programmed limit with PACTR.ATTN bit set	Attention Request <b>STATCTRL.INTMSK(4)</b>
Label List Counter Trigger 0	MD0_LBLCNT.CNT has reached half or full value as defined in CFARCFG3.LBLOLM	<b>STATCTRL.INTMSK(5)</b>
Label List Counter Trigger 1	MD1_LBLCNT.CNT has reached half or full value as defined in CFARCFG3.LBLOLM	<b>STATCTRL.INTMSK(6)</b>

## Signal Processing Unit 2 (SPU2)

**Table 823 Interrupt Trigger Definition (cont'd)**

Event	Definition	Comments
Radar Memory Read Error	Radar Memory has reported an error on read (see EMEM chapter for details)	Error Flag <b>STATCTRL.ERRMSK(0)</b>
Input DMA Unit write error	Address Overflow on Buffer Memory write	Error Flag <b>STATCTRL.ERRMSK(1)</b>
Radar Memory Write error	Radar Memory has reported an error on write (see EMEM chapter for details). This covers the Output DMA Engine, the Bypass Channel for RIF data and the MATH0 Output to Radar Memory	Error Flag <b>STATCTRL.ERRMSK(2)</b>
FIFO overrun	One or more of the TC3Ax SPU internal FIFOs has overflowed	Error Flag <b>STATCTRL.ERRMSK(3)</b>
Partial Acquisition Counter Error	Partial Acquisition Counter has reached limit with PACTR.ERR bit set	Error Flag <b>STATCTRL.ERRMSK(4)</b>
Input Data Overrun	The LOADER/FFT/MATH2 pipeline has not completed processing when the next set of FFTs have been fully written to buffer memory and the RIF has more data to be written for the following ramp. A ramp has (or ramps have) been skipped.	Error Flag <b>STATCTRL.ERRMSK(5)</b>

### 20.3.8 Streaming Processor 1, Buffer RAM Switching Behaviour

When the Input DMA Engine has finished writing a data block to the Buffer RAM, it will enable the switching of the Buffer RAMs to present the new data to the Loader module. If the Loader module is still reading the previous data block, the switch will not take place until the Loader module has finished.

The behaviour then varies depending on whether the data source is the Radar Interface or Radar Memory

#### 20.3.8.1 Data Source is Radar Interface

In the event that new data is presented at the Input DMA Engine inputs before the Loader has finished, the data will be written to the RAM and the switch of the buffer RAMs will not take place. This will be flagged as an "Input Data Overrun" error and can be used to trigger an TC3Ax SPU error interrupt (STATCTRL.ERRMSK(5)). As some applications may find controlled skipping of ramps useful, the maximum number of ramps skipped between buffer RAM switches occurring in a measurement cycle will be stored in the OVRRN field of the STAT register.

#### 20.3.8.2 Data Source is Radar Memory

Reading of further data from the Radar Memory will be stalled until the Loader has finished reading the previous data and the buffer RAM can be switched.

### 20.3.9 Configuration Memory

The configuration memory is used for several functions:

- Storing sets of configuration register settings for use by the linked list function of the TC3Ax SPU
- Storing Window Parameters for use by the FFT
- Storing the working data for the power histogram calculation

## Signal Processing Unit 2 (SPU2)

- Storing coefficients for integration (DBF and NCI)

The Configuration Memory is mapped into the system address space so that the application software can:

- write configuration register settings
- write window parameters and coefficients for integration (DBF and NCI)
- read power histogram information

Note that the operation of the histogram function requires all the available bandwidth of the RAM.

If the TC3Ax SPU is busy, then accesses to the configuration memory will be errored to prevent the bus access stalling for an extended period.

### 20.3.9.1 Safety/Security

As the configuration memory is primarily used for storing configuration settings, it is protected by the Access Enable mechanism used to prevent unauthorised modification of the TC3Ax SPU registers.

### 20.3.9.2 Configuration Register Data Format

The configuration register settings are stored in the configuration memory in the same organisation as they exist in the register space. Registers that can be updated from the configuration memory are in the address range ID\_CONF to CTRL. The ID\_CONF value will be stored at an address of  $0_H$  relative to the start address for the configuration set. The relative addresses of the data values for the other registers remain unchanged from their address map in system memory. The start address must be 64 bit aligned.

#### 20.3.9.2.1 Loading Configuration Settings

The loading of configuration settings into the registers can be triggered either manually or automatically by one of the following events:

- Software Trigger
- Trigger on TC3Ax SPU idle
  - This will trigger a complete register load when the last write is flushed to Radar Memory

### 20.3.9.3 Window Data Format

The window data is stored linearly in the configuration memory with the address offset corresponding to the data point that the window value should be used for. The address offset size is affected by the format of the window data set in LDR\_CONF2 and will vary between 2 and 8 bytes per coefficient. For complex window coefficients, the real component is stored at the lower address. An independent address offset can be defined for each antenna.

### 20.3.9.4 Configuration Memory Usage Restrictions

The configuration information is stored in a memory that is independent from the Radar memory. This memory is also used to store the results from the histogram unit and other parameters.

The histogram unit needs all the available bandwidth of this memory. The configuration memory is therefore organised as four independent banks. The use of the banks is allocated as shown in the following table.

## Signal Processing Unit 2 (SPU2)

**Table 824 Configuration Memory Bank Allocation**

	<b>Bank 1</b>	<b>Bank 2</b>	<b>Bank 3</b>	<b>Bank 4</b>
Address range	0 to CFG_RAM_SIZE/4-1	CFG_RAM_SIZE/4 to CFG_RAM_SIZE/2-1	CFG_RAM_SIZE/2 to 3*CFG_RAM_SIZE/4-1	3*CFG_RAM_SIZE/4 to CFG_RAM_SIZE-1
Register settings	Yes	Yes	Yes	Yes
Histogram data	Yes	Yes	No	No
Window parameters	Yes	Yes	No	No
Integration (NCI/DBF) coefficients	No	No	Yes	Yes

If the histogram is enabled, the window information and configuration linked lists must be stored in a different bank. Histogram data must not span more than one bank.

The TriCore™ subsystem should not attempt to access this memory during TC3Ax SPU run time. If a processor does attempt to access the memory while the TC3Ax SPU is using it the TC3Ax SPU will generate an error to the TriCore™ subsystem. This is to avoid stalling the processor execution for an excessive period of time.

The configuration memory is organised in 8 byte words. All register fields used to store configuration memory addresses must contain 8 byte aligned values. Any non-zero value written to bits[2:0] of these register fields will be ignored.

The configuration memory does not support byte or half-word (16 bit) write accesses.

## Signal Processing Unit 2 (SPU2)

## 20.4 Registers

Table 825 Register Overview - SPU\_2 (ascending Offset Address)

Short Name	Long Name	Offset Address	Access Mode		Reset	Page Number
			Read	Write		
CLC	Clock Control	00000 <sub>H</sub>	U,SV	U,SV,E,P	See page 73	73

### 20.4.1 Register Description

#### Clock Control

<b>CLC</b> <b>Clock Control</b> <span style="float: right;">Reset Value: <a href="#">Table 827</a></span>															
<b>(00000<sub>H</sub>)</b>															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
RES															
r															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RES												<b>EDIS</b>	<b>FDIS</b>	<b>DISS</b>	<b>DISR</b>
										rw		rw	rh	rw	
r															

Field	Bits	Type	Description
<b>DISR</b>	0	rw	<b>Disable Request</b> 0 <sub>B</sub> <b>Enable</b> , Request that the SPU clock tree be switched on 1 <sub>B</sub> <b>Disable</b> , Request that the SPU clock tree be switched off
<b>DISS</b>	1	rh	<b>Disable Status</b> This bit will be set to 1 if the SPU kernel clock is disabled 0 <sub>B</sub> <b>Enable</b> , The SPU clock tree is switched on 1 <sub>B</sub> <b>Disabled</b> , The SPU clock tree is switched off

## Signal Processing Unit 2 (SPU2)

Field	Bits	Type	Description
<b>FDIS</b>	2	rw	<b>Freeze Disable</b> This bit controls the freeze function for this module. The freeze function is not implemented for the SPU so this bit will have no effect. This bit can be set to 0 <sub>B</sub> 0 <sub>B</sub> <b>Enable</b> , Module operates on uncorrected clock, with full modulation jitter. 1 <sub>B</sub> <b>Disabled</b> , Module Operates on corrected clock with reduced modulation jitter. No effect for SPU
<b>EDIS</b>	3	rw	<b>Sleep Mode Enable Control</b> Reserved. This bit currently has no effect on the SPU. It should be kept at 0 <sub>B</sub> for future compatibility 0 <sub>B</sub> <b>Disabled</b> , Sleep Mode is Off 1 <sub>B</sub> <b>Enable</b> , Sleep Mode is On (no effect)
<b>RES</b>	31:4	r	<b>Reserved</b>

**Table 826 Access Mode Restrictions of CLC sorted by descending priority**

Mode Name	Access Mode		Description
ENDINIT and Master enabled in ACCEN	r	RES	Write Accesses Permitted during Initialisation
	rh	DISS	
	rw	DISR, EDIS, FDIS	
Otherwise (default)	r	DISR, EDIS, FDIS, RES	Default Access Mode (Bus Error on Write)
	rh	DISS	

**Table 827 Reset Values of CLC**

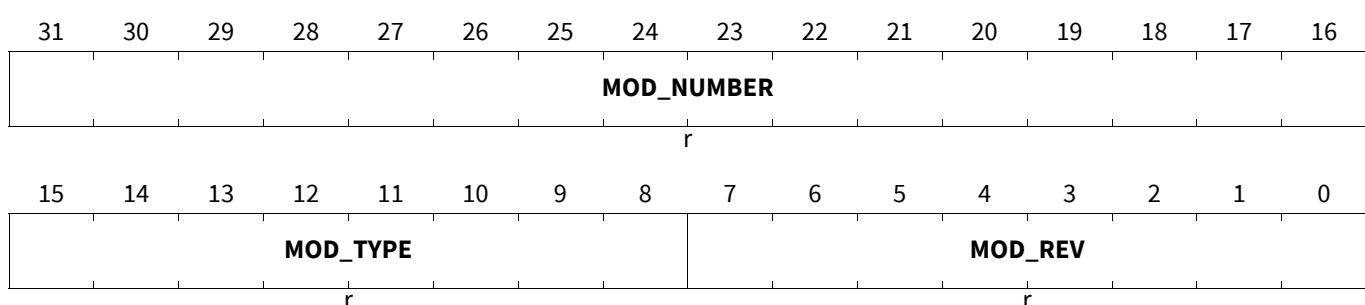

Reset Type	Reset Value	Note
Application Reset	0000 0003 <sub>H</sub>	Application Reset

### Module Identification Register

This register contains information intended to enable identification of the module and the version of the module. The Revision Number (MOD\_REV) of the SPU is 01<sub>H</sub> for TC39x, TC35x and TC33x and 02<sub>H</sub> for TC3Ax.

#### MODID

**Module Identification Register** (00004<sub>H</sub>) Application Reset Value: 00E4 C002<sub>H</sub>

## Signal Processing Unit 2 (SPU2)

Field	Bits	Type	Description
<b>MOD_REV</b>	7:0	r	<b>Module Revision Number</b> This bit field defines the module revision number. The value of a module revision starts with 01H (first revision)
<b>MOD_TYPE</b>	15:8	r	<b>Module Type</b> Set to 0xC0 to indicate a 32 bit module
<b>MOD_NUMBE R</b>	31:16	r	<b>Module Number Value</b> Set to 0x00E4. This number is unique to the SPU.

**Table 828 Access Mode Restrictions of MODID sorted by descending priority**

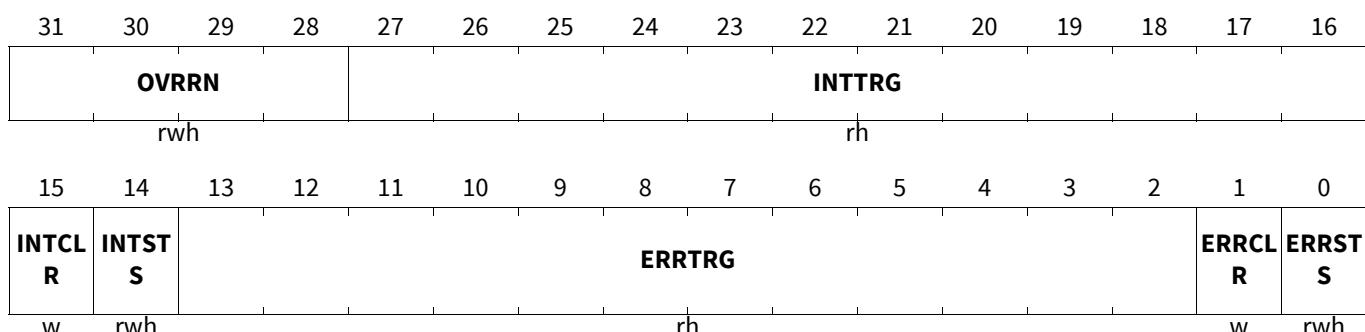

Mode Name	Access Mode		Description
Write Accesses	r	MOD_NUMBER, MOD_REV, MOD_TYPE	Any write access will cause bus error
Otherwise (default)	r	MOD_NUMBER, MOD_REV, MOD_TYPE	Default Access Mode (Bus Error on Write)

### Status and Reporting

This register allows the interrupt trigger masks to be set and the triggers causing interrupts to be read. See [Section 20.3.7.7, Interrupts](#) for bit allocation in the ERRMSK, INTMSK, ERRTRG and INTTRG fields

#### STAT

**Status and Reporting** **Reset Value:** [Table 830](#)

Field	Bits	Type	Description
<b>ERRSTS</b>	0	rwh	<b>Error Status</b> Set when an enabled error condition has triggered an interrupt
<b>ERRCLR</b>	1	w	<b>Error Clear</b> Set this bit to 1 while writing 0 to ERRSTS to clear the ERRSTS flag. Always reads as 0
<b>ERRTRG</b>	13:2	rh	<b>Interrupt Trigger</b> The bits in this bitfield correspond to the bits in ERRMSK. Bits set will indicate which condition or conditions have triggered an interrupt. This field will be cleared when ERRSTS is cleared

## Signal Processing Unit 2 (SPU2)

Field	Bits	Type	Description
<b>INTSTS</b>	14	rwh	<b>Interrupt Status</b> Set to 1 when an enabled interrupt condition (INTMSK) has triggered an interrupt
<b>INTCLR</b>	15	w	<b>Interrupt Clear</b> Set this bit to 1 while writing 0 to INTSTS to clear the Interrupt Status Flag. Always reads as 0
<b>INTTRG</b>	27:16	rh	<b>Interrupt Trigger</b> The bits in this bitfield correspond to the bits in INTMSK. Bits set will indicate which condition or conditions have triggered an interrupt. This field will be cleared when INTSTS is cleared
<b>OVRRN</b>	31:28	rwh	<b>Overrun</b> The maximum number of contiguous datasets skipped by the Input Data Manager due to overrun in the FFT processing. This field will continue to accumulate the maximum number of ramps skipped sequentially until it is explicitly cleared by writing 0. Any value written during configuration will be overwritten at this point.

### Input DMA Configuration

This register configures the base operating mode for the Input DMA and also provides the configuration parameters specific to accepting data from the RIF(s). The ANT, SMPLCNT, RAMPS and FORMAT fields are only used if the data source in the SRC field is specified as one or more RIFs. These fields will be ignored if the SRC field specifies that data is to be read from Radar Memory

## Signal Processing Unit 2 (SPU2)

### ID\_CONF

#### Input DMA Configuration

(00010<sub>H</sub>)

Reset Value: [Table 834](#)

r															rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0								SMPLCNT							
r															rw

Field	Bits	Type	Description
SMPLCNT	10:0	rw	<b>Sample Count</b> Number of samples per ramp (bin loop count). This field contains the number of data samples per ramp minus one. i.e. for a 512 point data set programme a value of 511.
RAMPS	26:16	rw	<b>Ramps per Measurement Cycle</b> The number of ramps expected to be input for this measurement cycle. The IDM will process this number of ramps and write the data to the buffer memory. Excess data will be silently ignored unless the SPU is retriggered. The number of ramps expected is the contents of this bitfield plus one. i.e. 0 equates to 1 ramp and 2047 equates to 2048 ramps.
0	15:11, 31:27	r	<b>Reserved</b>

### Input DMA Configuration 2

The Input DMA can bypass data from RIF1 if the incoming data for each ramp exceeds the capacity of the buffer memory. This register configures the bypass mode and also allows the bypassed data to be reloaded into the buffer memory by the Input DMA. Note that, when reloading bypassed data, the data source is still considered to be a RIF for configuration purposes.

Note that the REAL16BIT format must not be used if the TRNSPS bit is also set.</p> <ul style="list-style-type: none"> <li>0<sub>H</sub> <b>CMPLX16BIT</b>, 16 Bit Precision Complex Data</li> <li>1<sub>H</sub> <b>CMPLX32BIT</b>, 32 Bit Precision Complex Data</li> <li>2<sub>H</sub> <b>PWR32BIT</b>, 32 Bit Precision Power Data</li> <li>3<sub>H</sub> <b>COMPRESS</b>, Compressed Data Format</li> <li>4<sub>H</sub> <b>REAL16BIT</b>, 16 Bit Precision Real Data The format cannot be used if ID_RM_CONF.TRNSPS=1</li> <li>5<sub>H</sub> <b>REAL32BIT</b>, 32 Bit Precision Real Data</li> <li>6<sub>H</sub> <b>REAL16FP</b>, Half Precision Floating Point, real data The format cannot be used if ID_RM_CONF.TRNSPS=1</li> <li>7<sub>H</sub> <b>CMPLX16FP</b>, Half Precision Floating Point, complex data</li> <li>8<sub>H</sub> <b>PWR16FP</b>, Half Precision Floating Point, power data</li> <li>9<sub>H</sub> <b>RES9</b>,</li> <li>...</li> <li>F<sub>H</sub> <b>RES15</b>,</li> </ul>
TRNSPS	4	rw	<p><b>Transpose Addressing</b></p> <p>This bit should be set when the bins or samples used to construct an FFT input set in the Buffer memory do not occupy contiguous addresses in the Radar Memory. If set, it switches the operating mode of the Input DMA so that each of the bins in the 256 bit word read from radar Memory are treated as bins of different input FFT datasets when being written to buffer memory</p> <ul style="list-style-type: none"> <li>0<sub>B</sub> <b>LIN</b>, Linear Mode Bins stored in contiguous addresses of Radar Memory will be loaded directly into Buffer Memory as an input for an FFT dataset.</li> <li>1<sub>B</sub> <b>TRN</b>, Transpose Bins stored in contiguous addresses of Radar Memory will be treated as belonging to different FFT input datasets</li> </ul>

## Signal Processing Unit 2 (SPU2)

Field	Bits	Type	Description
<b>AM</b>	7:5	rw	<p><b>Antenna Mapping</b></p> <p>Several processing elements of the SPU need to identify each FFT dataset with a particular antenna. This field, in conjunction with the PM field, defines how this should be done. This field applies when PM is set to 0<sub>B</sub>. Setting PM to 1<sub>B</sub> is equivalent to setting this field to IDX.</p> <p>000<sub>B</sub> <b>OFF</b>, Default            Antenna ID passed to processing chain is permanently 0<sub>D</sub></p> <p>001<sub>B</sub> <b>IDX</b>, Index Mode            Antenna ID is derived from the dataset index</p> <p>010<sub>B</sub> <b>ILR</b>, Inner Loop Repeat            Antenna ID is derived from the Inner Loop Repeat Counter Value</p> <p>011<sub>B</sub> <b>OLR</b>, Outer Loop Repeat            Antenna ID is derived from the Outer Loop Repeat Counter Value</p> <p>100<sub>B</sub> <b>BLR</b>, Bin Loop Repeat            Antenna ID is derived from the Bin Loop Repeat Counter Value</p> <p>101<sub>B</sub> <b>RES5</b>, Reserved</p> <p>...</p> <p>111<sub>B</sub> <b>RES7</b>, Reserved</p>
<b>BLOCKS</b>	10:8	rw	<p><b>Number of Datablocks</b></p> <p>In Integration mode, the number of datablocks to be simultaneously constructed in the buffer memory. Normally when reading across antenna, most of the data read is discarded. If this field is non-zero, the Input DMA Engine will attempt to build multiple datablocks in memory using the additional data. The value of this field is then used to control the maximum number of datablocks that will fit into the physical limit of the buffer memory. The number of datablocks is the field value plus one. The maximum permissible value for this field is 3 for 64 bit data (32 bit precision complex) and 7 for 32 bit data (16 bit precision complex or 32 bit power)</p>

## Signal Processing Unit 2 (SPU2)

Field	Bits	Type	Description
PM	12	rw	<p><b>Processing Mode</b>  This bit is set when the Input DMA is required to build datablocks comprising one FFT from each attached antennae. This would be necessary when it is intended to use the coherent or non-coherent integration functions of the MATH2 unit.</p> <p>0<sub>B</sub> <b>DM</b>, Default Mode  This is the optimal mode for in-place FFT calculation. All the datapoints read from memory can be directly used to construct a single datablock in the buffer memory. This means that the 32<sub>D</sub> or 64<sub>D</sub> bit data read in each 256<sub>D</sub> bit word will be used by incrementing either the bin loop or inner loop</p> <p>1<sub>B</sub> <b>IM</b>, Integration Mode  In Integration Mode, it is assumed that the buffer memory must contain one FFT input dataset for each antenna. Setting this bit forces the buffer memory to be switched only after the completion of a complete pass through the inner loop. If this bit is set, then the Input DMA Engine is allowed to construct multiple datablocks in memory if this is needed to maximise utilisation of the Radar Memory bandwidth. This function is controlled by the ID_RM_CONF.BLOCKS bitfield.</p>
IMODE	14	rw	<p><b>Incremental Mode</b>  Incremental Processing Mode. If enabled, the IDM will pause before first loading the Buffer RAM and after each Buffer RAM switch until a pulse has been detected on the Incremental Trigger input from another SPU. The address generation parameters used in the ODM of the other SPU must be an exact match to the IDM address generation parameters in this SPU. The SPU will keep track of the number of outstanding incremental trigger events if the other SPU is processing data faster than the SPU.</p> <p>0<sub>B</sub> <b>OFF</b>, Incremental Mode is Disabled  1<sub>B</sub> <b>ON</b>, Incremental Mode is Enabled</p>

### Bypass Control

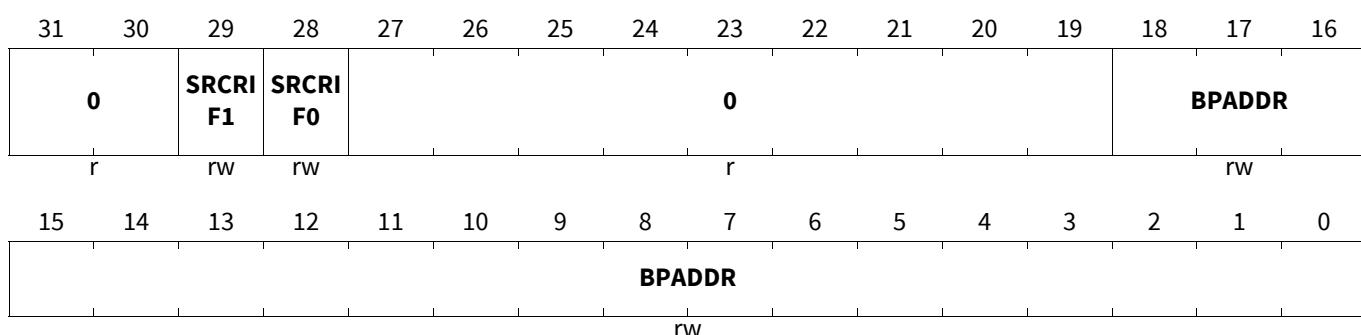

This register configures the bypass mode and also allows the bypassed data to be reloaded into the buffer memory by the Input DMA. Note that, when reloading bypassed data, the data source is still considered to be one or more RIFs for configuration purposes so the options controlling RIF data input in the ID\_CONF and ID\_CONF2 registers must be set to match the settings used to bypass the data to allow correct decoding of the data.

#### ID\_BYPASS\_CTRL

##### Bypass Control

(0003C<sub>H</sub>)

Reset Value: [Table 856](#)

Field	Bits	Type	Description
BPADDR	18:0	rw	<b>Bypass Address</b> This is the base address to be used when reading or writing bypass data. It is a 256 bit (32 byte) aligned address and needs to have five LSBs added to convert to a system address. It allows for a maximum addressable range of 16 MiB. Bypass data is written as a raw data stream as generated by the Radar Interface. No processing is performed by the SPU until the data is read back from the Radar Memory. This field is sized to address a 16 MiB Radar Memory. Accessing locations outside the range of the memory on the device will result in an error being generated by the Radar Memory module.
SRCRIFm (m=0-1)	m+28	rw	<b>Source RIF Enabled</b> Use RIF(m) as source for Bypass Data. At least one of these bits must be set to enable Bypass.
0	27:19, 31:30	r	<b>Reserved</b>

**Signal Processing Unit 2 (SPU2)**

**Table 855 Access Mode Restrictions of ID\_BYPASS\_CTRL sorted by descending priority**

<b>Mode Name</b>	<b>Access Mode</b>		<b>Description</b>
Master enabled in ACCEN	rw	BPADDR, SRCRIFm (m=0-1)	Write Access for permitted masters only, writes for non-permitted masters cause bus error
Otherwise (default)	r	BPADDR, SRCRIFm (m=0-1)	Default Access Mode (Bus Error on Write)

## Partial-Acquisition Counter

This counter is used to monitor and control partial-acquisition. If enabled, it will monitor the input data stream from the RIF and increment at the end of each ramp as determined by the sample count and number of antennae captured from the IDM configuration when the counter was last reset. As the counter increments at the end of the ramp, the first ramp of the measurement cycle will be considered as ramp 0.

Note: LDMST should be used only with bit mask enabled for the 'rh' bits in this register. Hardware updates occurring between the read and write phases of an RMW may be overwritten.

PACTR

### Double Pass Configuration

Double Pass Mode allows the configuration of the MATH1 unit to be changed during processing of ADC data. The selected configuration can be alternated on a ramp-by ramp basis or both programmed configurations can be applied to all ramps.

## Signal Processing Unit 2 (SPU2)

### DPASS\_CONF

#### Double Pass Configuration

(00044<sub>H</sub>)Reset Value: [Table 860](#)

Field	Bits	Type	Description
<b>EN</b>	0	rw	<b>Enable</b> The SPU allows all processing operations to be run twice per data block or different processing parameters to be used on sequences of data blocks. This mode is enabled using the DPASS_CONF.EN bitfield. This results in two sets of results being written to Radar Memory
<b>SWITCH</b>	1	rw	<b>Buffer Memory Switch</b> If set to 0 <sub>B</sub> , both configurations of the MATH1 and MATH2 units will be applied to all data blocks and two full sets of output data will be written to the Radar Memory. If set to 1 <sub>B</sub> , the two configurations for MATH1 and MATH2 will be applied to alternate data blocks. Each set of output data written to Radar memory will contain half the data.
<b>COUNT</b>	4:2	rw	<b>Switch Count</b> If DPASS_CONF.EN_CNT is set, this field determines the number of data blocks to be processed before the alternate sets of window parameters are switched. The number of data blocks processed by the Loader between parameter switches is COUNT+1. i.e. if COUNT=0 then the window parameters will be switched for every data block processed, if COUNT=7, then the parameters will be switched after every eight data blocks processed.
<b>EN_CNT</b>	5	rw	<b>Enable Count</b> This bit enables switching the two sets of window parameters based on the DPASS_CONF.COUNT bitfield rather than the "Double Pass" settings. When set, the window parameters are switched every time a counter counting the number of data blocks processed reached the terminal count stored in the COUNT field + 1. The DPASS_CONF.EN and DPASS_CONF.SWITCH settings have no effect on the window parameters when this bit is set.
<b>0</b>	31:6	r	<b>Reserved</b>

Kernel Reset (software controlled by KRST0-1 registers)	0000 0000 <sub>H</sub>	Kernel Reset (software controlled by KRST0-1 registers)

### Burst descriptor

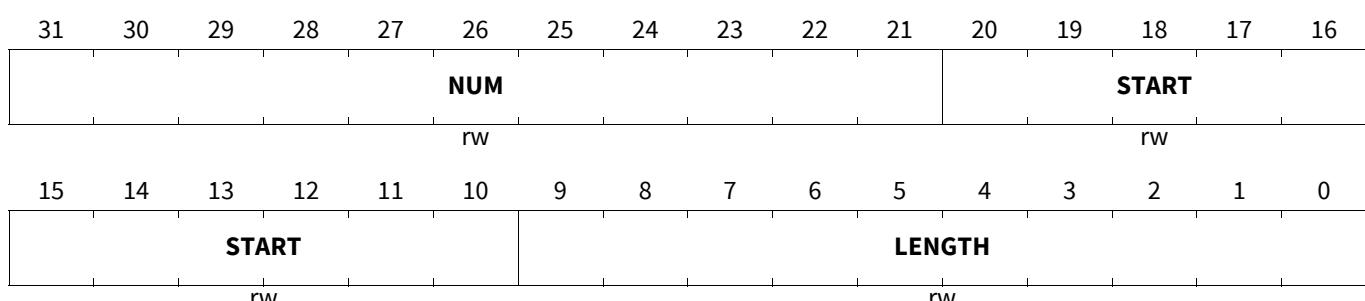

Interference burst ramp number, start bin and length. Used by the Combine Select and Taper Unit when the replacement function RPLCTRL.MODE==SOFT.

A burst is defined by the location and length of a burst. The location is given by the ramp number and sample number. The first ramp and first sample are both numbered zero.

Only the first RPLCTRL.NBURSTS registers shall have any effect.

#### BURST<sub>b</sub> (b=0-7)

**Burst descriptor** (00094<sub>H</sub>+b\*4) Reset Value: [Table 886](#)

Field	Bits	Type	Description
LENGTH	9:0	rw	<b>Length of Burst</b> The length of a burst is the value of this field plus one. The minimum length of a burst is one.
START	20:10	rw	<b>Start sample of the Burst</b>
NUM	31:21	rw	<b>Ramp Number of the Burst</b>

## Signal Processing Unit 2 (SPU2)

### DC offset sample count reciprocal

This register shall be programmed with the reciprocal of the number of samples as defined by the value of ID\_CONF.SMPLCNT encoded by calculating  $1/(ID\_CONF.SMPLCNT + 1)$  to 27 binary places. The number of leading zeros in the binary fractional value is the value of EXP and next 16 bits are the MANT value.

Otherwise setting the MANT bit-field to zero will disable DC offset removal by forcing the mean value to zero.

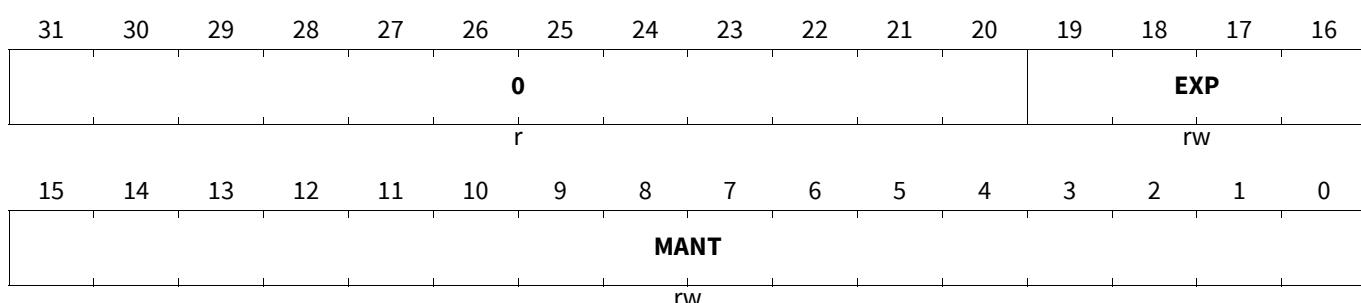

If MATH0 is disabled this register does not need to be configured and may be set to zero.

### SCRECIP

#### DC offset sample count reciprocal

(000B4<sub>H</sub>)

Reset Value: Table 888

The scaling factor used will be from the ODP_CONF.EXPNT bitfield 0 <sub>B</sub> <b>32BIT</b> , Output is writeen with 32 bit precision 1 <sub>B</sub> <b>16BIT</b> , Output is written with 16 bit precision
<b>EXPNT</b>	7:3	rw	<b>Common Exponent</b> When writing 16 bit precision data to the Radar Memory, this field indicates the number of LSBs to be removed. i.e. the 32 bit data will be shifted right by this number of bit positions before truncating to the 16 least significant bits. The remaining bits will be set to maximum or minimum value if overflow or underflow has occurred
<b>IPF</b>	8	rw	<b>In Place FFT</b> When set, the Output Data Processor will attempt to write FFT results to the memory locations freed up by the reading of the input data.
<b>ROF</b>	9	rw	<b>Real Only Format</b> When set, the Output Data Processor will write FFT output data in a real only format. The imaginary component of the results will not be written. This mode differs from the function of "Force to Real" (FTR) because any other calculations performed using the FFT data will use the imaginary component. If consistency is required between the real only data written and the results of the other channels, then FTR should also be set.

## Signal Processing Unit 2 (SPU2)

Field	Bits	Type	Description
<b>HPFP</b>	10	rw	<b>Half Precision Floating Point</b> When set, the Output Data Processor will write FFT output data in half precision floating point format. If this bit is set then SCALE is redundant and will be ignored. FTR and ROF can still be used.
<b>COMPRESS</b>	11	rw	<b>Compress FFT Data</b> If set and the HPFP bit is also set then data will be packed into 256 bit words in a compressed form.
<b>0</b>	31:12	r	<b>Reserved</b>

<b>SRCSEL</b>	10:9	rw	<p><b>CFAR Source Selection</b></p> <p>Input source selection for CFAR and Local Maximum units.</p> <ul style="list-style-type: none"> <li>00<sub>B</sub> <b>FFT</b>, Use FFT Data</li> <li>01<sub>B</sub> <b>INT0</b>, Use Data from Integration Unit 0 The relevant Integration unit must be configured to be active.</li> <li>10<sub>B</sub> <b>INT1</b>, Use Data from Integration Unit 1 The relevant Integration unit must be configured to be active.</li> <li>11<sub>B</sub> <b>RES</b>, Reserved</li> </ul>
<b>LFUNC</b>	18:11	rw	<p><b>Logical Function</b></p> <p>This bit field defines the logical function used to combine the three outputs from GOS-CFAR, CA-CFAR and LCLMAX units. The 8 bits form a one bit wide look-up table with 8 locations. The locations are addressed using an address constructed as follows: address(0) = LCLMAX, address(1) = GOS-CFAR and address(2) = CA-CFAR. The output of the function will be the bit value found at the addressed location in the register. For example, if bit 6 of this field is set then the output will be logical one only when the outputs of GOS-CFAR and CA-CFAR are one and LCLMAX is zero, otherwise the output will be zero.</p>
<b>SEWIN</b>	24:19	rw	<p><b>Spectrum Extension Window</b></p> <p>This bitfield defines the window size to be used for spectrum extension used for all detectors, CFAR and Local Maximum. The window size should be set to the maximum required by the active detectors and CFAR algorithm or algorithms. This field must not be set to a non-zero value unless at least one of the CFAR or Local Maximum Units is enabled.</p>

## Signal Processing Unit 2 (SPU2)

Field	Bits	Type	Description
<b>EXTNSN</b>	26:25	rw	<b>Spectrum Extension</b> Enable Spectrum Extension in either range or velocity modes for the CFAR or Local Maximum Units. This field must be set to "OFF" unless either at least one of the CFAR units or the Local Maximum Unit is enabled. 00 <sub>B</sub> <b>OFF</b> , No Spectrum Extension 01 <sub>B</sub> <b>RANGE</b> , Range Spectrum Extension 10 <sub>B</sub> <b>VELOCITY</b> , Velocity Spectrum Extension 11 <sub>B</sub> <b>Reserved</b> , Reserved
<b>CFAR_CAE</b>	27	rw	<b>CFAR CA Engine Enable</b> Select whether the CFAR CA Engine is enabled. 0 <sub>B</sub> <b>OFF</b> , CA Engine Off 1 <sub>B</sub> <b>ON</b> , CA Engine On
<b>CFAR_GOSE</b>	28	rw	<b>CFAR GOS Engine Enable</b> Select whether the CFAR GOS Engine is enabled. 0 <sub>B</sub> <b>OFF</b> , GOS Engine Off 1 <sub>B</sub> <b>ON</b> , GOS Engine On
<b>0</b>	2:0, 31:29	r	<b>Reserved</b> Reads as 0, shall be written with 0.

### Bin Rejection Unit Control

Control Parameters for the Bin Rejection Unit. The Bin Rejection Unit takes inputs from a 2048 set of registers (one bit per FFT data point) and data from the CFAR and Threshold Unit. These bits are used to zero bins or remove them from the outputs data stream. Additionally bins can be compared to a threshold value and set to zero if the threshold is exceeded. The threshold value is set as a magnitude. The Magnitude Approximation of the complex data bins is used for the comparison.

## Signal Processing Unit 2 (SPU2)

### SPU Control

Control Register for setting the SPU mode and triggering processing operations

### CTRL

#### SPU Control

(00310<sub>H</sub>)Reset Value: [Table 976](#)

## Signal Processing Unit 2 (SPU2)

Field	Bits	Type	Description
<b>TRIG</b>	0	rwh	<b>SPU Software Trigger</b> Write 1 to trigger the SPU by software. Always reads as 0. $0_B$ <b>NULL</b> , No Operation $1_B$ <b>TRIGGER</b> , Trigger the SPU to commence data processing
<b>BUSY</b>	1	rh	<b>SPU Busy Flag</b> $0_B$ <b>DONE</b> , SPU Idle SPU has finished processing and is guaranteed not to be using EMEM $1_B$ <b>BUSY</b> , SPU Busy SPU is currently processing data
<b>MODE</b>	4:2	rw	<b>SPU Trigger Mode</b> $000_B$ <b>OFF</b> , SPU is disabled $001_B$ <b>INT</b> , Internal Trigger $010_B$ <b>EXT</b> , External Trigger $011_B$ <b>SPU0</b> , Trigger on SPU0 Done $100_B$ <b>SPU1</b> , Trigger on SPU1 Done $101_B$ <b>RELOAD</b> , Reload configuration from memory with no processing Although the SPU main functions shall not be triggered in this mode the Bypass function shall be triggered if BPTRIG bit is set. $110_B$ <b>SW</b> , Software Trigger $111_B$ <b>STOP</b> , SPU will stop at end of current operation.
<b>NXT_CONF</b>	23:5	rw	<b>Next Configuration Base Address</b> This is the base address in the configuration RAM of the next set of configuration settings for the SPU. This is a byte address offset into the configuration RAM (i.e. first location in the configuration RAM is address 0) but it must be 64 bit aligned (i.e. bits [2:0] of the address must be 0).
<b>ATTN</b>	26	rw	<b>Generate Service Request Interrupt</b> If this bit is set in a loaded configuration and the related mask bit, STATCTRL.INTMSK(0), is also set, then a service request interrupt will be generated when the execution of the configuration is completed, even if this is not the last configuration in a linked list. $0_B$ <b>OFF</b> , No effect $1_B$ <b>ON</b> , A service request interrupt will be generated when execution of the loaded configuration has completed
<b>XTRIG</b>	27	rw	<b>Cross Trigger</b> If this bit is set a "DONE" event will be triggered at the end of execution of the current configuration (specifically when the last data has been written to Radar memory). This will be used by the SPU0 or SPU1 trigger modes defined for the CTRL.MODE bitfield

## Signal Processing Unit 2 (SPU2)

Field	Bits	Type	Description
<b>ITRIG</b>	28	rw	<b>Incremental Trigger</b> Control of Incremental Trigger Output. If enabled, the SPU will generate a pulse on the incremental trigger output after the MATH2 unit has completed processing the contents of the buffer memory and the ODM has successfully written all data to memory 0 <sub>B</sub> <b>OFF</b> , Incremental Trigger is Disabled 1 <sub>B</sub> <b>ON</b> , Incremental Trigger is Enabled
<b>BPTRIG</b>	29	rw	<b>Bypass Trigger</b> If this bit is set the Bypass function shall be triggered when the trigger condition specified by the MODE field occurs. The MODE==RELOAD may be used to trigger Bypass without triggering normal SPU operation.
<b>LAST</b>	31	rw	<b>Last Configuration</b> If this bit is set while loading a configuration, this will be the last configuration processed and no further configurations will be loaded
<b>0</b>	25:24, 30	r	<b>Reserved</b> Reserved. This was the DIV field which has been replaced by the fractional clock divider control.

**Table 975 Access Mode Restrictions of CTRL sorted by descending priority**

Mode Name	Access Mode		Description
Master enabled in ACCEN	rh	BUSY	Write Access for permitted masters only, writes for non-permitted masters cause bus error
	rw	ATTN, BPTRIG, LAST, MODE, NXT_CONF, XTRIG	
	wh	TRIG	
Otherwise (default)	r	ATTN, BPTRIG, LAST, MODE, NXT_CONF, XTRIG	Default Access Mode (Bus Error on Write)
	rh	BUSY, TRIG

### Label List Counter

This register is duplicated so that the stored information is available for each set of configuration options used in "Double Pass" mode.

This register has a field to hold the count of the number of times the Label List has output a label. It also has a control bit to allow the count to be cleared. The count should only be cleared when the SPU is idle.

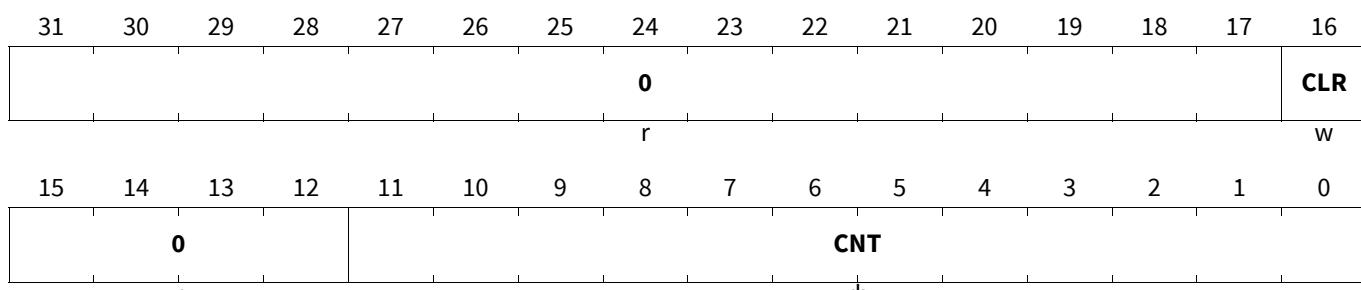

## Signal Processing Unit 2 (SPU2)

### MDq\_LBLCNT (q=0-1)

Label List Counter

(00358<sub>H</sub>+q\*54<sub>H</sub>)

Reset Value: [Table 982](#)

Field	Bits	Type	Description
CNT	11:0	rh	<b>Count</b> The count, since reset or cleared, of the number of times the Logical Function output was one.
CLR	16	w	<b>Counter clear</b> Writing a 1 <sub>B</sub> to this bit will clear the counter. Always reads as zero.
0	15:12, 31:17	r	<b>Reserved</b> Reads as 0, shall be written with 0.

**Table 981 Access Mode Restrictions of MDq\_LBLCNT (q=0-1) sorted by descending priority**

Mode Name	Access Mode		Description
Write Accesses and Master enabled in ACCEN	rh	CNT	Any write access will cause bus error
Master enabled in ACCEN	w	CLR	Write Access for permitted masters only, writes for non-permitted masters cause bus error
Otherwise (default)	rX	CLR	Default Access Mode (Bus Error on Write)
	rh	CNT

### Dataset Metadata

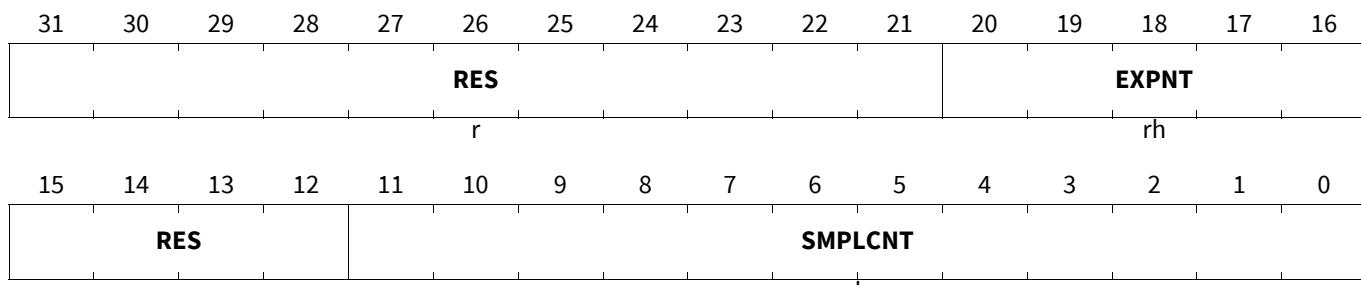

This register is duplicated so that the stored information is available for each set of configuration options used in "Double Pass" mode.

Secondary Information describing the data that has just been processed

## Signal Processing Unit 2 (SPU2)

### MDq\_METADATA (q=0-1)

Dataset Metadata

(0035C<sub>H</sub>+q\*54<sub>H</sub>)Reset Value: [Table 984](#)

Field	Bits	Type	Description
<b>SMPLCNT</b>	11:0	rh	<b>Sample Count</b> Number of samples per FFT written to memory. This is useful when using the CFAR inline as the number of bins in the FFT result that will pass the threshold test is not known ahead of processing. The field contains the actual number of samples written to the Radar Memory
<b>RES</b>	15:12, 31:21	r	<b>Reserved</b>
<b>EXPNT</b>	20:16	rh	<b>Common Exponent</b> This indicates the optimum alignment correction that could have been applied if reformatting to 16 bit precision. If "n" is the minimum number of redundant sign bits present in the data at the FFT output, it will be set to $(16_D - n)$ . This can then be used as the value of UNLDR_CONF.EXPNT to be programmed for the next measurement cycle if it is intended to use 16 bit precision data. The maximum permissible value for this field is $16_D$

**Table 983 Access Mode Restrictions of MDq\_METADATA (q=0-1) sorted by descending priority**

Mode Name	Access Mode		Description
Write Accesses	r	RES	Any write access will cause bus error
	rh	EXPNT, SMPLCNT

### Safety Mechanism Status

The SPU contains hardware safety mechanisms which monitor key areas of the SPU for correct functioning. In the event of an alarm being triggered by one of the safety mechanisms, this register can be read to determine which of the safety mechanisms has detected an error

#### SMSTAT

**Safety Mechanism Status** (00408<sub>H</sub>) **Reset Value:** [Table 992](#)

Field	Bits	Type	Description
<b>SMSTAT</b>	7:0	rh	<p><b>Safety Mechanism Status</b></p> <p>Each bit will be set to one if the associated safety mechanism has detected a fault. The flags can be cleared by writing 1<sub>b</sub> to SMSTAT.SMSCLR. The values read from this bitfield are interpreted as follows (multiple failure conditions will cause the individual values to be summed):</p> <ul style="list-style-type: none"> <li>01<sub>H</sub> <b>RIFCRC</b>, Check of computed CRC for RIF data against received value has failed</li> <li>02<sub>H</sub> <b>REGCRC</b>, Check of computed Register CRC against register value has failed</li> <li>04<sub>H</sub> <b>BYPASSCRC</b>, Check of computed Bypass Data CRC against value read from radar memory has failed</li> <li>08<sub>H</sub> <b>RDECC</b>, ECC Check Fail on Read from Radar Memory</li> <li>10<sub>H</sub> <b>RMCTRL</b>, Radar Memory Access Control Signals failed consistency check</li> <li>20<sub>H</sub> <b>RMTAERR</b>, Access to Radar Memory has resulted in an Error</li> <li>40<sub>H</sub> <b>R2BPCRC</b>, Check of computed CRC for RIF data in the Bypass module against received value has failed</li> <li>80<sub>H</sub> <b>FFTECC</b>, ECC check fail in register-based FFT memories</li> </ul>

### Safety Mechanism Control Functions (User)

This register provides access to the control functions for safety mechanisms not used as part of the normal configuration of the SPU. The various test bitfields defined in this register and used to test that the safety mechanisms can generate alarms are intended as a connectivity test only. It is therefore not necessary (or desirable) for the SPU to be running while these tests are run.

### User OCDS Trace Control

The USROTC control register bits are only effective while the system is in debug mode. Write access requires Supervisor Mode.

#### USROTC

**User OCDS Trace Control** **Reset Value: Table 1012**

Field	Bits	Type	Description
<b>RES</b>	15:0, 31:25	r	<b>Reserved</b>
<b>TRSCTRL</b>	24:16	rwh	<b>Trace Control</b> This field individually controls the tracing of the nine possible output streams to the OCDS trace port. The nine bits in the field correspond to the nine Output DMA channels in ascending order. Any four of the streams can be simultaneously enabled for trace provided that the SPU and SRI are set to the same clock frequency. This field will revert to the reset value when OCDS is disabled.

**Table 1011 Access Mode Restrictions of USROTC sorted by descending priority**

Mode Name	Access Mode		Description
Master enabled in ACCEN and Supervisor Mode	r	RES	Write Access for permitted masters only, writes for non-permitted masters cause bus error
	rwh	TRSCTRL	
Supervisor Mode	r	RES	Read Access Permitted for Supervisor Mode Accesses
	rh	TRSCTRL	
Otherwise (default)	r	RES	No Access, All accesses return Bus error
	rh	TRSCTRL

### Access Enable Register 0

The Access Enable Register 0 controls access for writes to registers and configuration memory using the on chip bus master TAG ID 000000B to 011111B (see On Chip Bus chapter for the products TAG ID <-> master peripheral mapping). The SPU is prepared for a 6 bit TAG ID. The registers ACCEN0 / ACCEN1 are providing one enable bit for each possible 6 bit TAG ID encoding.

Mapping of TAG IDs to ACCEN0.ENx: EN0 -> TAG ID 000000B, EN1 -> TAG ID 000001B, ... ,EN31 -> TAG ID 011111B.

#### ACCENO

### Kernel Reset Register 0

The KRST0, KRST1 and KRSTCLR registers are used to initiate and monitor a reset of the SPU kernel logic. The kernel reset is equivalent to a full application reset, only the registers implemented in the bus interface are not affected. All registers affected by kernel reset have an appropriate entry in the "reset values" table

Note, that if a debugger is connected, an application reset of the device will have the same effect on the KRST0 and KRST1 registers as a kernel reset. If KRST0.RST or KRST1.RST are set, they will be cleared and the KRST0.RSTSTAT bit will be set.

This instance of the kernel reset interface registers, KRST0, KRST1 and KRSTCLR, is an exception to the general rule that the kernel reset functionality is protected by ENDINIT. This instance is protected only by the ACCEN protection mechanism.

Reset Type	Reset Value	Note
Application Reset	0000 0000 <sub>H</sub>	Application Reset

## Signal Processing Unit 2 (SPU2)

### 20.5 Debug

For debugging purposes, it is possible to stop execution of a linked list. To avoid additional complexity, this can be done by software only before activating the next entry. However the debugger can stop execution using the system wide OCDS suspend functionality.

For availability reasons, the command to stop execution requires to write 3 bits,  $111_B$ , defined as STOP, to the CTRL.MODE bitfield

To reduce complexity, the Radar sequencer can only be stopped by the debugger. It is not possible to resume it. Once the OCDS suspend has been removed, the TC3Ax SPU should be initialised using kernel reset.

Two types of suspend are available

- Hard Suspend: this stops the kernel clock of the TC3Ax SPU immediately. Registers can still be read but should not be written. Config RAM cannot be accessed<sup>1)</sup>. EMEM control signals may suspend in the active state<sup>2)</sup>.
- Soft Suspend: The “GO” signals for the processing modules of the TC3Ax SPU are suppressed. The modules will complete, as far as possible<sup>3)</sup>, processing of the current dataset. Suspend will be acknowledged as soon as the Output Data Manager has completed all outstanding writes to Radar Memory<sup>4)</sup>.

#### 20.5.1 Trace Format

The TC3Ax SPU has a trace connection to the MCDS. The intention of the trace data is to allow synchronisation of TC3Ax SPU output events with CPU activity in the microcontroller. The MCDS has insufficient bandwidth to allow full trace of all FFT results written to EMEM so the data which can be traced simultaneously is limited. The trace logic contains sufficient buffering to allow any four<sup>5)</sup> of the nine available channels to be monitored. The following information can be output to the trace port.

**Table 1027 TC3Ax SPU Trace Data**

Output DMA Channel	Function	Trace Data
1	FFT Results Output	Address and the first 256 bit word written for each FFT processed
2	Signal Power	Address and the first 256 bit word written for each FFT processed
3	Statistical Data	Address and data trace of all values written.
4	CFAR CA Engine Data	Address and data trace of all values written.
5	CFAR Go Engine Data	Address and data trace of all values written.

- 1) The hard suspend function operates by stopping the kernel clock of the TC3Ax SPU. As the config RAM arbitration logic also runs off the kernel clock, the config RAM is not accessible during hard suspend.
- 2) In this case, the EMEM tile control can be used to error the stuck access and permit debugger access to the affected EMEM tile
- 3) In some cases, data will remain in the FFT accelerator pipeline. In these circumstances the UNLOADER module will be unable to complete processing.
- 4) If the histogram function is enabled, accesses to config RAM by the TC3Ax SPU may continue after soft suspend is acknowledged. This is because the FFT pipeline cannot be guaranteed to complete processing during soft suspend and is therefore not used to gate suspend acknowledgement.
- 5) For very short datasets, the bandwidth requirements for DMA channels 3 to 8 increase significantly and the number of simultaneous channels that can be traced drops. Each packet traced requires four clock cycles of the TC3Ax SPU clock. If the number of cycles to output the trace data exceeds the number of clock cycles required for the MATH2 unit to process the dataset, then trace data will be lost

## Signal Processing Unit 2 (SPU2)

**Table 1027 TC3Ax SPU Trace Data (cont'd)**

Output DMA Channel	Function	Trace Data
6	Integration unit 0 (INT0)	Address and the first 256 bit word written for each FFT processed
7	Integration unit 1 (INT1)	Address and the first 256 bit word written for each FFT processed
8	Local Maximum or Logical Function	Address and data trace of all values written.
9	Label List	Address and data trace of all values written.

Trace Data output is controlled by the USROTC.TRSCTRL bitfield. The nine bits in the field correspond to the nine Output DMA channels in ascending order.

### 20.5.2 Debugger events

The following event triggers are available as hardware events for the debugger via the configuration options in the OCS register.

**Table 1028 OTGB Hardware Triggers (Set A)**

0	TC3Ax SPU Processing Starts -Trigger event defined in CTRL register has been detected
1	TC3Ax SPU has completed processing
2	TC3Ax SPU has completed a configuration load
3	Input DMA Done Signal (data block processing completed)
4	Loader Done Signal (data block processing completed)
5	Unloader Done Signal (data block processing completed)
6	ODP Loader Done Signal (data block processing completed)
7	MATH2 Done Signal (data block processing completed)
8	Output DMA Done Signal (last write completed in EMEM, set once per measurement cycle)
9	Output DMA Done (data block processing completed)
10	
11	
12	
13	
14	
15	

**Table 1029 OTGB Hardware Triggers (Set B)**

0	Input DMA Run-time Error - read error signaled by Radar Memory
1	Loader Unit Run-time Error - out of range address generated or error converting half precision floating point input (NaN or Infinity value detected in input data)
2	Config RAM Run-time error - access aborted due to insufficient bandwidth
3	Fixed exponent format compression error - significant bits lost (UNLOADER and ODM) <sup>1)</sup>

## Signal Processing Unit 2 (SPU2)

**Table 1029 OTGB Hardware Triggers (Set B) (cont'd)**

4	Mean Power FIFO Overflow
5	Output DMA Port 1 Error
6	Output DMA Port 2 Error
7	Output DMA Port 3 Error
8	Output DMA Port 4 Error
9	Output DMA Port 5 Error
10	Output DMA Port 6 Error
11	Output DMA Port 7 Error
12	Output DMA Port 8 Error
13	Output DMA Port 9 Error
14	
15	

1) This check occurs even if compression is disabled. In this case the flag will be set if data would have been lost if compression had been enabled

## 20.6 Safety Measures

The TC3Ax SPU has the following safety mechanisms to assist in its use in safety related applications

### 20.6.1 Hardware Safety Mechanisms

The TC3Ax SPU has the following autonomous hardware safety mechanisms which report failures via SMU alarms

#### 20.6.1.1 Register CRC

The register CRC uses a 32 bit ethernet polynomial which assumes that the register contents are converted to an LSB first sequential data stream. The data stream will be generated using the registers from ID\_CONF to CTRL inclusive. Unused register addresses, and the address of the REGCRC register, itself shall be replaced by 0000<sub>H</sub> in the datastream. Additionally, the CTRL.TRIG bit and CTRL.BUSY bit should be assumed to be 0<sub>B</sub> (value when read) and the value of the PACTR.COUNT bitfield should be assumed to be 0<sub>D</sub> for calculating the reference CRC.

The polynomial shall run periodically once enabled and the CRC generated from the register contents compared with the value stored in the REGCRC.CRC bitfield. If the comparison fails, then an SMU alarm will be generated.

The Register CRC is enabled by writing 10<sub>B</sub> to the **SMCTRL**.REGCRCEN bitfield and disabled by writing 01<sub>B</sub>.

Control and comparison logic of the safety mechanism is replicated using negated logic. Any difference in behaviour between the two sets of logic will result in setting of the **SMSTAT**.SMCTRLSTS bit.

The alarm can be tested by writing an invalid CRC to REGCRC.CRC.

If this condition has triggered an alarm, bit 1 of the **SMSTAT**.SMSTAT bitfield will be set to 1<sub>B</sub>.

#### 20.6.1.2 RIF Interface CRC Check

The data path between the RIF and the TC3Ax SPU is protected by a CRC. The CRC is checked once per ramp. The ramp size is determined from the settings of the ID\_CONF register. The check will take place when the data is written into the internal assembly buffer of the Input Data Manager. A CRC failure will result in an SMU alarm. This mechanism is controlled by the **SMCTRL**.RIFCRC bitfield.

## Signal Processing Unit 2 (SPU2)

The CRC check enabled by writing 10<sub>B</sub> to the **SMCTRL**.RIFCRC bitfield and disabled by writing 01<sub>B</sub>. Writing either of the other two possible values will result in the **SMSTAT**.SMCTRLSTS bit being set

If this condition has triggered an alarm, bit 0 of the **SMSTAT**.SMSTAT bitfield will be set to 1<sub>B</sub>.

This alarm condition can be tested by writing 10<sub>B</sub> to the **SMUSER**.RIFCRCTST bitfield.

### 20.6.1.3 RIF Interface CRC Check for Bypass

The data path between the RIF and the TC3Ax SPU Bypass function is protected by its own CRC, separate from the normal RIF Interface CRC. The CRC is checked once per ramp. The ramp size is determined from the settings of the ID\_CONF register. The check will take place when the data is written into the internal assembly buffer of the Bypass function. A CRC failure will result in an SMU alarm. This mechanism is controlled by the **SMCTRL**.R2BPCRC bitfield.

The CRC check enabled by writing 10<sub>B</sub> to the **SMCTRL**.R2BPCRC bitfield and disabled by writing 01<sub>B</sub>. Writing either of the other two possible values will result in the **SMSTAT**.SMCTRLSTS bit being set

If this condition has triggered an alarm, bit 6 of the **SMSTAT**.SMSTAT bitfield will be set to 1<sub>B</sub>.

This alarm condition can be tested by writing 10<sub>B</sub> to the **SMUSER**.R2BPCRCTST bitfield.

### 20.6.1.4 Bypass Data CRC Check

The data stored by the TC3Ax SPU in Radar memory when bypass is enabled is protected by a CRC. One CRC per RIF interface instance selected by BYPASS\_CTRL.SRCRIFm is generated at the end of the measurement cycle using the same ethernet polynomial used elsewhere in the TC3Ax SPU and written at the next consecutive addresses after the last data word written. The CRC values shall be written in order of the RIF instance number. The end of the measurement cycle is determined from the settings of the ID\_CONF register. The CRCs will be checked by the Input Data Manager when the read back during the bypass reload operation. A CRC failure will result in an SMU alarm.

The CRC check enabled by writing 10<sub>B</sub> to the **SMCTRL**.BPCRC bitfield and disabled by writing 01<sub>B</sub>. Writing either of the other two possible values will result in the **SMSTAT**.SMCTRLSTS bit being set.

If this condition has triggered an alarm, bit 2 of the **SMSTAT**.SMSTAT bitfield will be set to 1<sub>B</sub>.

This alarm condition can be tested by writing 10<sub>B</sub> to the **SMUSER**.BPCRCTST bitfield.

This safety mechanism can be tested by writing a short dataset with a known, bad CRC to Radar memory and triggering a bypass reload operation.

### 20.6.1.5 Radar Memory Control Signal Redundancy

All control signals controlling accesses to Radar Memory are duplicated. The duplicate signals are set to the negated value of the primary control signal. In the event of the two signals becoming inconsistent, it can be assumed that an error has occurred. An inconsistent state is detected by comparators and will cause an SMU alarm.

This check is permanently enabled. If this condition has triggered an alarm<sup>1)</sup>, bit 4 of the **SMSTAT**.SMSTAT bitfield will be set to 1<sub>B</sub>.

### 20.6.1.6 Radar Memory Tile Access Error

Radar Memory tiles are enabled for TC3Ax SPU accesses by configuring the tile control mechanism in the EMEM. An TC3Ax SPU access can be directed to a blocked tile either by a configuration error or a fault in the TC3Ax SPU

<sup>1)</sup> The Error flag returned by the EMEM for an access address error is also a redundant signal but, as this is already a monitor rather than a control, an inconsistency in this pair causes the **SMSTAT**.SMCTRLSTS bit to set and does not generate an alarm

## Signal Processing Unit 2 (SPU2)

logic. In the event of the EMEM reporting that an access has failed because it has been mapped to a blocked tile, this mechanism can be used to trigger an SMU alarm.

The alarm is enabled by writing  $10_B$  to the **SMCTRL.RMTAERR** bitfield and disabled by writing  $01_B$ . Writing either of the other two possible values will result in the **SMSTAT.SMCTRLSTS** bit being set.

If this condition has triggered an alarm, bit 5 of the **SMSTAT.SMSTAT** bitfield will be set to  $1_B$ .

This alarm condition can be tested by writing  $10_B$  to the **SMUSER.RMTAERRTST** bitfield.

### 20.6.1.7 Radar Memory Read Data ECC

Read data returned for a Radar Memory access by the TC3Ax SPU is protected by an ECC computed in the EMEM from the address presented to the RAM and the data output from the RAM. This is checked by the TC3Ax SPU to ensure that the data is correct and has been read from the expected RAM location. A failed check will be signalled via an SMU alarm

The alarm is always enabled.

If this condition has triggered an alarm, bit 3 of the **SMSTAT.SMSTAT** bitfield will be set to  $1_B$ .

This alarm condition can be tested by writing  $10_B$  to the **SMUSER.RDECCTST** bitfield.

### 20.6.1.8 RAM ECC

RAM contents are protected by ECC. Corrupted locations will be corrected if a single bit is in error or detected if two bits are in error. Detected failures will be signalled via an SMU alarm

### 20.6.1.9 RAM Address Signature ROM

The RAM address decode is checked by a signature ROM. Failures in the address decode will be signalled via an SMU alarm

### 20.6.1.10 Access Enable

Write accesses to the registers and configuration memory<sup>1)</sup> are controlled by the Access Enable mechanism. This is configured using the ACCEN0/ACCEN1 registers and uses the master tag used to identify the originating master of each write transaction to permit or deny access to modify the contents of the register or memory.

## 20.6.2 Software Based Safety Mechanisms

The TC3Ax SPU supports the following safety mechanisms which require support from software. Failures are to be reported by the software rather than via the SMU

### 20.6.2.1 Software Based Self Test

A gap occurring between application processing operations can be used to run self test patterns through the TC3Ax SPU to detect faults in the TC3Ax SPU hardware and the interfaces between the TC3Ax SPU and the Radar Memory.

### 20.6.2.2 TC3Ax SPU Execution Time Check

A class of faults exist in the TC3Ax SPU hardware which could cause a deadlock of the TC3Ax SPU control hardware. A software check should be provided which does a “sanity check” on the time needed for the TC3Ax SPU to complete execution and flags an error if execution does not complete within the expected time. This check

<sup>1)</sup> The configuration memory is treated as module configuration information rather than system memory and it is therefore appropriate to apply the same protection as for the registers.

## Signal Processing Unit 2 (SPU2)

would also detect faults in the MMIC or MMIC<->uC interface which cause an interruption in the data stream and therefore a stall in the TC3Ax SPU processing. The TC3Ax SPU contains a hardware counter which can be used to support his check.

### 20.6.2.3 Configuration Memory Content Check

The contents of the configuration memory should be checked once written to ensure that all data has been transferred to the memory correctly

### 20.6.3 Hardware Functionality Supporting Software Safety Mechanisms

The following hardware functionality exists within the TC3Ax SPU to increase the effectiveness of the Software Based Safety Mechanisms

#### 20.6.3.1 Monitor CRC Units

The TC3Ax SPU contains CRC units used to provide a method of checking the activity on key internal interfaces. These include:

- The internal RAM interfaces of the FFT accelerator
- Buffer Ram Interfaces
- Input Data Manager EMEM Interfaces
- Output Data Manager EMEM Interface
- Configuration RAM Interfaces

The CRCs shall be separated into two blocks in the registers space.

- CRCs which are independent of the data being processed. These are enabled using **SMCTRL.CTRLCRCEN**
- CRCS which are dependent on the data being processed. These are enabled using **SMCTRL.DATACRCEN**

The first can be used for providing some detection of soft errors occurring during execution as well as during software based self test. The second can only be used while processing known data during software based self test.

The CRC units are mapped into the TC3Ax SPU register space as read only registers.

The CRC Units have an associated control field (**SMUSER.CINIT**). The CRC units are initialised to the reset value by writing  $10_B$  to **SMUSER.CINIT**.

*Note: Enabling in-line CFAR or local maximum based bin rejection will change the address sequence at the ODM output. This affects the CRC accessed via the CTRL2\_CRC register. If the control based CRC is being used then either the CTRL2\_CRC register must be excluded from the CRC checks or dynamic bin rejection based on the data being processed must not be used.*

#### 20.6.3.2 Redundant Control Logic

All control and status state bits (flip-flops) implementing safety mechanism functionality are duplicated. The duplicate flip-flops are used to store the negated value of the bit. This can be observed directly in the SMCTRL and SMUSER registers. In the event of the state of these bits becoming inconsistent, it can be assumed that either a programming or soft error has occurred. An inconsistent state is detected by comparators and can be observed by polling the SMSTAT.SMCTRLSTS bit.

### 20.6.4 SMU events

The following table list the events that can trigger an SMU alarm. See [Section 20.6.1](#) for a description of the hardware safety mechanisms.

## Signal Processing Unit 2 (SPU2)

**Table 1030 SMU Events**

Event	Definition	Source	Comments
uncorrectable ECC error in Radar memory	Read data from a Radar Memory RAM has been corrupted	MTU	One of Multiple alarms will be generated based on MTU configuration
uncorrectable ECC error in a RAM internal to the TC3Ax SPU	Read data from an TC3Ax SPU RAM has been corrupted		
Register CRC check	Computed Register CRC does not match pre-programmed value	TC3Ax SPU	Alarm Mapping is defined in the SMU Specification
Bypass Data CRC check	Computed bypass data CRC does not match the value read from memory		
Radar Memory Control Logic Failure	The control signals for accessing Radar Memory are implemented as redundant logic. This alarm condition indicates that the TC3Ax SPU has detected an inconsistency in the redundant logic		
RIF Data CRC Check	CRC computed from RIF data stream does not match expected value tagged onto the end of the ramp data		
Radar Memory Access Address Error	An access to the Radar Memory has been mapped to a tile that has not been enabled for TC3Ax SPU accesses by writing to the EMEM tile control registers		
Radar Memory Read Data ECC Check	The read data for Radar Memory accesses is returned with an ECC computed from the access address and data. This is checked and an alarm set if the check fails		

Note: *the SMU allows the user to define the action that will be taken as a result of these events (see SMU specification).*

### 20.6.5 Safety assumptions

The safety assumptions for the Radar signal processing unit are described here.

#### 20.6.5.1 Safety assumptions and safety goals

There are 2 safety cases

- Radar with 1 Radar TC3Ax SPU only for low end applications
- Radar with 2 x Radar SPUs for mid range and high performance radar

## Signal Processing Unit 2 (SPU2)

### 20.6.5.1.1 Case1 = Radar with 1 Radar TC3Ax SPU only for low end applications

In the worse case, the Radar/ECU is involved in decision making for emergency brake or active lane assist, where at system level, customers may find it appropriate to use 2 different sensors to confirm the decision.

The other application use case considered would be where the results from the Radar/ECU application are used only to provide advisory information to the driver.

### 20.6.5.1.2 Case2 = Radar with 2 Radar SPUs only for mid to high end Radar

The radar/AURIX™ here is involved at least in decisions for directly implementing emergency braking or active lane steering without driver intervention. Again, the application may be required to use sensor redundancy at the system level.

### 20.6.5.1.3 Case3 = Radar + sensor fusion with 2 Radar SPUs only for mid to high end Radar

From the Radar/AURIX™ perspective, this case is the same as above.

In addition to this, the TriCores in the Radar/AURIX™ will be involved in doing sensor fusion in order to support high integrity decisions based on data coming from the radar/TC3Ax SPU and independent data coming from an external sensor. From the AURIX™ perspective, this use case is similar to the sensor fusion explained separately.

## 20.6.5.2 Radar Application assumptions

The following constraints can be used in an application in order to implement application oriented safety mechanisms.

### 20.6.5.2.1 Case 1: A decision is never taken on single ADC acquisition

This is the basic principle of FFTs for Radar: the FFT is integrating the noise measured by Radar where random variations are filtered out and where only consistent signal variations are kept.

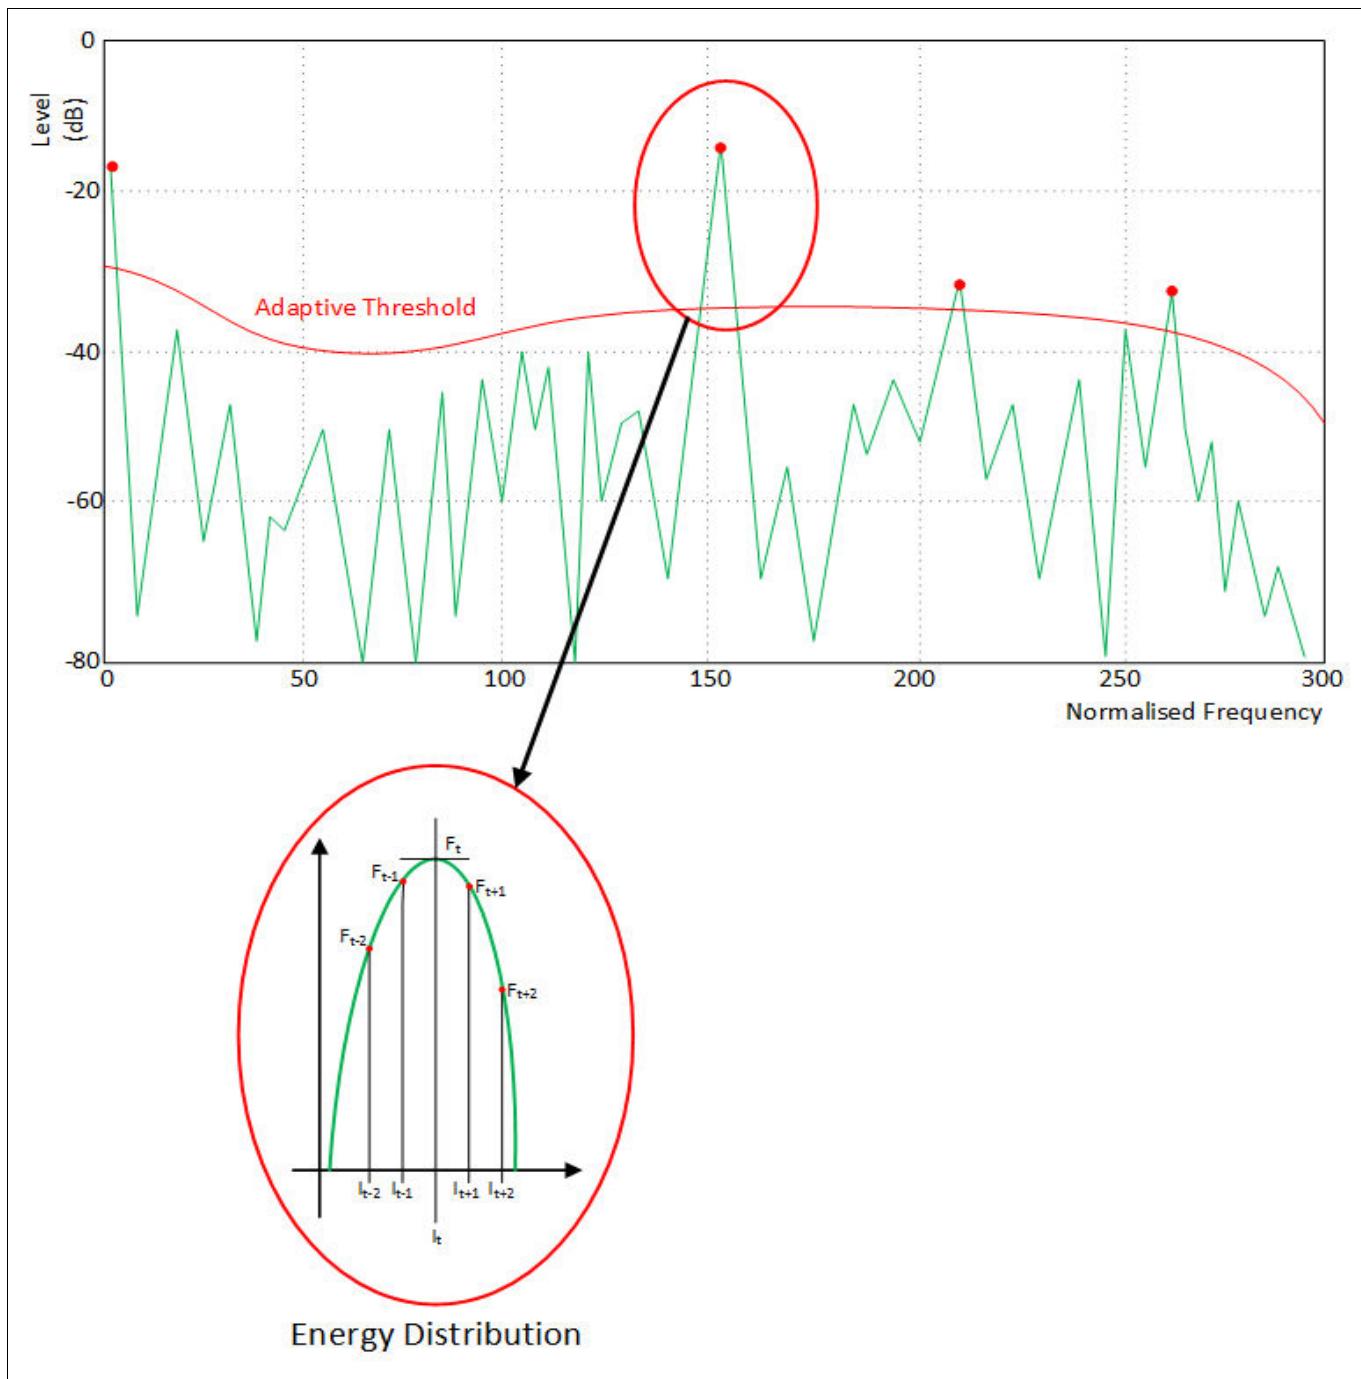

### 20.6.5.2.2 Case 2: A decision is never taken on a single FFT computation (1st stage and 2nd stage FFTs)

- Automotive Radar are now based on multiple antenna organized in phase array. So,
  - Antenna are separated by a distance
  - each antenna has same receiving lobe as the others
  - the difference between antenna is the phase of the signals: this phase difference allows the application to derive the angle of the object from the antenna.

### 20.6.5.2.3 Case 3: FFT peaks are never isolated

The figure below is showing that in fact, energy is distributed to adjacent FFT BINs so that a FFT peak is never isolated

## Signal Processing Unit 2 (SPU2)

**Figure 266 Example of FFT Result Energy Distribution**

A safety mechanism can be implemented to check if an FFT BIN is isolated to reject any isolated FFT BIN (where isolated means that the signal power on adjacent BINs is not high enough and where high enough is defined by application criteria).

Target acquisition is never taken from single acquisition

- this is definitely true for low end (see safety case1)
- this is not true for high performance radar.

Still, even if decision is taken from single acquisition, if we are allowed to assume that the RF device that is doing all preprocessing until the Analog to Digital Conversion is working fine, then, as we have a radar based on multiple

## Signal Processing Unit 2 (SPU2)

antenna with phase difference, an FFT peak leading to target decision is based on valid signal detected by multiple antenna. So

- there should be peaks detected on more than 1 antenna
- each peak on each antenna should meet the energy distribution criteria explained before

### 20.7 Use Cases

See SPU chapter for general assumed use case restrictions. This section covers any specific restrictions for SPU2.

#### 20.7.1 Using Fractional Clock Division (AUXCTRL.DIVF)

This bitfield is used to control the data throughput through the FFT pipeline including LOADER, MATH0, MATH1, FFT and UNLOADER. It is intended to be used to ensure that the FFT data is not passed to the ODP faster than it can be processed by the MATH2 unit. Although the MATH2 unit can exert back pressure on the UNLOADER to prevent overruns, this back pressure is then fed back to the LOADER and IDM. This is not an issue if data is being read from the Radar Memory but could potentially cause unpredictable slipping of input ramps if the data source is the RIF interface.

If data is being read from the RIF and ramp skipping is either intended or expected to be possible, the recommendation is that the AUXCTRL.DIVF bitfield should be set so that the FFT pipeline always takes longer to process the data than the MATH2 unit.

### 20.8 I/O Interfaces

Not in this release.

## Bit Manager (BITMGR)

### 21 Bit Manager (BITMGR)

BITMGR provides stand alone semi-autonomous hardware acceleration for bit wise-logical operations on large two dimensional bit-arrays stored in memory. The block is capable of combining two operands or perform reduction operations on a single operand. The operand in context is a two dimensional bit array packed into a wide memory such as EMEM of AURIXPlus.

**Figure 267 BITMGR**

#### 21.1 Feature List

The BITMGR has the following top level features

- A 256 bit RD port to Radar Memory at two cycles per access.
- A 256 bit WR port to Radar Memory at two cycles per access.
- DMA whose capabilities include
  - Read from two dimensional array of user configurable size and aspect ratio.
  - Write to two dimensional array of user configurable size and aspect ratio.
  - Concurrent Read and Write.
  - Two dimensional transfers broken into tiled blocks (non-configurable) size optimized for memory traffic.
  - Write to a circularly indexed region of fixed size

## Bit Manager (BITMGR)

- Simple descriptor chaining for stream processing with minimal supervisory overhead.
- Capability to start on SW or HW triggers and generate HW interrupts and Alarms.
- A logical processing unit capable of
  - transposing one bit array and overlay on another of complementary dimension  
-Or-
  - Combine multiple distinct rows from the same array
- Target labelling; remapping bit array indices to global addresses.

### 21.2 Overview

This section provides an overview of the BITMGR functionality

#### 21.2.1 Glossary of Terms

The following terms are used throughout this document

**Table 1032 Definition of Terms**

Term	Definition
CFAR	Constant False Alarm Rate. A processing operation designed to detect targets in a returned Radar signal compensating for varying amounts of noise in the signal
Transposition	Exchange the co-ordinates of a two dimensional array.
1D	One dimensional, a data structure whose elements can be address with a single index.
2D	Two dimensions, a data structure whose elements can be addressed with two indices.
SPU	Signal Processing Unit
LCLMAX	A short form reference to an algorithm.
DMA	Direct Memory Access

## Bit Manager (BITMGR)

**Start:**

- + Filled dot at the start of a line.
- + Example base address or index(0,0) for a 2D array.

**Contiguous entity:**

- + A contiguous region composed of some basic unit.
- + Example : A string of bits,  
row of a matrix in row major form  
Col of a matrix if in col major form

**Logical partition:**

- + A line comprised of many connected segments, to highlight some logical grouping.
- + Example partitioning of a word, such as adding a zero pad.

**Non contiguous:**

- + A break in a line, or broken line
- + Example: a memory word crossing or bits spread across multiple memory words  
Partition of a matrix.

**Continuation:**

- + Dashed thin line represents continuation.
- + Example access pattern for linear or circular addressing etc.

**Direction:**

- + Example a signal connection or an implication.

**Wide signal:**

- + Example, width of a signal bus.

**Figure 268 Diagram conventions**

### 21.2.2 Functional Overview

Within the context of SPU, the BITMGR post-processes SPU's CFAR and LCLMAX outputs. SPU stores these outputs as two dimensional bit-arrays arranged sequentially in memory. Each bit of the output represents the detection, or otherwise, of a peak in a related FFT bin within a two dimensional range-doppler map.

BITMGR can be configured in the following three modes to accelerate functions on two dimensional bit-arrays. For restrictions on mode usage refer section [Chapter 21.3.4](#)

#### Mode 0, Dual Array Overlay

Logical combination of two, 2D bit arrays of complementary size where the x-axis of one maps to the y-axis of the other and vice-versa.

#### Mode1, Sub-array overlay

Folding of a single, 2D bit array by combining rows at user configurable offsets using logical operations.

#### Mode2, Output Replication

Combine multiple adjacent rows from a single, 2D bit array using logical operations and write the resulting row multiple times to preserve the array size.

#### Target Labelling

In addition to the array processing modes, a post-processing step is also included in BITMGR. Target labelling can be selectively turned on to map valid bit indices in the result to global indices and system addresses, such as the range doppler map. See [Chapter 21.3.3](#)

## Bit Manager (BITMGR)

### 21.3 Functional Description

Though the concept of transpose is simple, its implementation especially on bit matrices remain expensive on most general purpose processors. The time complexity varies according to the size of the memory word, the granularity of the array elements and their packing. BITMGR addresses this problem with a divide and conquer approach to optimize memory bandwidth, throughput and power, details of which are described in this chapter. The performance parameters may be tuned down by altering the clock divider ratios to the IP.

#### 21.3.1 Array operand format

A legal operand to BITMGR shall be a two dimensional data structure in memory conforming to the following description. [Figure 269](#) illustrates the structure view(or matrix view or 2D array) of the required operand in a textbook convention. Rest of this section details how this data structure is stored in memory within the context of BITMGR. The first row shall begin at 256 bit aligned address and forms the base address of the array. Rows (or alternately referred to as the y-axis) are packed in memory. The number of columns per row and the size of a memory word gives rise to two packing modes, categorized as cases 1 and 2. Case 1 applies when the number of columns is greater than the memory word size, and case 2 when the number of columns is less than a memory word size. [Figure 270](#) illustrates case1, where the elements across columns (or alternately referred to as the x-axis) making up each row shall be packed into a multiplicity of 256bit words, contiguous in memory, the last of which may be partial. A partial last word shall be zero-padded to 256bits. [Figure 271](#) illustrates case2 where the elements making up each row shall first be padded to the next power of two size, and such padded rows packed into a 256b word. Therefore in case2, there also exist all zero padded rows following the last valid row. The additional padding thus appends the last row with all-zero rows to form a 256b word. In both cases, the complete two dimensional bit array occupies a contiguous region of memory, with rows packed sequentially in a little endian order within a memory word. The term ‘array-operand’ refers to an instance of this data structure.

BITMGR consumes up to two array-operands simultaneously.

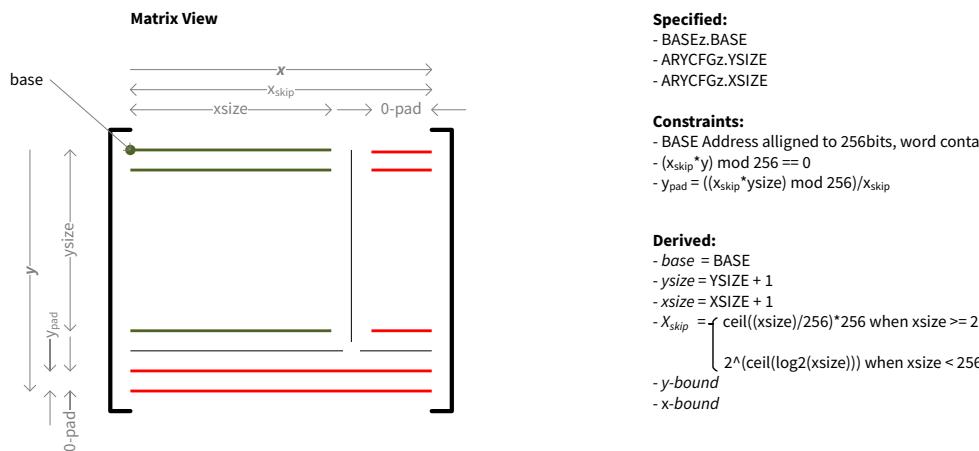

- **Specified:**

- BASE: Base address of Array in EMEM, aligned to 256bit word
- XSIZE: x-size or the columns of the array less 1, excluding zero padding
- YSIZE: y-size or the rows in the array less 1.
- Element granularity: restricted to single bit.

- **Derived:**

- xsize = XSIZE + 1
- ysize = YSIZE + 1
- $X_{skip}$  = The number of bits per row with zero padding.
- x-bound = XSIZE
- y-bound = derived from Mode0, 1 or 2

PAGE 1/19

**Figure 271 Array Operand Packing, Case2**

### 21.3.2 Operations

BITMGR defines three operations on array-operands, categorized as execution Modes 0, 1 and 2. Mode0 and Mode1/2 are executed sequentially in subsequent passes when both are enabled. Only one of Mode1 or 2 can be chosen after Mode0. If chaining is enabled both modes should have the same array operand size. See chaining operations [Chapter 21.3.4](#)

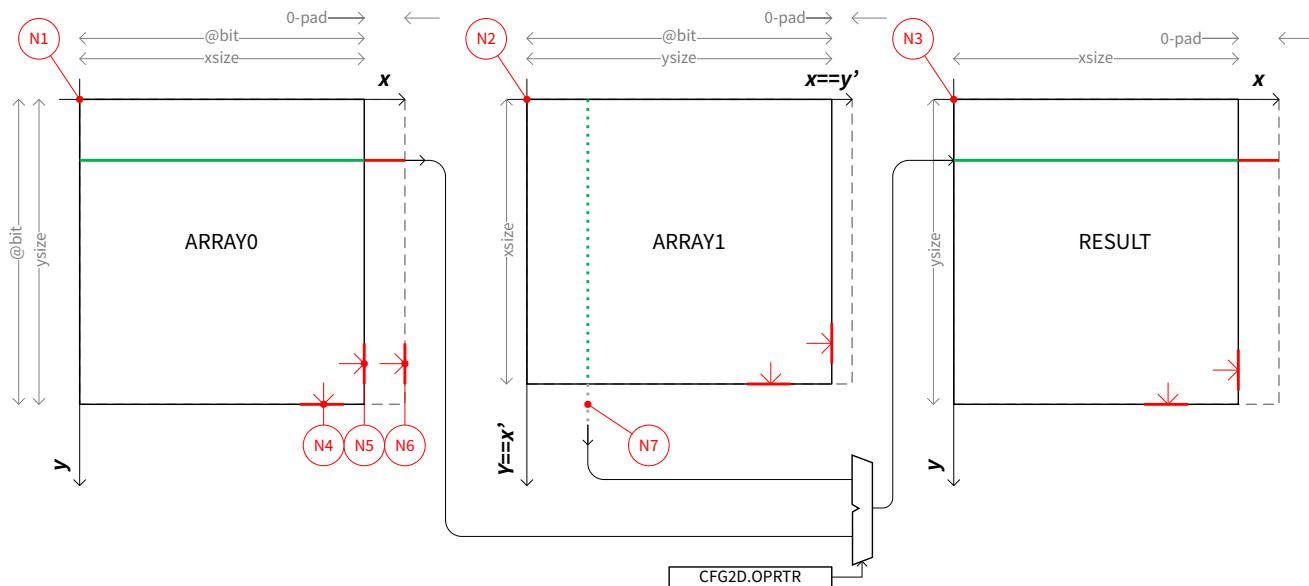

Logical operation is defined on elements of an array-operand where each element is a single bit. Logical operation is configured as a look-up table with the **CFG1D**, **CFG2D** ‘OPRTR’ fields. Lookup table output is indexed LSB to MSB. The binary value of this index shall be 2bits wide represented as {idx<sub>1</sub>, idx<sub>0</sub>}. A single bit from first array-operand shall be used as idx<sub>0</sub> and a corresponding bit from second array-operand shall be used as idx<sub>1</sub>.

#### 21.3.2.1 Mode 0, Dual Array Overlay

Logical combination of two array-operands of complementary size where the x-axis of one maps to the y-axis of the other and vice-versa. See [Figure 272](#)

- Pre-requisites and operation:
  - Enable **CTRL.DOEN**
  - Configure base address of the first array-operand; Array 0(BASE0.BASE)
  - Configure the base address of the second array-operand; Array1(BASE1.BASE)
  - Configure size of Array 0 (ARYCFG0.XSIZE, ARYCFG0.YSIZE). Array1 shall infer its size from ARYCFG0 such that it is complementary to Array0.
  - Configure bitwise logic operation (**CFG2D.OPRTR**) used to combine rows from first operand to corresponding columns on second operand, element wise. All elements from the array-operands shall be combined using the same operation.
  - Configure triggering mechanism using CTRL. Once triggered the process shall run autonomously until the y-bound row on Array 0. See also [Chapter 21.3.5](#)
  - Configure a base address (**DAOBASE.BASE**) to store the RESULT to. The RESULT dimensions shall be inherited from first array-operand.
  - The RESULT conforms to the definition of array-operand.

## Bit Manager (BITMGR)

all\_diagrams\_final.vsdx

TITLE Operational\_mode0

PAGE 1/19

**Figure 272 Mode0, Dual Array Overlay**

Note:

- (1) Base Address of Array0 corresponds to address of first row, of which the first column is implied.
- (2) Base Address of Array1, to be transposed, inherits complementary dimensions from Array0. Note how x and y coordinates are interchanged
- (3) Base address of result. Result inherits dimensions from Array0.
- (4) Array y-bound, beyond which memory is not reserved if the memory word contains only zeros all arising from padding.
- (5) Array x-bound where the 256 bit word can be partial, and is padded with zeroes.
- (6) a legal case1 or case2 packing boundary.
- (7) All zero padded rows may not exist in memory, instead zero extended by the fetch path.

### 21.3.2.2 Mode1, Sub-array overlay

Folding of a single array-operand by combining with a bit wise logical operation, multiple sub arrays of equal dimension placed at different offsets relative to base. The result sub array size is equivalent to the input sub-array.

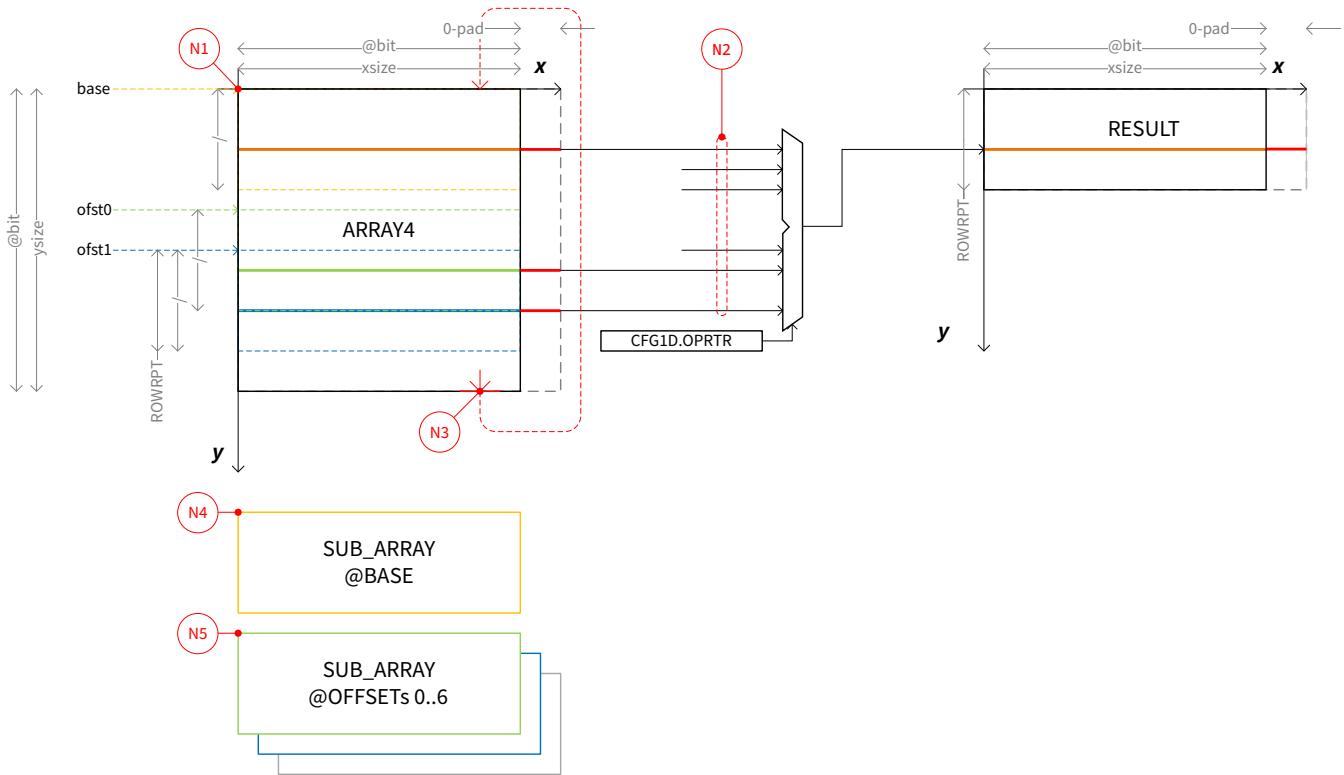

- Pre-requisites and operation:
  - Enable **CTRL.SOEN**
  - Mode 1 is selected over Mode2, when the (**CFG1D.SAF**) bit is  $0_B$ .
  - Configure base address for array-operand Array4 as **BASE4.BASE**.
  - Configure the x-dimension and y-dimension of the array-operand as **ARYCFG1.XSIZE**, **ARYCFG1.YSIZE**. If chaining is enabled, observe chaining mode constraints as detailed in **Chapter 21.3.4**, specifically on **XSIZE**
  - Configure the number of consecutive rows making up the sub arrays as row repeats (**CFG1D.ROWRPT**). This with inherited x-dimension, **XSIZE**, define the shape of all input sub arrays as well as the output.
  - Configure the row offsets to extract sub arrays from (**OFSTv(v=0-6).ROW\_OFST**) and enable the setting in **OFSTv.EN**. All row offsets are implied to align with column 0 of Array4. All sub-arrays have same y-dimension, and are exactly **XSIZE** wide.
  - Configure **CFG1D.IS** bit to include the implicit sub-array defined at **BASE4.BASE** in the computation. The implicit sub-array is included by default. If disabled, **OFST0** shall be configured and enabled. (Not enabling

## Bit Manager (BITMGR)

at least one OFSTv when CFG1D.IS is true, copies the input to output. Not enabling another OFSTv other than OFST0, will copy input to output with a row permutation, i.e a cyclic shift of the input along y.

- The number of sub arrays (2D) to be combined to produce the output (up to a maximum of 1 base+7 offsets, one always from base when included and up to 7 from offsets) shall be inferred from enabled offsets. Co-located row from each sub array is collected into a **row-group**. A **row-group** thus consists of a row from Base sub-array when included and a row each from the enabled offset sub-arrays in increasing order of precedence with respect to sub-array number.
- Configure the bitwise logical operation (**CFG1D.OPRTR**) used to combine the data from the **row-group**. Elements in the sub-arrays shall be combined using the same logical operation.
- On starting a fresh **row-group**, the second operand shall be from the sub-array pointed to by BASE4(or OFST0), and the first operand shall be from the sub-array pointed to by OFST0(or OFST1) forming the items 1 and 2 respectively in the **row-group**. On every successive row operation in the current **row-group**, the second operand shall be the result of the previous operation and the first operand shall be from remaining items of the **row-group** iterated in order. Here an operand refers to the chosen row.
- Offset sub arrays wrap around at YSIZE. Row access past the last row of the base array, continue from row0.
- ROWRPT should be less than or equal to YSIZE of the corresponding base array. ( Prevents the target labelling function from producing erroneous results)
- If the number of enabled offsets is less than 7, they shall use contiguous **OFSTv (v=0-6)**.
- For the purpose of target labelling, the index chosen corresponds to the index of the implicit sub-array portion or sub\_array from OFST0 depending on CFG1D.IS.
- The RESULT conforms to the definition of Array operand.

## Bit Manager (BITMGR)

all\_diagrams\_final.vsdx

TITLE Operational\_mode1

PAGE 1/19

**Figure 273 Mode 1, Sub-Array overlay**

Note:

(1) Base address, for array to be processed in mode1 (2) Combine multiple rows from the same array into a single output using the configured logical operation. illustrates row-group ordered top to bottom in figure (three rows shown, maximum seven configurable) (3) If the access crosses the y-bound, rows shall be fetched starting at row 0, i.e. cyclically (4) The sub array derived from base is selectively included in the operation. (5) up to 7 additional sub-arrays derived from the various configured offset can be included in the operation. All sub arrays (including base) have the same dimension. Figure depicts a y-dimension i.e. ROWRPT smaller than the ysize for clarity.

### 21.3.2.3 Mode2, Output Replication

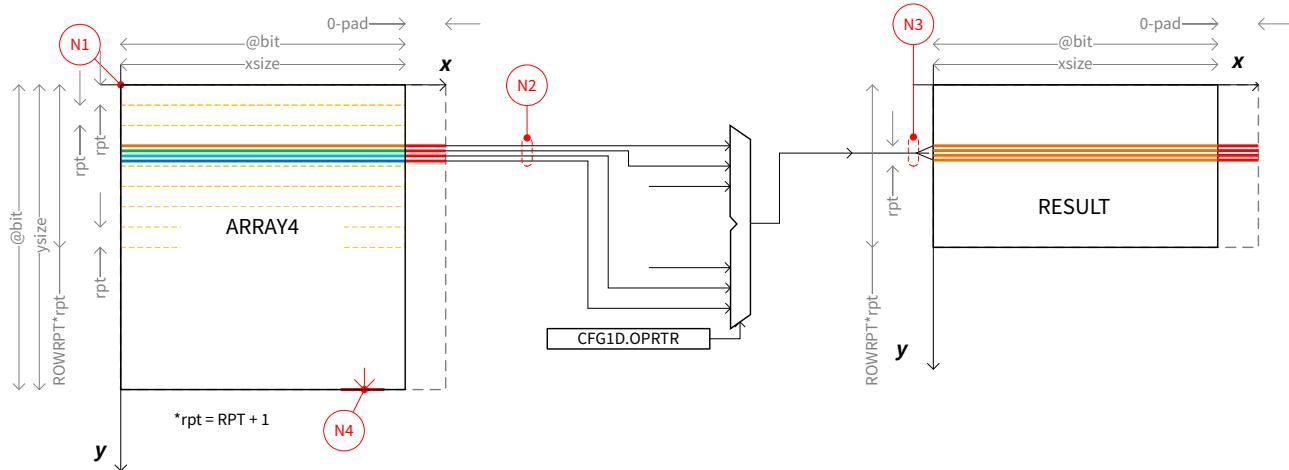

Combine using logical bit wise operations, ‘N’ adjacent rows from a single input array-operand and write the resulting row ‘N’ times. Repeat the above operation ‘M’ times to produce the result.

- Prerequisites and operation:
  - Enable **CTRL.SOEN**
  - Mode 2 is selected over Mode1, when the (**CFG1D.SAF**) bit is  $1_B$ . A RPT number of adjacent rows in ascending order is the **row-group** for Mode2
  - Mode 2 will use the same Array base and dimension as Mode 1.
  - Mode 2 will use the same x-dimension as base Array dimension.
  - Configure number of passes as row\_repeat (**CFG1D.ROWRPT**). ROWRPT provides the number of sub-arrays, such that they abut each other along the y dimension and are non-overlapping. The y-bound is derived from YSIZE. Crossing the y-bound continues row access from row index 0. The ysize of the RESULT

## Bit Manager (BITMGR)

is a function of **CFG1D.RPT**, **CFG1D.ROWRPT** and **ARYCFG1.YSIZE**. Note that only YSIZE rows can be accommodated in the output and in the event the total number of rows to be processed exceeds the YSIZE limit, the operation terminates when YSIZE rows are complete. Thus, the last row-group may be partial on the input, and only a similar number of rows are flushed to memory to form the result, or in other words a row from the input operand shall be used at the most once and the RESULT shall be at the max equivalent in dimension to the input Array-operand.

- The first **row-group** is the group starting at row 0 positioned at BASE if CFG1D.IS is enabled, or the first **row-group** is the group starting at OFST0. It is illegal not to configure and enable OFST0 if IS is 0<sub>B</sub>.
- Configure logical operation used to combine all the data in the **row-group**(**CFG1D.OPRTR**). All elements from the sub-arrays shall be combined using the same logical operation.
- All rows from the **row-group**, are combined to generate a single row result. The sequencing of the individual rows shall follow the combination order as defined in Mode1, where adjacent rows replace offset rows.
- The result generated by the previous step is replicated on the output by a similar number as the rows used in the combination. This implies that if the last row-group is partial, the replication will be less than RPT.
- If access crosses the y-bound they continue from row0, i.e. cyclical.
- Target labelling would use the absolute y-index as used in the row-group.
- The RESULT conforms to the definition of the Array operand.

all\_diagrams\_final.vsdx

TITLE Operational\_mode2

PAGE 1/19

**Figure 274 Mode 2, Output Replication**

Note:

- (1) Mode 2 shares Array parameters with Mode 1. Only one mode can be chosen
- (2) Adjacent rows are combined using configured operator. Illustrates row-group ordered top to bottom
- (3) Result from combining the entire row-group is written out as many times as the size of the row-group in rows.
- (4) Row access that cross y-bound wraparound, but operation terminates if BASE or OFST0 is reached depending on IS.

### 21.3.3 Target Label List Generation

The result from the operand combination steps above can be post processed to map each valid bit index (a non zero element) to a global index and system address. When **CTRL.TLBLE** is configured to a legal value, BITMGR shall enable this inline post process step. The generated list shall be referenced to the co-ordinate axes of the input array-operand (inherited from first array-operand specified at BASE0/2 for Mode0 or first enabled sub-array of array-operand used in Mode1,2 depending on CFG1D.IS).

## Bit Manager (BITMGR)

**Note:** Enabling the Target Label List function will significantly impact performance of the BITMGR since target identification is carried inline with every row of result computed.

For each word in the result, any bit set to one has its co-ordinates in input array computed. These are then written to memory along with an address computed using the **TLBLB.BASE**, **TLBLO.XMUL** and **TLBLO.YMUL** bitfields. If the co-ordinates are **X\_index** and **Y\_index** the address is

```
32b:SysAddress := TLBLB.BASE + (TLBLO.XMUL * X_index) + (TLBLO.YMUL * Y_index)
```

The format of the list generated is derived from the format used by the equivalent function in the SPU. The output consists of two, thirty-two bit words per target. The first word contains the generated system address. The second word contains the X-index in bits 9:0; the Y-index in bits 19:10. As the inputs to the BITMGR are always two-dimensional arrays, Z-axis co-ordinates do not exist. Therefore, Bits 27:20 shall be reused for the running batch count (**CTRL.PCNT\_STAT**) when batch mode processing is in progress. Bit 31 is used to flag a valid label. The list would mostly contain valid labels. However, at the end of every iteration in the batch or a single, a partial list entry could exist. In this instance, a list entry with at least one label is flushed to memory. The valid bit avoids ambiguity and optionally provides a quick method to test the validity of a target rather than testing address bounds.

```
32b:Label_ew := SysAddress
32b:Label_ow := {1, 3'b000, CTRL.PCNT_STAT, Y_index, X_index}
64b:Label_in := {Label_ow, Label_ew} // nth target
256b:Label_list_item := {Label_i3, Label_i2, Label_i1, Label_i0}
```

When a target list entry(i.e containing up to 4 targets) is written to radar memory, the value in the **TCNT.COUNT** bitfield is incremented by 1. **TCNT.COUNT** is initialised to  $0_D$  when the **CTRL** register is written. **TCNT.COUNT** is 16 bits, where bits 0 to 9 point to the current list index, and the higher order bits provide the number of roll-overs since initialization.

### 1D Circular addressing

The maximum size of the Target List shall be 32 KiB; enough to store 4096 targets. The BITMGR will treat the target list as a circular buffer and will reset the output address to the address stored in **TLBLBASE.BASE** every time the value of **TCNT.COUNT** reaches an integer multiple of 4096. To allow application software to manage the buffer, interrupts shall be generated at 50 and 100% buffer watermarks; i.e. **TCNT.COUNT** reaches multiples of 2048. Target generation, when enabled, will add an extra DMA inline with every 1x256 bit of result computed. The DMA uses a dedicated descriptor with 1D Circular mode. Writes are always 1x256bits. The only exception is at the end of configured processing or completion of every iteration within a batch, where a partial 256bit word might need to be flushed to complete the operation.

#### 21.3.4 Function triggers and function chaining

This sections details the control options within BITMGR used for selecting triggers, selecting functions, their sequencing and interdependencies between configured operations. The term ‘unit of work’ is broadly used to collect autonomous actions that follow a trigger event. It is illegal to change configuration parameters in an armed or triggered state.

##### 21.3.4.1 Independent operation of functions

**CTRL.DOEN** and **CTRL.SOEN** enable Dual Array overlay processing (Mode0) and Sub-Array overlay processing (Mode1/2) respectively. They can each be enabled independently or both together. If Mode0 is disabled, a trigger will initiate Mode1/2 without delay. However only one of Mode 1 or 2 is selected at a time by **CFG1D.SAF**. Also refer

## Bit Manager (BITMGR)

Array-operand pointer management in the section on **Batch mode trigger**. If only one function is enabled, the value of the CTRL.CHAIN bit should be ignored.

**Note:** *The chaining operation presents numerous structural hazards, and hence shall be blocking in that Mode0 and Mode1/2 will not be pipelined. Chaining impose further restrictions on operand dimension when **Run mode** is set to “CONTINUOUS”. Target labelling can be enabled either on Mode0 result or Mode 1/2 result. However in chained mode, Mode0 result area will be reused on every trigger.*

### 21.3.4.2 Function chaining

Chaining is active when **CTRL.CHAIN** and both **CTRL.DOEN** and **CTRL.SOEN** are enabled. This facilitates the output from a Dual Array Overlay Processing(Mode0) to be used as the input to a Sub-Array Overlay Processing (Mode1/2). However there shall be no internal forwarding of results between the two function. Instead, a fully formed operand array in EMEM shall be passed into the second function by configuring BASE4 and 5, ARYCFG1 to be the same as **DAOBASE** and ARYCFG0 respectively. DAOBASE shall not increment when chaining is enabled. Also refer Array-operand pointer management in the section on **Batch mode trigger**

Only one sub-array processing mode (mode1/2) can be chosen with **CFG1D.SAF**.

### 21.3.4.3 SW Trigger

Setting **CTRL.T\_SRC=SWTRIG** triggers BITMGR on completion of a TRIG register write with TRIG.EVENT set. If a MODE1/2 and MODE0 are both enabled, the sequence is executed by a trigger event. Trigger shall start Mode0, completely form its output in memory, and internally trigger Mode1/2 without further software intervention. Receiving a second trigger from software (when **CTRL.T\_SRC** sets software trigger) before the completion of an ongoing operation shall trigger an ERROR interrupt. The assumption is that untimely SPU activity corrupts input array-operands worked on by the BITMGR. BITMGR shall halt processing on this event, and ensure that its interfaces are transitioned to a benign state so as not to interfere with the rest of the system. Even on ERROR, TRIG.BUSY continues to reflect internal state of the module, such as pending Radar Memory writes for example.

### 21.3.4.4 HW Trigger

Alternately, BITMGR can be triggered with a SPU DONE signal by setting **CTRL.T\_SRC** to SPU0 or SPU1. On completion of TRIG register write with TRIG.EVENT set, BITMGR shall be armed, waiting for a corresponding DONE signal from the configured SPU to trigger processing. Both sequencing and monitoring operations work similar to that of the SW Trigger scheme.

## 21.3.5 Run mode

Triggers can be configured for single or batch mode processing of operands

### 21.3.5.1 One-Shot trigger

**CTRL.T\_TYPE** shall be set to single and **CTRL.T\_SRC** not OFF. The default triggering mode is fundamental to interrupt driven processing where BITMGR shall perform a single (Independent set or chained set) operation and halt. The BITMGR can be configured to generate an “ATTENTION” interrupt when processing completes. Operands configured at BASE0, BASE1 shall be used for Mode0 and BASE4 for Mode1/2.

If a Mode1/2 is chained with a Mode0 the chained sequence is executed by a trigger event. Trigger shall start Mode0, completely form its output in memory, and internally trigger Mode1/2 without further software intervention. The result is the output of Mode1/2 operation.

Result shall be placed at **DAOBASE** or **SAOBASE** or both. A previous result may be overwritten following a trigger.

## Bit Manager (BITMGR)

**Note:** One-shot trigger may be interpreted as a subset of batch mode trigger where the batch size is preset to one.

### 21.3.5.2 Batch mode trigger

Batch mode triggering, **CTRL.T\_TYPE** = “CONTINUOUS”, configures BITMGR to autonomously process a stream of array-operands. While it does work when **CTRL.T\_TYPE**=SWTRIG, the intent is to use it with **CTRL.T\_SRC**=SPU0 or **CTRL.T\_SRC**=SPU1 where BITMGR shall be triggered directly by the appropriate SPU DONE signal. A trigger is still required to advance the stream until a batch size of **CTRL.PCNT**.

- If the Target Labelling Function is enabled, then bits 27:20 of the second word shall contain a running count of the processing operation performed. (See the definition of the **CTRL.PCNT\_STAT** bitfield)
- The BITMGR shall only generate an ATTENTION interrupt at the completion of a number of processing operations as configured by **CTRL.PCNT**.
- Receiving a DONE input from the SPU (when **CTRL.T\_SRC** sets hardware trigger) or a new SW Trigger before the completion of an ongoing operation shall trigger an ERROR interrupt. The assumption is that untimely SPU activity corrupts input array-operands worked on by the BITMGR. BITMGR shall halt processing on such an event and ensure that its interfaces are transitioned to a benign state so as not to interfere with the rest of the system. Even on ERROR, TRIG.BUSY continues to reflect internal state of the module, such as pending Radar Memory writes for example.

Batch mode triggering shall manage input and result pointers as follows.

#### Mode 0 Mode1/2 independent operation

If the Dual Array Overlay Processing Mode (Mode0) is enabled, the base addresses for the two input array operands shall alternate between BASE0 (for Array 0), BASE1 (for Array 1) and BASE2, BASE3 respectively on each successive HW trigger. The configuration facilitates a ping pong buffer in EMEM, pipelining array operands between SPU and BITMGR (not to be confused with the private buffer inside BITMGR). The first processing operation after configuration shall be BASE0.BASE and BASE1.BASE.

The EMEM address used for writing results shall continuously increment starting from **DAOBASE**.BASE. There shall be **CTRL.PCNT** number of output operand-arrays in contiguous memory with the first positioned at **DAOBASE** (an array of array-operands). [Figure 269](#) depicts the valid packing for elements (each an array-operand) within an array of array-operands. Every result must conform to the Array-operand definition and hence should be placed at a base address which is aligned to a 256bit EMEM address.

If the Single Array Overlay Processing Mode (Mode1/2) is enabled, the base addresses for the two input array operands shall alternate between BASE4 and BASE5, respectively on each successive HW trigger. The configuration facilitates a ping pong buffer in EMEM, pipelining array operands between SPU and BITMGR (not to be confused with the private buffer inside BITMGR). The first processing operation after configuration shall be BASE4.BASE.

The EMEM address used for writing results shall continuously increment starting from **SAOBASE**.BASE. There shall be **CTRL.PCNT** number of output array-operands in contiguous memory with the first positioned at **SAOBASE** (an array of array-operands). [Figure 269](#) depicts the valid packing for elements (each an array-operand) within an array of array-operands. Every result must conform to the Array-operand definition and hence should be placed at a base address which is aligned to a 256bit memory address.

#### Mode0 chained with Mode1/2

Batch processing of operand stream in Mode0 continues as above. However, an important distinction is that the position of result array-operand remains fixed to **DAOBASE**.BASE i.e. the results shall be overwritten on every subsequent trigger.

## Bit Manager (BITMGR)

BASE4/5 shall point to **DAOBASE**, so as to pass the result from Mode 0 to Mode1/2 through memory. It is also required that ARRAYCFG0 and ARRAYCFG1 are configured to the same values.

The result array from Mode1/2 will now be placed at incrementing addresses starting from **SAOBASE.BASE**. The next result array will be placed starting at the next contiguous location. There will be exactly **CTRL.PCNT** number of result arrays when the batch process completes. Every result must conform to the Array-operand definition and hence should be placed at a base address which is aligned to a 256bit boundary.

### 21.3.6 Interrupts

The BITMGR generates two interrupts:

- **ATTENTION** will be generated under the following conditions
  - If **CTRL.T\_TYPE=ONESHOT**, the interrupt will be generated when the configured processing operations have completed following one trigger.
  - If **CTRL.T\_TYPE=CONTINUOUS**, the interrupt will be generated if **CTRL.PCNT** is not equal to  $0_D$  and the enabled processing operations have completed following **CTRL.PCNT** triggers.
  - To allow application software to manage the target buffer, the BITMGR will generate interrupts when the value of **TCNT.COUNT** reaches integer multiples of 2048 i.e. every time the buffer reaches 50% or 100% of capacity
- **ERROR** is used to signal that an event has occurred that either potentially or actually has corrupted the execution results.
  - If a trigger is received before the completion of an ongoing operation triggered by the last trigger, an ERROR may be flagged. The trigger event monitored is a HW or SW trigger event depending on the **CTRL.T\_SRC** setting. Note that target labelling in continuous mode could create error conditions as the compute time is no longer deterministic.
  - When the ERROR interrupt is raised, the default behaviour of BITMGR is to halt and transition all its interfaces to a benign idle state so as not to interfere with the rest of the system. **TRIG.BUSY** continues to reflect internal state of the module, such as pending Radar Memory writes for example.

**Table 1033 Bit map for Interrupt mask register STATCTRL.INTMASK**

Event	Description	Note
End of execution	End of operation, <b>CTRL.T_TYPE==”ONESHOT”</b>	STATCTRL.INTMASK[0]
End of execution	End of PCNT operations, <b>CTRL.T_TYPE==”CONTINUOUS”</b>	STATCTRL.INTMASK[1]
Target list @2048 entries	Target list crossed half watermark	STATCTRL.INTMASK[2]
Target list @4096 entries	Target list crossed full watermark	STATCTRL.INTMASK[3]

**Table 1034 Bit map for Error mask register STATCTRL.ERRMASK**

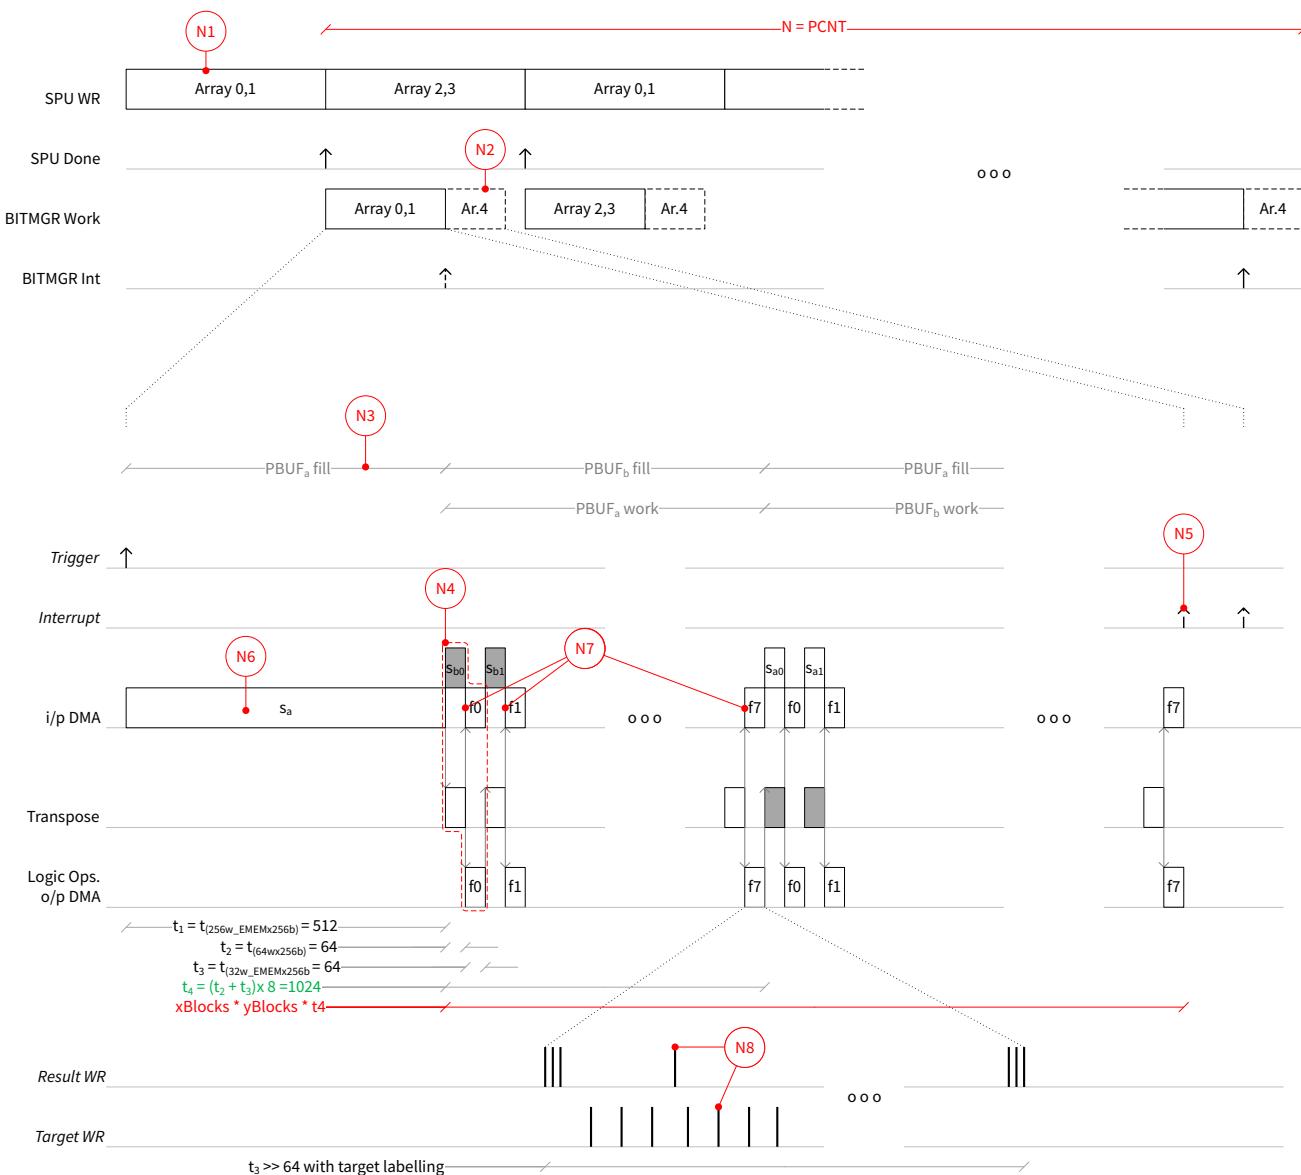

Event	Description	Note
Radar Memory Read Error	Error was seen on the RADAR memory Read port	STATCTRL.ERRMASK[0]
Radar Memory Write Error	Error was seen on the RADAR memory Write port	STATCTRL.ERRMASK[1]
Trigger overlap one	New trigger received when operation is in progress	STATCTRL.ERRMASK[2]

## Bit Manager (BITMGR)

### 21.4 Process pipeline

BITMGR interacts with SPU and rest of the system via triggers and interrupts and exchange data through EMEM buffers. The ideal case depicted in **Figure 275** as time dependencies on the pipeline is an indicative reference to optimize scheduling and mitigate resource conflicts. The pipeline illustrates one of the many scenario where array-operand size is greater than 256x256 and does not explicitly show differences due to chaining. This scenario was chosen as a good representation of the maximum throughput case. When both Mode0 and 1/2 are enabled each trigger executes the chained function and consequently interrupts are generated only towards the end of that operation. Refer **Chapter 21.3.4** for details. Note that target labelling is not deterministic, but dictated by the no of targets in the output instead.

Note: **Figure 275** is only an informational aid providing a thematic overview of the procedural time line. Due to variations on the workload imposed by a chosen configuration and other system level interactions, no claim is made to the exactness of the numbers depicted in the figure.

**Figure 275 Observable traffic pattern and process pipe**

---

**Bit Manager (BITMGR)**

Note: (1) SPU writes its results to memory, A ping-pong buffer in memory is available for continuous operation. (2) In optional chained operation mode. Figure only expands mode 0 (3) DMA activity with regards to Mode 0 execution (4) 256x256 blocks are processed in batches of 32 rows/columns. Entire operation on 32rows, 32 columns to produce 32 rows of result without target labelling depicted. (5) Interrupts may or may not be generated following every execution trigger depending on the trigger, run mode and interrupt configuration. (6) parts of one operand are read in continuously (7) parts of a second operand are read in burst and take priority over the read in [4]. 8 such bursts match the quantity read in [6] and also [4] (8) Optional target labelling operation and its impact on performance. Target labelling shares the write port, but exact sequence is variable depending on the number of identified targets and their density.

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
						<b>0</b>									
						r									rw

Field	Bits	Type	Description
<b>ROW_OFST</b>	9:0	rw	<b>Row Offset for Array y</b> Index of the first row of a sub-array relative to row0 of its parent, Array4. A sub array placed at the defined offset will be included in sub array recombination, based on the state of EN. The maximum permissible offset is 1023 and the minimum offset is 1. If less than 7 sub-arrays are configured the valid offset definitions shall be placed contiguously starting from OFST0. Valid offsets must always be less than or equal to YSIZE .
<b>EN</b>	31	rw	<b>Enable this Offset</b> 0 <sub>B</sub> <b>NOT_VALID</b> , Exclude this row offset configuration 1 <sub>B</sub> <b>VALID</b> , Use this row offset configuration
<b>0</b>	30:10	r	<b>Reserved</b>

**Table 1049 Access Mode Restrictions of OFSTv (v=0-6) sorted by descending priority**

<b>0</b>												<b>SAF</b>	<b>RPT</b>		
r												rw	rw		
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
<b>IS</b>	<b>0</b>	<b>ROWRPT</b>												<b>OPRTR</b>	
rw	r													rw	

Field	Bits	Type	Description
<b>OPRTR</b>	3:0	rw	<b>Logical Operator</b> Defines the truth table for the 2 input, 1 output logical function used to combine elements from sub-array rows. The 4 bits provide a lookup for the output, where the 2 bit binary index to the table is generated by concatenating the input elements as {Accumulator bit, Sub array bit}. The accumulator bit is initialised from Implicit Sub Array or OFST0. A single row result is obtained by applying the operator across the column elements in the row group reduced two bits at a time. Please refer the Mode1, 2 function description for further details.
<b>ROWRPT</b>	13:4	rw	<b>Row Repeat</b> Iteration count for Modes 1 or 2. For Mode1, the iteration defines the number of rows in a sub-array. For Mode2 the iteration define the number of sub-arrays of size RPT. This will therefore also influence the number of rows in the output array. The maximum is bounded by the YSIZE configuration, which shall not be exceeded. For further details please refer section on Execution Modes.
<b>IS</b>	15	rw	<b>Include Implicit Sub Array(IS) in Mode1/2 function.</b> Controls if the implicit sub-array, which is the one located at BASE, is included in computation for Mode1/2. When IS is included the operation starts from the BASE or row 0. When IS is excluded the operation starts from OFST0. When the implicit sub-array is excluded, software must configure OFST0 as the alternate start location. <b>0<sub>B</sub></b> <b>EXCLUDE</b> , Exclude the Implicit sub_array from computation. <b>1<sub>B</sub></b> <b>INCLUDE</b> , Include the Implicit sub_array in computation.
<b>RPT</b>	18:16	rw	<b>Row Read Repeat</b> Configures number of rows, N, to be combined in function Mode2, when RPT is configured to N-1. Allows N rows to be read from the input array, combined using an arbitrary logical operator and the combined result written back 'N' times to consecutive rows in the output array. Ignored when function Mode 2 is not enabled. Minimum and maximum values for N-1 are 1 and 1023 respectively.
<b>SAF</b>	19	rw	<b>Single Array Function</b> Enables Mode2 over Mode1 when set. <b>0<sub>B</sub></b> <b>MODE1</b> , Choose Mode 1 Function for Single array overlay <b>1<sub>B</sub></b> <b>MODE2</b> , Choose Mode 2 Function for Single array overlay

### Target Count

Stores a count of how many target entries (four targets per entry) have been written to the Target Label List

The count is initialised when the CTRL register is written.

The count will rollover. Bits 9 to 0 provide the current buffer index.

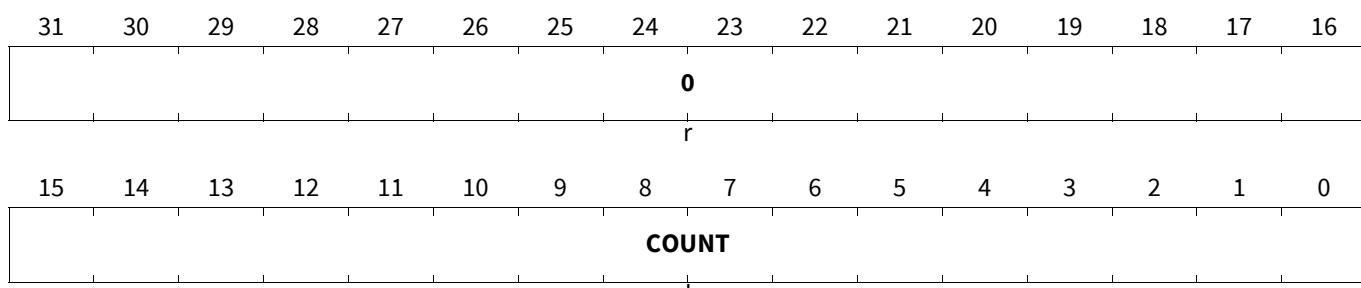

The higher order bits provide rollover status.

Ignoring the bit partition, the counter provides an estimate of targets identified since initialisation.

## Bit Manager (BITMGR)

### TCNT

**Target Count** (06C<sub>H</sub>) **Reset Value:** Table 1068

Field	Bits	Type	Description
COUNT	15:0	rh	<b>Target Count</b> This is a counter storing the number of entries written to the Target Label List since the last write to the CTRL register. The counter is read only and is cleared when the CTRL register is written.
0	31:16	r	<b>Reserved</b>

**Table 1067 Access Mode Restrictions of TCNT sorted by descending priority**

**Bit Manager (BITMGR)****Safety Mechanism Control Functions (User)**

This register provides access to the control functions for safety mechanisms not used as part of the normal configuration of the BITMGR. The various test bitfields defined in this register and used to test that the safety mechanisms can generate alarms are intended as a connectivity test only. It is therefore not necessary (or desirable) for the BITMGR to be running while these tests are run.

**SMUSER****Safety Mechanism Control Functions [User] (214<sub>H</sub>)****Reset Value: Table 1088**

### Access Enable Register 0

The Access Enable Register 0 controls access for writes to registers and configuration memory using the on chip bus master TAG ID 000000B to 011111B (see On Chip Bus chapter for the products TAG ID <-> master peripheral mapping). The BITMGR is prepared for a 6 bit TAG ID. The registers ACCEN0 / ACCEN1 are providing one enable bit for each possible 6 bit TAG ID encoding.

Mapping of TAG IDs to ACCEN0.ENx: EN0 -> TAG ID 000000B, EN1 -> TAG ID 000001B, ..., EN31 -> TAG ID 011111B.

#### ACCEN0

**Table 1096 Reset Values of ODA**

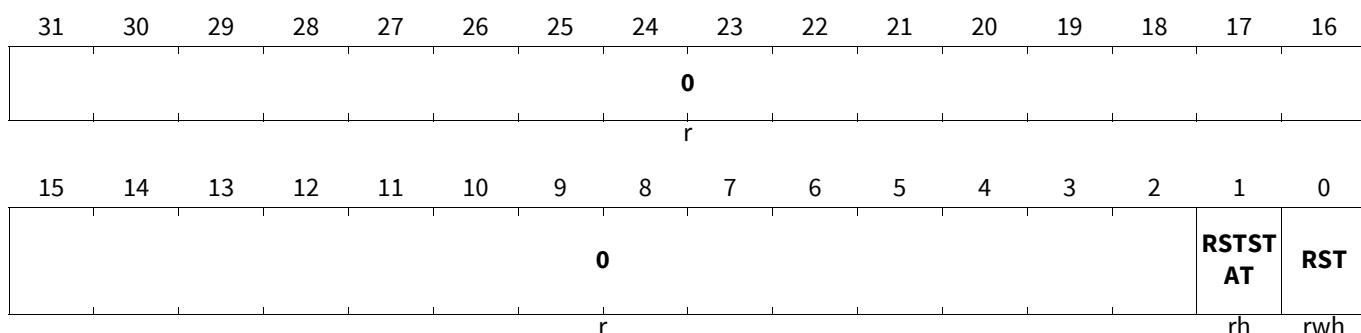

Reset Type	Reset Value	Note
Power On Reset	0000 0000 <sub>H</sub>	"Power on Reset"

**Kernel Reset Register 0**

The KRST0, KRST1 and KRSTCLR registers are used to initiate and monitor a reset of the BITMGR kernel logic. The kernel reset is equivalent to a full application reset, only the registers implemented in the bus interface are not affected. All registers affected by kernel reset have an appropriate entry in the "reset values" table

Note, that if a debugger is connected, an application reset of the device will have the same effect on the KRST0 and KRST1 registers as a kernel reset. If KRST0.RST or KRST1.RST are set, they will be cleared and the KRST0.RSTSTAT bit will be set.

Note, this register is an exception to the general use of ENDINIT to protect register related to Kernel Reset. This register is protected only by ACCEN.

**Bit Manager (BITMGR)****KRST0****Kernel Reset Register 0**(228<sub>H</sub>)Reset Value: [Table 1098](#)

Field	Bits	Type	Description
<b>RST</b>	0	rwh	<b>Kernel Reset</b> This reset bit can be used to request for a kernel reset. The kernel reset will be executed if the reset bits of both kernel registers are set. The RST bit will be cleared (reset to 0B) after the kernel reset is executed 0 <sub>B</sub> <b>Run</b> , Normal Operation 1 <sub>B</sub> <b>Reset</b> , Request a kernel reset of the BITMGR This reset bit can be used to request for a kernel reset. The kernel reset will be executed if the reset bits of both kernel registers are set. The RST bit will be cleared (reset to 0B) after the kernel reset is executed
<b>RSTSTAT</b>	1	rh	<b>Kernel Reset Status</b> This bit indicates whether a kernel reset was executed or not. This bit is set after the execution of a kernel reset in the same clock cycle both reset bits are cleared (KRST0.RST and KRST1.RST). 0 <sub>B</sub> <b>Run</b> , No reset has occurred 1 <sub>B</sub> <b>Reset</b> , A kernel reset was executed
<b>0</b>	31:2	r	<b>Reserved</b> Will always read as 0 <sub>B</sub> . Should be written with 0 <sub>B</sub>

## Bit Manager (BITMGR)

### 21.6 Debug

For purposes of debug, it is possible to stop execution at well defined functional handshakes by Software or using the system wide OCDS suspend functionality to break an autonomous cycle.

For availability reasons, the command to stop execution requires to write 3 bits,  $111_B$ , defined as STOP, to the CTRL.MODE bitfield

When such finer control is exercised by the debugger, operation cannot resume after the break. Once the OCDS suspend has been removed, the BITMGR should be initialised using kernel reset.

Two types of suspend are available

- Hard Suspend: this stops the kernel clock of the BITMGR immediately. Registers can still be read but should not be written. EMEM control signals may suspend in the active state.
- Soft Suspend: Operation is suspended when the control logic reaches a stable state and the interfaces are transitioned to a benign state. Suspend will be acknowledged as soon all outstanding writes to Radar Memory complete.

#### 21.6.1 Trace

BITMGR will not use the trace port as data is easily visible in memory.

#### 21.6.2 Debugger events

The following event triggers are available as hardware events for the debugger via the configuration options in the OCS register.

## 21.7 Safety Measures

The BITMGR has the following safety mechanisms to assist in its use in safety related applications

### 21.7.1 Hardware Safety Mechanisms

The BITMGR has the following autonomous hardware safety mechanisms which report failures via SMU alarms

#### 21.7.1.1 Functional logic redundancy

The internal functional logic apart from RAMs within BITMGR is implemented with a fully redundant copy. This redundant copy is neither inverted nor delayed. At runtime, a checker checks for discrepancies between the copies and generates an SMU alarm in case of a mismatch.

#### 21.7.1.2 Register CRC

The register CRC uses a 32 bit ethernet polynomial which assumes that the register contents are converted to an LSB first sequential data stream. The data stream will be generated using the registers from **ARYCFG<sub>z</sub> (z=0-1)** to **CTRL** inclusive. Unused register addresses shall be replaced by 0000 0000<sub>H</sub> in the datastream.

The polynomial shall run periodically once enabled and the CRC generated from the register contents compared with the value stored in the **REGCRC.CRC** bitfield. If the comparison fails, then an SMU alarm will be generated.

The Register CRC is enabled by writing 10<sub>B</sub> to the **SMCTRL.REGCRCEN** bitfield and disabled by writing 01<sub>B</sub>.

Control and comparison logic of the safety mechanism is replicated using negated logic. Any difference in behaviour between the two sets of logic will result in setting of the **SMSTAT.SMCTRLSTS** bit.

The alarm can be tested by writing an invalid CRC to **REGCRC.CRC**.

If this condition has triggered an alarm, bit 1 of the **SMSTAT.SMSTAT** bitfield will be set to 1<sub>B</sub>.

#### 21.7.1.3 Radar Memory Control Signal Redundancy

All control signals controlling accesses to Radar Memory are duplicated. The duplicate signals are set to the negated value of the primary control signal. In the event of the two signals becoming inconsistent, it can be

## Bit Manager (BITMGR)

assumed that an error has occurred. An inconsistent state is detected by comparators and will cause an SMU alarm.

This check is permanently enabled. If this condition has triggered an alarm<sup>1)</sup>, bit 4 of the **SMSTAT**.SMSTAT bitfield will be set to 1<sub>B</sub>.

### 21.7.1.4 Radar Memory Tile Access Error

Radar Memory tiles are enabled for BITMGR accesses by configuring the tile control mechanism in the EMEM. An BITMGR access can be directed to a blocked tile either by a configuration error or a fault in the BITMGR logic. In the event of the EMEM reporting that an access has failed because it has been mapped to a blocked tile, this mechanism can be used to trigger an SMU alarm.

The alarm is enabled by writing 10<sub>B</sub> to the **SMCTRL**.RMTAERR bitfield and disabled by writing 01<sub>B</sub>. Writing either of the other two possible values will result in the SMSTAT.SMCTRLSTS bit being set.

If this condition has triggered an alarm, bit 5 of the SMSTAT.SMSTAT bitfield will be set to 1<sub>B</sub>.

This alarm condition can be tested by writing 10<sub>B</sub> to the SMUSER.RMTAERRTST bitfield.

### 21.7.1.5 Radar Memory Read Data ECC

Read data returned for a Radar Memory access by the BITMGR is protected by an ECC computed in the EMEM from the address presented to the RAM and the data output from the RAM. This is checked by the BITMGR to ensure that the data is correct and has been read from the expected RAM location. A failed check will be signalled via an SMU alarm

The alarm is always enabled.

If this condition has triggered an alarm, bit 3 of the SMSTAT.SMSTAT bitfield will be set to 1<sub>B</sub>.

This alarm condition can be tested by writing 10<sub>B</sub> to the SMUSER.RDECCTST bitfield.

### 21.7.1.6 Private buffers based on RAM

All RAMs used to build private buffers are instances of safety qualified library components. Therefore no additional mechanism are required to be implemented to instance such module. In addition, the SSH interfaces to functional logic are fully compliant.

### 21.7.1.7 Access Enable

Write accesses to the registers are controlled by the Access Enable mechanism. This is configured using the ACCEN0/ACCEN1 registers and uses the master tag used to identify the originating master of each write transaction to permit or deny access to modify the contents of the register or memory.

## 21.7.2 Software Based Safety Mechanisms

The BITMGR supports the following safety mechanisms which require support from software. Failures are to be reported by the software rather than via the SMU

## 21.7.3 Hardware Functionality Supporting Software Safety Mechanisms

The following hardware functionality exists within the BITMGR to increase the effectiveness of the Software Based Safety Mechanisms

1) The Error flag returned by the EMEM for an access address error is also a redundant signal but, as this is already a monitor rather than a control, an inconsistency in this pair causes the SMSTAT.SMCTRLSTS bit to set and does not generate an alarm

## Bit Manager (BITMGR)

### 21.7.3.1 Monitor CRC Units

These are place holders for future use.

The BITMGR may implement CRC units used to provide a method of checking the activity on key internal interfaces. The CRC results are made available to software via registers.

The CRCs shall be separated into two blocks in the registers space.

- CRCs which are independent of the data being processed. These are enabled using **SMCTRL**.CTRLCRCEN
- CRCS which are dependent on the data being processed. These are enabled using **SMCTRL**.DATACRCEN

The first can be used for providing some detection of soft errors occurring during execution as well as during software based self test. The second can only be used while processing known data during software based self test.

The CRC units are mapped into the BITMGR register space as read only registers.

CRC functions shall be disabled if the corresponding mask is set or globally if the SMCTRL.CTRLCRCEN or SMCTRL.DATACRCEN bit is set.

The CRC Units have an associated control field (**SMUSER**.CINIT). The CRC units are initialised to the reset value by writing  $10_B$  to **SMUSER**.CINIT.

**Note:** *With full logic redundancy, it is expected that the CRC registers will be defunct in which case they are treated as reserved. As these are read only registers they do not interfere with the workings of mission mode logic.*

### 21.7.3.2 Redundant Control Logic

All control and status state bits (flip-flops) implementing safety mechanism functionality are duplicated. The duplicate flip-flops are used to store the negated value of the bit. This can be observed directly in the **SMCTRL** and **SMSTAT** registers. In the event of the state of these bits becoming inconsistent, it can be assumed that either a programming or soft error has occurred. An inconsistent state is detected by comparators and can be observed by polling the **SMSTAT**.SMCTRLSTS bit.

### 21.7.4 SMU events

The following table list the events that can trigger an SMU alarm. See [Section 21.7.1](#) for a description of the hardware safety mechanisms.

**Table 1105 SMU Events**

Event	Definition	Source	Comments
uncorrectable ECC error in Radar memory	Read data from a Radar Memory RAM has been corrupted	MTU	One of Multiple alarms will be generated based on MTU configuration
uncorrectable ECC error in a RAM internal to the BITMGR	Read data from an BITMGR RAM has been corrupted		

**Bit Manager (BITMGR)****Table 1105 SMU Events (cont'd)**

Event	Definition	Source	Comments
Register CRC check	Computed Register CRC does not match pre-programmed value	BITMGR	Alarm Mapping is defined in the SMU Specification
Radar Memory Control Logic Failure	The control signals for accessing Radar Memory are implemented as redundant logic. This alarm condition indicates that the BITMGR has detected an inconsistency in the redundant logic		
Radar Memory Access Address Error	An access to the Radar Memory has been mapped to a tile that has not been enabled for BITMGR accesses by writing to the EMEM tile control registers		
Radar Memory Read Data ECC Check	The read data for Radar Memory accesses is returned with an ECC computed from the access address and data. This is checked and an alarm set if the check fails		
Logic redundancy check failure	The internal core logic of BITMGR is implemented with full redundancy. This alarm indicates that the checker has detected a run time inconsistency between the two copies.		

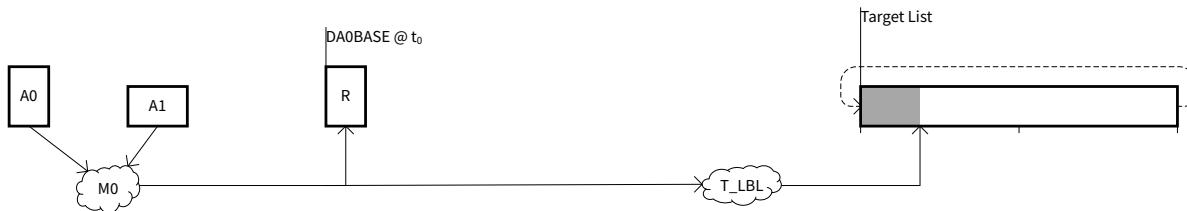

Note: *the SMU allows the user to define the action that will be taken as a result of these events (see SMU specification).*

## 21.8 Use Cases

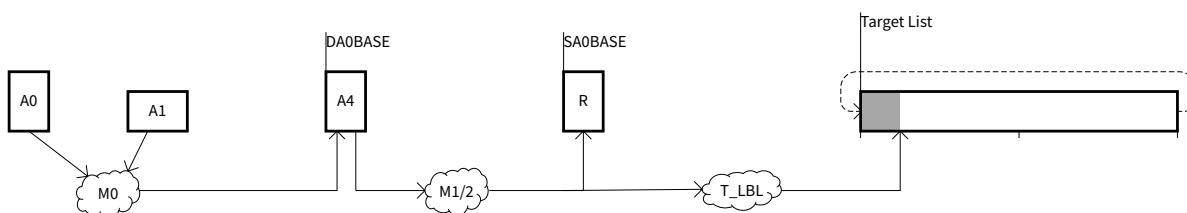

This section details assumed use case restrictions for the use of the BITMGR

## SPU Lockstep Comparator (SPULCKSTP)

### 22 SPU Lockstep Comparator (SPULCKSTP)

The SPU Lockstep Comparator module provides output comparators and difference detection for the two SPU instances. It is configured via the BBB.

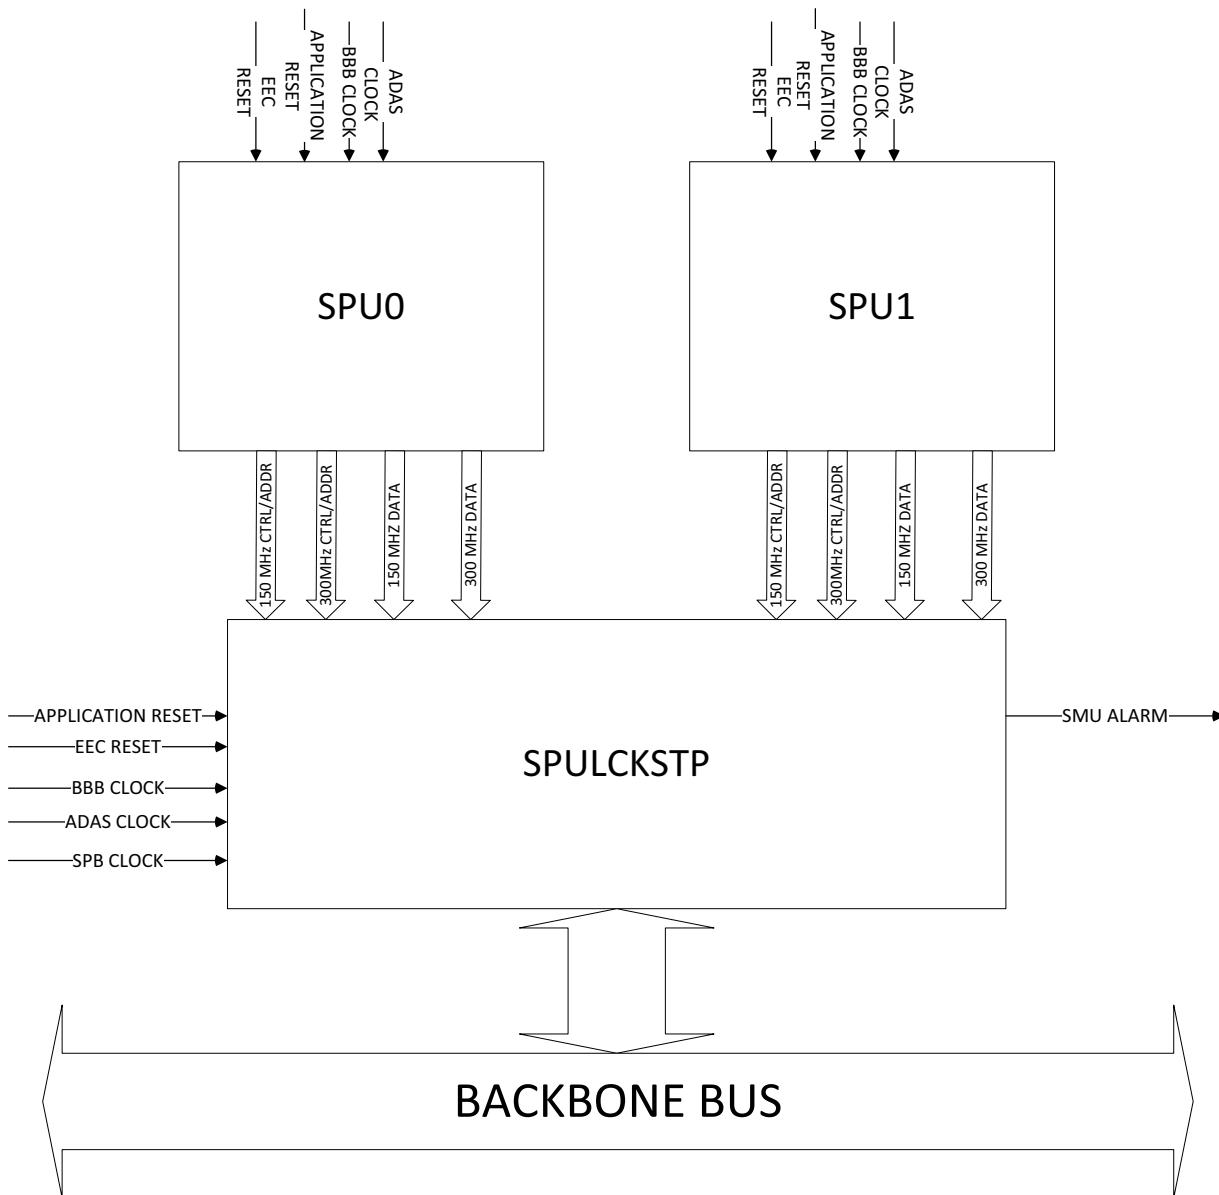

Figure 278 SPULCKSTP Interfaces

#### 22.1 Feature List

An overview of the features implemented in the SPU Lockstep Comparator follows:

- Control and Status Registers accessed via the BBB.
- Monitoring the output comparators for the two SPU instances and flagging any differences
- Running background, continuous self test on the lockstep comparators to validate the correct operation of the logic.

## SPU Lockstep Comparator (SPULCKSTP)

- Providing the necessary logic to trigger the two SPUs in the same clock cycle. This is necessary to allow the two SPUs to operate synchronously and allow the outputs to be successfully compared

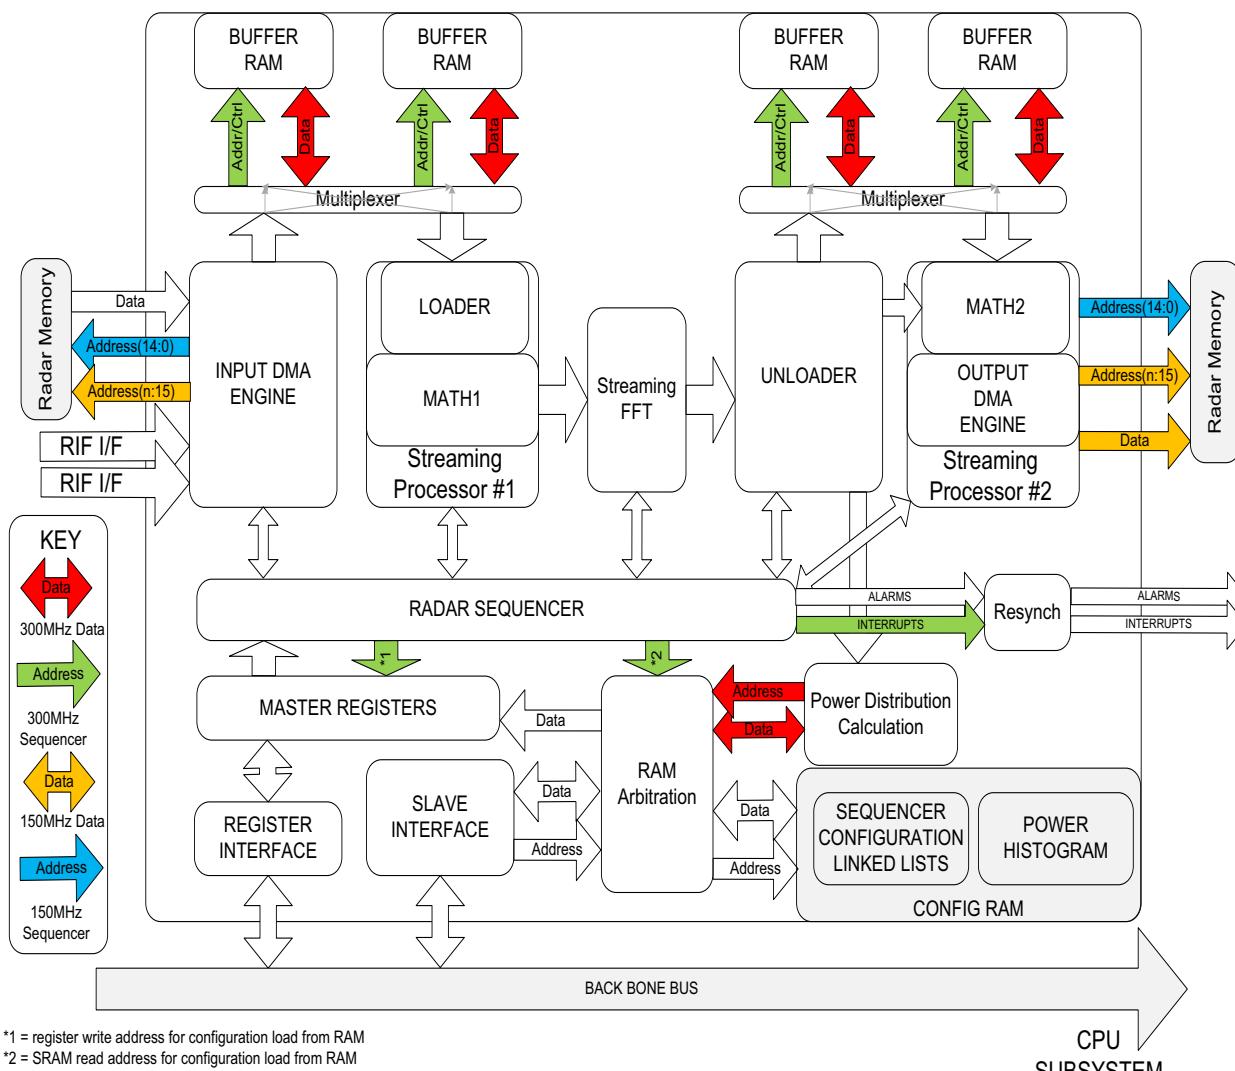

### 22.2 Overview

The SPU Lockstep implements four independent comparators. This allows for the two clock domains of the SPU, and also allows independent control of comparators on the address/control signals and the data signals. The SPU clock domains are:

- the 300MHz processing clock
- the 150 MHz BBB clock used for the interfaces to the RADAR memory (also known as EMEM),

The intention is to allow the operation sequence of identical SPU configurations to be checked even if the two SPU instances are processing different data. This is the “Partial Lockstep” mode. The normal operating mode where data signals are also checked is known as “Full Lockstep”.

**Figure 279** below shows the monitoring points associated with each of the four comparators.

**Figure 279 Lockstep Comparator Monitoring Points**

## SPU Lockstep Comparator (SPULCKSTP)

To enable partial lockstep, the 300MHz and 150MHz “sequencer” comparators are needed. To enable full lockstep, all four comparators are needed.

It is also a condition of use for the SPU that two SPU instances cannot use the same RADAR memory tile for data output. If this is attempted SPU1 write data will be lost. If the SPU instances are operating on different data then the read address used by the SPUs for retrieving data from RADAR memory will also be different. These operating constraints mean that only the offset addresses within the RADAR memory tiles will be compared for Partial Lockstep. This allows different tiles to be used for input data and output data for the two SPU instances. All address bits of the RADAR memory busses will be compared for full lockstep.

This split in the RADAR memory address bus is shown in [Figure 279](#). In the diagram “n” is used to indicate the MSB of the address bus. “n” depends on the amount of RADAR memory in the system (e.g. for 4 MiB of RADAR memory<sup>1)</sup>, “n” will be 17<sub>D</sub>).

Full lockstep assumes that SPU configurations, including RADAR memory addresses, are identical. In this case, the full addresses are compared. Since both SPUs will be reading and writing the same data, the accesses from the second SPU (SPU1) will be ignored.

## 22.3 Functional Description

### 22.3.1 SPU Lockstep Control

The lockstep functions are enabled by the LSENx bitfields in the control register ([CTRL](#)) of the SPULCKSTP module. Each lockstep comparator has its own instance of the LSEN bitfield.

These registers are initialised by an application reset. In the initialisation state, all lockstep comparators will be disabled. The lockstep function can be enabled by the application software writing a 10<sub>B</sub> to the LSENx bitfield.

Writes to the control register will be subject to the access enable protection mechanisms of the module.

Bitfields are allocated as follows:

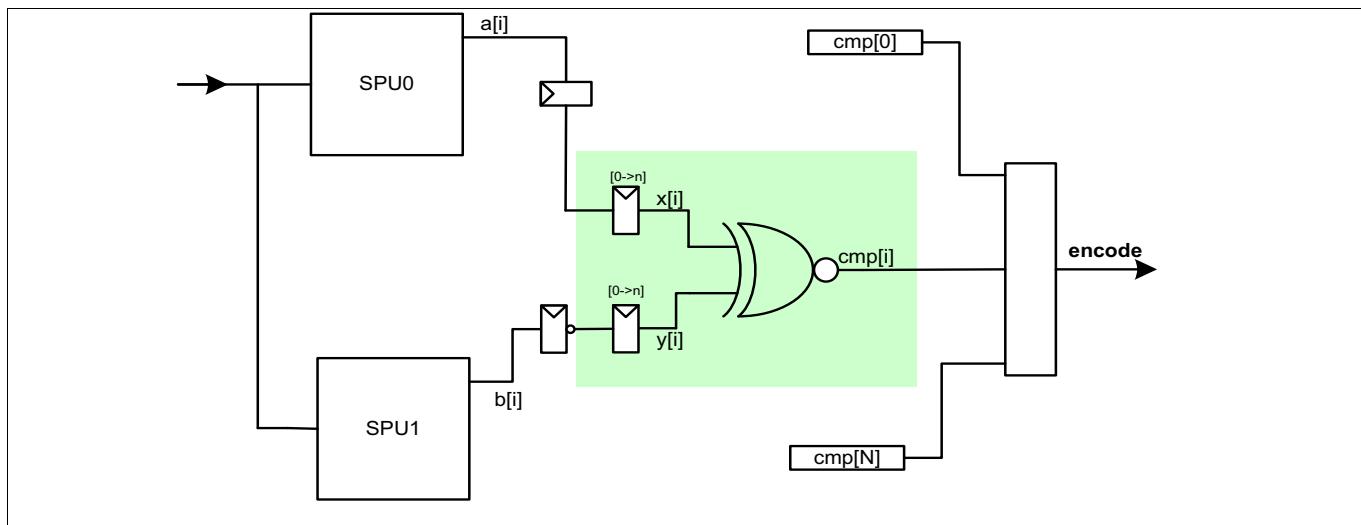

- CTRL.LSEN0: 300 MHz Sequencer Comparator
- CTRL.LSEN1: 150 MHz Sequence Comparator
- CTRL.LSEN2: 300 MHz Data Comparator
- CTRL.LSEN3: 150 MHz Data Comparator

### 22.3.2 SPU Lockstep Monitoring

The lockstep monitoring function will compare the outputs from the two SPU instances and report any difference that occurs to the Safety Management Unit (SMU) for appropriate action.

1) Radar Memory uses 256 bit words and the SPU uses word addressing

### SPU Lockstep Comparator (SPULCKSTP)

**Figure 280 Node Comparator**

**Figure 280** above shows the equivalent circuit of an arbitrary node comparator,  $i$ , of 0 to  $N$  comparators. The comparator monitors two signals, **a** and **b**, which are connected to the same output node of both SPU instances. The signals will be synchronised in the relevant instance using the instance clock to minimise impact on the instance timing.

After the optional synchronisation, one monitor point is inverted to reduce the risk of a common mode failure in the two monitored signals. The two inputs to the comparator are generated from **a** and **b**.

**x** which is equivalent to **a** delayed by  $n+1$  clock cycles, where  $n$  is an implementation dependent number of flip-flop stages inserted to allow timing closure

**y** which is equivalent to **b** delayed by  $n+1$  clock cycles.

As either **a** or **b** is inverted at the input to the delay stages, if the nodes differ (i.e. **x** and **y** are the same), the CMP signal is set to  $1_B$ .

The cmp[i] bus is scanned by two counters. One counter starts at the top index of the bus and the other at the bottom index. Each counter will stop when it encounters a bit of the cmp[i] bus which is indicating a failure. The counter values are then combined and output as the “encode” signal. This will cause the **encode** signal to flag the failing node and the failure will be detected. In the event that multiple nodes fail, the encode output will be the minimum and maximum values of all the indices,  $i$ , of the failing nodes. This has no impact on normal functioning but allows the self test logic to detect a real failure occurring in the same clock cycle that a fault is injected for test purposes.

The SPU Lockstep module transmits a single alarm to the SMU. The individual comparator which causes the alarm can be determined from the LCFAILx bitfields in the ERROR register. Bitfields are allocated as follows

- ERROR.LCFAIL0: 300 MHz Sequencer Comparator
- ERROR.LCFAIL1: 150 MHz Sequence Comparator
- ERROR.LCFAIL2: 300 MHz Data Comparator
- ERROR.LCFAIL3: 150 MHz Data Comparator

#### 22.3.3 Lockstep Self Test

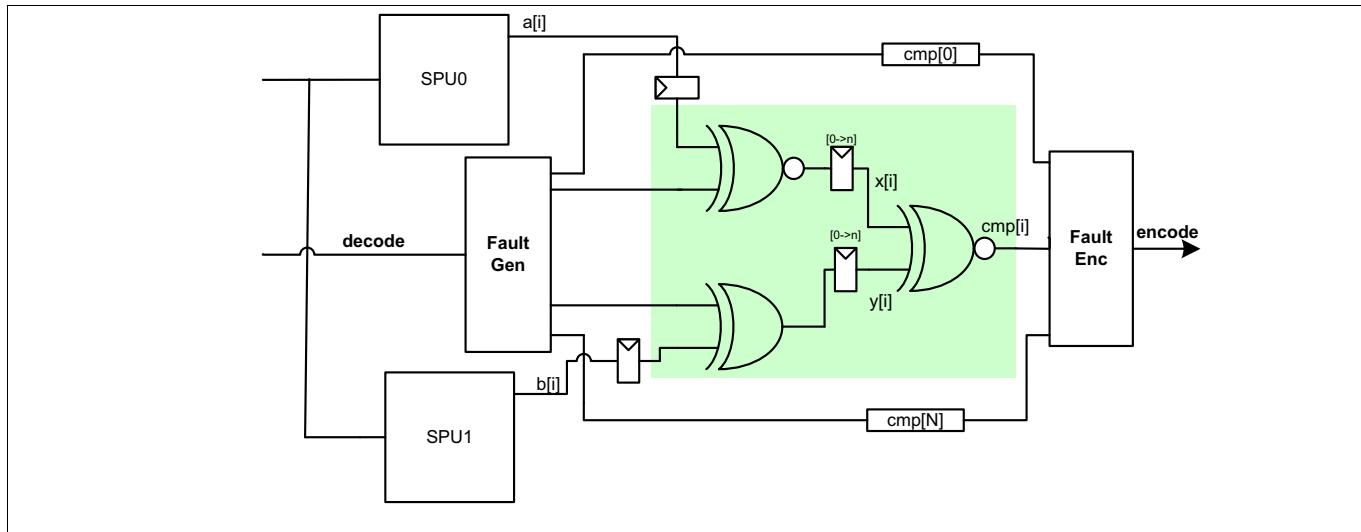

The SPU lockstep has a continuously running background self test of the lockstep comparator.

The self test function will inject faults into both inputs of each of the monitored nodes and verify that the fault is correctly detected by the monitoring logic.

## SPU Lockstep Comparator (SPULCKSTP)

In the event of a self test failure being detected, the failure will be reported to the Safety Management Unit for an appropriate response.

An equivalent circuit of a node comparator showing the fault injection logic is shown in [Figure 281](#)

**Figure 281 Node Comparator with Fault Injection**

Faults are injected using the **Fault Gen** block. This will use a binary number, **decode**, to calculate which node is to be tested. **decode** will be generated from a free running, binary counter using gray code number representation (the **input counter**). The Self test circuit will test every node at most once every 8192 clock cycles. Alternate test cycles will inject faults into either the **a** or **b** side of the comparator node. The complete self test cycle will therefore repeat at most every 16384 clock cycles.

Injecting a fault into either side of the comparator node will cause that node to fail unless a real fault occurs in the same clock cycle in which case the two faults will cancel out.

The node failing is processed by the **Fault Enc** block to generate a binary representation of the failing node, **encode**. This contains two numbers, the node index of the first node found to be failing counting up from the lowest minimum node index and the node index of the first node found to be failing counting down from the maximum node index.

If the lockstep block is functioning correctly, both values in **encode**, will either be 0 if no failures have been detected or the number of the node which has had a fault induced by the self test logic.

The values in **encode** are checked against a second, independent binary counter (the **monitor counter**). The **monitor counter** is also compared against the value of the **input counter**. In the event that either of the values in **encode** or the **input counter** fails to match the value of the monitor counter, a failure condition will be flagged to the SMU.

With this implementation, any of the following conditions will cause a self test fail:

- an actual fault occurring on any of the **a** or **b** nodes
- a stuck at  $0_B$  fault occurring on any of the **cmp** nodes
- a stuck at  $1_B$  fault occurring on any of the **cmp** nodes
- a failure in the **Fault Gen** block causing an incorrect or no fault to be injected
- a failure in the **Fault Enc** block causing an incorrect detection or no fault to be detected
- a stuck at fault on **x** (assuming that an injected fault does not always coincide with a masking pulse on **b**)
- a stuck at fault on **y** (assuming that an injected fault does not always coincide with a masking pulse on **a**)
- an actual fault on any of the **a** or **b** nodes coinciding with an injected fault

## SPU Lockstep Comparator (SPULCKSTP)

- a soft error occurring on either the **input counter** or **monitor counter**.

### 22.3.4 Functional Redundancy

All registers in the lockstep block which are not capable of being directly monitored for correct operation by the self test function will be duplicated. The duplicate register will store the inverse state of the master register. In the event of the duplicated registers not storing the inverse state value, an error will be flagged in the LCRFAILx fields of the ERROR register. The bitfields are allocated as follows

- ERROR.LCRFAIL0: 300 MHz Sequencer Comparator
- ERROR.LCRFAIL1: 150 MHz Sequence Comparator
- ERROR.LCRFAIL2: 300 MHz Data Comparator
- ERROR.LCRFAIL3: 150 MHz Data Comparator

The duplication extends to the register control bits (e.g. the LSEN bitfields).

### 22.3.5 Lockstep Failure Signalling Test

The lockstep comparator allows a failure to be injected into one of the comparator nodes to allow the signalling of failures to be verified. A failure can be injected by writing  $10_B$  to any of the LSTST bitfields of the TEST register. To avoid masking a real error, this test should only be conducted when the SPUs are idle.

- TEST.LSTST0: 300 MHz Sequencer Comparator
- TEST.LSTST1: 150 MHz Sequence Comparator
- TEST.LSTST2: 300 MHz Data Comparator
- TEST.LSTST3: 150 MHz Data Comparator

	rwh	TRIGGER	
Otherwise (default)	r	RES	Default Read Access
	rh	TRIGGER	

### Access Enable Register 0

The Access Enable Register 0 controls access for transactions to registers with the on chip bus master TAG ID 000000B to 011111B (see On Chip Bus chapter for the products TAG ID <-> master peripheral mapping). The SPULCKSTP is prepared for an 6 bit TAG ID. The registers ACCENO / ACCEN1 are providing one enable bit for each possible 6 bit TAG ID encoding.

Mapping of TAG IDs to ACCENO.ENx: EN0 -> TAG ID 000000B, EN1 -> TAG ID 000001B, ... ,EN31 -> TAG ID 011111B.

#### ACCENO

## 22.5 Use Cases

This section describes the use of the SPU Lockstep Module.

## SPU Lockstep Comparator (SPULCKSTP)

### 22.5.1 Conditions of Use

The main assumption of use is that the SPU module will be in a known and deterministic state when it is idle. Its state changes, and therefore the sequence of output states feeding onto the lockstep comparators, after leaving the idle state will be determined entirely by the configured register settings. There are two exceptions to this where the data values can affect the flow of operation:

- Bin Rejection based on either CFAR or Local MAX
- Power Histogram

The Power Histogram signals are excluded from the “Partial Lockstep” comparison for this reason. Bin Rejection affects the output interface to the RADAR memory and this interface is not excluded from “Partial Lockstep”. Bin Rejection cannot therefore be used with “Partial Lockstep”.

### 22.5.2 Set Up

The write interfaces to both the registers and the configuration memory from the bus are outside the zone of duplication and can therefore be configured as normal. Both SPU instances need to be configured identically. The lockstep comparators should only be enabled when the SPUs are idle, so this should be done once configuration is complete but before the SPUs are triggered.

The comparators can be disabled at any time.

#### 22.5.2.1 Specific Setup for Full Lockstep

The use of full lockstep requires both SPUs to be reading the same input data and writing to the same addresses in RADAR memory in exactly the same clock cycles. For this to work, two configuration changes need to be made to the RADAR memory configuration

- Write accesses from SPU1 to the RADAR memory must fail silently.
  - Errors on an arbitration collision can be disabled for SPU1 by changing the CTRL.ERRDIS bitfield from its default value of  $01_B$  to  $10_B$ .
- Read accesses from SPU1 to RADAR memory must be ignored. Data returned to SPU0 must be echoed onto the SPU1 pins.
  - This operating mode is enabled by changing the CTRL.MS bitfield from its default value of  $01_B$  to  $10_B$ .

### 22.5.3 SPU Triggering

The SPUs must start processing in the same clock cycle for the lockstep to work as intended. This is done by setting the SPUs to external trigger (SPU\_CTRL.MODE=EXT) and starting processing by writing a  $1_B$  to the TRIG bitfield of the SPUTRIG register.

When the data is being sourced from both RIFs, the RIFs also need to be configured to operate in a synchronous manner by setting RIF\_RSM0.LCKSTP. This ensures that both RIFs consistently output data on the same clock edge.

### 22.5.4 Expected Use Cases

Three specific use cases have been anticipated when developing this module. Other use cases are possible but behaviour may not be as expected.

## SPU Lockstep Comparator (SPULCKSTP)

**Table 1122 SPU Lockstep Use Cases**

<b>Configuration</b>	<b>CTRL</b>

## Extension Memory (EMEM)

### 23 [[[Extension Memory (EMEM)]]]

[The EMEM (at [Figure 282]) contains RAM blocks (EMEM Tiles) which can be alternatively used for application (ADAS), calibration or trace data storage. The EMEM has interfaces to MCDS, SEP, SRI and BBB. ]

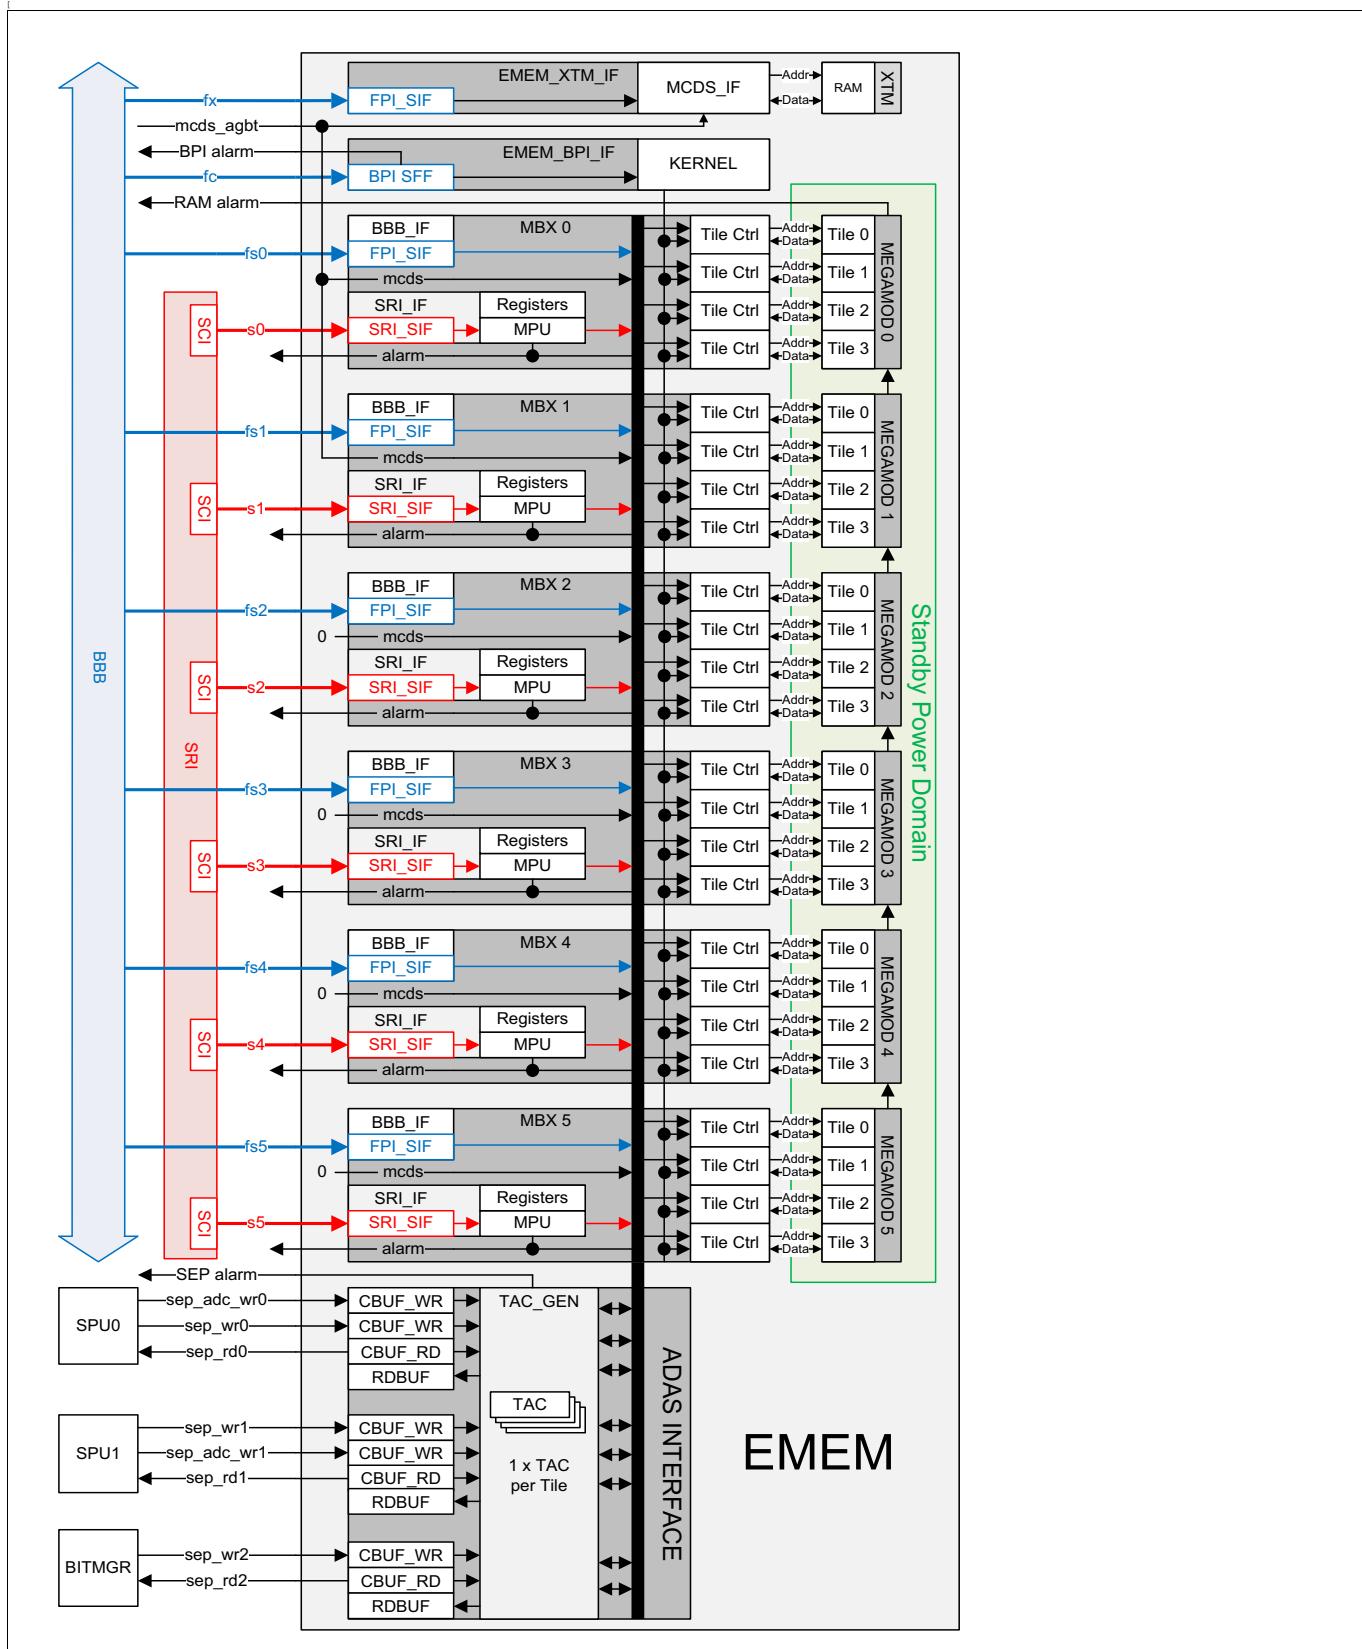

Figure 282 [Block Diagram of EMEM]]

**Extension Memory (EMEM)****[[EMEM Glossary]]****Table 1124 [[EMEM Acronyms[ ]]]**

[Acronym]	[Description]
[AGBT]	[Aurora Gigabit Trace Interface]
[EMEM]	[Extension Memory]
[MCDS]	[Multi Core Debug Solution]
[MPU]	[Memory Protection Unit]
[MTU]	[Memory Test Unit]
[NTN]	[Next Tile Now]
[SECDED]	[Single Error Correction Double Error Detection]
[SEP]	[SPU to EMEM Protocol]
[TCM]	[Trace or Common Memory]
[XCM]	[Extended Common Memory]
[XTM]	[eXtra Trace Memory]

**Table 1125 [[EMEM Terms[ ]]]**

[Acronym]	[Description]
[EMEM Core]	[An EMEM core contains the EMEM configuration interface and registers.]
[EMEM Module]	[An EMEM module consists of four EMEM tiles. Potentially each EMEM module has four interfaces propagated down to each EMEM tile: <ul style="list-style-type: none"><li>• [[MCDS interface (TCM and XTM)]]</li><li>• [SEP interface (TCM and XCM)]</li><li>• [SRI slave interface (TCM and XCM)]</li><li>• [BBB slave interface (TCM, XTM and XCM)]]</li></ul>
[EMEM Tile]	[An EMEM tile consists of 256 Kbyte RAM with SECDED capability.]
[XTM Tile]	[An XTM tile consists of 8 Kbyte RAM with SECDED capability.]

**23.1 [[Feature List]]**

[The EMEM has the following features:]

- [[Software may configure the operation mode of each individual **[EMEM Tile]**.]]
- [16 Kbyte XTM for trace data only.]
- [Standby power supply for TCM and XCM.]]

[The EMEM supports the following applications:]

- [[Application/ADAS data]]
- [Program code]
- [Calibration data]
- [Measurement data]
- [Trace data]
- [ED Prolog Code]]]

## Extension Memory (EMEM)

### 23.2 [[Overview]]

[Two different types of [EMEM Module] are available: ]

- [[[TCM]] may be split into Application/ADAS, Calibration and Trace Memory parts.]
- [[XCM]] may be used as Application/ADAS or Calibration Memory only.]

[The [XTM] is used for tracing without reducing the Common Memory. The XTM has two 8 Kbyte Tiles, which is sufficient for continuous trace over DAP.]

[Devices with AGBT use XTM0 and XTM 1 as an AGBT Trace buffer.]

### 23.3 [[Functional Description]]

[The EMEM configurations (at [Table 1126]) are instanced on AURIX TC3xx devices.]

**Table 1126 [EMEM Configurations]**

[Device]	[TC39x]	[TC37xEXT]	[TC35x]	[TC33xEXT]	[TC3Ax]
[Isolation Logic]	[Yes]	[Yes]	[No]	[No]	[No]
[TCM Size]	[2048 Kbyte]	[2048 KByte]	[2048 Kbyte]	[1024 Kbyte]	[2048 Kbyte]
[XCM Size]	[2048 Kbyte]	[1024 KByte]	[ - ]	[ - ]	[4096 Kbyte]
[XTM Size]	[16 Kbyte]				
[Total RAM Size]	[4096 + 16 Kbyte]	[3072 + 16 Kbyte]	[2048 + 16 Kbyte]	[1024 + 16 Kbyte]	[6144 + 16 Kbyte]
[SPU0 sep_adc_wr0]	[Yes]	[No]	[Yes]	[Yes]	[Yes]
[SPU0 sep_wr0]	[Yes]	[No]	[Yes]	[Yes]	[Yes]
[SPU0 sep_rd0]	[Yes]	[No]	[Yes]	[Yes]	[Yes]
[SPU1 sep_adc_wr1]	[Yes]	[No]	[Yes]	[No]	[Yes]
[SPU1 sep_wr1]	[Yes]	[No]	[Yes]	[No]	[Yes]
[SPU1 sep_rd1]	[Yes]	[No]	[Yes]	[No]	[Yes]
[BITMGR sep_wr2]	[No]	[No]	[No]	[No]	[Yes]
[BITMGR sep_wr2]	[No]	[No]	[No]	[No]	[Yes]

#### 23.3.1 [[Isolation Logic]]

[If the EMEM configuration (at [Table 1126]) instances [Isolation Logic], the [Isolation Logic] is implemented around each [EMEM Module] to prevent any power drain via powered gate outputs into the unpowered section of the device.]

[The logic isolating the inputs into the standby domain are controlled by the power on reset ([PORST]).]

[The logic isolating the outputs from the standby domain are controlled by the standby locked mode signal.]

Note: [[The local input to the EMEM to control the inputs to the standby domain is enable\_core\_ed\_i. This is driven from the EVR power on reset circuitry via a level shifter]]]

#### 23.3.2 [[EMEM Modes]]

[The EMEM shall be in one of the following modes:]

- [[[Standby Locked Mode].]
- [[Locked Mode].]

## Extension Memory (EMEM)

- [Unlocked Mode.]

[The mode of the EMEM depends on the power supply and the status flag SBRCTR.STBLOCK:]

**Table 1127 [EMEM Modes depending on V[ ]<sub>DD</sub> , V[ ]<sub>DDSB</sub><sup>1)</sup> and SBRCTR.STBLOCK[ ]]**

[SBRCTR.STBLOCK]	[V/ <sub>DDSB</sub> Only]	[V[ ] <sub>DD</sub> [ Only]]	[V[ ] <sub>DD</sub> [ and V[ ] <sub>DDSB</sub> ]]
[Locked Mode]	[Standby Locked Mode]	[Allowed]	[Locked Mode]
[Unlocked Mode]	[Not allowed]	[Not allowed]	[Unlocked Mode]

1) EMEM Standby Power Domain

### [[RAM Isolation]]

[The RAM shall be isolated prior to removing the power supplies. This assures that spikes or uncontrolled signal patterns applied to its interfaces during power cycling of the logic will not corrupt the content.]

[It is not allowed to remove the EMEM isolation logic when V[ ]<sub>DDSB</sub> is not powered since this will damage the chip.]

[Software and tools may monitor SBRCTR.STBPON to determine the availability of V[ ]<sub>DDSB</sub>.]

[If V[ ]<sub>DD</sub> is powered and V[ ]<sub>DDSB</sub> is not powered, the EMEM may report ECC errors.]

### 23.3.2.1 [[Locked Mode]]

[After EEC reset, the EMEM is in **Locked Mode**. If the EMEM is in **Locked Mode** then accesses from chip interfaces (MCDS, SEP, SRI and BBB) are treated as errors (at **Chapter 23.3.3.4**). Software shall configure the SBRCTR register to change the EMEM Mode. Both Unlocked Mode and the **Standby Locked Mode** may only be entered from Locked Mode.]

### 23.3.2.2 [[Standby Locked Mode]]

[As long as the standby power supply (V[ ]<sub>DDSB</sub>) is powered, the content of the RAM shall be retained.]

[On chip bus accesses to the **EMEM Core** CLC, ID and SBRCTR registers and **EMEM Module** registers are serviced normally. All other register and RAM accesses are terminated with error.]

### 23.3.2.3 [[Changing the EMEM Mode]]

[The mode of the EMEM shall be changed as follows:]

#### [[Transition from Locked Mode to Unlocked Mode]]

[To enter **Unlocked Mode**, software shall write the following sequence to the SBRCTR register:]

- [[[0000 0002<sub>H</sub>],]]
- [[0000 0006<sub>H</sub>],]
- [[0000 000E<sub>H</sub>] ]]

[If software writes any other value to SBRCTR before the complete sequence is written then the state machine shall be reset. To enter **Unlocked Mode**, the complete sequence shall be started again. If software writes to another register, the state machine sequence checking shall not be influenced. The current state is signalled with bit SBRCTR.STBLOCK.]

#### [[Transition from Unlocked Mode to Locked Mode]]

[To enter **Locked Mode** from **Unlocked Mode**, software shall write [0000 0090<sub>H</sub>] to the SBRCTR register.]

Note: [[The EMEM may only enter Locked Mode when there are no ongoing or pending accesses.]]]

## Extension Memory (EMEM)

### [[Transition from Locked Mode to Standby Locked Mode]]

[If the EMEM is in [Locked Mode] then [Standby Locked Mode] shall be entered by setting the [PORST] pin low and removing all supplies apart from VDDSB. Setting [PORST] low shall maintain the isolation of the standby domain after the supplies are removed.]]

### [[Transition from Standby Locked Mode to Unlocked Mode]]

[The transition from [Standby Locked Mode] to [Unlocked Mode] shall be performed with the following steps:]

1. [[The [PORST] pin shall be active.]
2. [All the power supplies shall be stable.]
3. [After the [PORST] release the EMEM shall be in [Locked Mode].]
4. [Software shall check the standby power domain is available (SBRCTR.STBPON = [1<sub>B</sub>]).]
5. [Software may configure [Unlocked Mode] (see [Changing the EMEM Mode], Transition from Locked Mode to Unlocked Mode). ]
6. [The [Isolation Logic] around the standby domain shall be switched off.]]]]]

### 23.3.3 [[Tile Modes]]

[After EEC reset, all EMEM Tiles shall be in [Unused Mode] (at [Figure 283]). Software shall configure the TILECONFIG register to assign [TCM] tiles to Common Memory, Trace Memory or Unused Mode and [XCM] tiles to Common Memory or Unused Mode. An [EMEM Tile] assigned to Trace Memory shall not be re-configured for Common Memory directly, or vice versa, but only after having been intermediately set to [Unused Mode].]

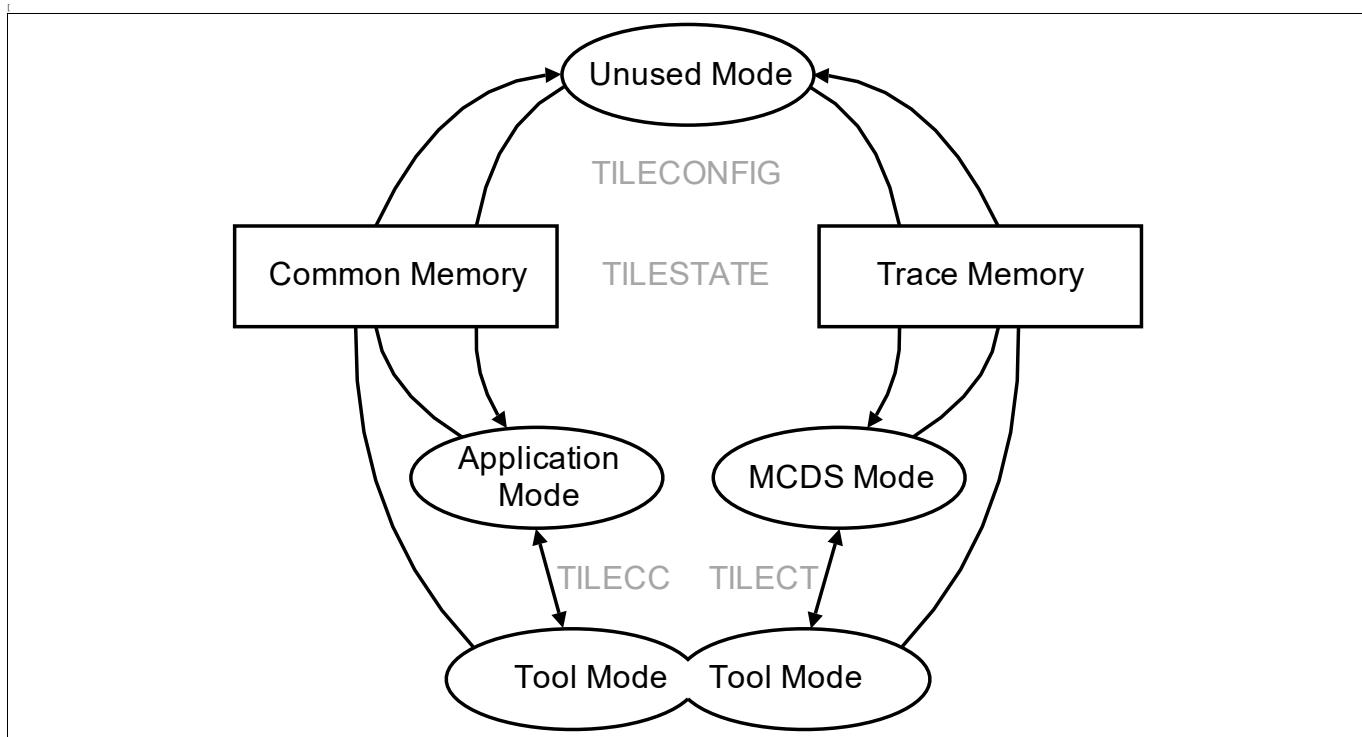

[An [EMEM Tile] assigned to Common Memory shall initially be in [Application Mode], and an [EMEM Tile] assigned to Trace Memory shall initially be in [MCDS Mode]. The assignment of each Tile is indicated by the TILESTATE register.]

[Each [EMEM Tile] assigned to Common Memory shall be individually configured between [Application Mode] and [Tool Mode]. The status of Tiles assigned to Common Memory is indicated by the TILECC register.]

[Each [EMEM Tile] assigned to Trace Memory shall be individually configured between [MCDS Mode] and [Tool Mode]. The status of Tiles assigned to Trace Memory is indicated by the TILECT register.]

[If an [EMEM Tile] is in [Unused Mode], then the settings in the TILECC and TILECT registers have no effect.]

## **Extension Memory (EMEM)**

**Figure 283 [Tile States and Modes]]**

### **23.3.3.1 [[Application Mode]]**

[If an [EMEM Tile] is assigned to Application Mode then read and write accesses may be performed by the SEP and SRI interfaces in an arbitrary sequence. The internal EMEM arbitration assigns higher priority to the SEP interface. When configuring writes to EMEM, each SEP write source should be allocated to a different [EMEM Tile]. ]

[For multiple simultaneous SEP accesses to an [EMEM Tile](#) see [TC39xED SEP Accesses to EMEM Tiles](#) for behavior.]

**Note:** [[The application should only assign EMEM tiles to Common Memory which are actually used. This protects the EMEM tile from unintended tool accesses via DAP/JTAG and BBB. It also allows an automatic cooperative sharing of the EMEM between an application and tool(s).]]

### 23.3.3.2 [[MCDS Mode]]

[The MCDS shall store trace messages in Trace Memory. The MCDS requires a consecutive selection of EMEM tiles as a trace buffer. The configuration of EMEM shall be consistent with the MCDS configuration concerning the address ranges. An [EMEM Tile] in MCDS Mode can only be written from the MCDS with trace data.]

**Note:** [For tracing the OSCU control bit OSTATE.EECDIS must be inactive (refer to OCDS documentation).]]

### 23.3.3.3 [[Tool Mode]]

[A tool shall check the configuration of the EMEM tiles to verify there are no conflicts in the EMEM configuration. A tool shall check for EMEM tiles in Unused Mode as indicated by the EMEM TILESTATE register and shall configure these EMEM tiles as part of the Common Memory in Tool Mode.]

**Note:** *[[It is important that a DAP/JTAG tool shall always access the EMEM via the IOC32P/E and not via Cerberus. This ensures that the tool cannot unintentionally corrupt a Tile in Application Mode.]]*

## Extension Memory (EMEM)

### [[Independent Calibration and Debug Tool Operation]]

[The two step approach to globally assigning EMEM tiles to Common Memory ([**Application Mode**]/Tool Mode) or Trace Memory ([**MCDS Mode**]/Tool Mode) supports safe operation with independent calibration and debug tools. The following rules apply:]

- [[A calibration tool shall only change the tile state between Common Memory and [**Unused Mode**.]]
- [A trace tool shall only change the tile state between Trace Memory and [**Unused Mode**.]]]

[The only resource shared by the calibration and debug tools is the EMEM TILECONFIG register. The tool(s) shall exercise care when changing the configuration of the [**MCDS**] and [**XCM**] tiles.]]

### 23.3.3.4 [[Accessing Tiles in Different Modes]]

[As soon as an EMEM interface receives an access request to an [**EMEM Tile**], the EMEM shall determine if the requesting interface has access rights. The EMEM shall check the mode of the addressed [**EMEM Tile**].]

■

**Table 1128 [Tile Access Options and Error Signaling[ ]]**

[Mode]	[SEP Interface]	[MCDS Interface]	[SRI Interface]	[BBB Interface]
[Application Mode]	[Access <sup>1)</sup> ]	[Error signalled]	[Access <sup>1)</sup> ]]	[BBB error]
[MCDS Mode]	[Error signalled]	[Access <sup>1)</sup> ]]	[SRI error]	[BBB error]
[Tool Mode]	[Error signalled]	[Error signalled]	[Access <sup>1)</sup> ]]	[Access <sup>1)</sup> ]]
[Unused Mode]	[Error signalled]	[Error signalled]	[SRI error]	[BBB error]

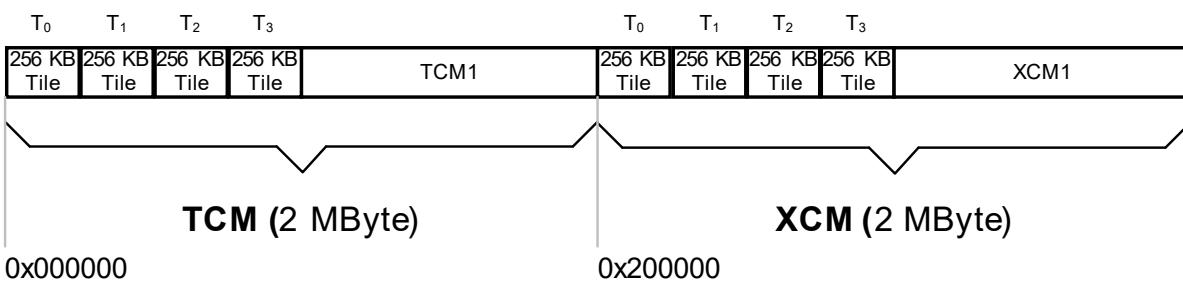

1) If an ECC error is detected then an access error is signalled to the corresponding interface.

### 23.3.4 [[Address Map]]

[The EMEM address map shall be such that any 1024 Kbyte TCM modules are contiguous. All 1024 Kbyte modules shall start at a 1024 Kbyte address offset. The 16 Kbyte XTM organized as 2 x 8 Kbyte tiles is located at the next 1024 Kbyte address boundary after the TCM and XCM modules.]

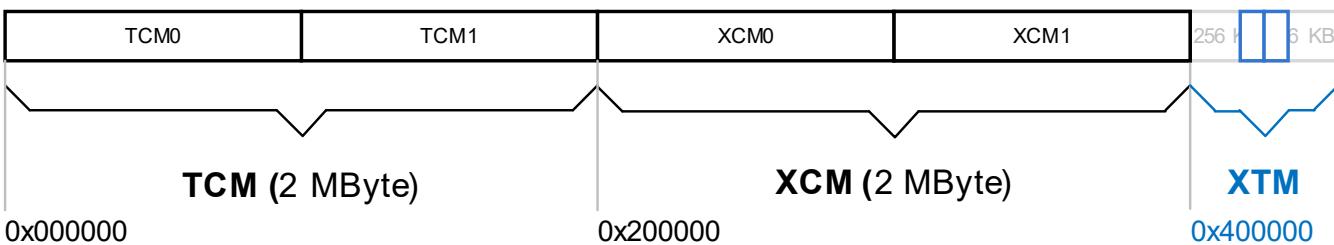

## Extension Memory (EMEM)

### Offset Address View from SEP and SRI

### Offset Address View from BBB

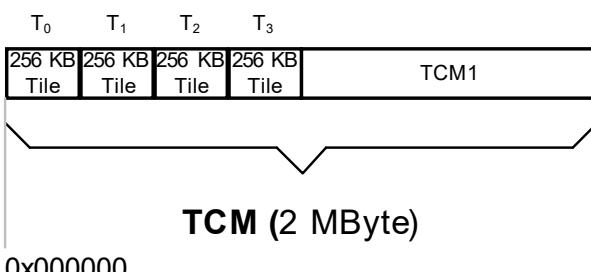

8 Kbyte XTM Tile mirrored in 256 Kbyte region

### Offset Address View from MCDS

XTM0 (8 KB address mirroring); AGBT Trace Tile  
XTM1 (address mirroring)

XTMx overlaid if XTMx is in Trace Mode .

### MCDS Overlay

If TILECT.XTM0 = 0  
XTM0 is overlaid to TCM Tile 0

If TILECT.XTM1 = 0  
XTM1 is overlaid to TCM Tile 1

Figure 284 [Offset Address View of TCM, XCM and XTM]]

#### 23.3.4.1 [[Address View]]

[The assignment of EMEM tiles to Trace Memory should start with Tile index 0 to maintain a continuous address range. The address view shows an example EMEM configuration and the address view from each interface.]]

#### 23.3.4.2 [[XTM Addressing]]

[The XTM shall be used in one of two modes indicated by the EMEM TILECT register:]

## Extension Memory (EMEM)

### 23.3.4.2.1 [[MCDS Mode]]

[The MCDS interface shall see an 8 Kbyte physical XTM tile address mirrored into the 256 Kbyte address space of a TCM tile. The MCDS may access the XTM. The DAP shall utilize the MCDS [NTN] capability when the XTM is used to generate a continuous MCDS trace output. NTN allows the MCDS trace output to be switched from one XTM tile to the other XTM tile before the complete 8 Kbyte XTM tile is written.]

#### [[AGBT ]]

[If AGBT is activated, XTM Tile0 and XTM Tile1 are used as an AGBT FIFO buffer.]

[The MCDS interface shall be able to write the EMEM Tiles.]

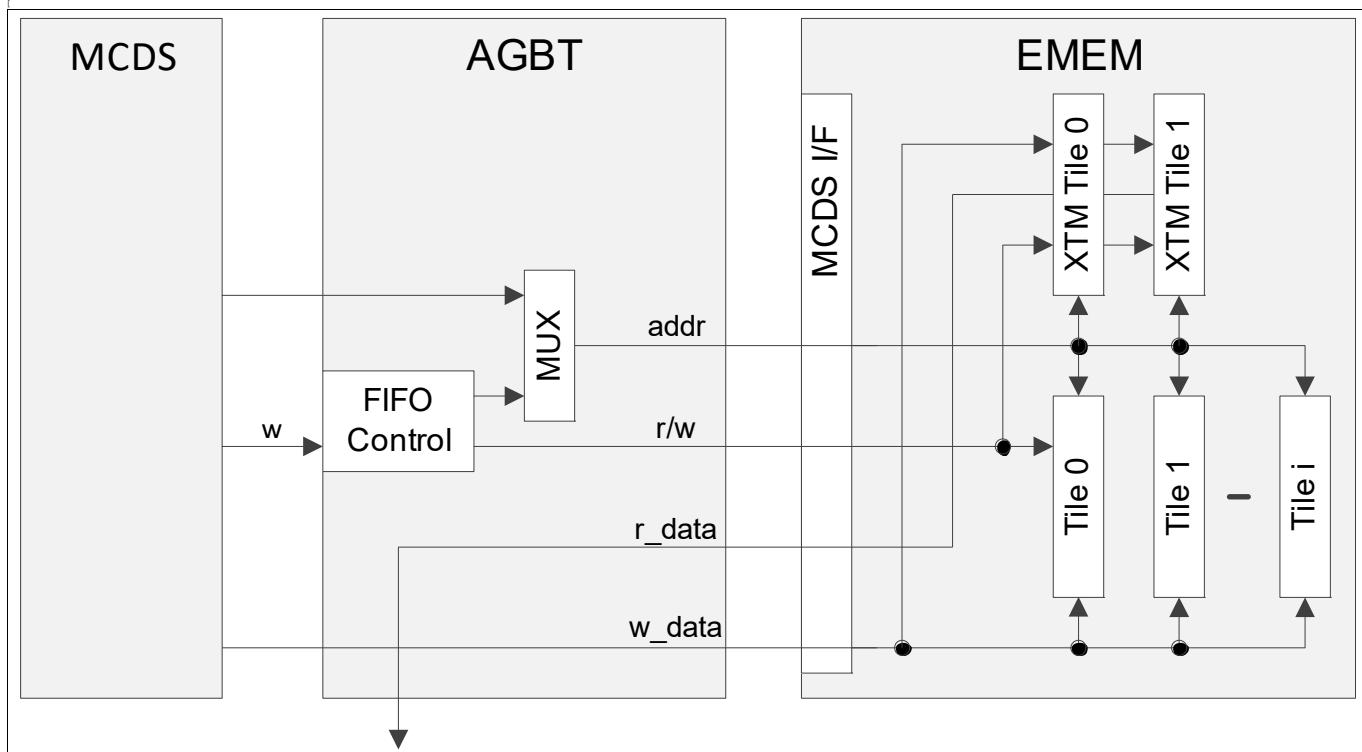

Figure 285 [[AGBT XTM0 and XTM1 read and write capability]]]]

### 23.3.4.2.2 [[Tool Mode]]

[The XTM is only accessible via the BBB fx slave interface.]]]]

## 23.3.5 [[EMEM Module SRAM]]

[An [EMEM Module] shall store data in the [EMEM Module] SRAM with a SECDED ECC generated checksum to provide protection against soft errors.]

### 23.3.5.1 [[SRAM Initialization]]

[After power-on the [EMEM Module] SRAM contents are random. To initialize the [EMEM Module] SRAM, software shall perform a write access to each 32-byte address aligned word line.]

#### [[SRI Slave Interface]]

[All access sizes may be used to initialize the [EMEM Module] SRAM as follows:]

- [[STDB, STDH, SDTW, SDTD and BTR2]]

## Extension Memory (EMEM)

- [[The [EMEM Module] shall perform an internal Read Modify Write (iRMW) to the SRAM. If the [EMEM Module] SRAM is un-initialized, the [EMEM Module] may generate a read phase ECC error preventing the write phase.]]
- [Prior to [EMEM Module] SRAM initialization, software shall configure Test Mode (MEMCON.ERRDIS = [1<sub>B</sub>]) to suppress read phase ECC errors.]
- [It is sufficient for software to perform one write access to any part of each 32-byte word line.]
- [As soon as [EMEM Module] SRAM initialization is complete, software shall configure Normal Mode (MEMCON.ERRDIS = [0<sub>B</sub>]) to enable the [Memory Integrity Check].]]
- [BTR4]
  - [[The [EMEM Module] shall not perform an iRMW.]]
  - [Software shall initialize the [EMEM Module] SRAM in Normal Mode (MEMCON.ERRDIS = [0<sub>B</sub>]).]]]

Note: [[For SRI accesses, an SDTD write access is the preferred method for initializing a 32-byte wordline.]]]

### [[BBB Slave Interface]]

[All access sizes may be used to initialise the [EMEM Module] SRAM. The [EMEM Module] ignores iRMW read phase ECC errors and always completes the write phase.]

Note: [[For BBB accesses, an SDTW write access is the preferred method for initializing a 32-byte wordline.]]]

### 23.3.5.2 [[Memory Integrity Check]]

[As soon as data is read from the SRAM, the EMEM module shall perform a [Memory Integrity Check] on the EMEM module SRAM read data to detect uncorrectable ECC errors.]

### 23.3.5.3 [[RAM Alarm]]

[If the EMEM detects an unexpected write to an [EMEM Module] SRAM, the EMEM shall trigger a RAM alarm.]

### 23.3.6 [[SRI Interface]]

[Each [EMEM Module] has its own SRI slave interface and configuration registers used to configure safety and security. When accessed via the SRI slave interface(s), the EMEM may be used for code execution, data storage or overlay memory. SRI accesses may be via cached (Segment [9<sub>H</sub>]) or non-cached (Segment [B<sub>H</sub>]) addresses.]

#### 23.3.6.1 [[Register Protection]]

[Each [EMEM Module] SRI slave interface defines independent write access enable<sup>1)</sup> to the [EMEM Module] registers.]

#### 23.3.6.2 [[Memory Protection]]

[An [EMEM Module] SRI slave interface controls access to its SRAM address space via a [MPU]. Each on chip resource with bus master capability has a unique master tag identifier that is used to identify the source of an on chip bus transaction. The master tag identifier based access protection is used to enable accesses to individual slave address ranges. Each [EMEM Module] shall have eight access protection regions of SRAM<sup>2)</sup>.]

[Each [Memory Protection] region shall be defined using six registers:]

1) See On-Chip System Connectivity for details.

2) Applies to SRAM and not SFR.

## Extension Memory (EMEM)

- [[The upper and lower 32-byte aligned address boundaries of the [Memory Protection] region shall be defined by:]
  - [[RGNLAX ( $i = 0-7$ ) shall define the lower address of the EMEM module [Memory Protection] region i.]]
  - [[RGNUAX ( $i = 0-7$ ) shall define the upper address of the EMEM module [Memory Protection] region i.]]
- [Two registers RGNACCENWAX ( $i = 0-7$ ) and RGNACCENWBX ( $i = 0-7$ ) shall select the on chip resources permitted to have write access to EMEM module [Memory Protection] region i.]
  - [[If Cerberus is present, then a Cerberus write access shall be enabled/disabled by [Memory Protection].]]
  - [[If HSM is present, then a HSM write access shall be enabled/disabled by [Memory Protection].]]
- [Two registers RGNACCENRAx ( $i = 0-7$ ) and RGNACCENRBx ( $i = 0-7$ ) shall select the on chip resources permitted to have read access to EMEM module [Memory Protection] region i.]
  - [[If Cerberus is present, then a Cerberus read access shall always be enabled.]]
  - [[If HSM is present, then a HSM read access shall always be enabled.]]

[After the application of a reset, all on chip resources shall have read and write access to all EMEM module [Memory Protection] regions.]

[If the [Memory Protection] defines overlapping EMEM module [Memory Protection] regions, then a read or write access made by an on chip resource access shall succeed if enabled by only one EMEM module [Memory Protection] region.]

### [[Reconfigure SRAM Protection]]

[If the EMEM module [Memory Protection] is to be re-configured, then the user should:]

- [[Wait for all pending EMEM module SRAM and SFR accesses to complete.]]
- [Write the EMEM module [Memory Protection] SRAM region registers to define updated configuration settings.]
- [Read the EMEM module [Memory Protection] SRAM region registers to check the configuration settings.]
- [As soon as the updated settings are confirmed, the system shall enable EMEM module accesses.]]]]

### 23.3.6.3 [[Memory Disabled]]

[If the [EMEM Module] SRAM is disabled (e.g. [EMEM Module] SRAM clock disabled), then an SRI access to the EMEM SRAM shall be terminated with an SRI bus error.]

### 23.3.6.4 [[True and Inverted Logic]]

[The [EMEM Module] SRI slave interface shall replicate the [Memory Integrity Check] using both true logic and inverted logic SECDED ECC decoders to eliminate common failure modes. If the true and inverted logic report a single error correction, the [EMEM Module] shall reconstruct the SRAM read data to be the original error free data.]]

### 23.3.6.5 [[Error Detection and Signalling]]

[Each [EMEM Module] shall detect several different classes of error (at [Table 1129]):]

- [[The [EMEM Module] shall trigger an alarm to the SMU.]]
- [The [EMEM Module] may set a status flag in the [EMEM Module] MEMCON register.]
- [The [EMEM Module] may complete the SRI access unless explicitly stated below.]]

## Extension Memory (EMEM)

Table 1129 [EMEM Module Alarms[ ]]

[Error Detection Event]	[Alarm]	[Status]
[[Access Enable Violation]]	[MPU Violation Alarm]	[ - ]
[[SRI Access Address Phase Error]]	[SRI Slave Address Phase Error Alarm]	[MEMCON.ADDERR]
[[SRI Write Access Data Phase Error]]	[SRI Slave Write Phase Error Alarm]	[MEMCON.DATAERR]
[[SRI Write Access to SRAM Error]]	[ECC Error Alarm]	[MEMCON.RMWERR]
[[SRI Read Access to SRAM Error]]	[ECC Error Alarm]	[ - ]
[[True and Inverted Logic Error]]	[EDC Read Phase Error Alarm]	[ - ]
[[Internal Data Transfer ECC Error]]	[ECC Error Alarm]	[MEMCON.INTERR]

[The EMEM and LMU share the same SMU alarms.]

## 23.3.6.5.1 [[Access Enable Violation]]

[If during a SRI access the [EMEM Module] detects either an [Register Protection] or [Memory Protection] violation, the [EMEM Module] shall trigger a [MPU Violation Alarm].]

- [[A SRI read access shall be terminated with a bus error.]
- [A SRI write access shall fail silently (no bus error). The [EMEM Module] shall not perform a write to SRAM.]]

## 23.3.6.5.2 [[SRI Access Address Phase Error]]

[If the [EMEM Module] detects an ECC error during the address phase of a SRI access, the [EMEM Module] shall record an address phase error (MEMCON.ADDERR = [1<sub>B</sub>]) and trigger a [SRI Slave Address Phase Error Alarm]. The SRI access shall terminate with an error.]

## 23.3.6.5.3 [[SRI Write Access Data Phase Error]]

[If the [EMEM Module] detects an ECC error during the data phase of a SRI write access, then the [EMEM Module] shall record a data phase error (MEMCON.DATAERR = [1<sub>B</sub>]) and trigger a [SRI Slave Write Phase Error Alarm].]

## 23.3.6.5.4 [[SRI Write Access to SRAM Error]]

[The [EMEM Module] SRAM is internally organized as a 256-bit SRAM. Any SRI write access of less than 256-bit shall require the [EMEM Module] to perform an internal Read-Modify-Write (iRMW) operation to correctly write the data and update the ECC checksum. If the [Memory Integrity Check] detects an uncorrectable ECC error during the read phase of the iRMW, the [EMEM Module] shall record a data error (MEMCON.RMWERR = [1<sub>B</sub>]) and trigger an [ECC Error Alarm].]]

## 23.3.6.5.5 [[SRI Read Access to SRAM Error]]

[If the [Memory Integrity Check] detects an uncorrectable ECC error during a SRI read access to the [EMEM Module] SRAM, the [EMEM Module] shall trigger an [ECC Error Alarm]. The SRI read access shall terminate with an SRI transaction ID error.]

[If ECC error disable is set (MEMCON.ERRDIS = [1<sub>B</sub>]), then the SRI read access shall terminate normally. The protection bit (MEMCON.PMIC) shall enable/disable configuration of the ECC error disabled bit (MEMCON.ERRDIS).]]

---

**Extension Memory (EMEM)****23.3.6.5.6 [[True and Inverted Logic Error]]**

[If the [EMEM Module] detects a difference in the [True and Inverted Logic] outputs during a [Memory Integrity Check], the [EMEM Module] shall trigger an [EDC Read Phase Error Alarm].]]

**23.3.6.5.7 [[Internal Data Transfer ECC Error]]**

[If the [EMEM Module] detects an uncorrected ECC error in an ECC protected internal data path, the [EMEM Module] shall record an internal error (MEMCON.INTERR = [1<sub>B</sub>]) and trigger an [ECC Error Alarm].]]]

## Extension Memory (EMEM)

## 23.3.6.6 [[Control Redundancy]]

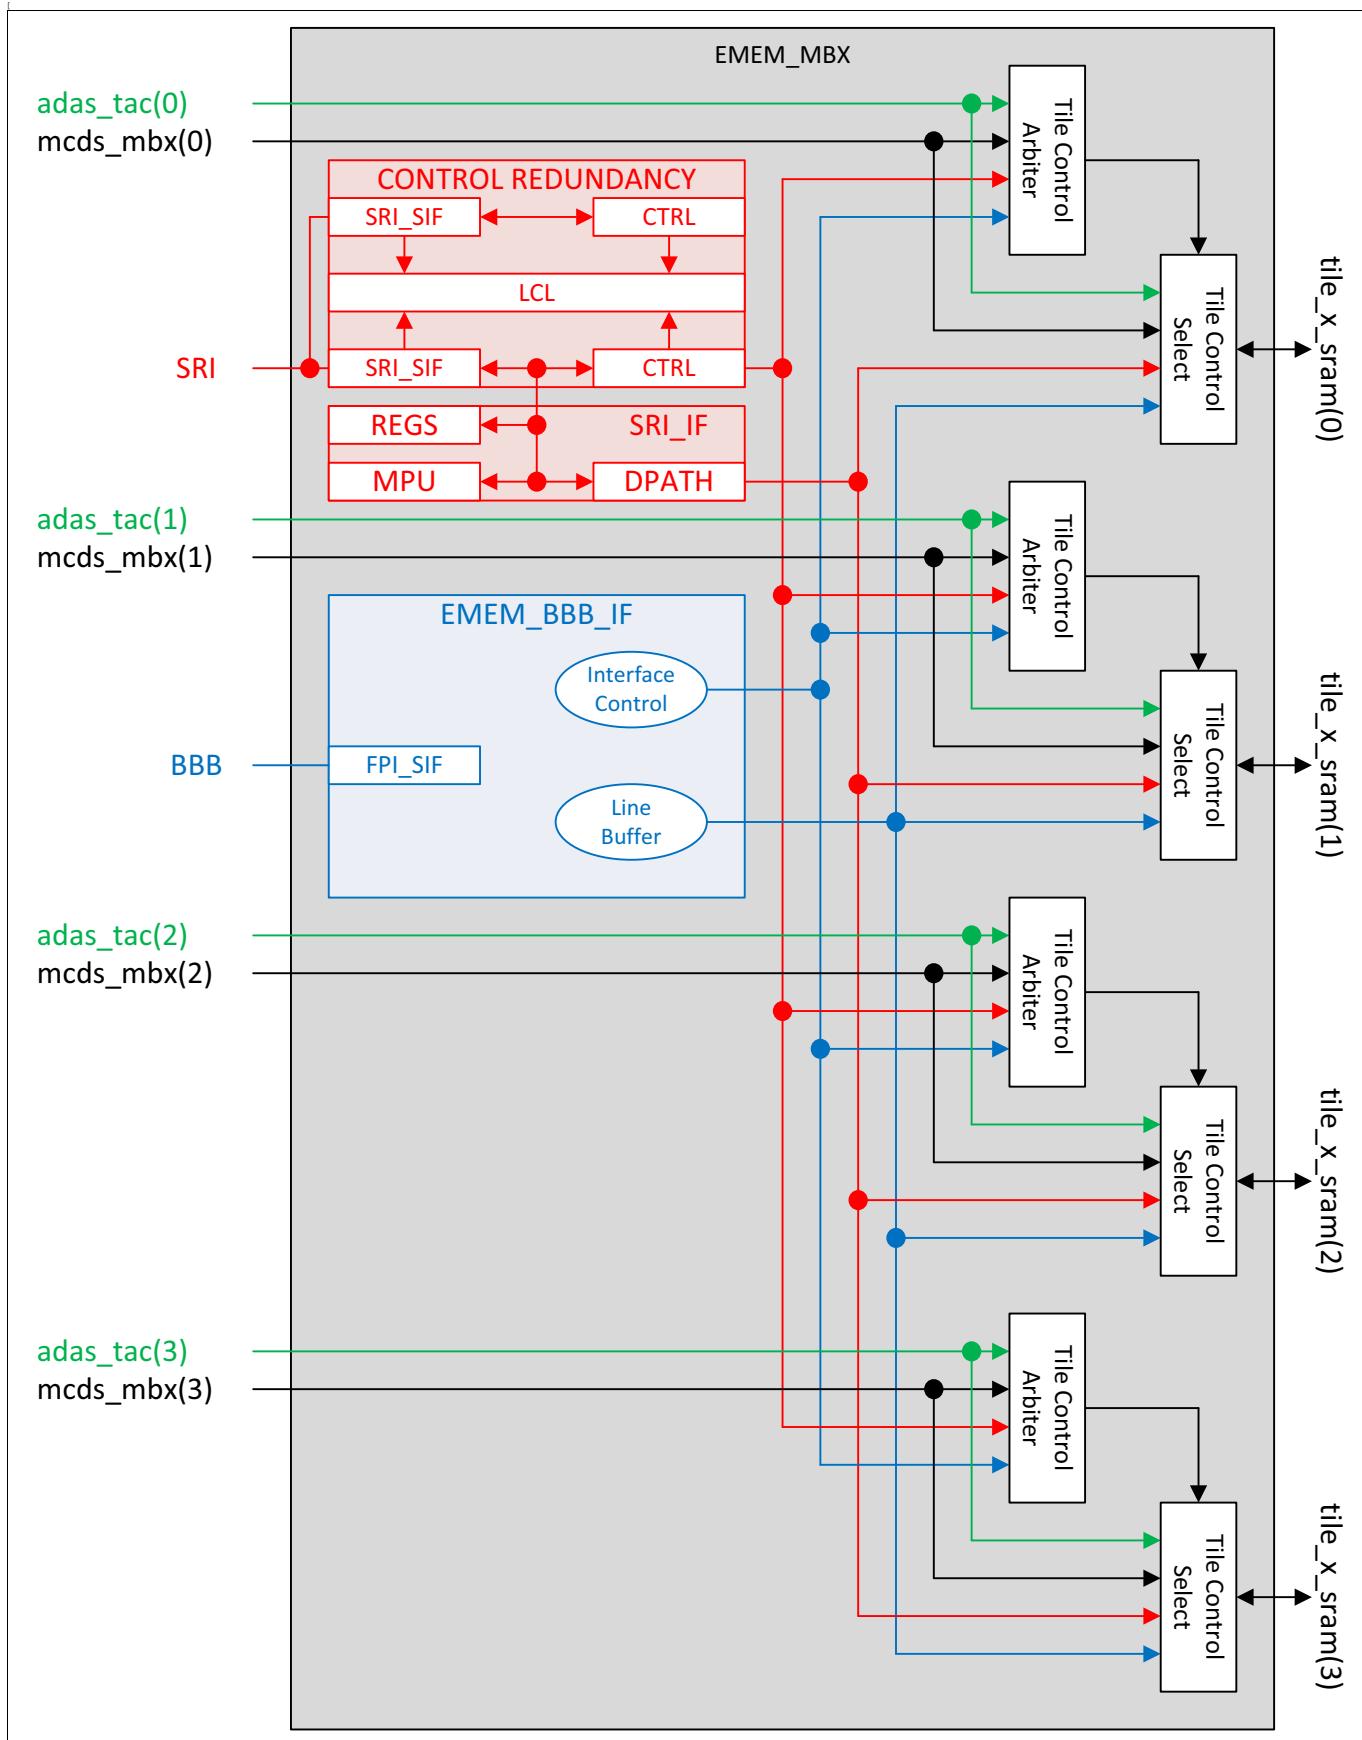

Figure 286 [Block Diagram of EMEM MBX]]

## Extension Memory (EMEM)

[The [EMEM Module] MBX block (at [Figure 286]) implements control redundancy to detect control faults during sub word SRI accesses to an [EMEM Module] register or SRAM. If the control redundancy detects a fault, the [EMEM Module] shall trigger an alarm to the SMU. The control redundancy shall be enabled after reset. The [EMEM Module] control redundancy and shall be disabled by software writing [01<sub>B</sub>] (OFF) to [EMEM Module] SCTRL.LSEN. The status of the [EMEM Module] control redundancy is reported by SCTRL.LSSTAT.]

### 23.3.6.6.1 [[Control Redundancy Test]]

[Software shall write [10<sub>B</sub>] to [EMEM Module] SCTRL.LSTST to test the [EMEM Module] control redundancy alarm. The control redundancy runs a background self test to periodically check the comparator functionality. If the self test fails, the [EMEM Module] shall trigger a SMU alarm.]

### 23.3.6.6.2 [[Consistency Check]]

[The [EMEM Module] control redundancy shall check the consistency of its own control state by maintaining all such information in redundant pairs of flip-flops where one flip-flop is the logical inverse of the other. If one of these pairs is in an inconsistent state (i.e. [00<sub>B</sub>] or [11<sub>B</sub>]), the [EMEM Module] shall trigger a SMU alarm.]]]

### 23.3.7 [[SEP Interface]]

[Multiple 256-bit [SEP] interfaces are used for dedicated data communication between SPU0/SPU1 and EMEM.]

[The EMEM shall give precedence to SEP accesses.]

#### 23.3.7.1 [[TC39xED SEP Accesses to EMEM Tiles]]

[The EMEM shall service the following multiple simultaneous SEP accesses to the same [EMEM Tile]:]

- [[One SEP write access and one SEP read access to the same EMEM tile.]]
- [[Two SEP read accesses to the same EMEM tile.]]

[SPU0 and SPU1 should only perform one SEP write access to one EMEM tile at any time. If SPU0 and SPU1 perform two or more simultaneous SEP write accesses to the same EMEM tile, the EMEM shall service the higher priority SEP write access and return an access error for the lower priority SEP write accesses. The order of precedence for SEP write accesses is:]

- [[sep\_wr0]]
- [sep\_wr1]
- [sep\_adc\_wr0]
- [sep\_adc\_wr1]]]

#### 23.3.7.2 [[TC35x SEP Accesses to EMEM Tiles]]

[The EMEM shall service the following multiple simultaneous SEP accesses to the same [EMEM Tile]:]

- [[If SPU0 and SPU1 are writing FFT results, two SEP write accesses to the same EMEM tile.]]
- [One SEP write access and one SEP read access to the same EMEM tile.]
- [[Two SEP read accesses to the same EMEM tile.]]

[If SPU0 and SPU1 are simultaneously writing FFT results to the same EMEM tile, the EMEM shall service SPU0 sep\_wr0 access and delay the servicing of the SPU1 sep\_wr1 access to the next clock cycle. If the EMEM is unable to service the SPU1 sep\_wr1 access, the EMEM will return an access error.]

[Else SPU0 and SPU1 should only perform one SEP write access to one EMEM tile at any time. If SPU0 and SPU1 perform two or more simultaneous SEP write accesses to the same EMEM tile, the EMEM shall service the higher

## Extension Memory (EMEM)

priority SEP write access and will return an access error for the lower priority SEP write accesses. The order of precedence for SEP write accesses is:]

- [[sep\_wr0]]
- [sep\_wr1]
- [sep\_adc\_wr0]
- [sep\_adc\_wr1]]]

### 23.3.7.3 [[TC3Ax SEP Accesses to EMEM Tiles]]

[The EMEM shall service the following multiple simultaneous SEP accesses to the same [EMEM Tile]:]

- [[If SPU0 and SPU1 are writing FFT results, two SEP write accesses to the same EMEM tile.]
- [One SEP write access and one SEP read access to the same EMEM tile.]
- [Two SEP read accesses to the same EMEM tile.]]

[If SPU0 and SPU1 are simultaneously writing FFT results to the same EMEM tile, the EMEM shall service SPU0 sep\_wr0 access and delay the servicing of the SPU1 sep\_wr1 access to the next clock cycle. If the EMEM is unable to service the SPU1 sep\_wr1 access, the EMEM will return an access error. If BITMGR attempts a write to the same tile when an SPU is writing then BITMGR shall be stalled until there is no other write access to that tile.]

[Else SPU0 and SPU1 should only perform one SEP write access to one EMEM tile at any time. If SPU0 and SPU1 perform two or more simultaneous SEP write accesses to the same EMEM tile, the EMEM shall service the higher priority SEP write access and will return an access error for the lower priority SEP write accesses. The order of precedence for SEP write accesses in this case is:]

- [[sep\_wr0]]
- [sep\_wr1]
- [sep\_adc\_wr0]
- [sep\_adc\_wr1]]]

[When there are two SEP read accesses to the same EMEM tile from the sep\_rd0 and sep\_rd1 interfaces the accesses shall be serviced using a round robin arbitration scheme. This gives a fair share of the read bandwidth between these two interfaces and avoids starvation. The sep\_rd2 is not included in the round robin and any read access by BITMGR to the same EMEM tile as a read access from sep\_rd0 or sep\_rd1 shall be stalled until there is no other read access to that EMEM tile.]]

### 23.3.7.4 [[TC33xED SEP Accesses to EMEM Tiles]]

[The EMEM shall service the following multiple simultaneous SEP accesses to the same [EMEM Tile]:]

- [[One SEP write access and one SEP read access to the same EMEM tile.]]

[If SPU0 performs two simultaneous SEP write accesses to the same EMEM tile, the EMEM shall service the higher priority SPU0 sep\_wr0 access and will return an access error for the lower priority SPU0 sep\_adc\_wr0 access.]]

### 23.3.7.5 [[SEP Error]]

[If SPU0/SPU1 accesses a disabled EMEM tile (via tile control), the EMEM shall signal an SEP error to SPU0/SPU1.]]

### 23.3.7.6 [[SEP ECC Error]]

[The SEP Interface protocol includes redundant error detection information (a combined address and data checksum) to allow the integrity checking of an [SEP Write Access] or [SEP Read Access]. ]

## Extension Memory (EMEM)

### 23.3.7.6.1 [[SEP Write Access]]

[If an SPU performs an SEP write access to EMEM, the EMEM shall check the integrity of the SEP write access.]

- [[The EMEM shall analyze the SEP control signal differential pairs.]
  - [[If the EMEM detects a differential error, the EMEM shall trigger an SEP alarm to the SMU.]]
- [The EMEM shall check the integrity of the access by analyzing the combined address and data checksum.]
  - [[If the EMEM detects an integrity error, the EMEM shall trigger an SEP alarm to the SMU.]]
  - [The EMEM shall service the SEP write access by performing a write to SRAM.]]]]]

### 23.3.7.6.2 [[SEP Read Access]]

[If an SPU performs an SEP read access to EMEM, the EMEM shall check the integrity of the SEP read access.]

- [[The EMEM shall analyze the SEP control signal differential pairs.]
  - [[If the EMEM detects a differential error, the EMEM shall trigger an SEP alarm to the SMU.]]
- [The EMEM shall calculate a combined address and data checksum for propagation from EMEM to SPU0/1.]]]]]

### 23.3.7.7 [[SPU Full Lockstep]]

[If SPU0 and SPU1 are configured for full lockstep operation, the EMEM shall function as follows:]

- [[SPU1 SEP write accesses to EMEM shall fail silently.]]
- [SPU1 SEP read accesses to EMEM shall be ignored.]
  - [[The EMEM shall return the SPU0 read data to SPU1.]]]]]

### 23.3.8 [[Reset Control]]

[The EMEM has two types of reset control:]

- [[The **[EMEM Module]** SRI interface shall be reset by application reset.]]
- [The remainder of EMEM shall be reset by EEC reset.]]

[If OCDS is disabled, the ECC reset is tied to the application reset. ]]

### 23.3.9 [[Clock Control]]

[The EMEM has two types of clock control registers:]

- [[The **[EMEM Core]** clock control register shall enable and disable the internal  $f_{[BBB]}$  clock in order to control the power consumption.]
  - [[If the **[EMEM Core]** clock control register disables the clock, then software shall be able to write to the **[EMEM Core]** clock control register to enable the internal EMEM clock.]]
- [Each **[EMEM Module]** has an independent clock control register to enable and disable the internal  $f_{[SRI]}$  clock to the **[EMEM Module]** SRI slave interface.]
  - [[If the **[EMEM Module]** clock control register disables the clock, then the **[EMEM Module]** shall service SRI accesses to the **[EMEM Module]** registers. SRI accesses to EMEM tiles shall not be serviced. ]
  - [The **[EMEM Module]** shall service and SRI access to an **[EMEM Tile]** when the **[EMEM Module]** clock is enabled and the **[EMEM Tile]** is configured for use via the **[EMEM Core]** TILECONFIG and TILEECC registers. ]]]]]]

## 23.4 [[Registers]]

[This section describes the registers of the EMEM module.]

## Extension Memory (EMEM)

### 23.4.1 [[EMEM Core Register Description]]

[[The [EMEM Core] registers shall be accessed via the BBB fc BPI SFF. The register description shows the maximum configuration. The number of active control and status bits shall depend on the EMEM configuration.]

[[**Table 1130 [Register Address Space - EMEM[ ]]**]]

[Module]	[Base Address]	[End Address]	[Note]
fc	[00000000 <sub>H</sub> ]	[0000FFFF <sub>H</sub> ]	BPI SFF (access to EMEM core registers)

## Radar Interface (RIF)

### 24 Radar Interface (RIF)

RIF module connects one fast external ADC with up to four channels, or up to 4 single channel internal ADCs with an SPU (Signal Processing Unit) module. Each multi-channel external ADC is connected over LVDS pads conforming to IEEE 1596.3 General Purpose Link standard.

The group of four data signals shares one clock and one frame signal. The four channel data flow path consists of an ADC, quad deserializer performing serial to parallel conversion, quad FIFO and lane management block, and data memory interface.

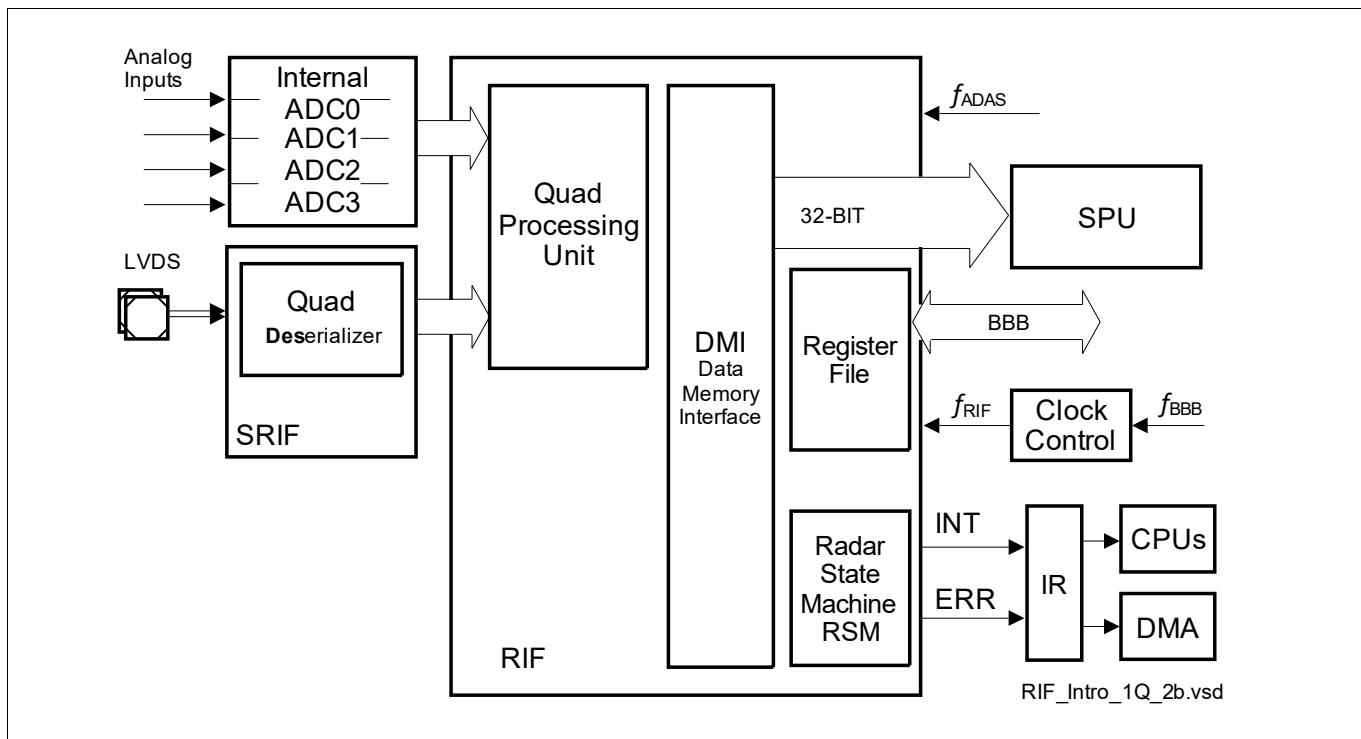

Figure 287 RIF Overview

#### 24.1 Feature List

This section describes the features of the RIF module.

- One interface for external four channel ADC
  - LVDS physical layer conform to IEEE-1596.3 standard, General Purpose Link
  - one frame signal, one clock signal, four data signals
  - independent frequency domains for each interface
  - independent deserializer unit
  - DDR (Double Data Rate) signalling with baud rate of up to 200MHz (400MBaud)
  - TC3Ax supports DDR signalling with baud rate of up to 300MHz (600MBaud)
  - data 10, 12, 14 or 16 bits wide, 2's complement format.
  - shift direction MSB or LSB first
  - data alignment left or right (integer or fractional)
- Interfaces to four internal single channel ADCs
  - 12-bit samples
- Intermediate layer providing data ordering and de-interleaving
  - Multiple lane data management

## Radar Interface (RIF)

- Real and complex sampling support
- De-interleaving
- Parallel memory interface to an internal SPU unit with FFT engine
  - 32-bit bus width
- Radar State Machine
  - 1, 2, 3 ... up to 2048 samples in a ramp
  - 1, 2, 3, ... up to 2048 ramps in a chirp
- Interrupts
  - Start of Ramp, End of RampCRC Error per channel

### 24.2 Overview

The RIF module chapter is based on describing the interfaces that connect the RIF module to its external and internal counterparts.

There are two data input interfaces (see [Figure 288](#)):

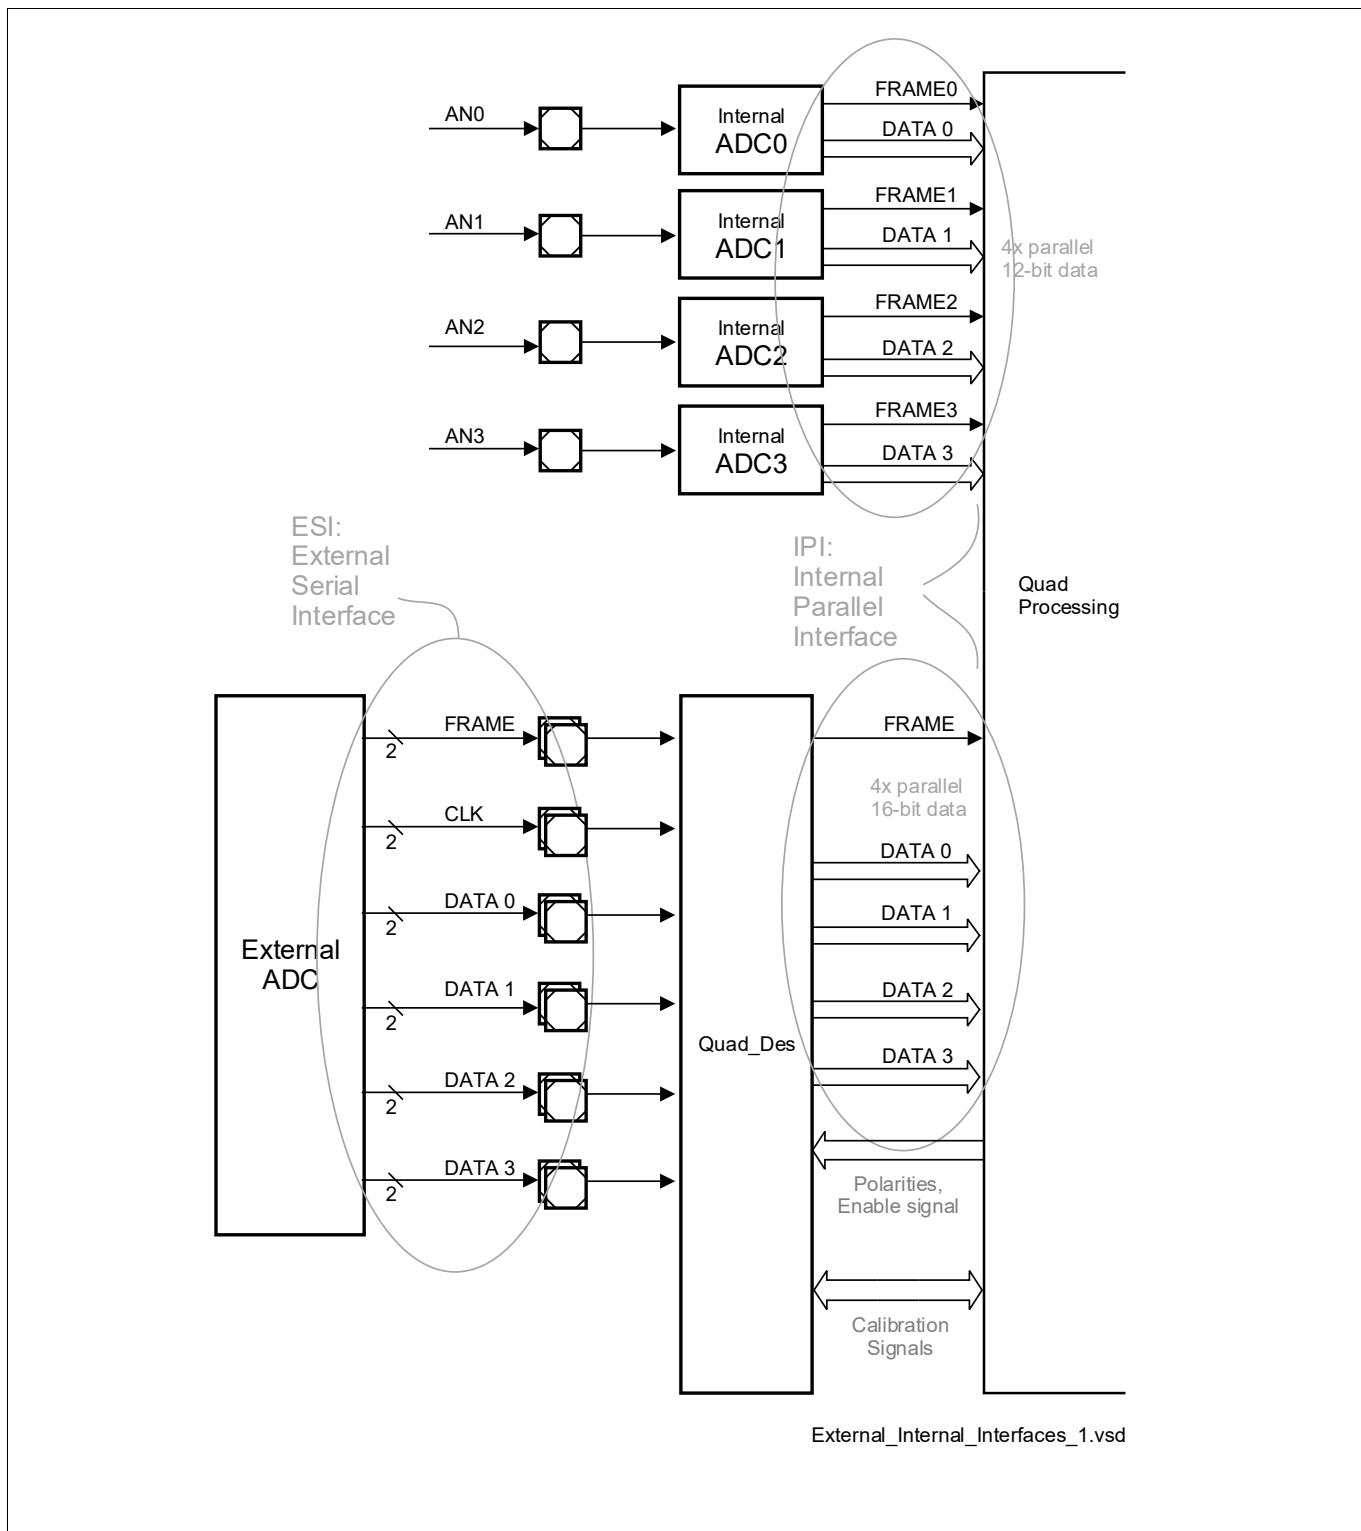

- External Serial Interface (ESI)
  - connects external ADCs to the quad deserializers
- Internal Parallel Interface (IPI)
  - connects the internal on-chip ADCs to the digital kernel of the RIF module
  - connects the quad deserializers to the digital kernel of the RIF module
- Data Memory Interface (DMI), see [Figure 305](#)

Additionally, the RIF module provides a Radar State Machine (RSM) monitoring the radar cycle.

**Table 1137 RIF Module Identification Numbers**

RIF Derivative	Module ID
RIF_TC33x	00E3 C001H
RIF_TC35x	00E3 C001H
RIF_TC39x	00E3 C001H
RIF_TC3Ax	00E3 C002H

### Radar Interface (RIF)

**Figure 288 Input Interfaces of the RIF Module**

## Radar Interface (RIF)

### 24.3 Functional Description

#### 24.3.1 External Serial Interface (ESI)

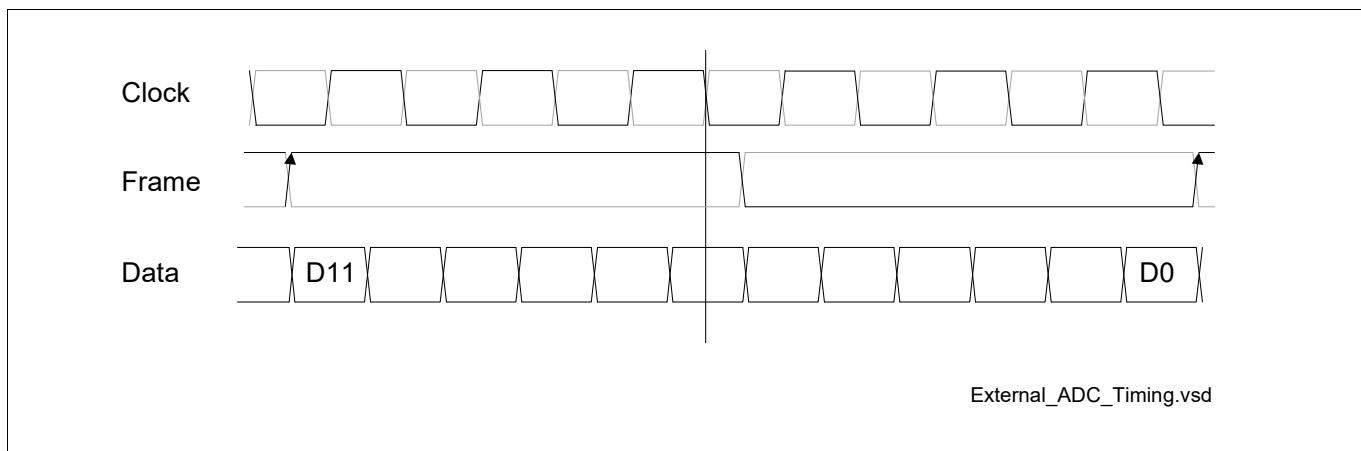

The external ADC interface consist of the following differential signals:

- Serial clock
- Frame
- Four data signals

The ADC provides continuous clock and continuous stream of data, back-to-back without pauses between the samples. This stream can only be made faster or slower by changing the sampling frequency delivered to the ADC.

The [Figure 289](#) shows an example of serial transmission of one 12-bit sample. The external ADC shifts the data bits approximately one half shift clock period later than the clock signal, in order to ensure sampling in the middle of the data bit time.

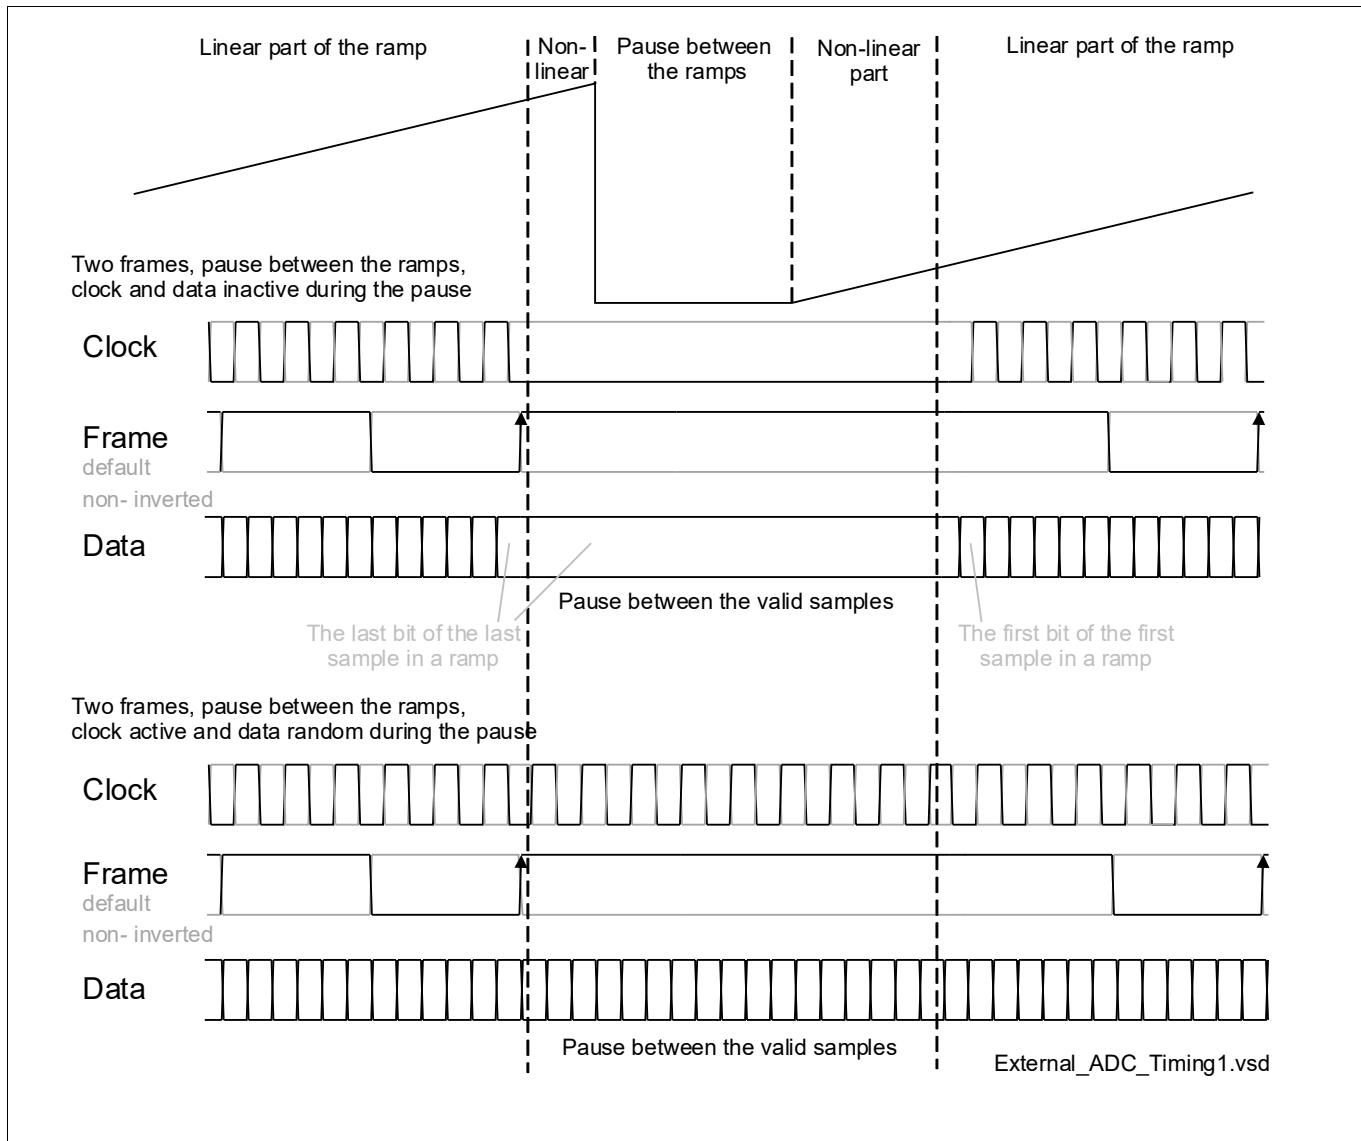

The frame signal marks each end of sample, per default with a rising edge (low-to-high differential transition). The frame signal toggles back in the middle of the sample, but this second edge does not have any special meaning.

**Figure 289 Waveforms of the External Serial Interface, Detailed View**

The [Figure 290](#) shows an overview of the waveforms in case a pause in the FRAME signal is used to mark the time interval between the ramps. Two scenarios are shown: one with the clock and data signals remaining static during the time between the linear/valid parts of the ramps, and one with the clock and data signals active.

## Radar Interface (RIF)

**Figure 290 Waveforms of the External Serial Interface, Overview**

### 24.3.2 Internal Parallel Interface (IPI)

The IPI interface consists of the following signals:

- Frame signal, used to write each sample in the FIFOs of the RIF kernel, see [Figure 288](#) and [Figure 293](#) for more detail.
- Data signals
  - 12-bit wide parallel data connection per internal ADC or
  - 16-bit wide parallel data connection per deserializer
- Configuration signals:
  - polarity of the clock, frame, and data
  - enable / disable = start / stop

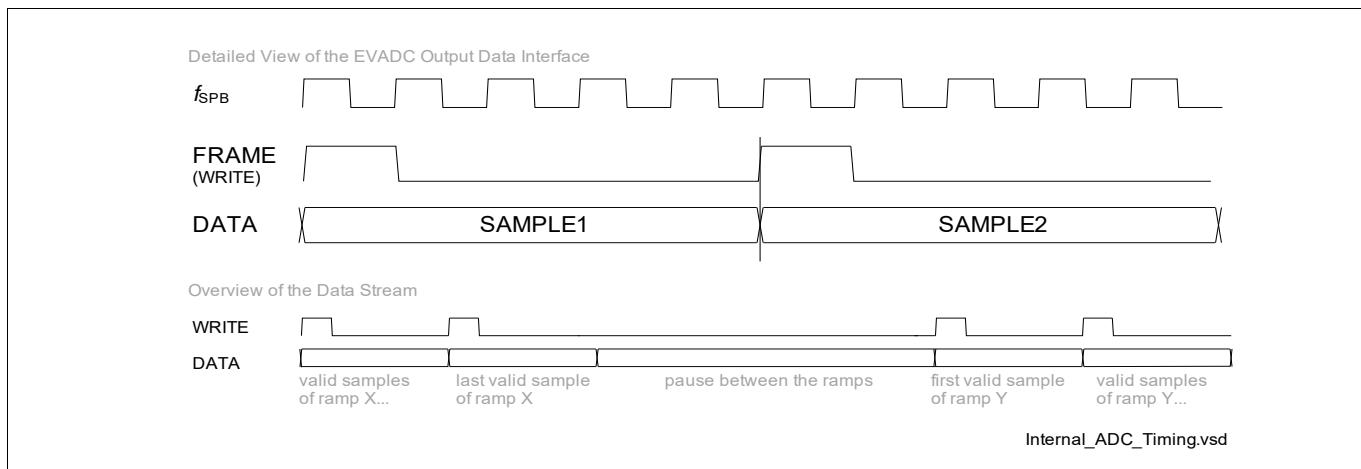

#### Connection to the Internal ADCs

The internal EVADCs (Enhanced Versatile ADCs) are single ended converters providing 12-bit unsigned integer data. Four internal EVADCs provide parallel data connection and FRAME (write) signal each.

## Radar Interface (RIF)

The **Figure 291** shows an overview of the waveforms generated by the EVADCs for writing their data into the RIF module. The FRAME (write) signal of the internal EVADC modules is  $1*f_{SPB}$  wide. Therefore, the internal RIF clock  $f_{ADAS}$  must be higher than  $f_{SPB}$ . For more details, see the section “Hardware Data Interface” in the EVADC module chapter.

The EVADCs provide two characteristic maximal sample rates, depending on the used clock frequency, of 2.6 MSamples/sec and 2.2 MSamples/sec. For more details of supported sampling rates, see the section “Conversion Timing Configurations” in the EVADC module chapter.

**Figure 291 Waveforms of the Internal Parallel Interface to the internal ADC**

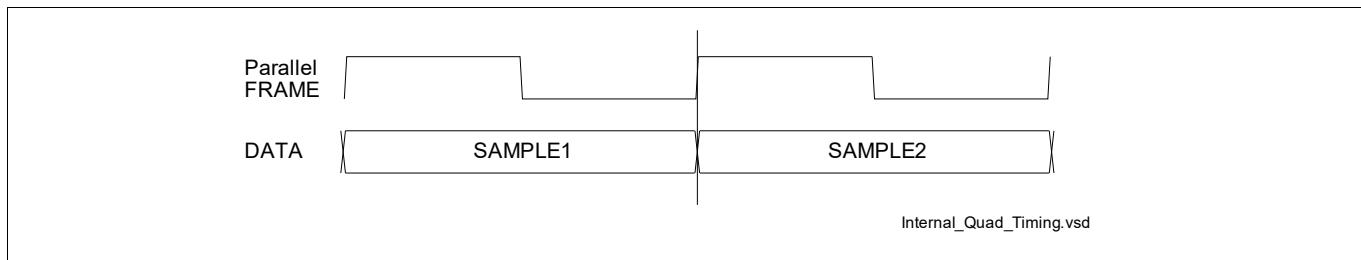

## Connection to the Quad Deserializer Unit

The Quad Deserializer Unit consists of four deserializers. A deserializer receives serial ADC data and delivers it in parallel form to the Quad Processing Unit.

The deserializer always delivers valid, non-corrupted samples. Dynamic start / stop during run time is allowed. After ending the stop state, the deserializer waits for the next frame and delivers valid samples.

Note that when the deserializer is disabled, the corresponding frame clock will be gated to low, which could trigger the Frame Watchdog to start and result in unintended Ramp1 error. Therefore for each radar cycle, in order to suppress the Ramp 1 error, after checking the R1EF, if there is no Ramp1 error it is recommended that the user will reset the Frame Watchdog threshold to 0 until the next radar cycle before disabling the deserializer.

The **Figure 292** shows an overview of the waveforms generated by the serializer for writing its received data into the RIF module by using the Internal Parallel Interface.

**Figure 292 Waveforms of the Internal Parallel Interface to the Quad Deserializer**

## Radar Interface (RIF)

### 24.3.3 Quad Processing Unit

After entering the frequency domain of the Quad, the data goes through a processing pipeline consisting of synchronization FIFOs, CRC check, FIFO and Lane Management block FLM and Data Formatting Unit DFU.

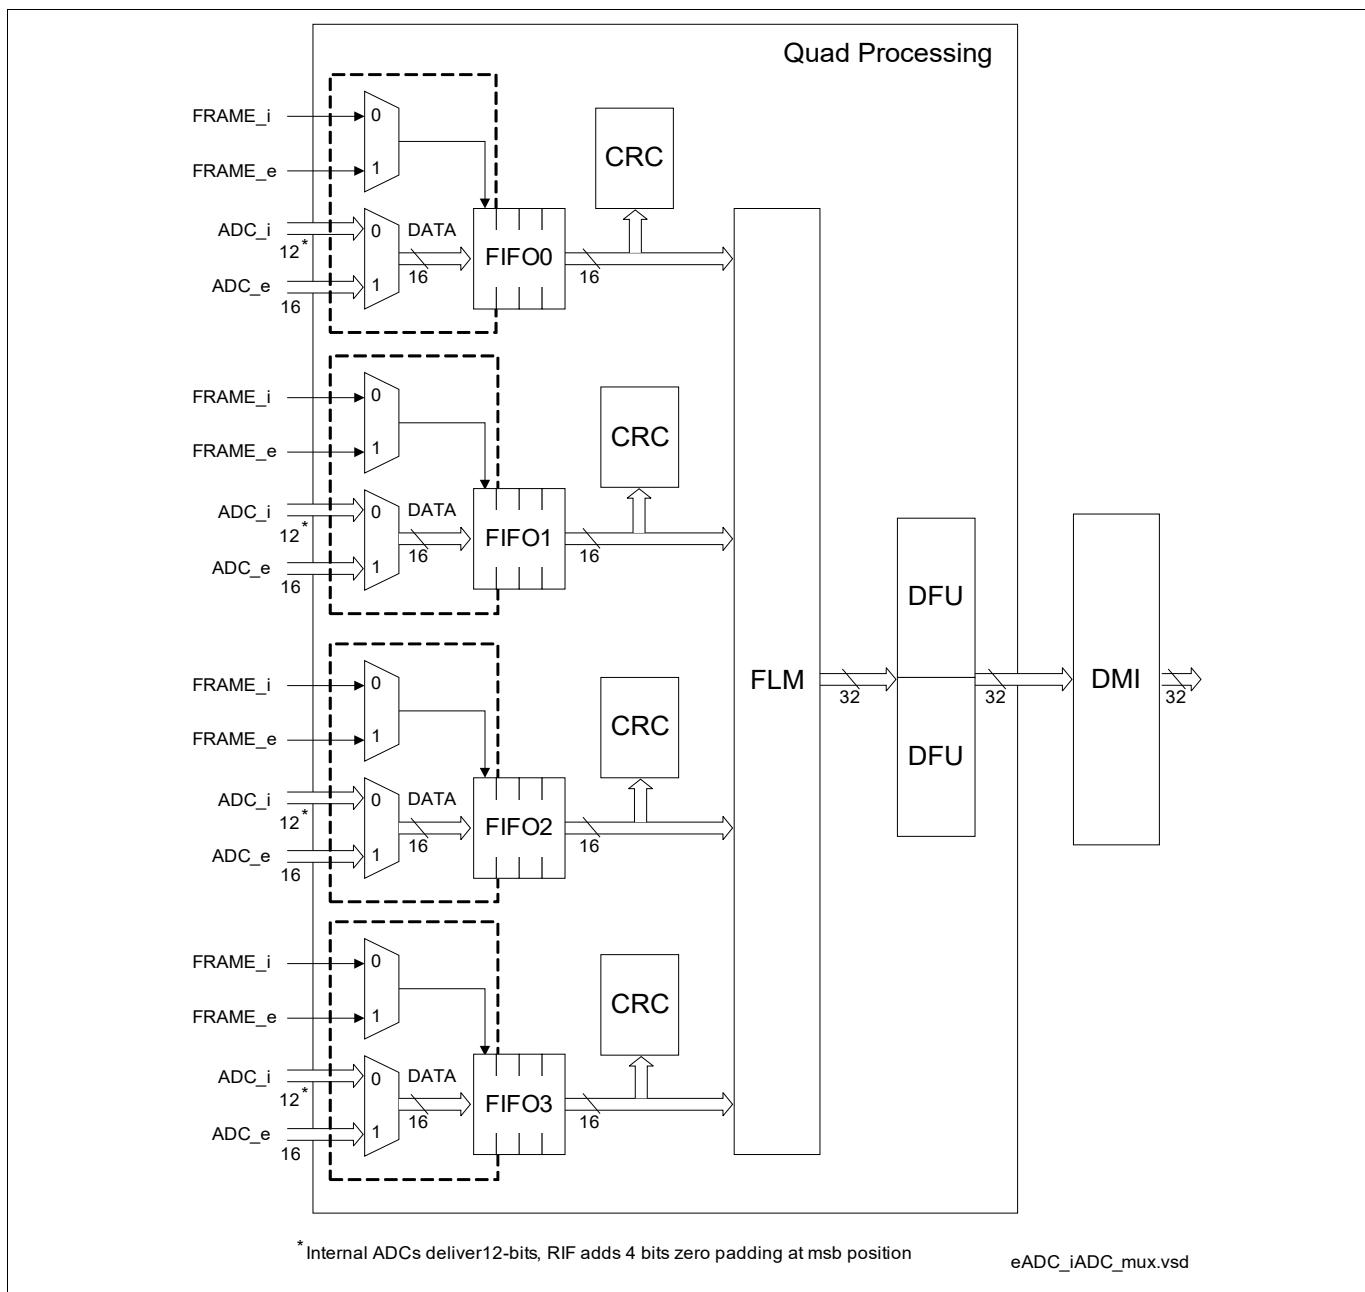

Figure 293 Quad Processing Unit

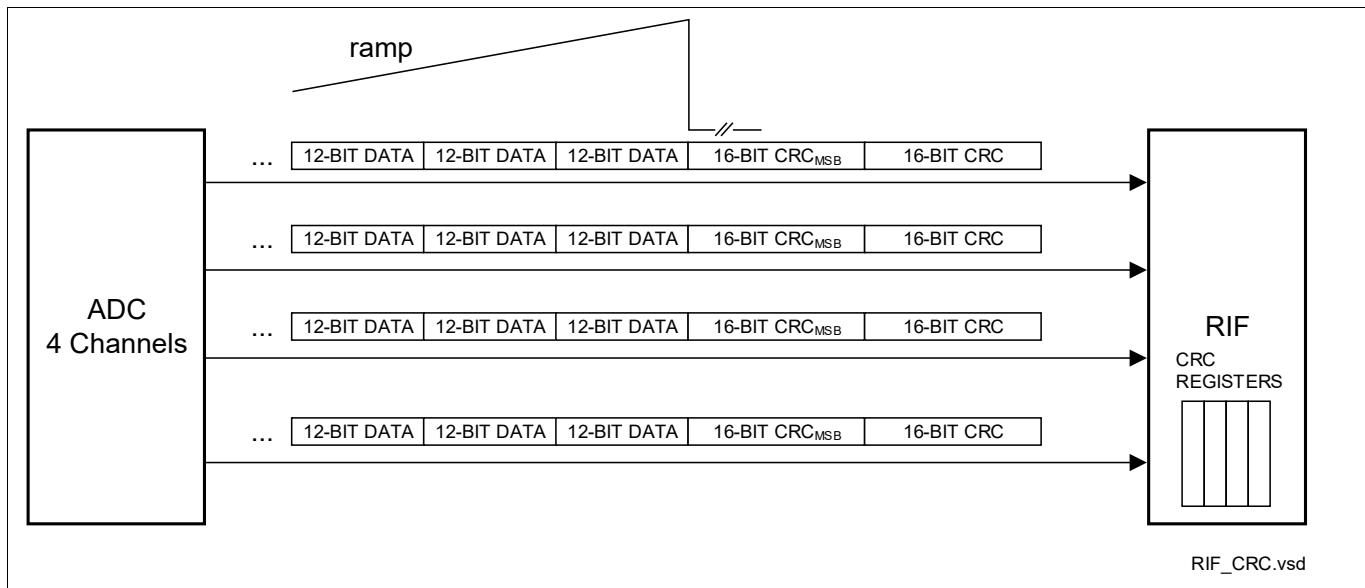

### 24.3.4 Default CRC Scheme

Each data channel contains one CRC (Cyclic Redundancy Check) calculation block which can be enabled or disabled. The CRC engine uses the 32-bit CRC polynomial 0x04C1 1DB7 with the initial value 0xFFFF FFFF. The external ADCs optionally provide the CRC in each data channel, at the end of the ramp. The CRC is transmitted MSB first. The CRC feature can be enabled or disabled by using the bit **FLM.CRCEN**.

If a CRC error occurs in a channel, an error interrupt is raised, if enabled by using the bit fields **INTCON.CRCE0 ... 3**. The CRC is transmitted in two 16-bit frames, because the size of the receive shift register is 16-bit. In case there is no external RAMP1 signal, the RIF module uses the FRAME watchdog and distinguishes between data and CRC

## Radar Interface (RIF)

samples by counting the predefined number of data samples and then taking the next two frames as the CRC for the ramp. Note that TC3Ax does not support Ramp1 signal and relies on the FRAME watchdog to distinguish between data and CRC samples. The order in which the two CRC frames are sent is configured with the bit **FLM.EXPCRCWO**.

**Figure 294 CRC Overview**

**Attention:** *The internal ADCs do not generate CRC. It is the application software responsibility not to enable the CRC feature when using the internal ADCs.*

## Radar Interface (RIF)

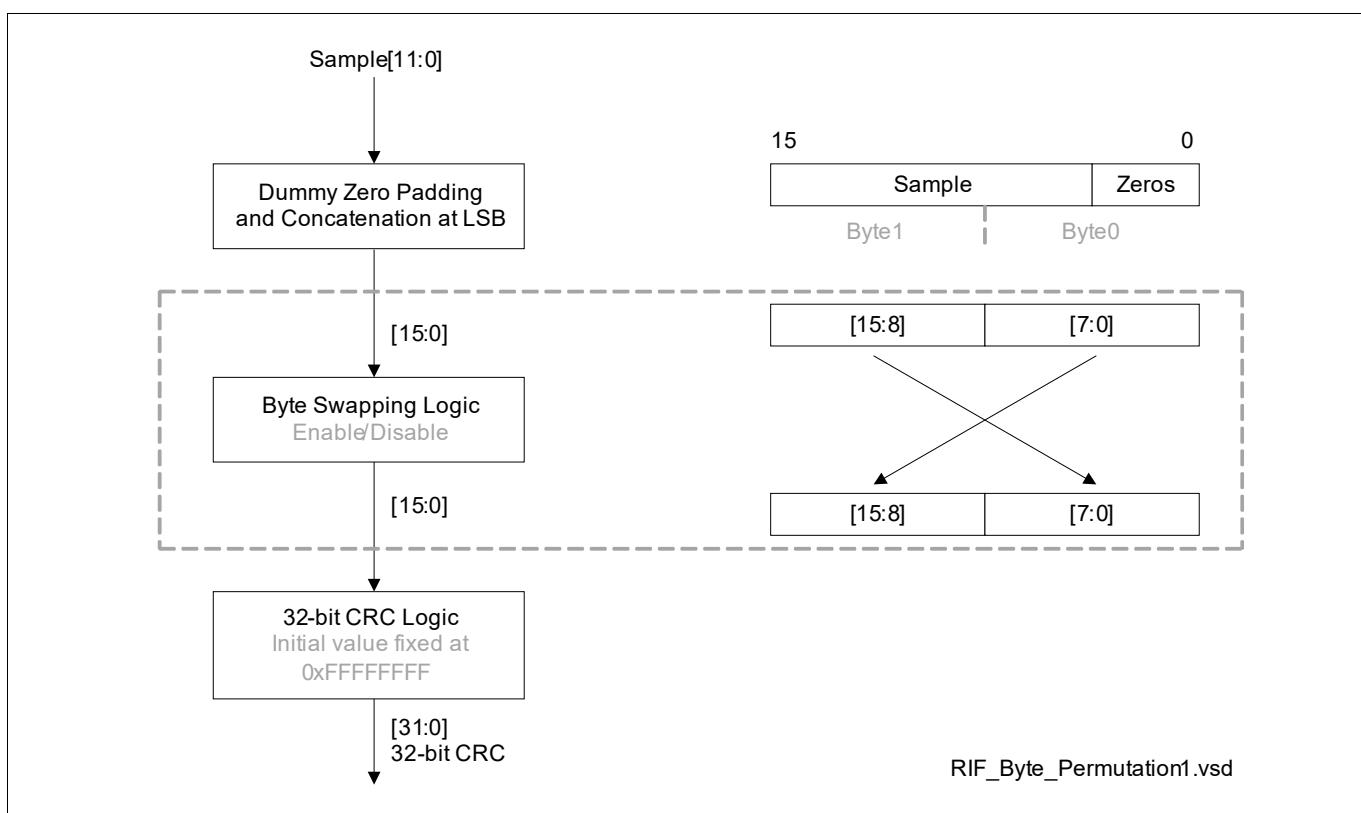

### 24.3.5 Alternative CRC Scheme

The RIF module provides an alternative way of calculating CRC. The features of this alternative CRC are:

- The CRC polynomial and the initial value are the same as the basic CRC. It is the 32-bit polynomial CRC 0x04C1 1DB7 with initial value 0xFFFF FFFF.
  - The RIF module pads the received ADC values with zeros on the LSB side to 16-bit and uses the padded values for calculating the CRC
  - The CRC is calculated always in the msb first direction independent of the shift direction on the serial bus
- The Alternative CRC Scheme can be selected by setting the bit **FLM.CRCALT**.

#### 24.3.5.1 Byte Swapping

If the bit **FLM.CRCALT=1**, then the bit **FLM.CRCSB** provides an option to swap the bytes of each sample before writing them to the CRC engine. The **Figure 295** shows an example of byte swapping of a 12-bit ADC sample, extended to 16-bit. The byte swapping operates independently of the sample width: 10, 12 , 14 or 16-bit.

**Figure 295 CRC Byte Swapping**

### 24.3.6 CRC as a Safety Mechanism

Additionally to covering EMI disturbances, the serial CRC can be used as a basis for software safety mechanism for checking the correct operation of the deserializer.

## Radar Interface (RIF)

### 24.3.7 Data Formatting Unit (DFU)

The following configuration parameters of DFU are programmable:

Input data properties:

- shift direction msb/lsb first
- even total data width of 10, 12, 14, 16 bits:
  - signed / unsigned integer of 10, 12, 14, 16 bits
  - unsigned Q1.9, Q1.11, Q1.13 and Q1.15 (total width 10, 12, 14, 16 bits)
  - signed Q1.8, Q1.10, Q1.12, Q1.14 (total width 10, 12, 14, 16 bits)
- Output data properties:
  - alignment: left / right (fractional / integer data)
  - data length fixed to 16-bit
  - data format fixed to signed integer

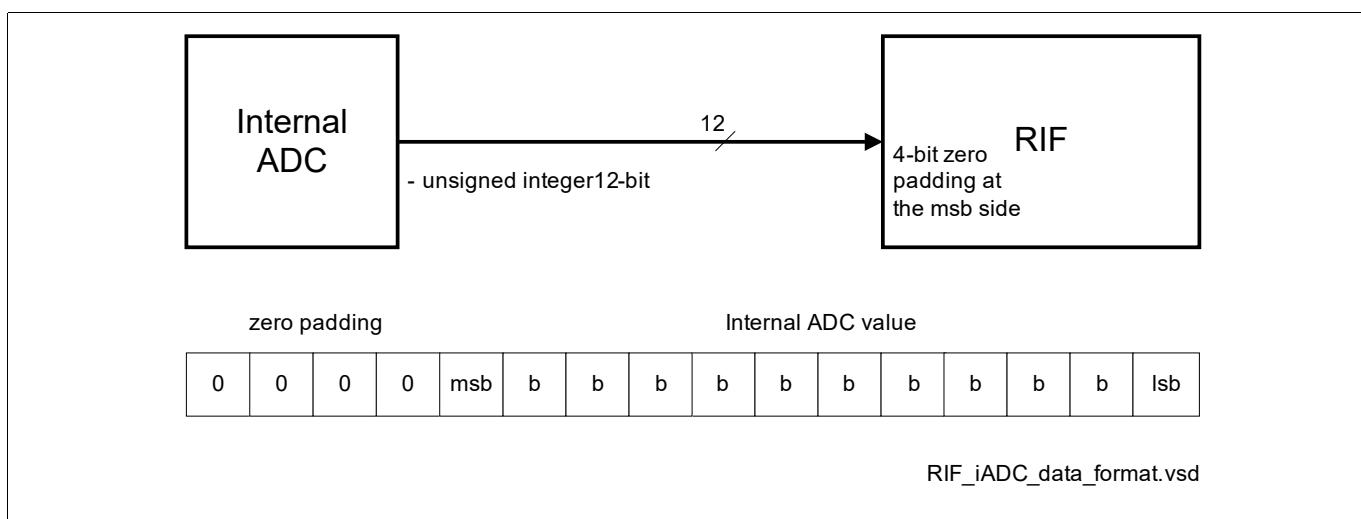

The parameters are initialized at the start of the application, after reset, and then they remain constant either until the end of the application (the power down or the next reset) or the module is stopped for configuration change and then restarted again. The frame length is the only parameter requiring dynamic reconfiguration.

There is one set of configuration bits valid for all four channels. Separate format of each channel is not possible.

Regarding the fixed point Q data formats, the data length of unsigned Qm.n format is m+n bits, and the data length of signed Qm.n format is m+n+1. This means that for example, Q1.11 datum is 12 bit long as unsigned, and 13 bit long as signed. Due to the fact that RIF can receive only even width data, signed Q1.11 is not supported, but Q1.10 or Q1.12 are supported, because they have even total data width.

This raw received data is always right aligned in its 16-bit slot, and in case of signed integer input data format, the RIF sets the padding msb bits, which are per default zeros, to the sign (the msb bit) of the raw input data.

The [Figure 296](#) shows the data format delivered by the internal ADC: 12-bit unsigned integer padded by RIF with zeros on the msb side. The reset values of the bits **DFU.DF** and **MSB** correspond to this data type.

**Figure 296 Data Format from the Internal ADC**

The [Figure 297](#) shows the overview of all data formats in the data path, starting with an external ADC.

## Radar Interface (RIF)

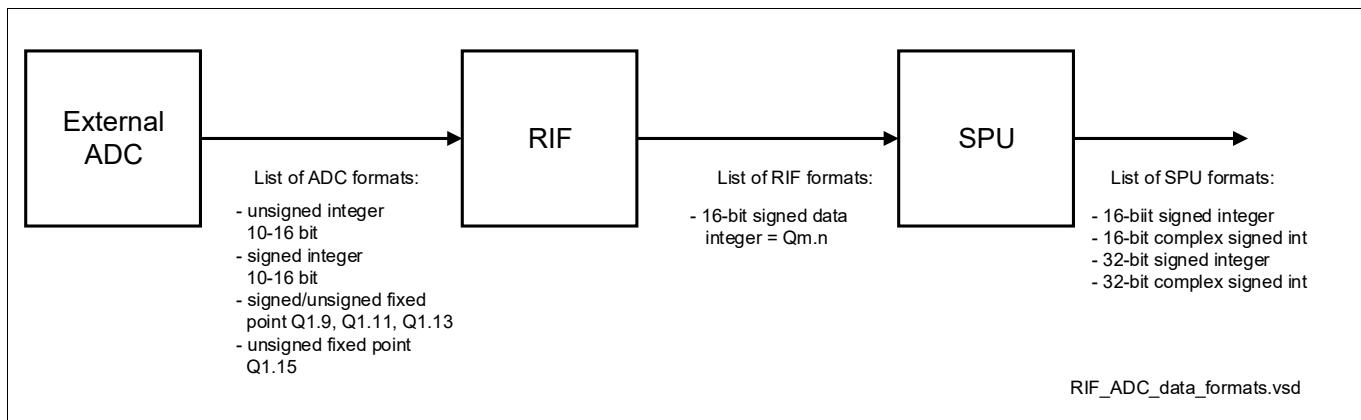

Figure 297 Data Formats from the External ADC

The RIF deserializer receives the data from the external ADC and delivers the data as shown in [Figure 298](#). If the serial data comes msb first, the lsb bit is on the parallel lsb position and no further operation is necessary. If the serial data comes lsb first, then the msb bit is on the parallel lsb position and the DFU has to bit reverse the data (see [DFU.MSB](#)).

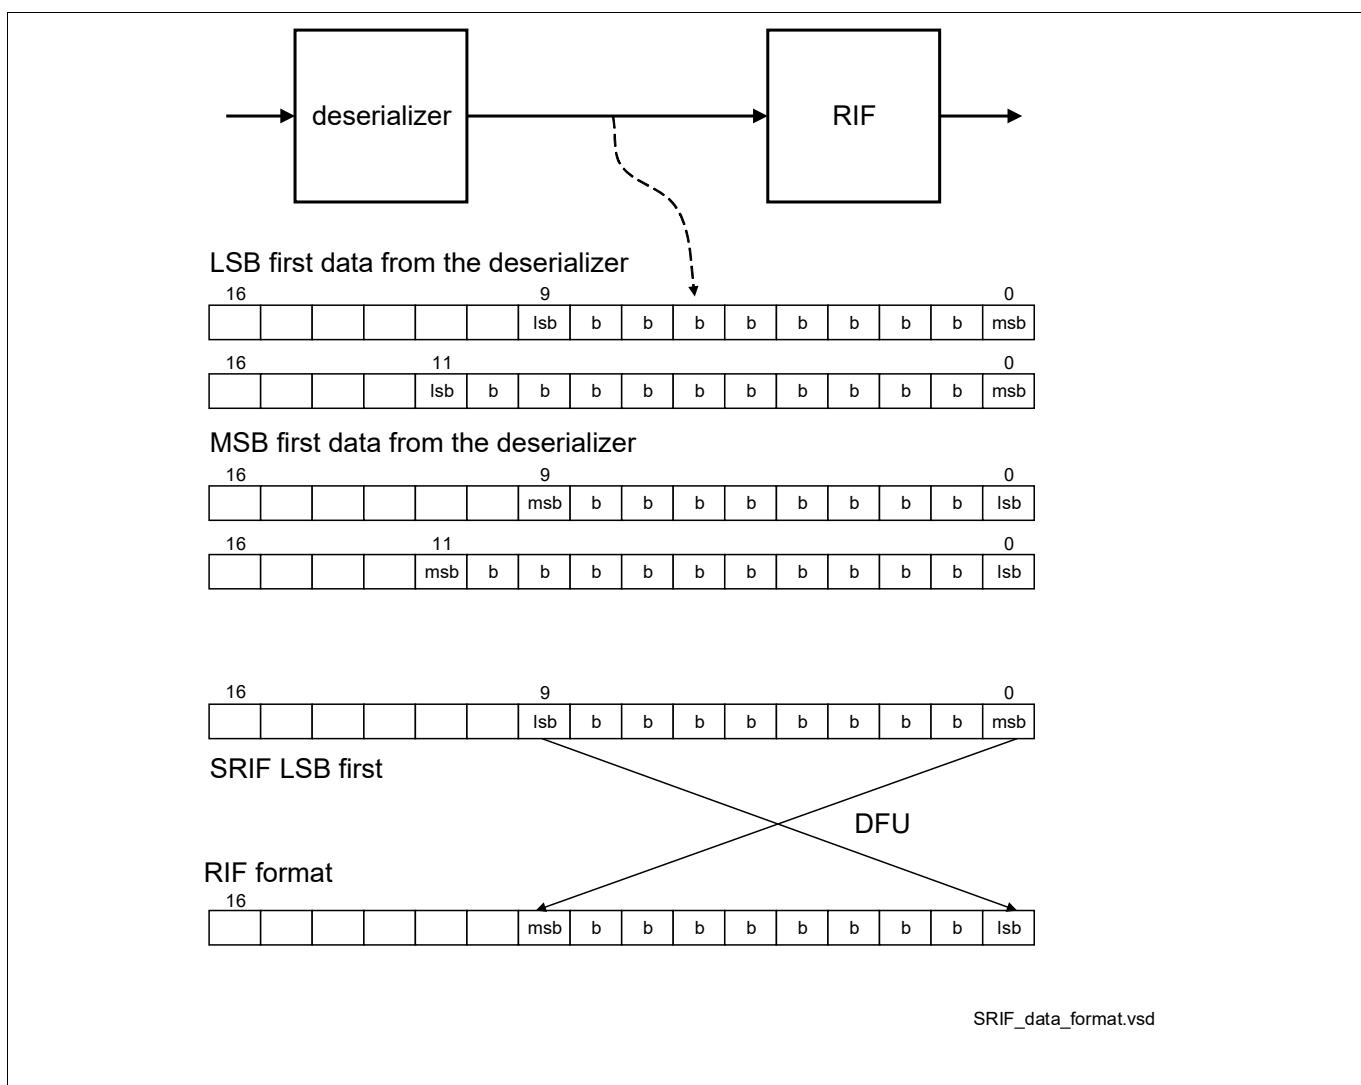

Figure 298 Shift Direction Management

## Radar Interface (RIF)

After optionally bit-reversing the data, the DFU can further re-format the data (see [DFU.DA](#)).

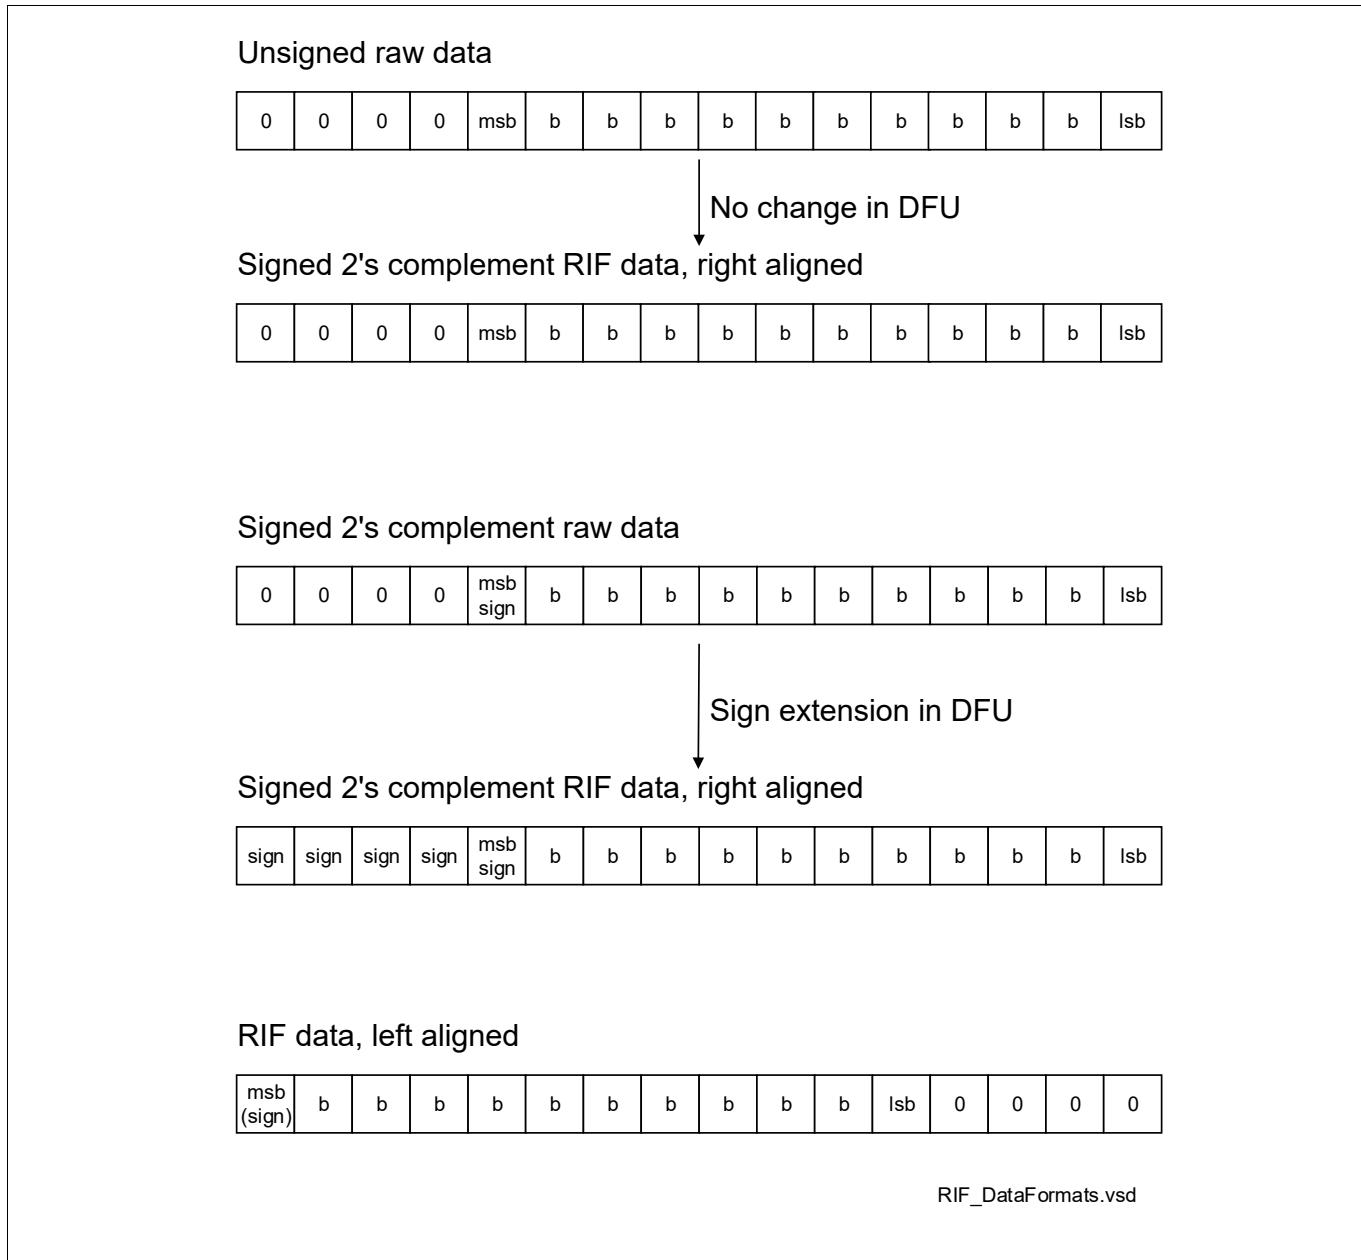

Figure 299 DFU Processing of the Data Formats

### 24.3.8 FIFO and Lane Management (FLM)

The streams of samples from external ADC can be transmitted over one, two or four lanes, depending on the sampling rate. Additionally, radar signals can be sampled either as real only, or in quadrature, resulting in real samples or complex samples (consisting of real and imaginary sample).

The samples of these streams are distributed in certain order in the Data Memory Interface, as described in the following subsections.

#### 24.3.8.1 FLM Operating Modes

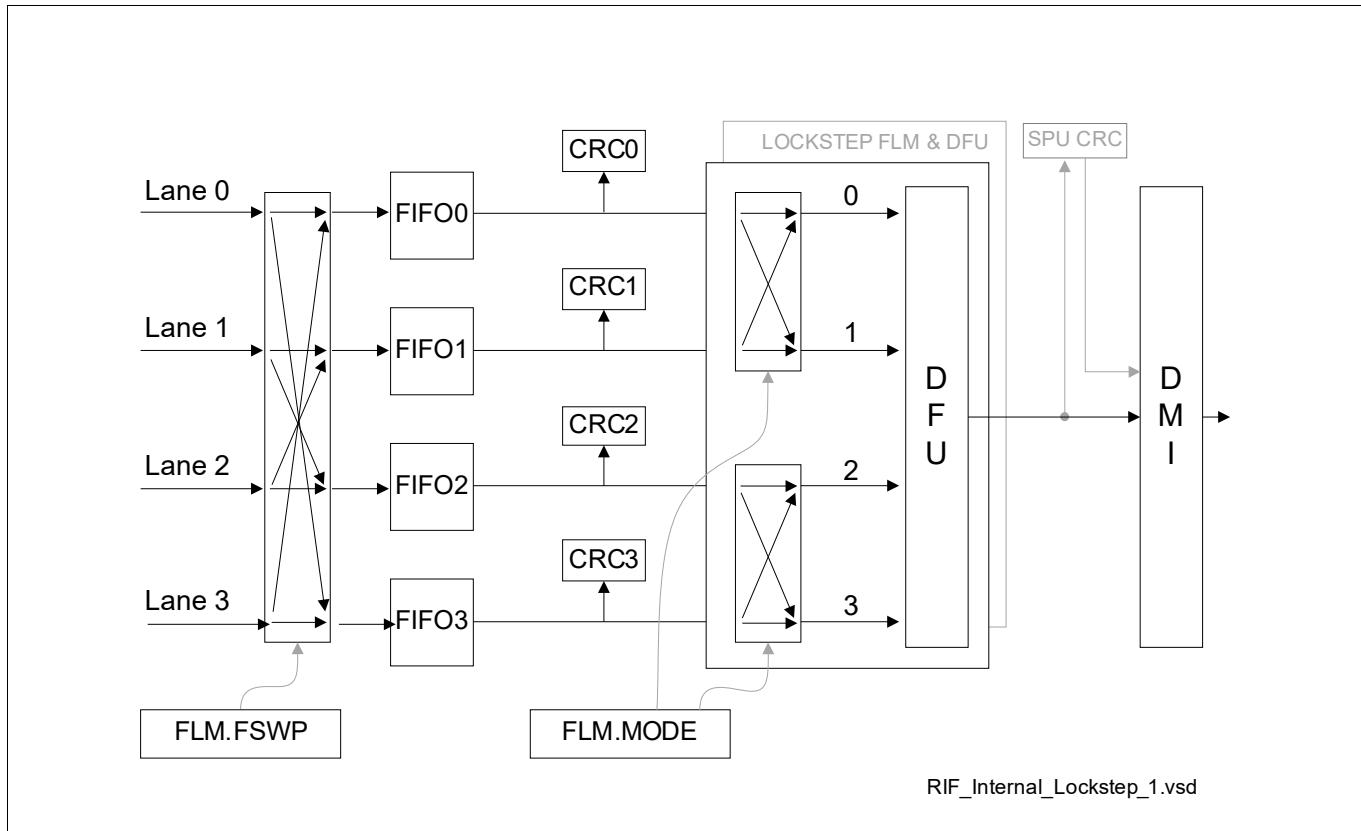

Each Quad\_FLM supports the following operating modes (see also register [FLM](#)):

- Direct complex mapping (radar front end chip soldered at the same side of the PCB with the uC)

## Radar Interface (RIF)

- Flipped complex mapping (radar front end chip soldered at the other side of the PCB).

The purpose of the flipping is to ensure always the same position of the real and complex part when delivered to the SPU.

**Figure 300 FLM Operating Modes**

The analog part of the quad, Quad\_Des, is not affected by the difference between the use cases of real and complex sampling. The different handling of the samples is done in the digital part of the quad, QUAD\_FLM.

In case of real sampling, if one antenna is being used, then it must be connected to lane 0. If two antennas are being used, they must be connected to lanes 0 and 1, for three antennas, lanes 0 to 2 must be used, for four antennas, lanes 0 to 4. Use [IPI.EN0 ... 3](#) accordingly.

In case of complex sampling, if one antenna is being used, it has to be connected to lanes 0 and 1. If a second antenna is being used, it has to be connected to lanes 2 and 3.

TC3Ax supports I and Q samples transmitted from the MMICs interleaved on a single LVDS lane. This feature can be enabled or disabled by [FLM.MULCMPX](#). When this feature is enabled, if one antenna is used, it has to be connected to lane 0. If two antennas are used, they must be connected to lanes 0 and 1, for three antennas, lanes 0 to 2 and for four antennas, lanes 0 to 3 must be used. A detailed description of this feature is available in [Section 24.3.8.5](#).

### 24.3.8.2 RIF Internal Lockstep and SPU CRC)

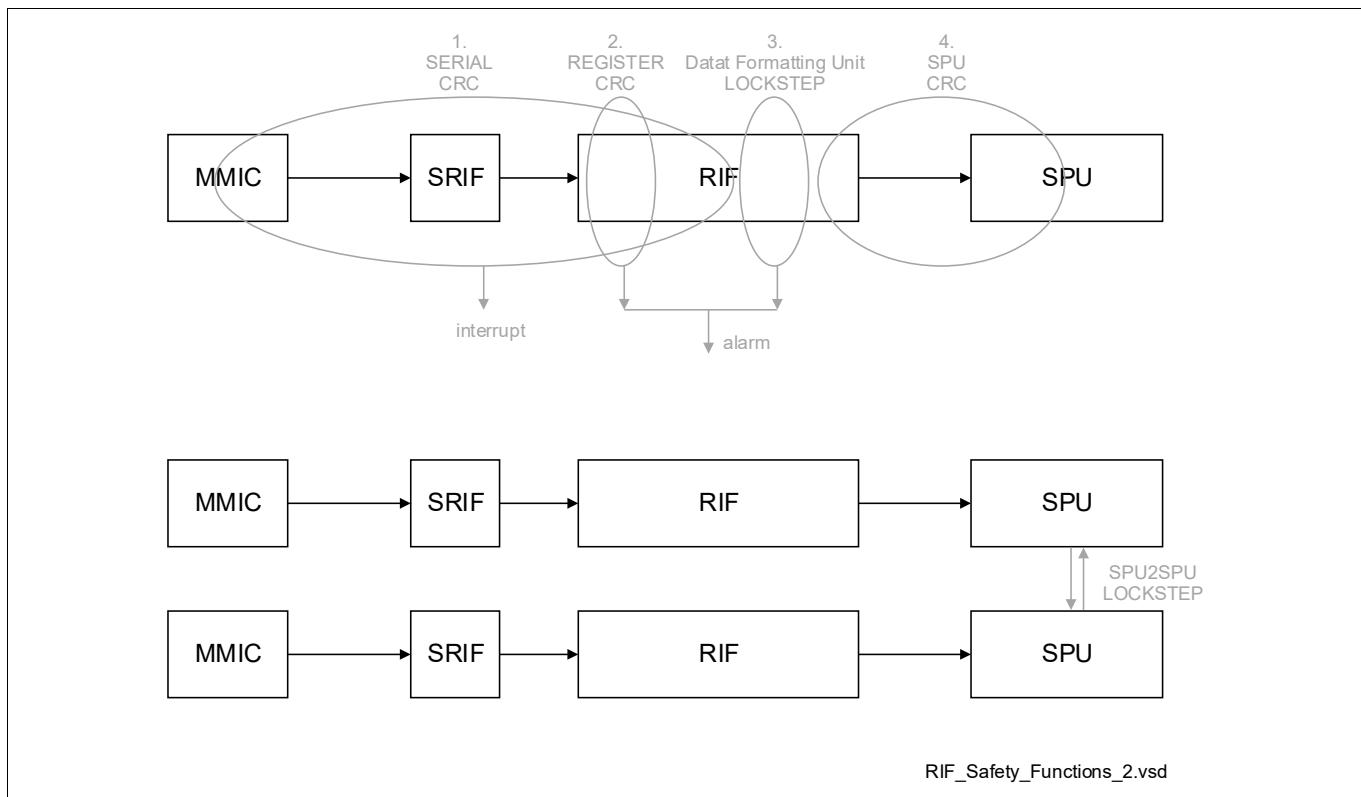

The RIF module provides an optional safety feature providing increased data path integrity. The safety feature consists of:

- a lockstep function covering the data multiplexers that is controlled by the bit [FLM.MODE](#) and the DFU unit
- 32-bit CRC is compatible with the TriCore CRC-32 implemented algorithm. It is done on the 32-bit RIF data output to the SPU.

## Radar Interface (RIF)

The safety feature is disabled by default, and can be enabled by software by using the bit-fields **SFCON.SPUCRC** and **LOCKI**. When enabled, the CRC values are attached at the end of the data stream for each ramp as a 32-bit value, and delivered in one move to the SPU. If the lockstep comparator detects mismatch, an SMU alarm is triggered.

The [Figure 301](#) shows an overview of all safety functions in the RIF module.

**Figure 301 Safety Functions Overview**

## Radar Interface (RIF)

## 24.3.8.3 Real and Complex Sampling

The diagram below describes two scenarios: first, where each of the four lanes delivers one real sample (a, b c, d), and second, where two lanes deliver one complex sample (r and i), and the second two lanes second complex sample (R and I).

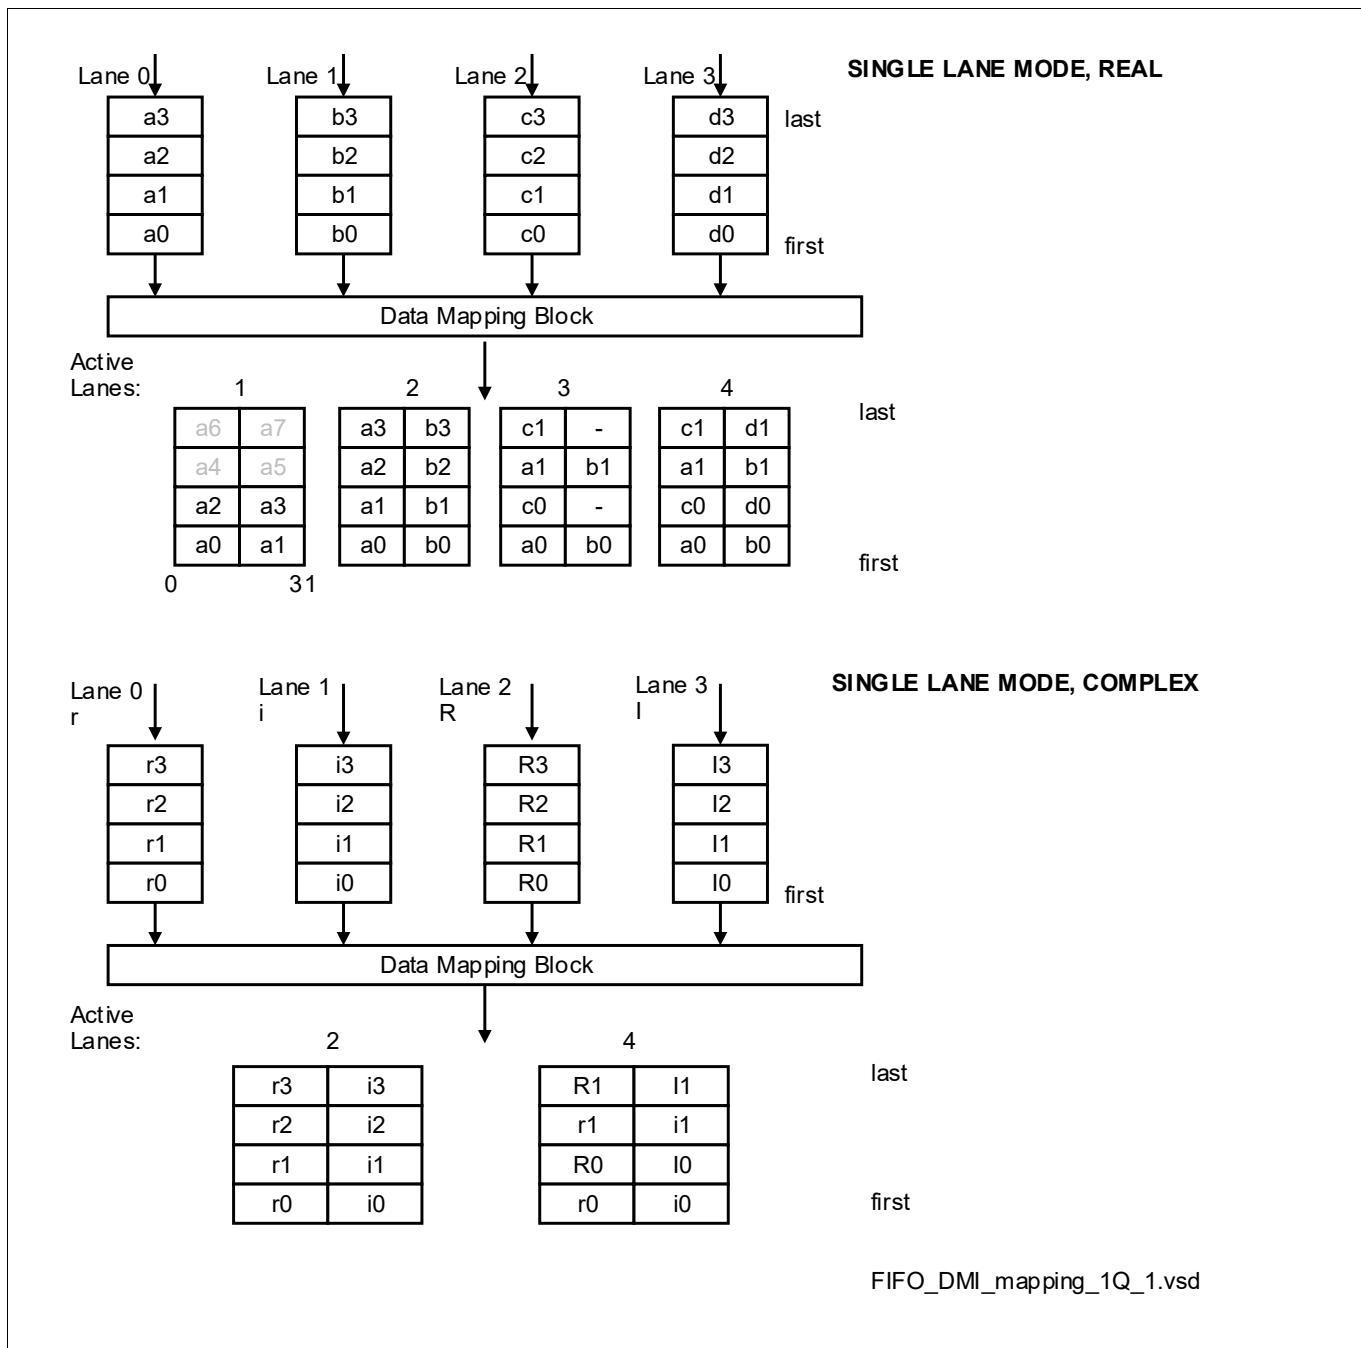

Figure 302 Single Lane, Real and Complex Sampling

## Radar Interface (RIF)

### 24.3.8.4 Multi Lane Real Sampling

The diagram below describes two scenarios: first, where pairs of FIFOs deliver high speed streams, and second, where four FIFOs deliver very high speed streams from one ADC.

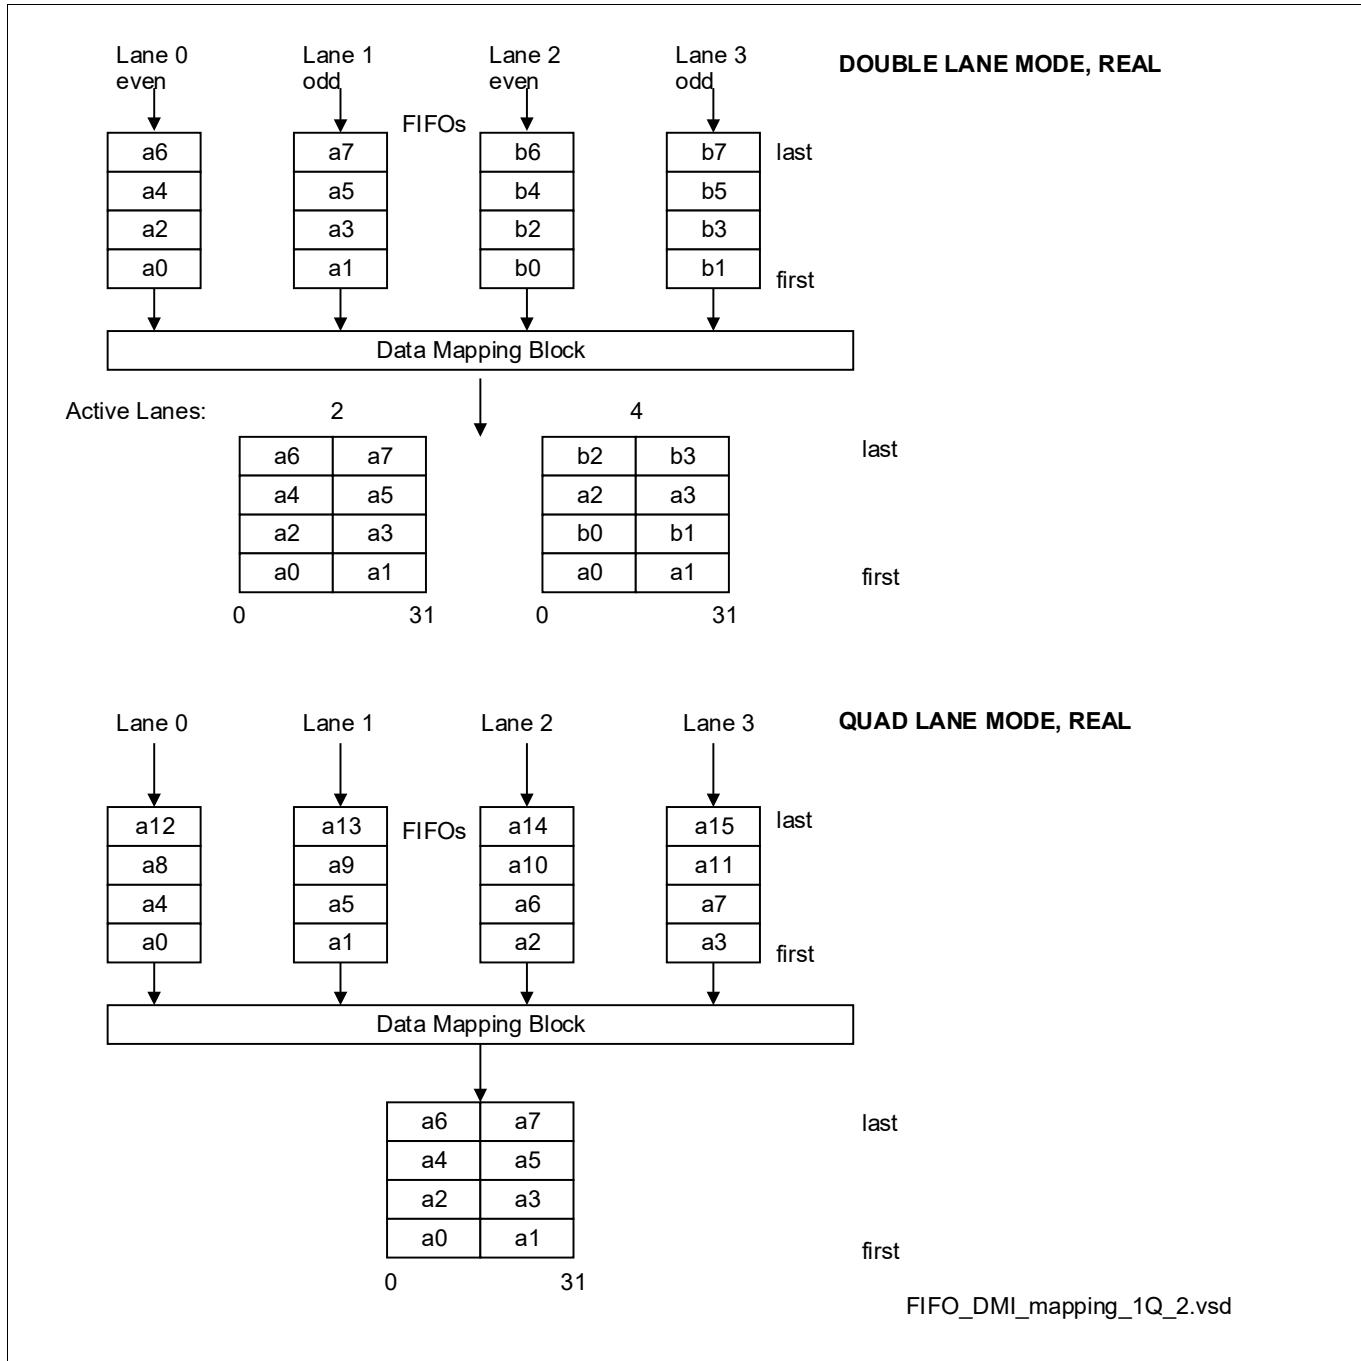

Figure 303 Multi Lane Real Sampling

### 24.3.8.5 Multiplex Complex Mode

This mode is only supported for TC3Ax. It can be activated by setting the **FLM.MULCMPX** bit to 1. In this mode, each of the four lanes deliver both the real and the imaginary components of the complex samples successively. The diagram below describes two scenarios: first, real component ( $r, R, ar, AR$ ) of the complex sample arrives first, followed by the imaginary component ( $i, I, ai, AI$ ), and the second where imaginary component of the complex sample arrives first, followed by the real component. This can be controlled using the bitfield **FLM.EXPIQ**. Note

## Radar Interface (RIF)

that **FLM.EXPIQ** can only be set to 1 when each LVDS lane is set deliver complex data by setting the bitfield **FLM.MULCMPX** to 1. Moreover, current internal ADCs are not capable of transmitting I and Q samples on a single LVDS lane. Therefore, use of external ADCs which are capable of interleaving I and Q data on a single LVDS lane is required to implement this mode.

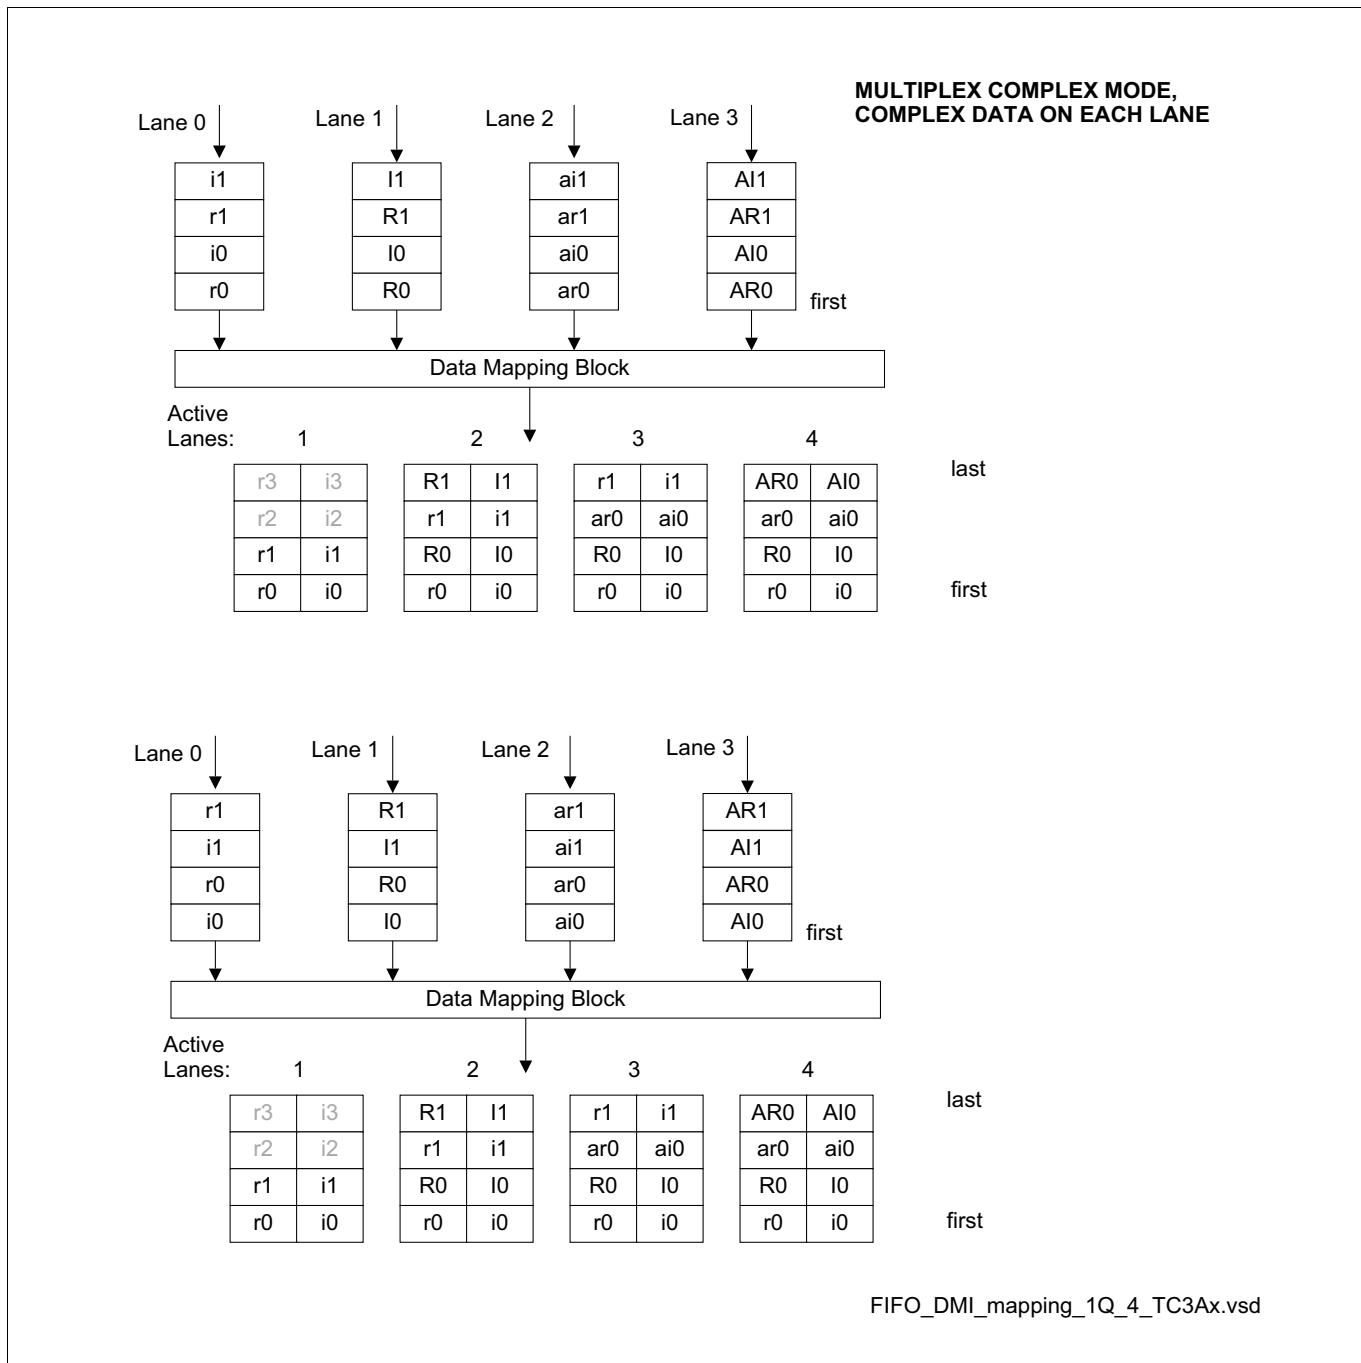

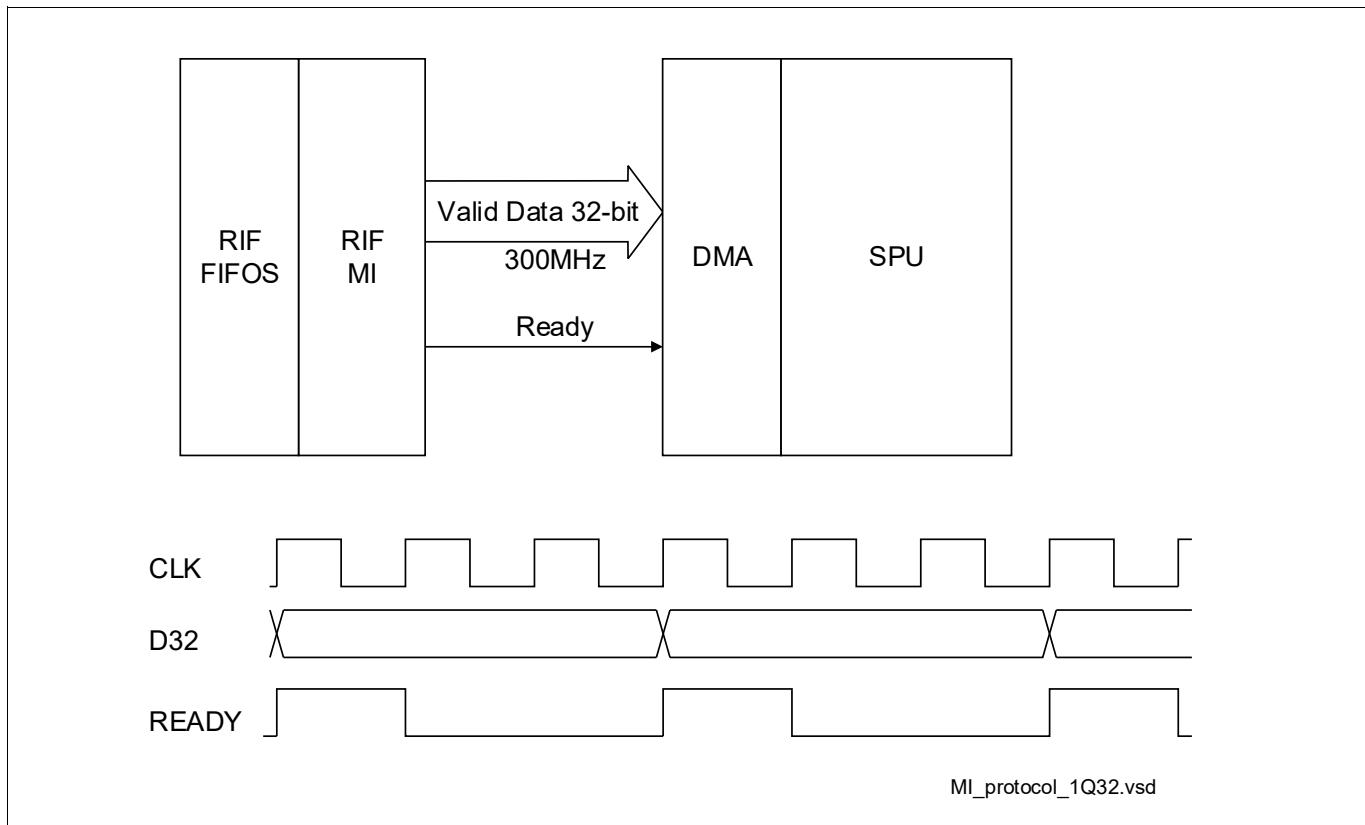

Figure 304 Multiplex Complex Sampling for Tc3Ax

## Radar Interface (RIF)

### 24.3.9 Data Memory Interface (DMI)

The data interface to the internal FFT provides the following signals:

- Output Signals
  - 32-bit data
  - READY signal

**Figure 305 Data Memory Interface (DMI)**

#### 24.3.9.1 Data Format of the Memory Interface

The ADC samples are ordered in Little Endian order in the memory interface, formatted as configured in the Data Formatting Unit.

## Radar Interface (RIF)

### 24.3.10 Radar State Machine (RSM)

The radar state machine RSM provides monitoring of the radar operation cycle.

The radar use-cases can be sub-divided into two classes: “[External ADC Use-Case](#)” and “[Internal ADCs Use-Case](#)”.

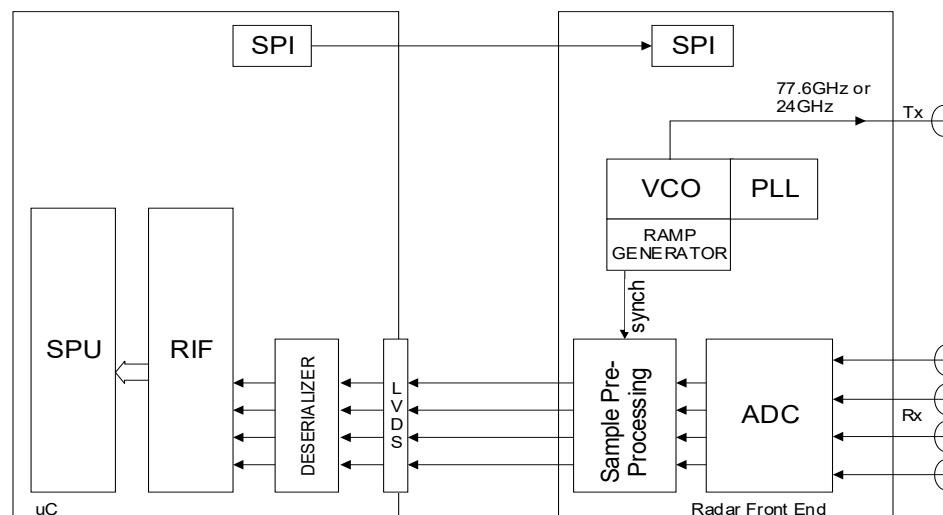

### 24.3.11 External ADC Use-Case

The optimal external system provides a pre-processed set of ADC samples for each ramp of the RF transmitter, filtered to remove invalid samples, and terminated with a CRC compatible with the CRC checker integrated into the RIF. The CRC is optional but allows the integrity of the data transferred into the RIF to be verified. In this kind of system, the RIF Frame Watchdog can be used to maintain or verify synchronisation of the RIF with the frequency ramps of the external RF components

For legacy systems using “free running” ADCs which sample continuously, the external system can provide the optional RAMP1 signal marking the start and the end of the linear part of each ramp. The RAMP1 signal is active only during the valid part of the frequency ramp and allows the RIF to filter the incoming stream of samples to ensure that only valid samples are. Interrupts can be triggered, if enabled.

The RAMP1 signal generated by the radar front-end must satisfy the sample and hold requirements relative to the FRAME signals as defined in the datasheet. Because this timing puts limit on the maximum achievable baud rate, and uses more pins, it is recommended to use the watchdog timer mode using the Frame Watchdog.

In TC3Ax, Ramp1 signal is not supported and Frame Watchdog must be used instead.

**Figure 306 System View: External ADCs with Pre-processing**

## Radar Interface (RIF)

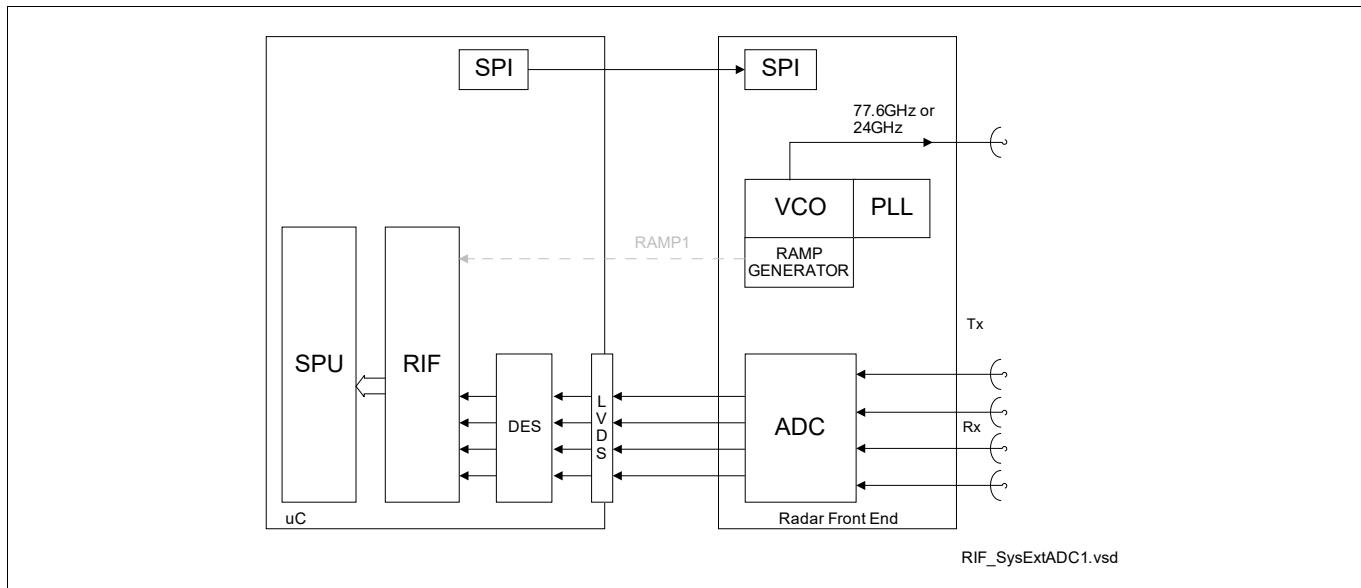

Figure 307 System View, External ADCs Use-Case

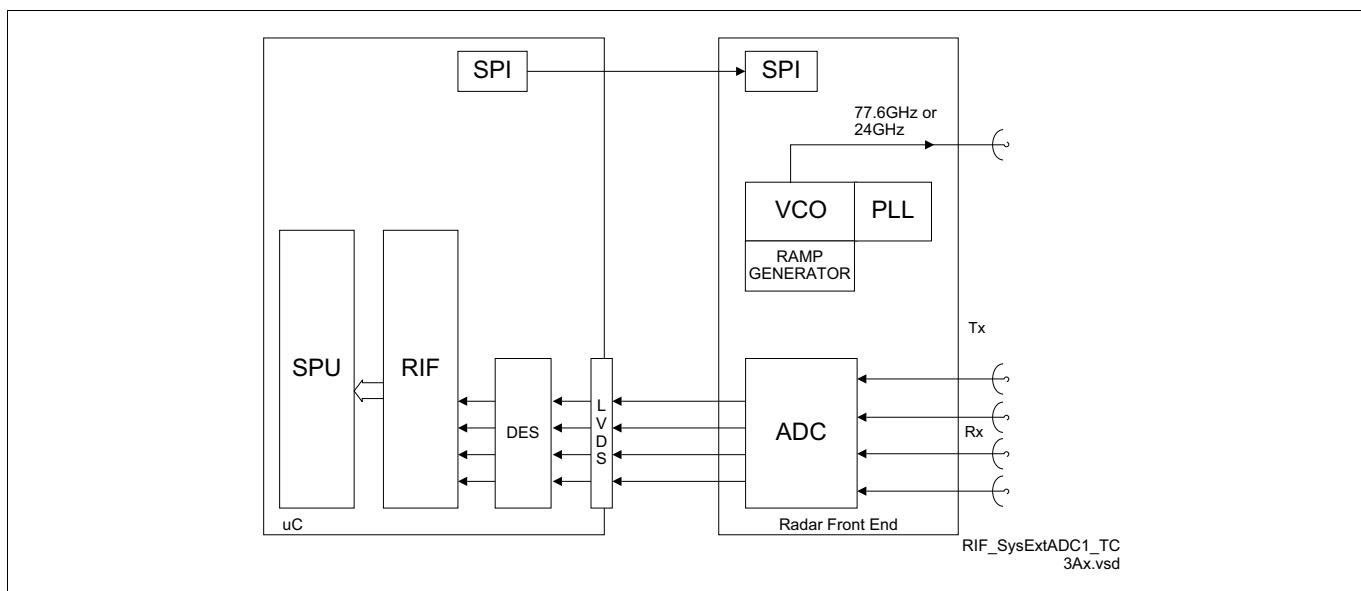

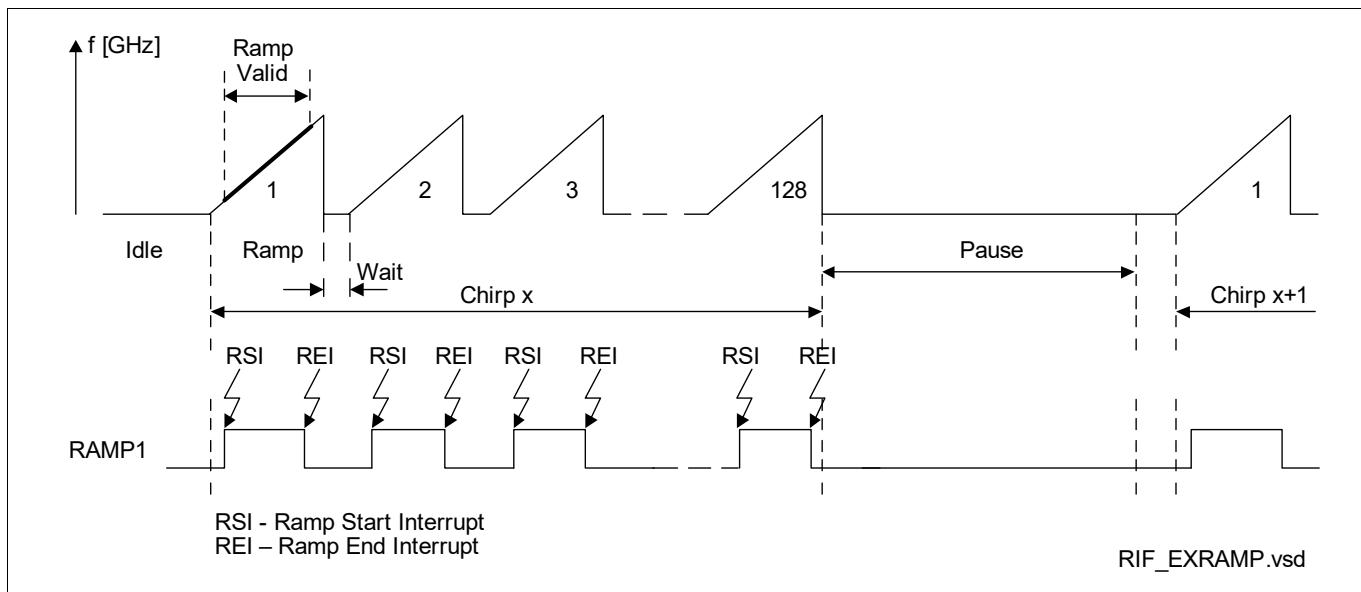

Figure 308 System View, TC3Ax External ADCs Use-Case

## Radar Interface (RIF)

**Figure 309 Radar Operating Cycle, External Radar Front-End**

The radar cycle is a simple sequence consisting of the following steps:

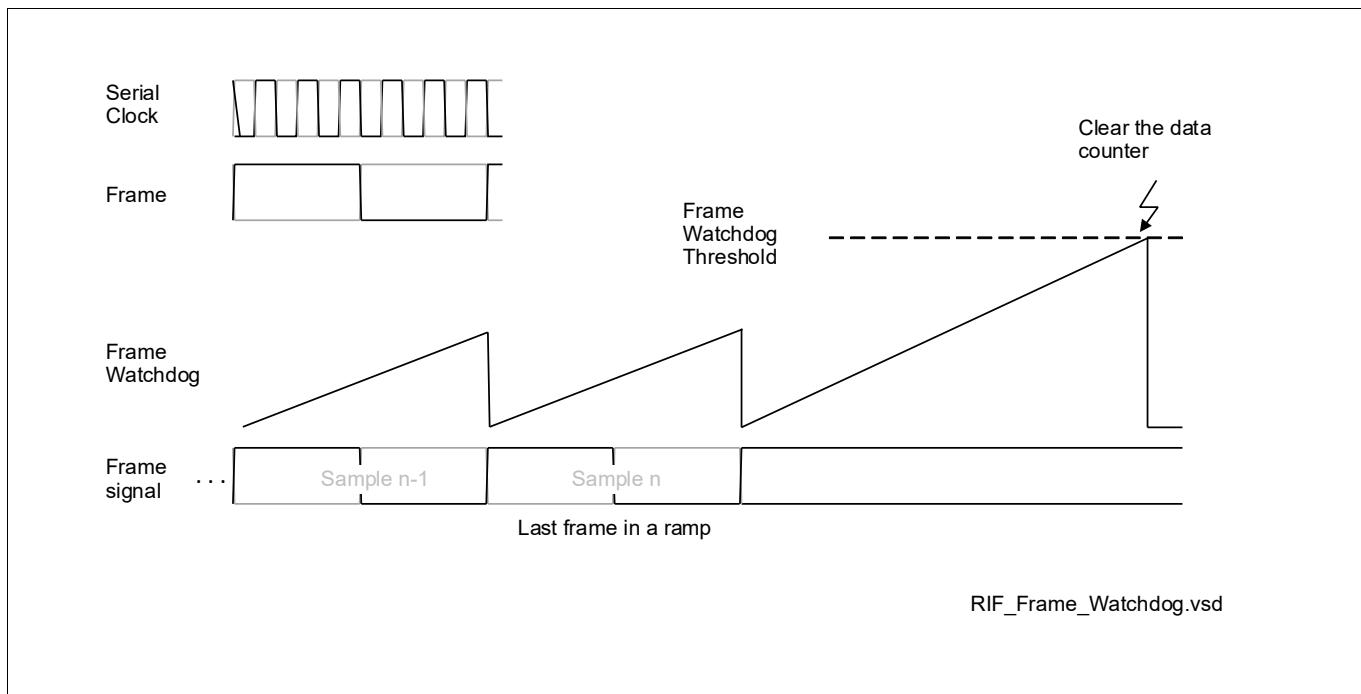

- CPU starts the RIF module
- CPU starts the external ADC by sending an SPI message
- CPU sends SPI command to start the ramp(s), the external ramp generator starts and when the ramp is in its valid part, the external ADC starts sending samples
- The external ADC completes the ramp by itself. In parallel the RIF module counts the samples and the ramps and raises an error in case of mismatch.

### 24.3.11.1 Frame Watchdog

Frame Watchdog is one 10-bit free running timer monitoring the frame signal and being reset by the incoming frames. It is driven by the RIF kernel frequency  $f_{ADAS}$ . It is configured to count for longer than the maximal serial frame length that appears in an application (CRC frame length if CRC is used, otherwise data frame length). If there is a pause in the data stream, the watchdog timer reaches the threshold. This is interpreted as an end of a ramp and the sample counter is reset to zero. The Frame Watchdog is started when receiving a frame, and stopped when the FWDG event has occurred, until the next frame is received.

Frame watchdog also monitors the data flow from the internal ADCs.

After reset, the default value of the register **FWDG.THRESHOLD** is 0. With this setting, the frame watchdog does not generate Ramp End interrupts or Frame Watchdog interrupts.

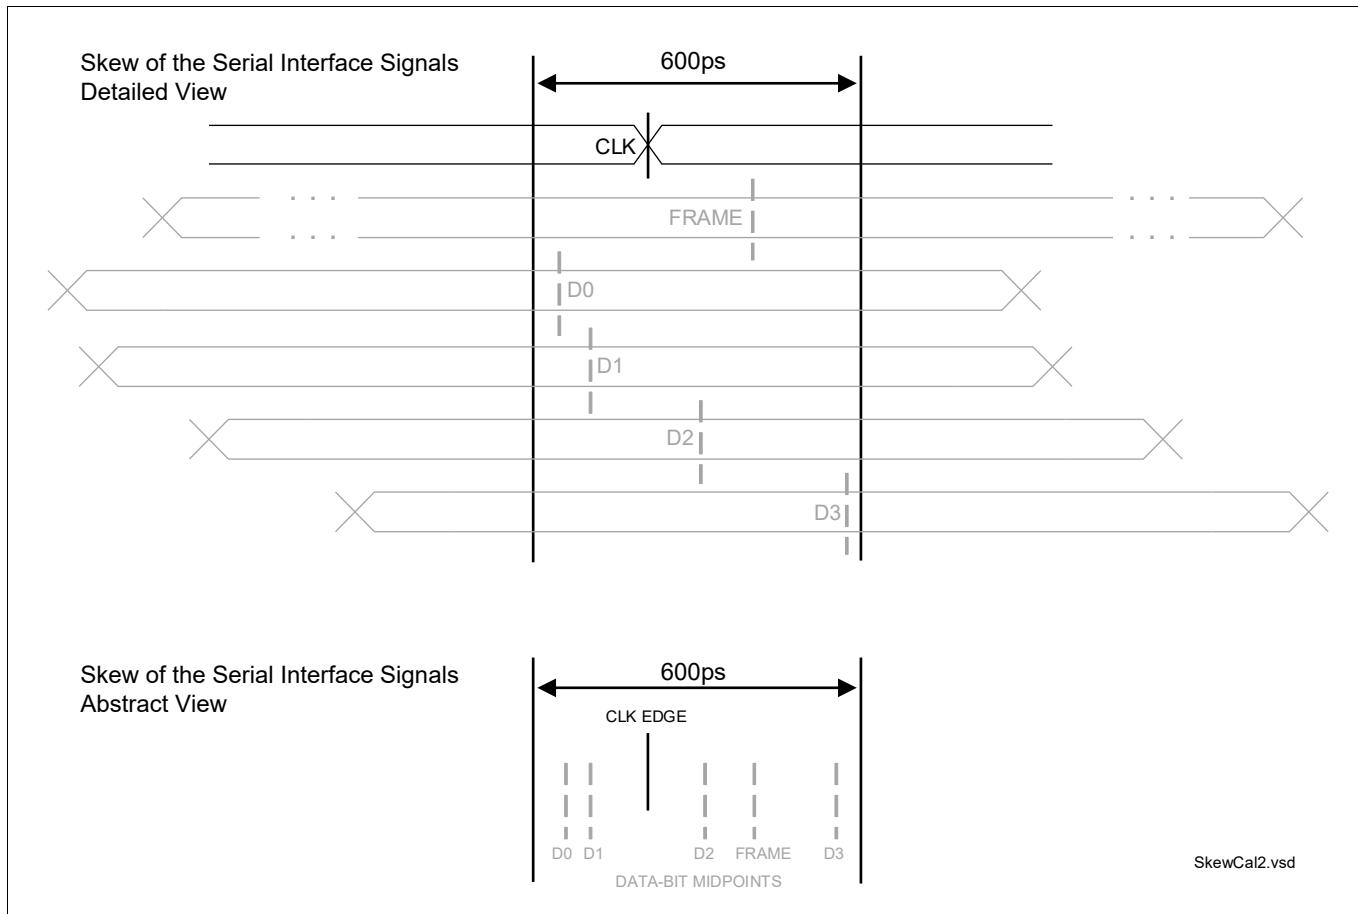

**Radar Interface (RIF)****Figure 310 Frame Watchdog Operation**

## Radar Interface (RIF)

### 24.3.11.2 On-Chip Signal Delay Calibration

To support TC3Ax data rates up to 600Mbit/s, a new skew calibration algorithm will be introduced.

Each SRIF quad comprises 4 LVDS data receivers supporting the IEEE 1596.3 standard with data rates up to 400MBit/s. This standard allows a skew of 600ps between any two LVDS input signals. A dedicated calibration mode allows to compensate for these skews.

**Figure 311 Overview of the Allowed Skew**

The skew calibration feature can calibrate the skew only for baud rates in the range of 200MBaud to 400MBaud. Do not use the skew calibration for baud rates below 200MBaud. Use the uncalibrated interface considering the timings defined in the data sheet.

The deserializer unit needs to calibrate the delay lines at least one time at the start of the application. The command for the external device to start the calibration is sent over the SPI interface.

During the initialization phase of the system the user just needs to trigger the skew compensation (Calibration Enable, bit **ESI.CALEN**) and wait till all serial channels have been compensated. The end of this sequence will be indicated to the user by special control signals (Calibration Busy, bit **ESI.CALBSY** and Calibration Status, bit **ESI.CALSTAT**).

The compensation is triggered by the user via SFRs but then steered entirely by a state machine within the RIF. To enable this feature it is necessary to set the external LVDS transmitter (radar front-end) into a special calibration mode via the SPI interface.

One calibration is necessary after system start before the interface is used. Calibration should be repeated if:

- Data seems corrupted, indicated by CRC-errors.
- A significant change in the operating environment of the system has been detected.

## Radar Interface (RIF)

### 24.3.11.3 On-chip Signal Delay Calibration Sequence

In order to perform delay calibration, the following sequence must be followed:

- Disable the deserializers by using the bits **IPI.EN0, 1, 2, 3**
- Initiate the calibration pattern transmission by the radar front-end, for example by sending a corresponding QSPI frame
- Start the calibration procedure by writing "1" to **ESI.CALEN**, and ensure that the calibration has been successful by monitoring the status bits **ESI.CALBSY** and **ESI.CALSTAT**.

When performing delay calibration after reset, the step 1 can be omitted, because the default value of the **IPI.ENx** bits is disabled.

When performing delay recalibration during run-time, it has to be done after a ramp has finished, by following the three steps above.

Afterwards, after successful calibration, the normal operation can be resumed by initiating the next ramp at the radar front-end.

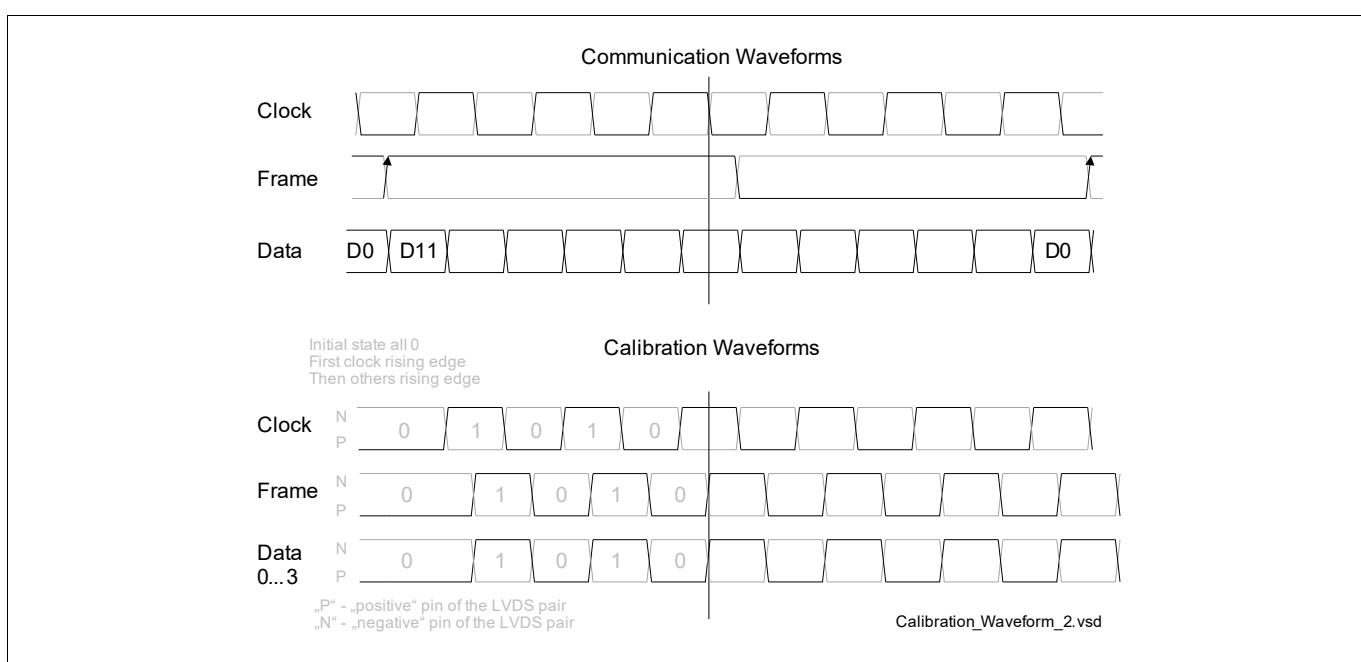

The total time allowed for calibration is 10us, SPI communication time not included.

The application software should check by polling the RIF module if the calibration sequence has finished within the time window as defined above, because heavily distorted signals on the serial lines can cause the calibration pattern to run without terminating.

**Note:** *If the application software activates an application reset for the RIF module while CCUCON5.ADASDIV=0<sub>B</sub>, the start-up software cannot update the default delay calibration value inside the RIF module. The application software must take care that CCUCON5.ADASDIV!=0 when triggering application reset and the RIF module is used afterwards.*

### 24.3.11.4 Waveforms Required to Perform On-Chip Signal Delay Calibration

**Figure 312** shows the optimal waveform for performing delay calibration of the RIF serial signals compared to the normal communications waveforms. All signals Clock, Frame and Data toggle with same frequency. Frame and Data rising edges are delayed relative to the Clock rising edge for a quarter of the toggle period.

**Figure 312 Delay Calibration Waveforms**

## Radar Interface (RIF)

The skew between Frame and Data signals must be within the specified skew limits of +/-600ps to ensure correct behaviour of the calibration circuit.

The register field RIF.ESI.CALBSY is set when calibration starts. The calibration is finished when the register field RIF.ESI.CALBSY is cleared. Successful completion of calibration is signaled by setting the register field RIF.ESI.CALSTAT.

The completion of calibration can also be signaled by interrupt. The interrupt is enabled by setting the RIF.INTCON.CALE register field. If an interrupt occurs, it can be determined if the cause was end of a calibration by reading the INTCON.CALF register field. This will be set if a "calibration end" event has occurred.

The calibration sequentially attempts to set to zero the skew on the signals

- FRAME (DATA0)
- DATA0
- FRAME (DATA1)
- DATA1
- FRAME (DATA2)
- DATA2
- FRAME (DATA3)
- DATA3

Calibration is only attempted for enabled data channels. An independent skew compensation is determined for each data channel for the single FRAME input to the MCU.

If, at any point in the calibration sequence, a channel remains uncalibrated even if the delay is set to maximum or minimum direction, the clock delay for the channel is adjusted by one step in the other direction (e.g. if the delay for the signal under calibration is at maximum, then the clock delay is adjusted one step towards minimum value) and the entire calibration process is restarted.

### 24.3.11.5 Delay Adjustment During Calibration

Compensation for skew is made using a block comprising seven, identical delay elements. The delay through each element varies with the operating point of the MCU .

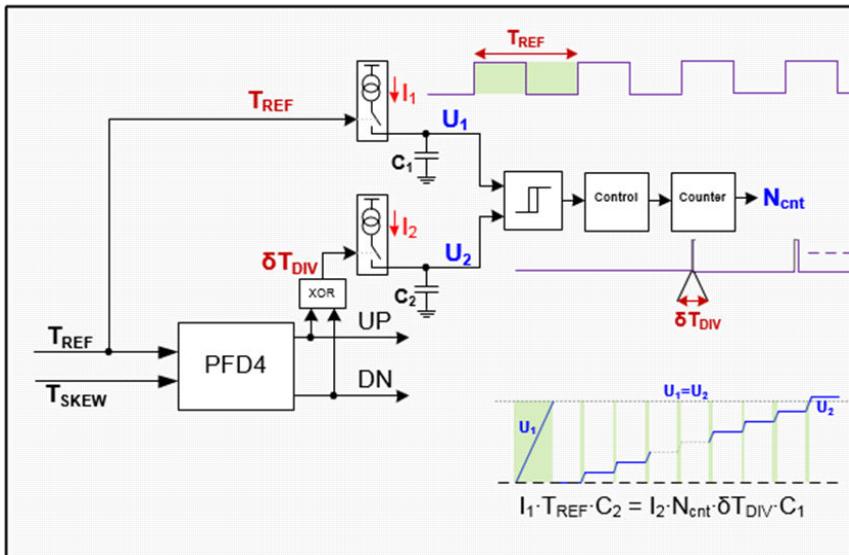

**Table 1138 Variation of Delay with Operating Point**

Corner	LSB Delay
Nominal	150ps
Slow Process/VDD <sub>Min</sub> /TEMP <sub>Max</sub>	240ps
Fast Process/VDD <sub>Max</sub> /TEMP <sub>Min</sub>	75ps

### 24.3.11.6 Skew Measurement During Calibration

Skew is measured by a charge measurement process. A reference level is established by using a current source to charge a capacitor for one period of the reference signal. A second signal is derived from the phase difference between the reference signal and the signal under test. The second signal is used to charge a second capacitor. The skew value is a count derived from the time needed for the second capacitor to reach the voltage stored on the first capacitor.

## Radar Interface (RIF)

**Figure 313 Skew Measurement schematic**

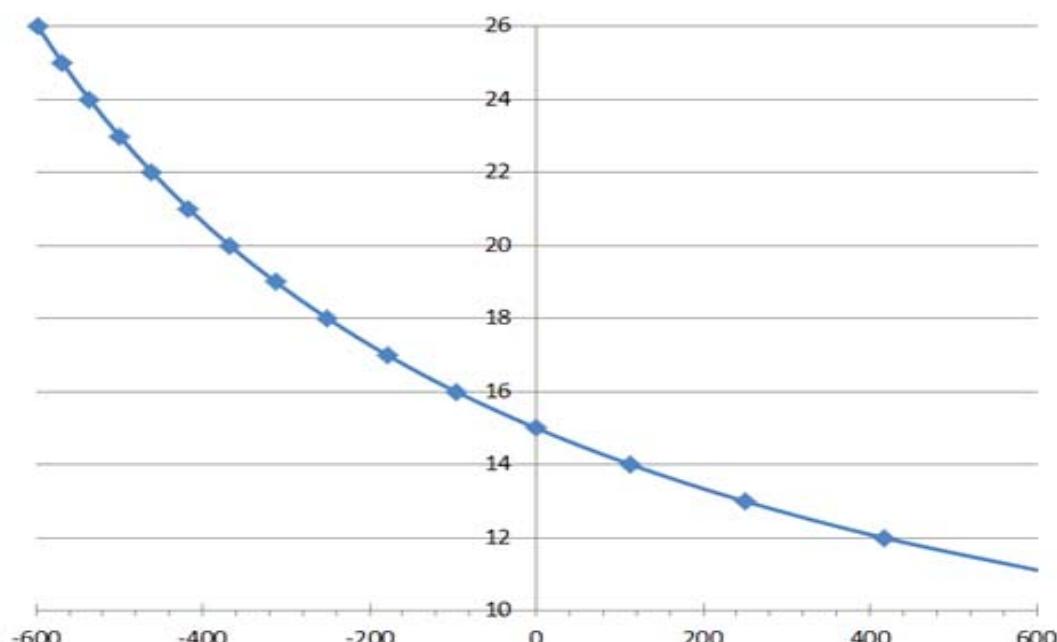

It's a consequence of this method that the relationship between the count and the skew is non-linear.

(24.1)

$$N_{CNT} = \frac{I_1 \times T_{REF} \times C_2}{\sigma T_{DIV} \times C_1 \times I_2}$$

The method is also prone to variation between devices caused by circuit mismatch. Calibration during production test to determine the reference count equivalent to zero skew is required.

The reference count is expected to vary around a value of 16 between limits of 14 and 18.

**Figure 314 Relationship between skew and count**

---

**Radar Interface (RIF)****24.3.11.7 Reference Skew Value and Error Limits**

The reference value and positive and negative error limits are determined at device calibration during production test and are stored in the UCB\_SSW table. They are transferred to the RIF.SKEWCAL register by system firmware and should not be modified by application software.

The UCB values are stored in the fields RIF\_SKEWCAL.ACCEP, RIF\_SKEWCAL.ACCEC and RIF\_SKEWCAL.VALUE

The RIF\_SKEWCAL.CALRESULT field contains the last measured skew value. This field is intended for use during calibration of the RIF skew measurement function at production test. It will only contain meaningful data after production test calibration.

The value read from this field during production test will be stored in the UCB\_SSW table.

*Note:* SKEWCAL register is not applicable for TC3Ax

**24.3.11.8 RAMP1 Signal**

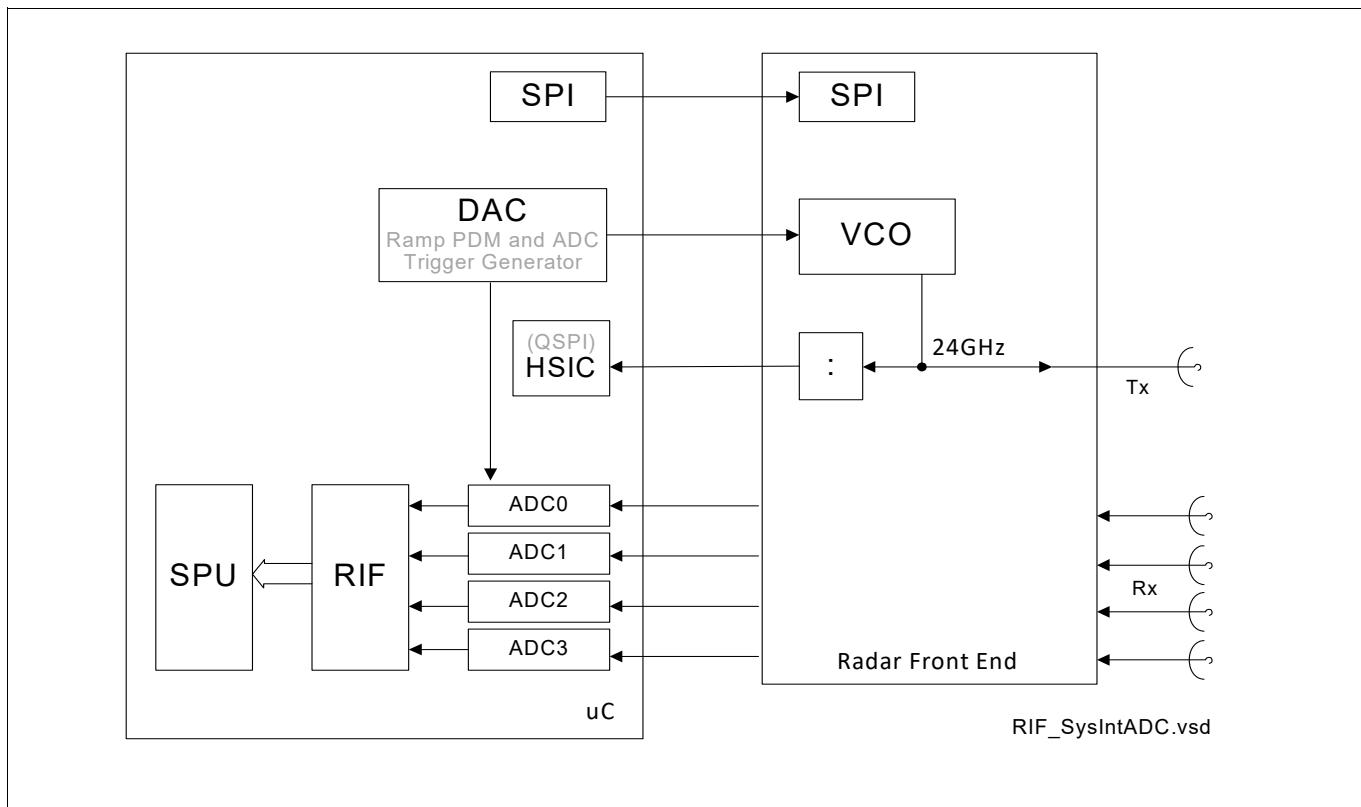

RAMP1 resets the sample counter at activation. A check is performed to verify that the programmed number of samples has been received at deactivation. If a mismatch is detected, the error interrupt is raised.

This feature is unavailable in TC3Ax.

## Radar Interface (RIF)

### 24.3.12 Internal ADCs Use-Case

In this use-case, the internal ADC is used for sampling the radar data.

**Figure 315 System View, Internal ADCs Use-Case**

The radar interface is an input only receiver for the data provided by the internal ADC. Control functions for the internal ADC have to be provided by other modules like HSPDM or timer modules.

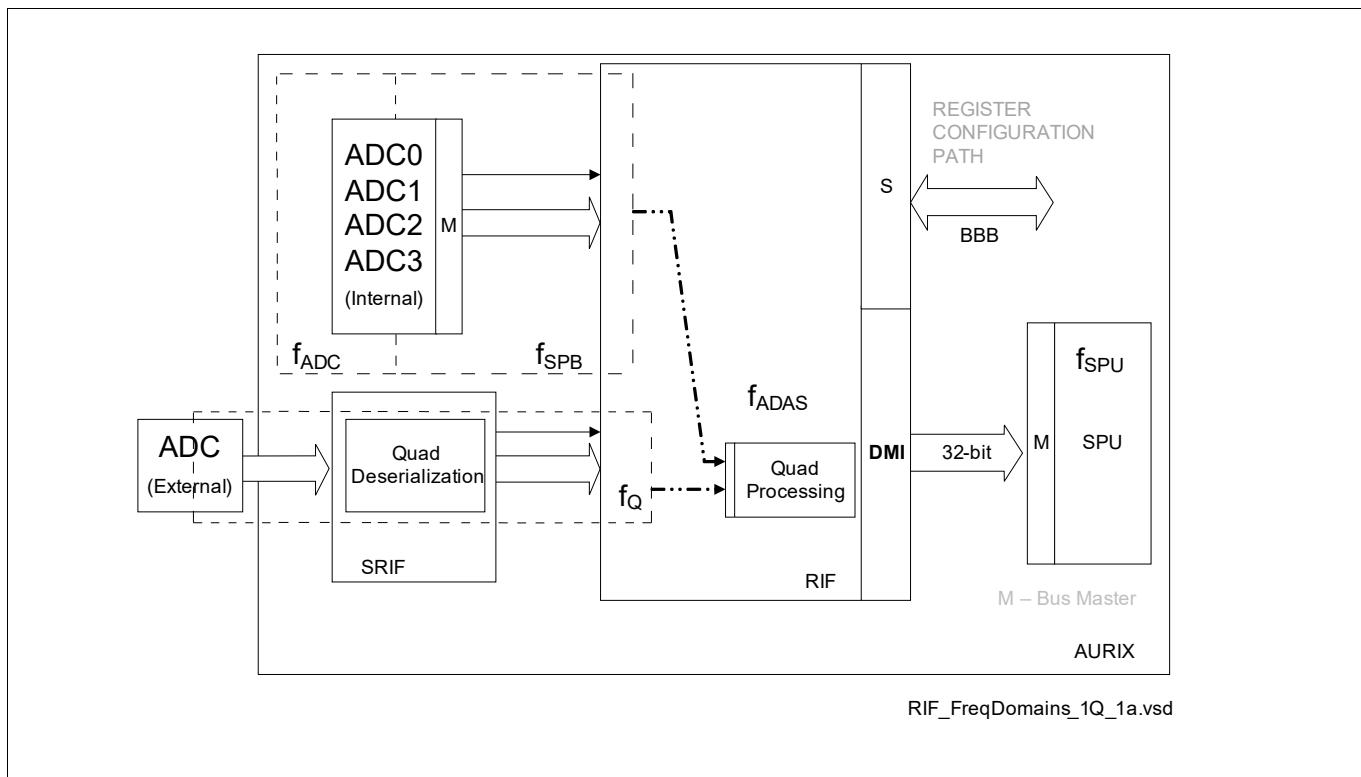

Internal ADC use-case uses the Frame Watchdog feature. It sends only valid samples with pauses between the ramps.

### 24.3.13 Frequency Domains

The RIF module contains several asynchronous frequency domains.

There are four internal ADCs that share the FIFO with Quad deserializer and support the same modes of lane management as the external ADCs:

## Radar Interface (RIF)

**Figure 316 Top View of the Frequency Domains**

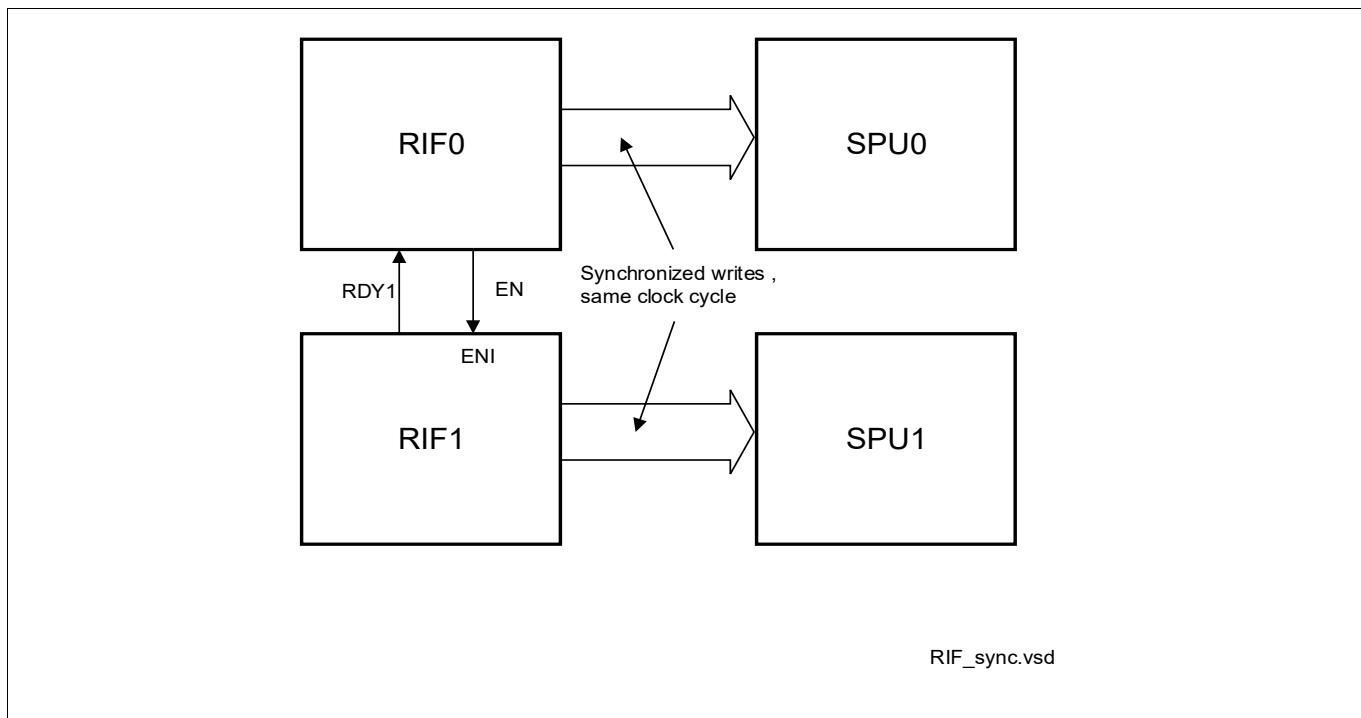

- Quad 0 frequency domain  $f_{Q0}$ , and internal ADC Quad  $f_{Q4}$
- Core frequency domain  $f_{ADAS}$
- ADC frequencies  $f_{ADC}$  and  $f_{SPB}$

### 24.3.13.1 Synchronization of two RIF Modules

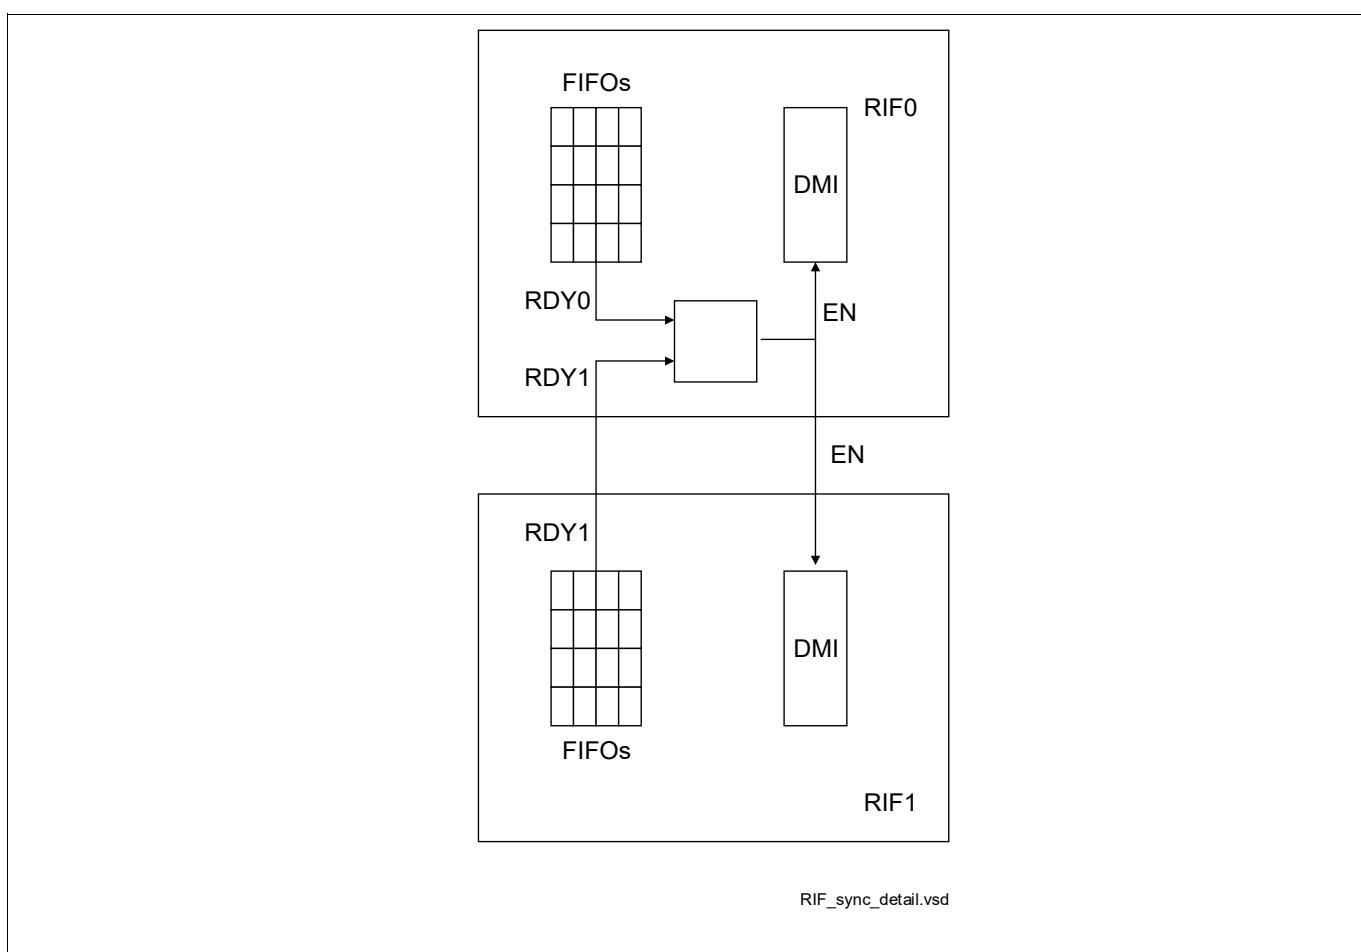

Two RIF modules can operate synchronously and provide their corresponding data to in the same clock cycle, enabling lockstep operation of the Signal Processing Units (SPUs). RIF synchronization is also necessary when two RIF modules communicate with one SPU. The RIF0 module takes the role of the “master”, generating from the ready signals RDY0 and RDY1 the enable signal EN for both RIF0 and RIF1 module.

Two RIF modules are capable of maintaining synchronization if the skew between the inputs of the two RIF instances is up to two frames long.

### Radar Interface (RIF)

**Figure 317 Synchronization of RIF Instances**

**Figure 318 Synchronization Architecture**

---

## Radar Interface (RIF)

### 24.3.13.2 Interrupts

There are two interrupt lines which are driven by several event sources. They are:

- ERR Interrupt
  - CRC Error Channel 0 - triggered on CRC Error on Channel 0
  - CRC Error Channel 1 - triggered on CRC Error on Channel 1
  - CRC Error Channel 2 - triggered on CRC Error on Channel 2
  - CRC Error Channel 3 - triggered on CRC Error on Channel 3
  - RAMP1 Error - triggered if at RAMP End event the number of received samples is not equal to the programmed value
- INT Interrupt
  - Calibration End - triggered after the Calibration Sequence of the input delay lines has been finished
  - Frame Watchdog Overflow - triggered when the watchdog timer value is about to exceed the threshold value
  - Ramp Start - triggered when the first sample of the new ramp has been received
  - Ramp End - triggered when the Frame Watchdog is about to exceed the threshold value or the RAMP1 signal goes inactive

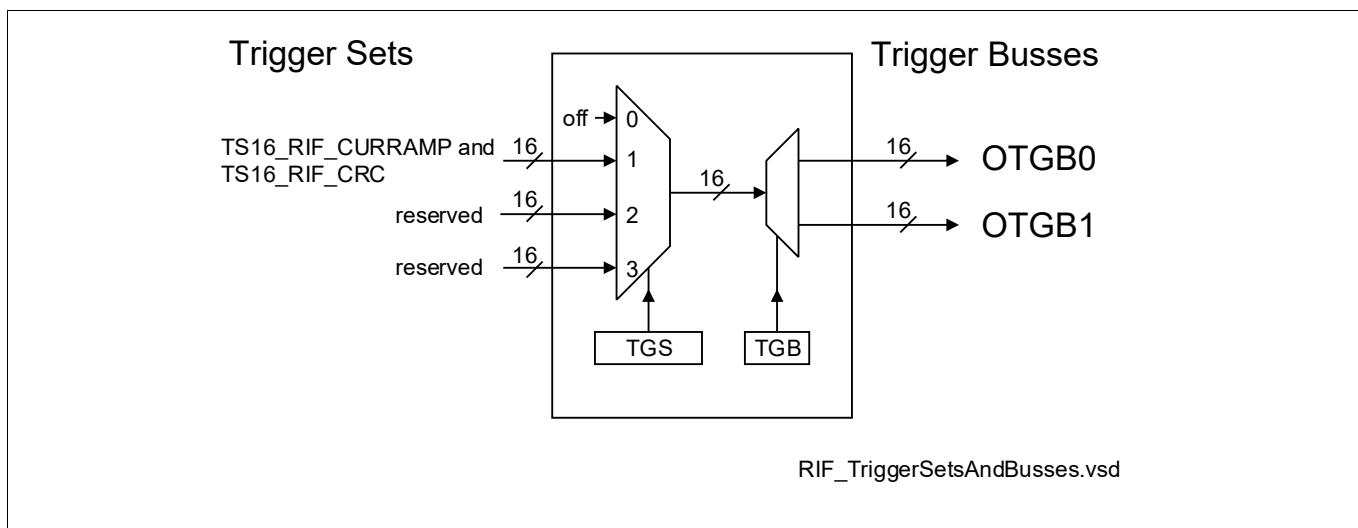

Each source have its own enable, flag, set and clear bit, see register **INTCON**.

## Radar Interface (RIF)

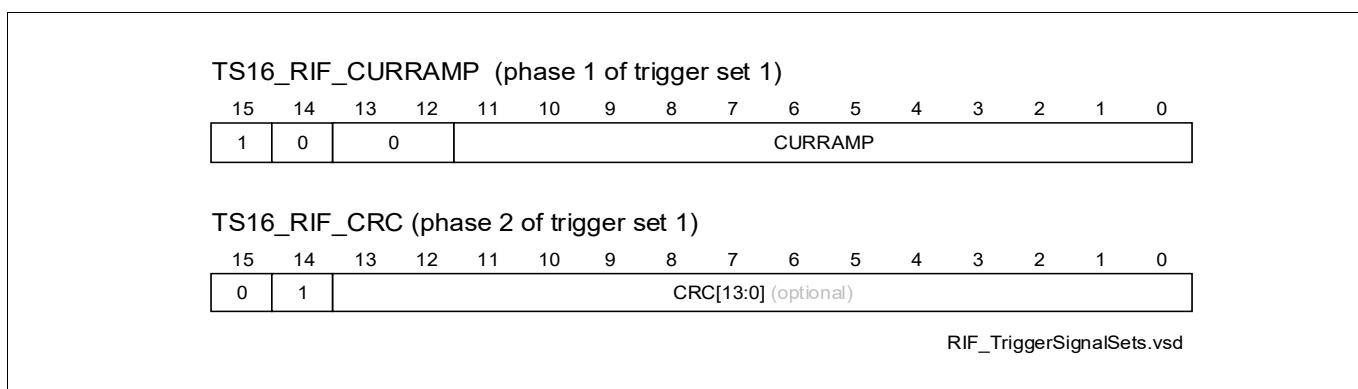

### 24.3.14 OCDS Trigger Sets

In order to support the debugging activities, the RIF module provides a set of internal signals to the on-chip debug system OCDS. An overview of this feature is shown in [Figure 319](#). Its configuration is done by using the bits **OCS.TGS** and **TGB**.

An edge on any module internal signal belonging to the selected set going out on one of the two OTGB busses triggers an action of the OCDS system.

**Figure 319 Overview of the Trigger Sets and Busses**

**Figure 320 Overview of the Trigger Signal Sets**

**Table 1139 RIF Trigger Sets**

Name	Description
TS16_RIF_CURRAMP	Counter value of the ramp counter
TS16_RIF_CRC	CRC0 value for the latest ramp

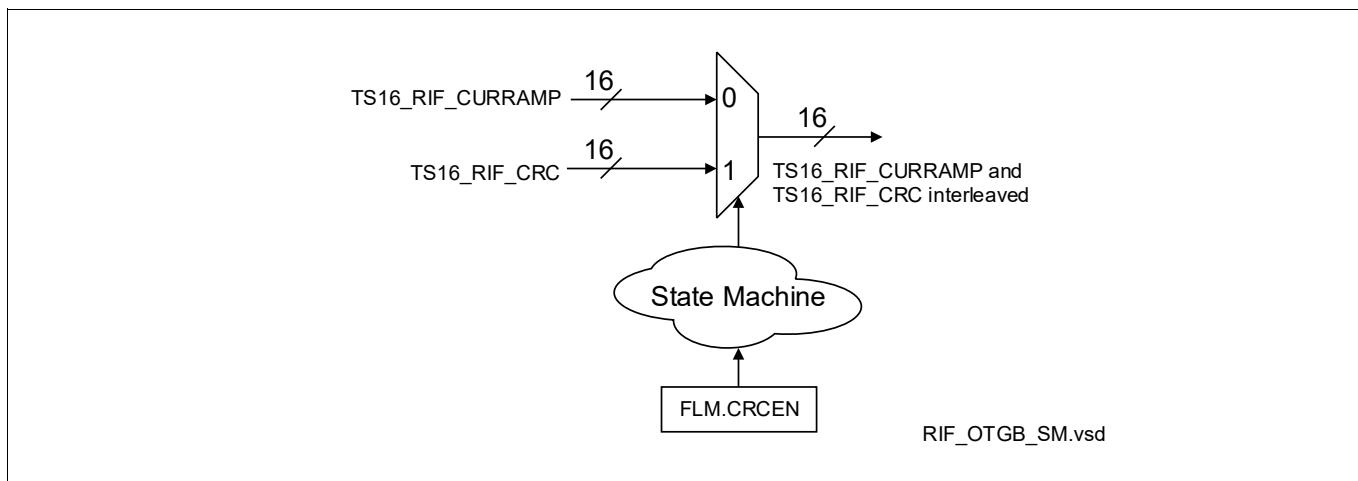

**Attention:** The value **CRC0** corresponds to **Channel 0** if no channel swapping is performed, see [FLM.FSWP](#) and [FLM.MODE](#). If swapping is enabled, the **CRC0** corresponds to the appropriate channel, see [Figure 300](#).

The trigger set 1 is used, the sets 2 and 3 are not used (padded with 0).

Set 1, two times 16 bit:

## Radar Interface (RIF)

- 12 bits: **RSM1.CURRAMP**
- 14 bits: CRC[13:0]. If the CRC is disabled, the first value **RSM1.CURRAMP** is output instead.

**Figure 321 Trigger Set State Machine**

The state machine toggles between TS16\_RIF\_CURRAMP and TS16\_RIF\_CRC if the CRC is enabled, or statically selects TS16\_RIF\_CURRAMP if the CRC is disabled. The toggling is done with the  $f_{SPB}$  frequency. The state machine is started when OCDS is enabled and a valid RIF Trigger Set is selected () .

### 24.3.15 Register CRC

The register CRC uses a 32-bit polynomial compatible with the TriCore CRC instruction and assumes that the register contents are converted to an LSB first, serial data stream.

- The RIF module generates the Register CRC using all the “rw” configuration bit-fields, from the registers **ESI** to **SFCON**
- The **BPI\_FPI Registers** and the **REGCRC** register itself are not part of the Register CRC
- The unused register address space between **DBGDLY1** and **DBG0** (address offsets  $005C_H$  to  $0007C_H$ ) is excluded from the CRC calculation (the addresses are skipped rather than the data being replaced by  $0000\_0000_H$ )
- The volatile “rh” bit-fields showing status data that are modified during run time by the RIF module itself are replaced by zeros
- The write-only “w” bit-fields return “0” on read and therefore are included in the Register CRC as zeros

When calculating the register CRC, the RIF module replaces the following bits by zeros:

- **ESI.CALEN**, **CALSTAT**, **CALBSY**
- **IPI.SDDV**
- **RSM1.CURRAMP**
- **RSM2.CURSAMPLE**
- **INTCON.[X]F** bits (i.e. all the flag bits... the ENABLES are left alone & passed to the CRC)
- Entire **FLAGSSET** register
- Entire **FLAGSCL** register
- Entire **RSM2CAP** register
- **SKEWCAL.R16**
- Entire **DBGDLY0** register

## Radar Interface (RIF)

- Entire **DBGDLY1** register
- Entire **DBG0** register
- Entire **DBG1** register

The CRC polynomial runs periodically once enabled and the CRC value generated from the register contents is compared with the value stored in the **REGCRC.CRC** bit-field. If the comparison fails, than an SMU alarm is generated.

The CRC-32 polynomial is compatible with the TriCore CRC-32 algorithm.

The Register CRC is enabled and disabled by writing to the Safety Function Register **FLM.REGCRCEN**.

The control and comparison logic of the safety mechanism is replicated using negative logic. Any difference in behavior between the two sets of logic results in an alarm.

The alarm can be tested writing an invalid CRC to **REGCRC.CRC**.

The register CRC mechanism operates in a round robin fashion, it takes a value of a register and writes it to the CRC engine each  $64 f_{ADAS}$  clock cycles.

Fault in safety mechanism is latent fault and is detected by BIST, which is performed each power on reset.

It is responsibility of the application software to stop the register CRC by using **FLM.REGCRCEN**, update the configuration of the RIF, write new CRC value in the CRC register, and enable the register CRC engine again, which restarts it from the initial state.

The application software has to write this bit field at the end of the configuration update. The CRC calculated by the software has to assume that this bit field has a value of “10b = enabled”.

### 24.3.16 Operating Modes

#### 24.3.16.1 Sleep Mode

The RIF module does not support sleep mode. See the **CLC.EDIS** bit-field description.

#### 24.3.16.2 OCDS Suspend Mode

The RIF module supports hard suspend. After hard suspend, the module should be reset. Soft suspend is not supported. See the **OCS.SUS** bit-field description.

### 24.3.17 Module Implementation

This section describes the product specific configuration of the RIF module instances with the clock control, port connections, interrupt control, and address decoding.

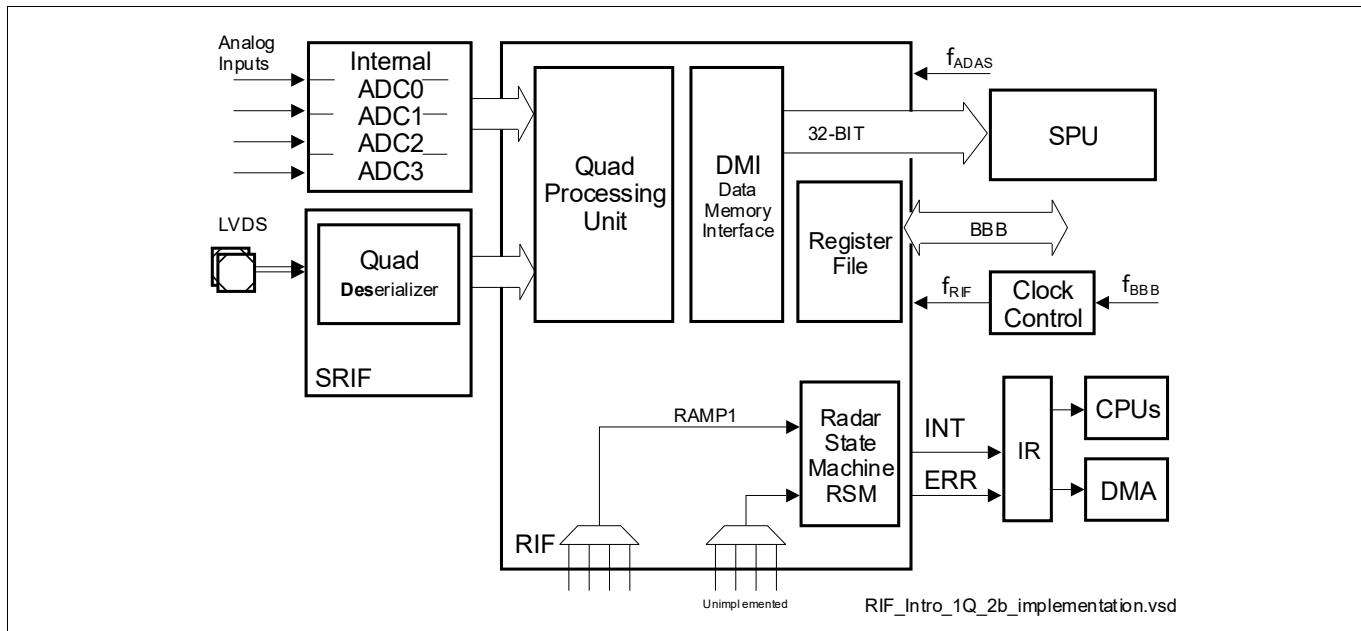

#### 24.3.17.1 ID Registers

The reset values of the RIF\_ID module identification registers are 00YY C0XX<sub>H</sub>.

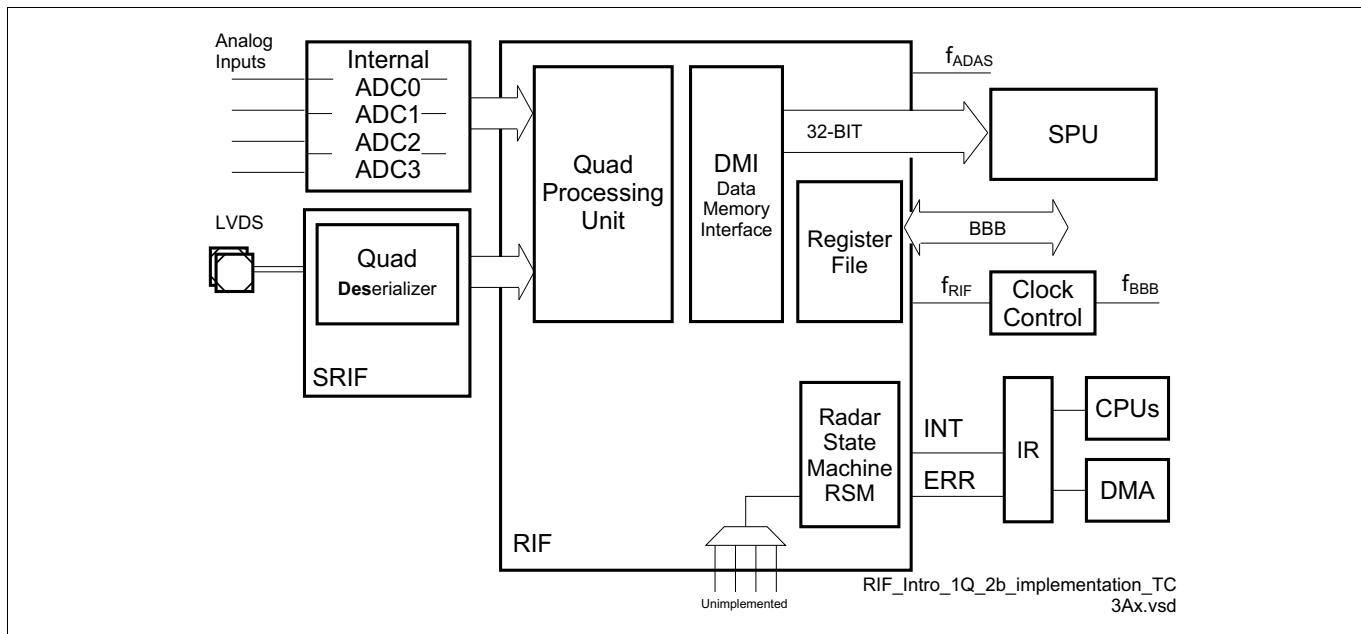

#### 24.3.17.2 Implementation Details

The following diagram shows the implementation details and interconnections of the RIF module.

### Radar Interface (RIF)

**Figure 322 RIF Implementation**

**Figure 323 RIF Implementation for TC3Ax**

#### 24.3.17.3 On-Chip Connections

The RIF module is connected to the LVDS pins, internal ADCs, and external pin(s) for the RAMP1 signal. See the pinning chapter for details.

##### 24.3.17.3.1 Connections to the internal ADCs

Each RIF module is connected to 4 internal ADCs, depending on the specific microcontroller derivative. The connections are listed in the corresponding derivative specification.

---

**Radar Interface (RIF)****24.3.17.3.2 RAMP1 Connections**

The RAMP1 signal is per default (reset value) low active. The unused inputs are connected to 1, the default inactive level. The default selected input is input 0, and it is always connected to default inactive 1.

The reset state of the RIF module is: Frame Watchdog enabled, RAMP1 connected to inactive level.

## Radar Interface (RIF)

### 24.4 Registers

This section describes the kernel registers of the RIF module. All RIF kernel register names described in this section will be referenced in other parts by the module name prefix “RIF\_”.

All kernel registers are initialised on application reset. All BPI registers belong to EEC reset except OCS, which belongs to debug reset (for definition see SCU section “Reset Operation”).

#### RIF Kernel Register Overview

Identification Register	Control Registers	Status Registers

## Radar Interface (RIF)

### 24.4.1 Kernel Registers

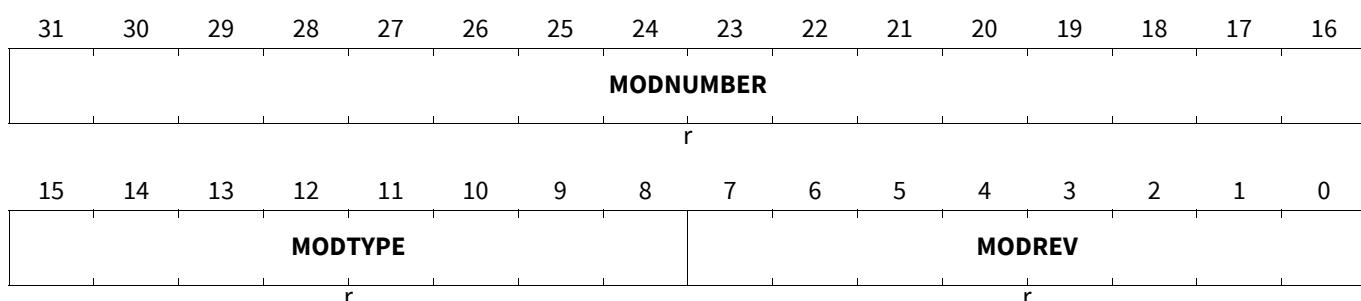

#### Module Identification Register

The Module Identification Register ID contains read-only information about the module version.

Current module identification number for Tc3Ax is 0x00e3c002 and for other derivatives it is 0x00e3c001.

##### ID

#### Module Identification Register (0008<sub>H</sub>) Application Reset Value: 00E3 COXX<sub>H</sub>

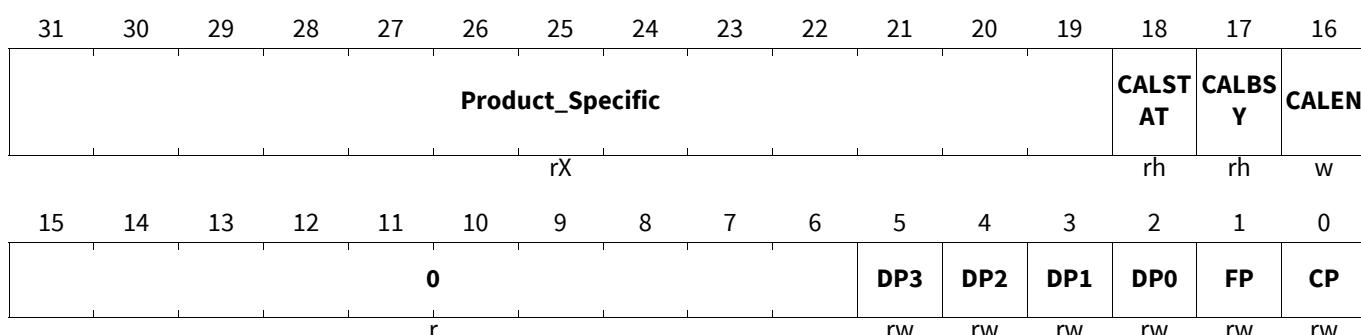

Field	Bits	Type	Description
<b>MODREV</b>	7:0	r	<b>Module Revision Number</b> MODREV defines the module revision number. The value of a module revision starts with 01 <sub>H</sub> (first revision).
<b>MODTYPE</b>	15:8	r	<b>Module Type</b> This bit field is C0 <sub>H</sub> . It defines a 32-bit module.
<b>MODNUMBER</b>	31:16	r	<b>Module Number Value</b> This bit field together with MODTYPE uniquely identifies a module.

#### External Serial Interface Register

The ESI register contains configuration parameters for the External Serial Interface.

##### ESI

#### External Serial Interface Register (0010<sub>H</sub>) Reset Value: Table 1141

## Radar Interface (RIF)

Field	Bits	Type	Description
CP	0	rw	<b>Clock Polarity</b> Defines the polarity of the clock signal on the clock input pins. 0 <sub>B</sub> default 1 <sub>B</sub> inverted
FP	1	rw	<b>Frame Polarity</b> Defines the polarity of the frame signal on the frame input pins 0 <sub>B</sub> default 1 <sub>B</sub> inverted
DP0	2	rw	<b>Data Polarity for Lane 0</b> Defines the polarity of the data signals on the data input pins 0 <sub>B</sub> default 1 <sub>B</sub> inverted
DP1	3	rw	<b>Data Polarity for Lane 1</b> Defines the polarity of the data signals on the data input pins 0 <sub>B</sub> default 1 <sub>B</sub> inverted
DP2	4	rw	<b>Data Polarity for Lane 2</b> Defines the polarity of the data signals on the data input pins 0 <sub>B</sub> default 1 <sub>B</sub> inverted
DP3	5	rw	<b>Data Polarity for Lane 3</b> Defines the polarity of the data signals on the data input pins 0 <sub>B</sub> default 1 <sub>B</sub> inverted
CALEN	16	w	<b>Calibration Enable</b> Enables the calibration mode of the deserializer and with its rising edge sets the CALBSY bit. In this state, the incoming bitstream is treated by the deserializer as calibration stream of 10101... and no parallel data is delivered to the digital part of the RIF. This bit is write only and returns 0 on read. 0 <sub>B</sub> write of zero - no effect 1 <sub>B</sub> write of one - brings the deserializer in calibration mode
CALBSY	17	rh	<b>Calibration Busy</b> Shows the current state of the deserializer, if a calibration or normal data reception is going on. 0 <sub>B</sub> no calibration ongoing 1 <sub>B</sub> calibration ongoing
CALSTAT	18	rh	<b>Calibration Status</b> Shows the status of the latest timing calibration sequence. The end of a calibration sequence is signalled by an interrupt, which is used by the CPU to check the status, and if OK, to switch the RIF to normal mode of operation. 0 <sub>B</sub> not OK (failed, signal paths uncalibrated) 1 <sub>B</sub> OK (successful)

## Radar Interface (RIF)

Field	Bits	Type	Description
<b>Product_Specifc</b>	31:19	rX	<b>Product_Specific</b> This bitfield is product specific.
<b>0</b>	15:6	r	<b>Reserved</b> Read as 0; should be written with 0.

### 24.4.2 BPI\_FPI Registers

Figure 325 shows all registers associated with the BPI\_FPI module, configured for one kernel.

## Radar Interface (RIF)

### BPI\_FPI Registers Overview

**Figure 325 BPI\_FPI Registers**

The writes of the bus masters to the RIF module are controlled by Access Protection registers ACCENx.

The RIF implements two ACCENx registers, ACCEN0 and ACCEN1.

The ACCENx registers are protected by Safety Endinit mechanism.

#### Clock Control Register

The Clock Control Register CLC allows the programmer to adapt the functionality and power consumption of the module to the requirements of the application. The description below shows the clock control register functionality which is implemented in the BPI\_FPI for the module. The CLC controls the  $f_{\text{ADAS}}$  module clock signal, sleep mode and disable mode for the module.

<b>CLC</b> <b>Clock Control Register</b>																<b>(0000<sub>H</sub>)</b>				<b>EEC Reset Value: 0000 0003<sub>H</sub></b>			
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	0	r						
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	0	r	rw	rw	rh	rw		

Field	Bits	Type	Description
<b>DISR</b>	0	rw	<b>Module Disable Request Bit</b> 0 <sub>B</sub> Enable, Request that the RIF clock tree be switched on 1 <sub>B</sub> Disable, Request that the RIF clock tree be switched off
<b>DISS</b>	1	rh	<b>Module Disable Status Bit</b> This bit will be set to 1 if the RIF kernel clock is disabled 0 <sub>B</sub> Enabled, The RIF clock tree is switched on 1 <sub>B</sub> Disabled, The RIF clock tree is switched off
<b>FDIS</b>	2	rw	<b>Freeze Disable</b> This bit controls the freeze function for this module. The freeze function is not implemented for the RIF so this bit will have no effect. This bit can be set to 0 <sub>B</sub>

## Radar Interface (RIF)

Field	Bits	Type	Description
<b>EDIS</b>	3	rw	<b>Sleep Mode Enable Control</b> Reserved. This bit currently has no effect on the RIF. It should be kept at 0 for future compatibility. 0 <sub>B</sub> Disabled, Sleep Mode is Off 1 <sub>B</sub> Enabled, Sleep Mode is on (no effect)
<b>0</b>	31:4	r	<b>Reserved</b> Read as 0; should be written with 0.

### OCDS Control and Status

The OCDS Control and Status (OCS) register is cleared by Debug Reset.

The register can only be written when the OCDS is enabled. If OCDS is being disabled, the OCS value will not change. When OCDS is disabled the OCS suspend control is ineffective. Write access is 32 bit wide only and requires Supervisor Mode.

### OCS

#### OCDS Control and Status (00E8<sub>H</sub>) Reset Value: Table 1165

**Table 1165 Reset Values of OCS**

Reset Type	Reset Value	Note
Debug Reset	0000 0000 <sub>H</sub>	

### Access Enable Register 0

The Access Enable Register 0 controls write access<sup>1)</sup>for transactions with the on chip bus master TAG ID 000000B to 011111B (see On Chip Bus chapter for the products TAG ID <-> master peripheral mapping). The BPI\_FPI is prepared for a 6-bit TAG ID. The registers ACCENO / ACCEN1 are providing one enable bit for each possible 6-bit TAG ID encoding.

Mapping of TAG IDs to ACCENO.ENx: EN0 -> TAG ID 000000B, EN1 -> TAG ID 000001B, ..., EN31 -> TAG ID 011111B. The BPI\_FPI Access Enable functionality controls only write transactions to the CLC, OCS, KRSTx and the kernel registers. Read transactions are not influenced. SW has to take care for destructive/modifying read functionality in kernel registers.

### ACCENO

(00FC <sub>H</sub> )																EEC Reset Value: FFFF FFFF <sub>H</sub>

1)

## Radar Interface (RIF)

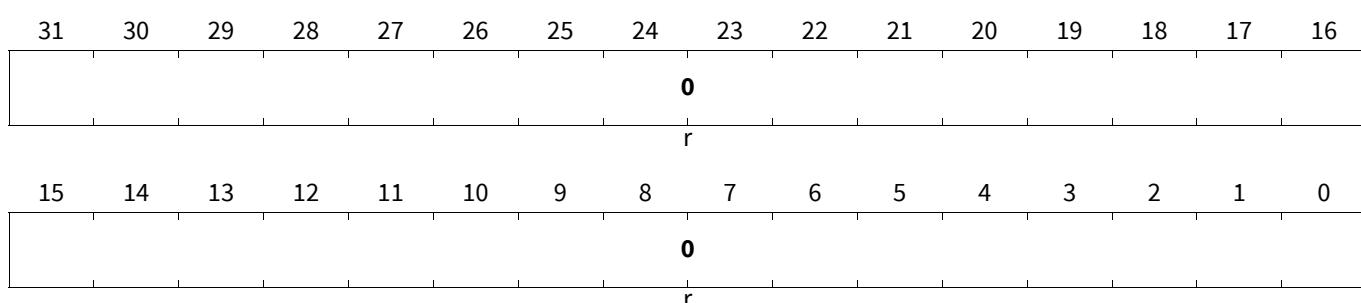

### Access Enable Register 1

The Access Enable Register 1 controls write access for transactions with the on chip bus master TAG ID 100000B to 111111B (see On Chip Bus chapter for the products TAG ID <> master peripheral mapping). The BPI\_FPI is prepared for a 6-bit TAG ID. ACCEN1 is not implemented with register bits as the related TAG IDs are not used in the AURIX devices.

Mapping of TAG IDs to ACCEN1.ENx: EN0 -> TAG ID 100000B, EN1 -> TAG ID 100001B, ..., EN31 -> TAG ID 111111B.

#### ACCEN1

##### Access Enable Register 1 (00F8<sub>H</sub>) EEC Reset Value: 0000 0000<sub>H</sub>

Field	Bits	Type	Description
0	31:0	r	<b>Reserved</b> Read as 0; should be written with 0.

### Kernel Reset Register 0

The Kernel Reset Register 0 is used to reset the related module kernel. Kernel registers related to the Debug Reset (Class 1) are not influenced. To reset a module kernel it is necessary to set the RST bits by writing with '1' in both Kernel Reset Registers. The RST bit will be re-set by the BPI with the end of the BPI kernel reset sequence.

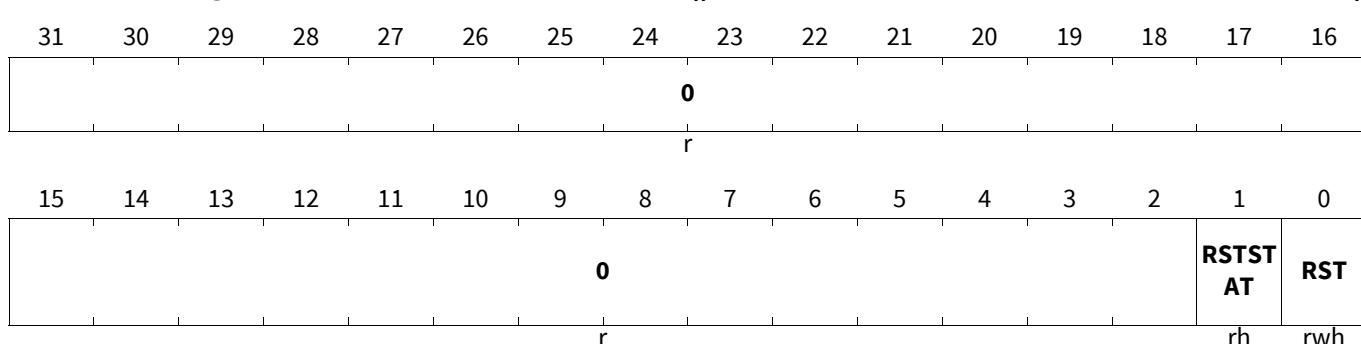

Kernel Reset Register 0 includes a kernel reset status bit that is set to '1' by the BPI\_FPI in the same clock cycle the RST bit is re-set by the BPI\_FPI. This bit can be used to detect that a kernel reset was processed. The bit can be re-set to '0' by writing '1' to the KRSTCLR.CLR register bit.

During the execution of the kernel reset until RSTSTAT is set, access to the kernel registers will result in an error acknowledge.

The instance of the kernel reset interface registers, KRST0, KRST1 nad KRSTCLR, is an exception to the general rule that the kernel reset functionality protected by ENDINIT. This instance is protected only by the ACCEN protection mechanism.

#### KRST0

## High Speed Pulse Density Modulation Module (HSPDM)

### 25 High Speed Pulse Density Modulation Module (HSPDM)

The HSPDM is intended to generate up to two 1-bit bit-streams. Each bit-stream represents the 16-bit data stored inside the dedicated 8 KB SRAM. This bit-stream is a pulse-density modulated (PDM) bit-stream which can be averaged outside the microcontroller using a low pass filter (LPF) to generate the analog voltage. [Figure 326](#) shows the architecture of the HSPDM and its interface to other IPs. [Figure 326](#) also highlights the signal flow from SRAM to bit-stream blocks at the output pads. In a system, HSPDM is conceived to generate an analog signal in conjunction with a LPF implemented external to the microcontroller. The signal-to-noise ratio (SNR) of the generated analog voltage is a function of the cutoff frequency, order and the implementation of the LPF and the frequency of operation of the Bit-Stream block.

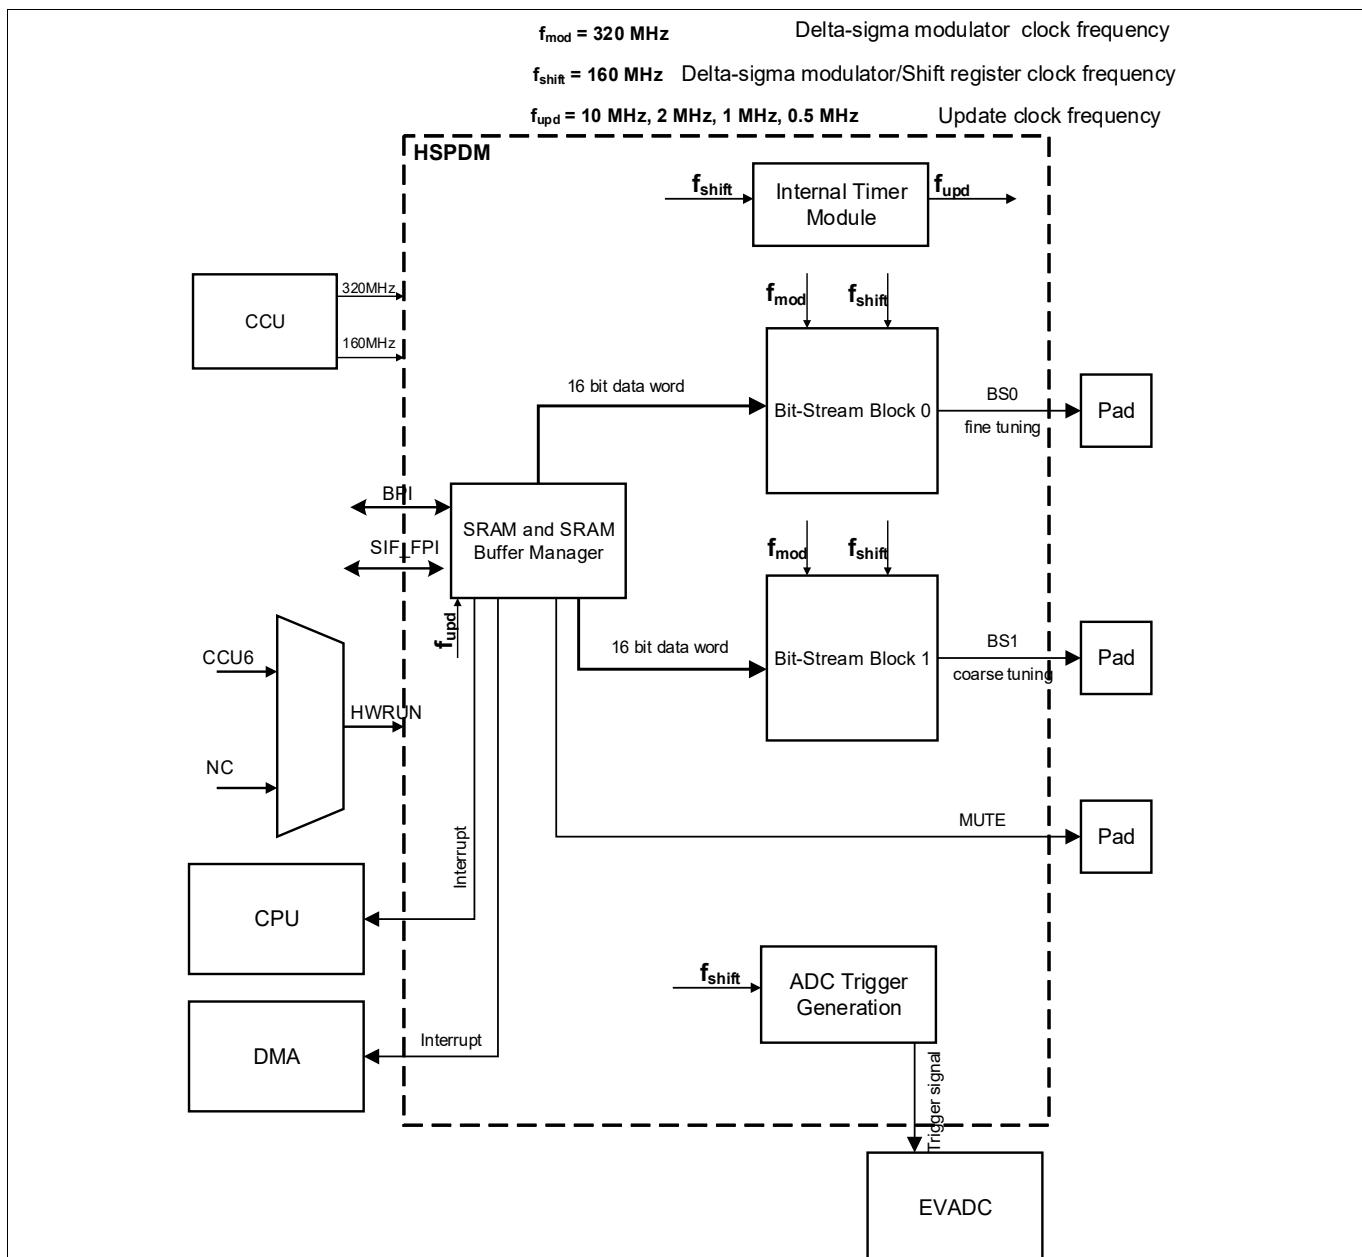

Figure 326 High speed pulse density modulation block level diagram

#### 25.1 Feature List

This section lists the features of the HSPDM module:

## High Speed Pulse Density Modulation Module (HSPDM)

- Two independent synchronous PDM bit-streams using the Delta-sigma modulator or bit-streams shifted serially using the shift register up to 160 Mbps
- Trigger signal to EVADC to signal the start of conversion
- Programmable offset in EVADC trigger signal
- MUTE signal output from the microcontroller which can be used to turn on or turn off the external transmitter for details see [Chapter 25.2.4.2](#)
- Support burst mode for fast upload into the SRAM through an addition slave interface (SIF)

## 25.2 Functional Description

### 25.2.1 HSPDM Modes of Operation

HSPDM generates up to two bit-streams with bit-stream block 0 (BSB0) and bit-stream block 1 (BSB1). The correct mode of operation must be set by the user using **CON.SM**. The user must not change the mode of operation during the run time. Before changing the mode of operation, the user must stop the bit-streaming by setting the **CON.RUNC** bit, followed by setting the correct mode of operation using the **CON.SM** bit and then restarting the bit-streaming by setting the **CON.RUNS** bit. Mode changes during the run time will result in an undefined behavior of the bit-stream. Each bit-stream block supports up to three modes of operation ([Figure 327](#)):

- Shift register generated bit-stream
- Delta-sigma modulator generated bit-stream with the CIC filter and the Compactor enabled
- Delta-sigma modulator generated bit-stream with the CIC filter and the Compactor disabled

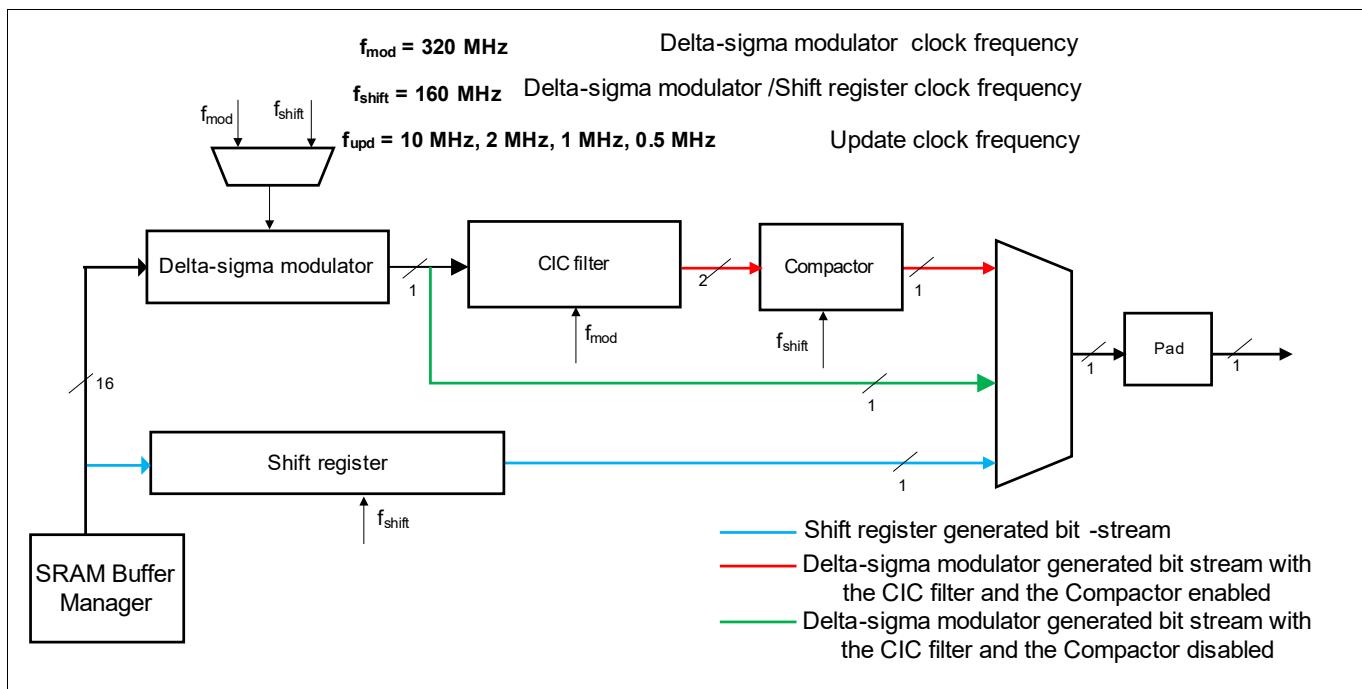

Figure 327 HSPDM modes of operation

#### 25.2.1.1 Shift Register Generated Bit-Stream

The mode can be entered by setting **CON.SM** = 10<sub>B</sub>. In this mode of operation a 16-bit digital word is loaded by the bit-stream loader (inside the SRAM & SRAM buffer manager block) at the input of the shift register. The Delta-sigma modulator, the CIC filter and the Compactor are disabled in this mode of operation. The shift register

## High Speed Pulse Density Modulation Module (HSPDM)

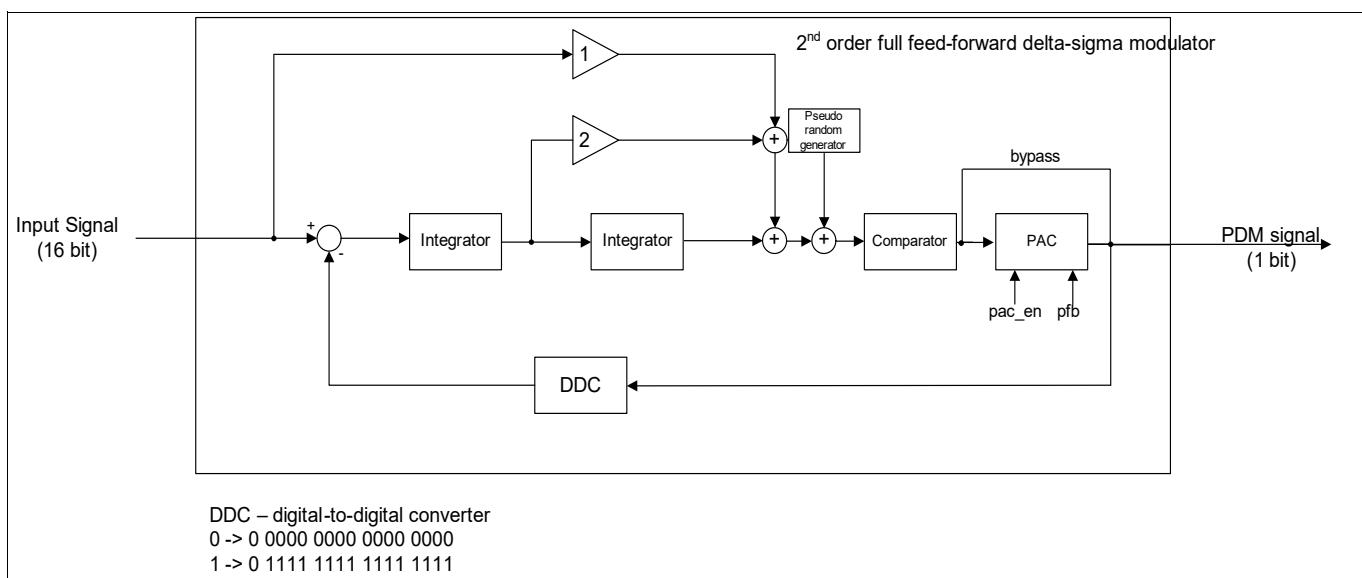

serializes the 16-bit word and sends it bit-wise (lsb first) on the rising edge of the  $f_{shift}$  clock. At the output, a 1-bit bitstream at 160 Mbps is generated which can be pushed out of the microcontroller through the multiplexer. The update frequency of the loader  $f_{upd}$  must be 10 MHz in this mode. User must take care to configure the correct  $f_{upd}$  during this mode using **CON.ITMDIV**.

**Note:** System SNR performance is limited during this mode.

### 25.2.1.2 Delta-sigma Modulator Generated Bit-Stream with the CIC filter and the Compactor enabled

The mode can be entered by setting **CON.SM** = 00<sub>B</sub>. In this mode of operation, a 16-bit digital word is loaded by the bit-stream loader (inside the SRAM & SRAM buffer manager block) at the input of the Delta-sigma modulator. Shift register is disabled in this mode of operation. The Delta-sigma modulator generates a PDM bit-stream at its output. The Delta-sigma modulator runs at 320 MHz in this mode, generating PDM bit-stream at 320 Mbps. The data rates higher than 160 Mbps are not supported by the microcontroller pads, therefore, in this mode of operation the output of the modulator is decimated.

In the HSPDM, a 2<sup>nd</sup> order full feed-forward Delta-sigma modulator (**Figure 328**) is used. The full feed-forward architecture offer the advantage of higher stability due to the fact that the inputs to the integrators are the difference between the input and the feedback signal. Therefore, the swings at the input of the integrators are much smaller than the full scale value. As depicted in the **Figure 328**, the feedback of the Delta-sigma modulator is a digital-to-digital converter (DDC) which converts a 1-bit output from the comparator to the 17-bit value to be subtracted from the input. The pulse density of the generated bit-stream depends on the absolute input level with respect to the full scale value. **Table 1169** demonstrates some PDM output bit-streams from the Delta-sigma modulator. To showcase the pulse density, **Table 1169** assumes a full scale value of  $2^{16}$ , in actual implementation the full scale value is  $2^{16}-1$ .

**Figure 328 Full feed forward Delta-sigma modulator**

**Table 1169 PDM Bit-Stream Examples**

Input to the Delta-sigma modulator	Output of the Delta-sigma modulator
0000 <sub>H</sub>	0000000000000000....
8000 <sub>H</sub>	1100110011001100.....

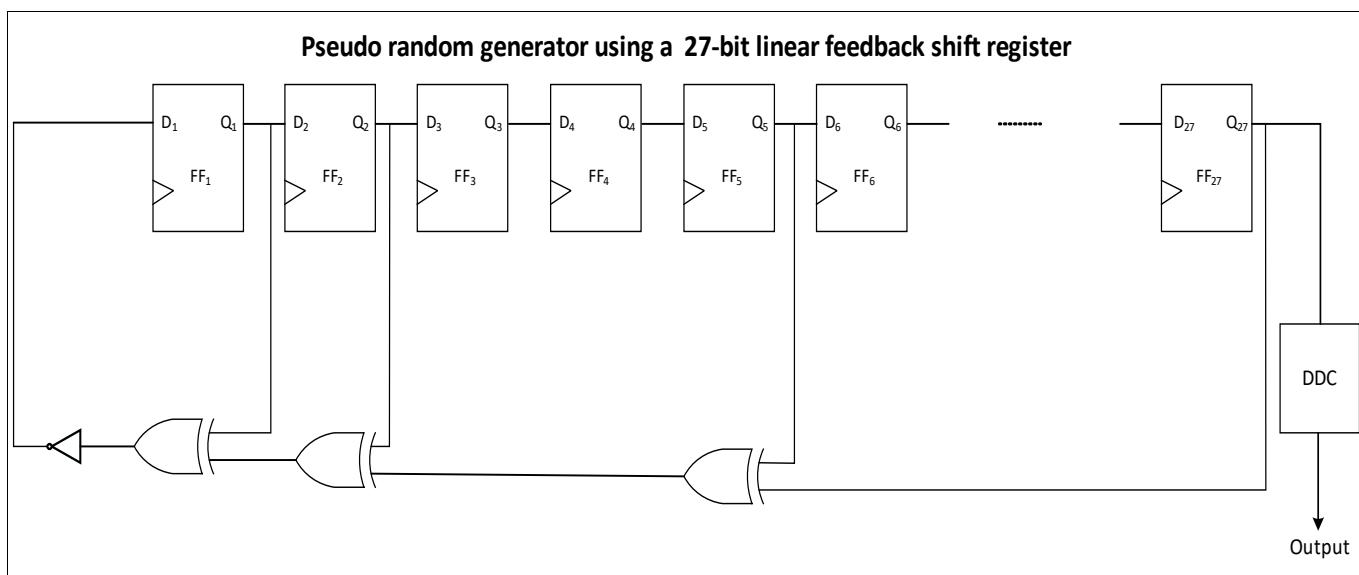

## High Speed Pulse Density Modulation Module (HSPDM)

**Table 1169 PDM Bit-Stream Examples**

Input to the Delta-sigma modulator	Output of the Delta-sigma modulator
4000 <sub>H</sub>	1000010010000100....
FFFF <sub>H</sub>	1111111111111111....

For DC or low frequency input signal the output of the modulator contains periodic quantization noise components and some of these noise components could fall within the passband of interest and limit the dynamic range of the modulator. This phenomenon is called ‘Limit cycling’. Limit cycling results in spurious tones in the output spectrum of the modulator and deteriorates the performance. To overcome the impact of limit cycle, white noise is added in after the second integrator inside of delta sigma modulator to dither the output and thereby, reduce or eliminate the level of the periodic quantization noise. Adding of noise increases the overall noise floor and reduces the effective signal-to-noise ratio, therefore, the level of dither must be chosen efficiently by the user.

Dither is implemented inside the modulator using a pseudo-random generator ([Figure 328](#)). Pseudo-random generator is implemented with the help of 27-bit Linear Feedback Shift Register (LFSR)

**Figure 329 Dither generation**

A 27-bit LFSR results in a period of dither of  $2^{27}-1$  samples or 839 ms for 160 MHz clock. The dither levels are defined in [Table 1170](#). User can configure the described dither levels using [CON.DITH](#).

**Table 1170 Dither Levels**

Setting	Dither Level
000	Disabled
001	Minimum dither level
010	Low dither level
011	Low-medium dither level
100	Medium dither level
101	Medium-high dither level
110	High dither level
111	Highest dither level

## High Speed Pulse Density Modulation Module (HSPDM)

Decimation in HSPDM is implemented in two steps using the CIC filter and the Compactor. The CIC filter (Figure 330) follows the Delta-sigma modulator and decimates the 1-bit PDM signal from the Delta-sigma modulator at 320 Mbps to 160 MSps, with each sample size of 2-bit. This 2-bit sample at the output of the CIC filter must be mapped to a 1-bit sample without any loss of information. This task is accomplished by the Compactor which maps the 2-bit sample into 1-bit.

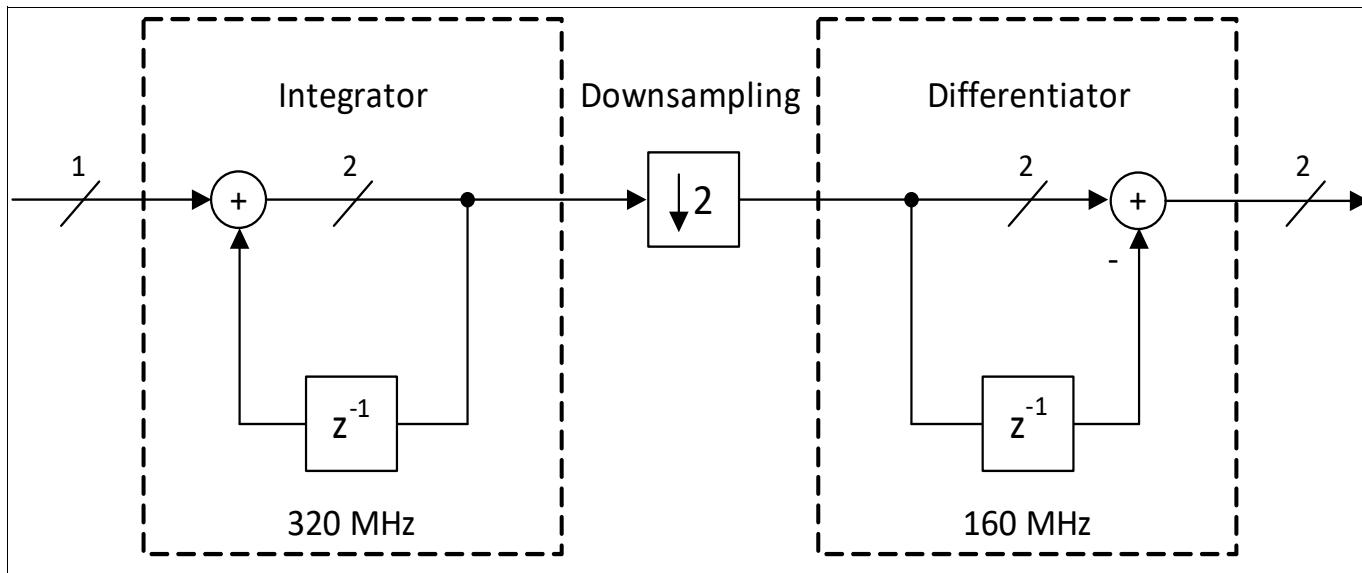

Figure 330 CIC filter with decimation by a factor of 2

Inside of the Compactor a mapping algorithm is implemented, in which a ' $0_D$ ' input is mapped to a ' $0_B$ ', a ' $2_D$ ' input is mapped to a ' $1_B$ ' and for ' $1_D$ ' as input, Compactor flips the output bit between ' $0_B$ ' and ' $1_B$ '. The algorithm is initialized: when for the very first time a ' $1_D$ ' comes at the input of the Compactor a ' $0_B$ ' is mapped at the output. After that whenever a ' $1_D$ ' is generated at the output of the CIC, the Compactor flips the output between a ' $0_B$ ' and a ' $1_B$ ' based on whether the previous output for input ' $1_D$ ' was ' $1_B$ ' or ' $0_B$ ', respectively. An example demonstrating the functionality of the mapping algorithm is shown in Figure 331 and Table 1171 explains the truth table for the mapping algortihm of the Compactor.

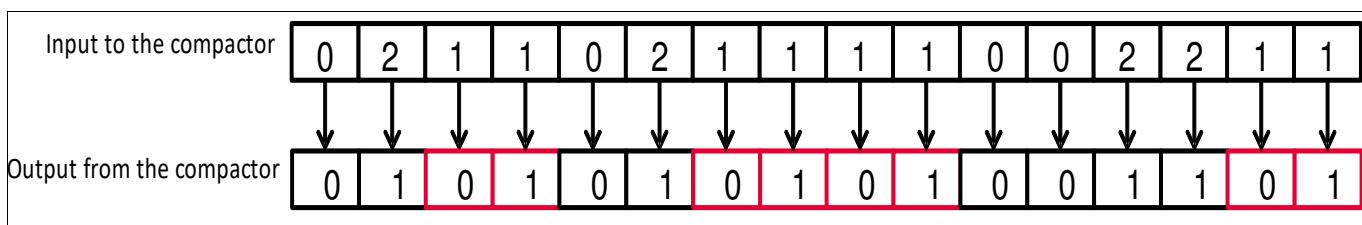

Figure 331 Mapping algorithm

Table 1171 Mapping algorithm of the Compactor

Input to the Compactor	Output of the Compactor
$0_D$	$0_B$
$1_D$	$0_B$ (at the start or if the previous output was 1) $1_B$ (if the previous output was 0)
$1_D$	$1_B$
$2_D$	$1_B$

## High Speed Pulse Density Modulation Module (HSPDM)

During this mode of operation, the default update frequency of the loader,  $f_{upd}$ , is 1 MHz. User can also program the internal timer module [Chapter 25.2.2.1 CON](#).ITMDIV to change the update frequency in this mode. A  $f_{upd}$  of 10 MHz is not allowed in this mode.

### 25.2.1.3 Delta-sigma Modulator Generated Bit-Stream with the CIC filter and the Compactor disabled

The mode can be entered by setting [CON.SM](#) = 01<sub>B</sub>. This mode of operation is very similar to the previously discussed mode of operation [Chapter 25.2.1.2](#), with the difference that the Delta-sigma modulator is run at 160 MHz. Due to a lower data rate at the output of the Delta-sigma modulator, the CIC filter and the Compactor must be disabled. This mode is highlighted in [Figure 327](#) with a direct connection from the output of the modulator to the input of the multiplexer. During this mode of operation, the default update frequency of the loader  $f_{upd}$  is 1 MHz. User can also program the internal timer module [Chapter 25.2.2.1 CON](#).ITMDIV to change the update frequency. A  $f_{upd}$  of 10 MHz is not allowed in this mode.

*Note:* System SNR performance is limited in this mode.

### 25.2.2 HSPDM clocking and EVADC trigger generation

HSPDM receives two balanced and synchronized clocks of 320 MHz ( $f_{mod}$ ) and 160 MHz ( $f_{shift}$ ) from the CCU. For the shift register,  $f_{shift}$  is used to shift the data serially. For the Delta-sigma modulator signal path, the user can configure the modulator clock with 320 MHz or 160 MHz by selecting the appropriate mode using [CON.SM](#).

#### 25.2.2.1 Internal Timer Module (ITM)

The Internal Timer Module (ITM) generates the update frequency  $f_{upd}$  to control the loading of the 16-bit data from the SRAM. The ITM is a programmable clock divider which can be programmed to one of the possible four different divider values. These divider value can be configured using [CON.ITMDIV](#). Input clock to the ITM is always 160 MHz ( $f_{shift}$ ). The default value of the divider is 160, to support the default mode of operation of the bit-stream block [Chapter 25.2.1.2](#). [Table 1172](#) illustrates all the possible divider ratio which could be configured by the user. The user must read [Chapter 25.2.1](#) to set the correct divider value. The divider value, [CON.ITMDIV](#), must not be changed during the run time.

**Table 1172 Internal Timer Module Divider Value**

Bit Setting	Divider Value (ITMDIV)	$f_{upd}$
00 <sub>B</sub>	160	1 MHz
01 <sub>B</sub>	320	0.5 MHz
10 <sub>B</sub>	80	2 MHz
11 <sub>B</sub>	16	10 MHz

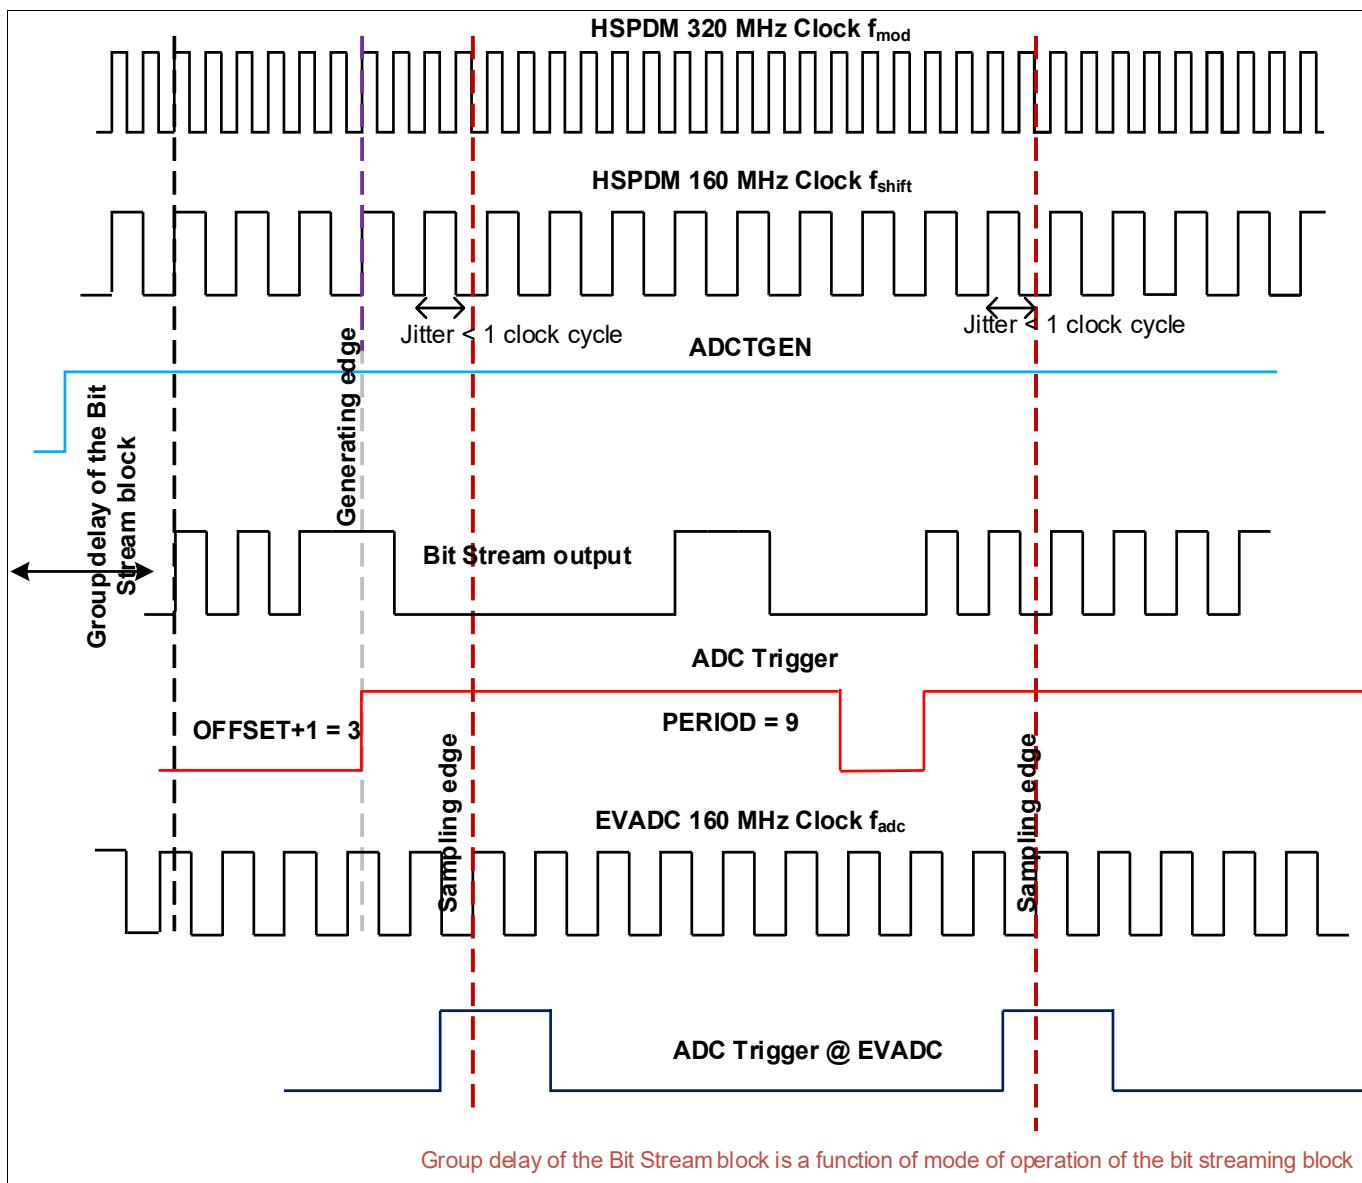

#### 25.2.2.2 ADC Trigger Generation

The ADC trigger generation block inside of the HSPDM ([Figure 326](#)) generates a signal to trigger to a group of EVADCs inside of the microcontroller, the start of conversion (SOC). The EVADC is used to convert the received analog signal on one of the analog input channels of the microcontroller into digital data. Using the [CON.ADCTGEN](#), the user can enable or disable the ADC trigger generation and configure the trigger signal generation using [ADCTG.OFFSET](#) and [ADCTG.PERIOD](#). The user can specify the offset value for the generation of the first trigger signal in [ADCTG.OFFSET](#) from the time of first output bit from the bit-stream block. This value can

## High Speed Pulse Density Modulation Module (HSPDM)

be between 0 and 409.59 us with a resolution step of 6.25 ns. The user can specify the period (after how much 160 MHz clock cycle must be the next trigger signal be generated) of the trigger signal using **ADCTG.PERIOD** field. This is a 16-bit down counter which after reaching zero, generates a trigger signal and starts counting again from the top. The total number of trigger signals can be configured using the **ADCTGCNT.TGCNT**. The total number of trigger signals is equal to **ADCTGCNT.TGCNT +1**. The maximum number of trigger signals which can be configured is 65536 ( $\text{FFFF}_H +1$ ). The pulse width of the trigger signal is fixed at eight cycles of 160 MHz clock. For **ADCTG.PERIOD<9**, there would only be one trigger signal with pulse width equal to  $\text{TGCNT} \times \text{PERIOD} +8$ . Setting of **ADCTG.PERIOD = 0** must be avoided.

**Figure 332** shows an example where **ADCTG.OFFSET =2**, that is, two clock cycles after the ADC trigger enable and the period of the ADC trigger signal is 9 clock cycles or 56.25 ns.

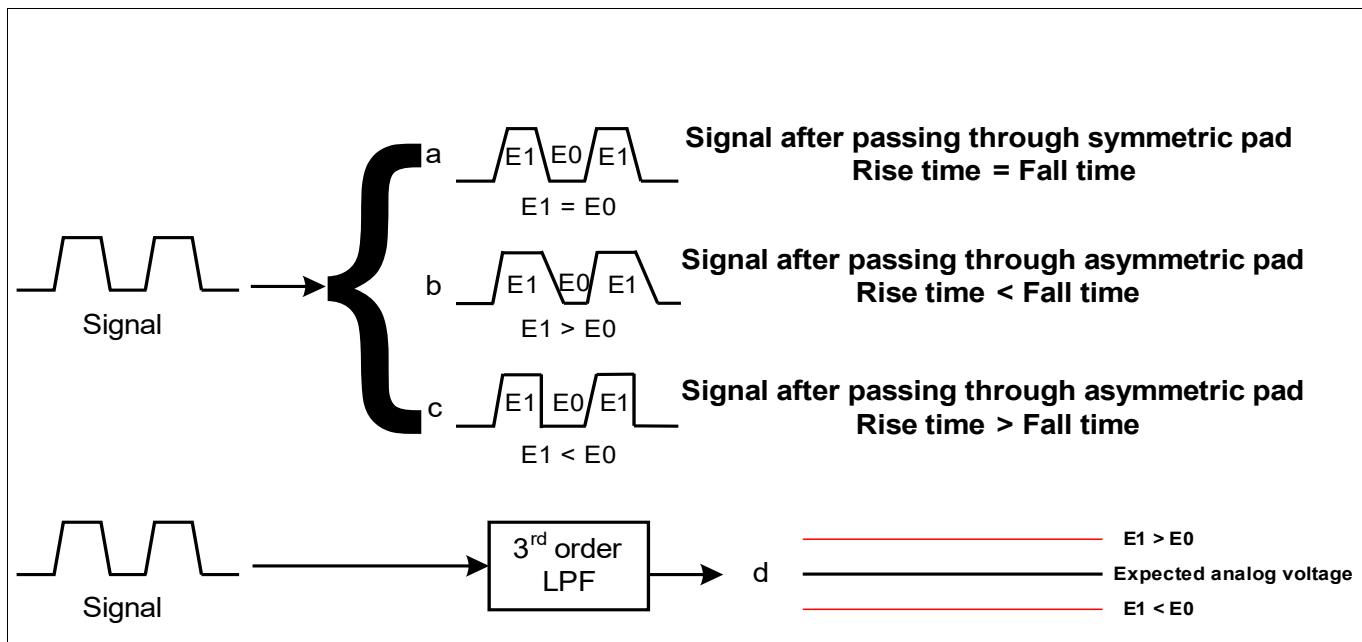

**Figure 332 ADC Trigger Concept**

### 25.2.3 Pad Asymmetry Compensation (PAC)

PAC is an optional feature included in HSPDM to give the user the possibility to easily predict the impact of pad asymmetries and compensate for it. Pad asymmetry degrades the SNR of the signal and also introduces an offset in the analog voltage.

## High Speed Pulse Density Modulation Module (HSPDM)

**Figure 333 (a) Symmetric pad (b) Asymmetric pad with the rise time < fall time (c) Asymmetric pad with the rise time> fall time (d) DC voltage offset after passing of the PDM through the LPF**

Every PDM bit-stream comprises of certain number of ones and zeros. When this bit-stream is passed through a low pass filter (LPF), an average voltage is created at the output of the LPF. This voltage is proportional to the number of ones and number of zeros. In reality the voltage is not only proportional to the number of ones and zeros, but also on the duty cycle of the signal. When the PDM signal is passed through a symmetric pad, the output signal has equal rise time and fall time and therefore, the duty cycle is maintained ([Figure 333\(a\)](#)). But pads are not symmetric and alter the rise time and fall time of the signal ([Figure 333\(a and b\)](#)). This signal when passed through a LPF ([Figure 333 \(d\)](#)) creates an offset from the expected analog voltage. The magnitude of this offset depends on the number of edges in the signal. The higher the number of edges, the higher is the impact of the pad asymmetries on the final voltage. Highest number of edges for a 2<sup>nd</sup> order Delta-sigma modulator can be seen in '110011001100...' output bit-stream. Therefore, the biggest offset is produced with such a bit-stream.

Referring to [Table 1169](#); the number of edges at the output of the Delta-sigma modulator increases from zero to maximum for input range 0000<sub>H</sub> to 8000<sub>H</sub> and decreases from maximum back to zero for input range 8000<sub>H</sub> to FFFF<sub>H</sub>. If there is a constant relation between the input to the Delta-sigma modulator and the number of edges in the PDM bit-stream at the output, then the user can easily compensate for offset voltage by applying a constant gain factor already to the 16-bit input word. PAC is intended to linearize the relationship between the input to the Delta-sigma modulator and the number of edges produced at the output.

PAC is implemented as a comparator inside the Delta-sigma modulator. The principle of the PAC is to increase the number of edges but not to alter the number of ones and zeros in the PDM bit-stream. By increasing the number of edges at the output, the offset which is produced after the LPF also increases. But this in turn gives a linear relation between the input word, the number of edges in the PDM bit-stream and also the final voltage offset after the LPF.

By default, the PAC is disabled inside the Delta-sigma modulator and the user shall enable it using **CON.PAC** bit ([Figure 328](#)). PAC is implemented as an algorithm which compares the output of the comparator, previous output of the Delta-sigma modulator and the PAC flip bit (pfb). The pfb ([Figure 328](#)) is used to flip the operation of the PAC; when the input to the Delta-sigma modulator is less than half of the full scale value (<2<sup>15</sup>) then the pfb is set to '1', and when the input is greater than or equal to half of the full scale value then the pfb is reset to '0'.

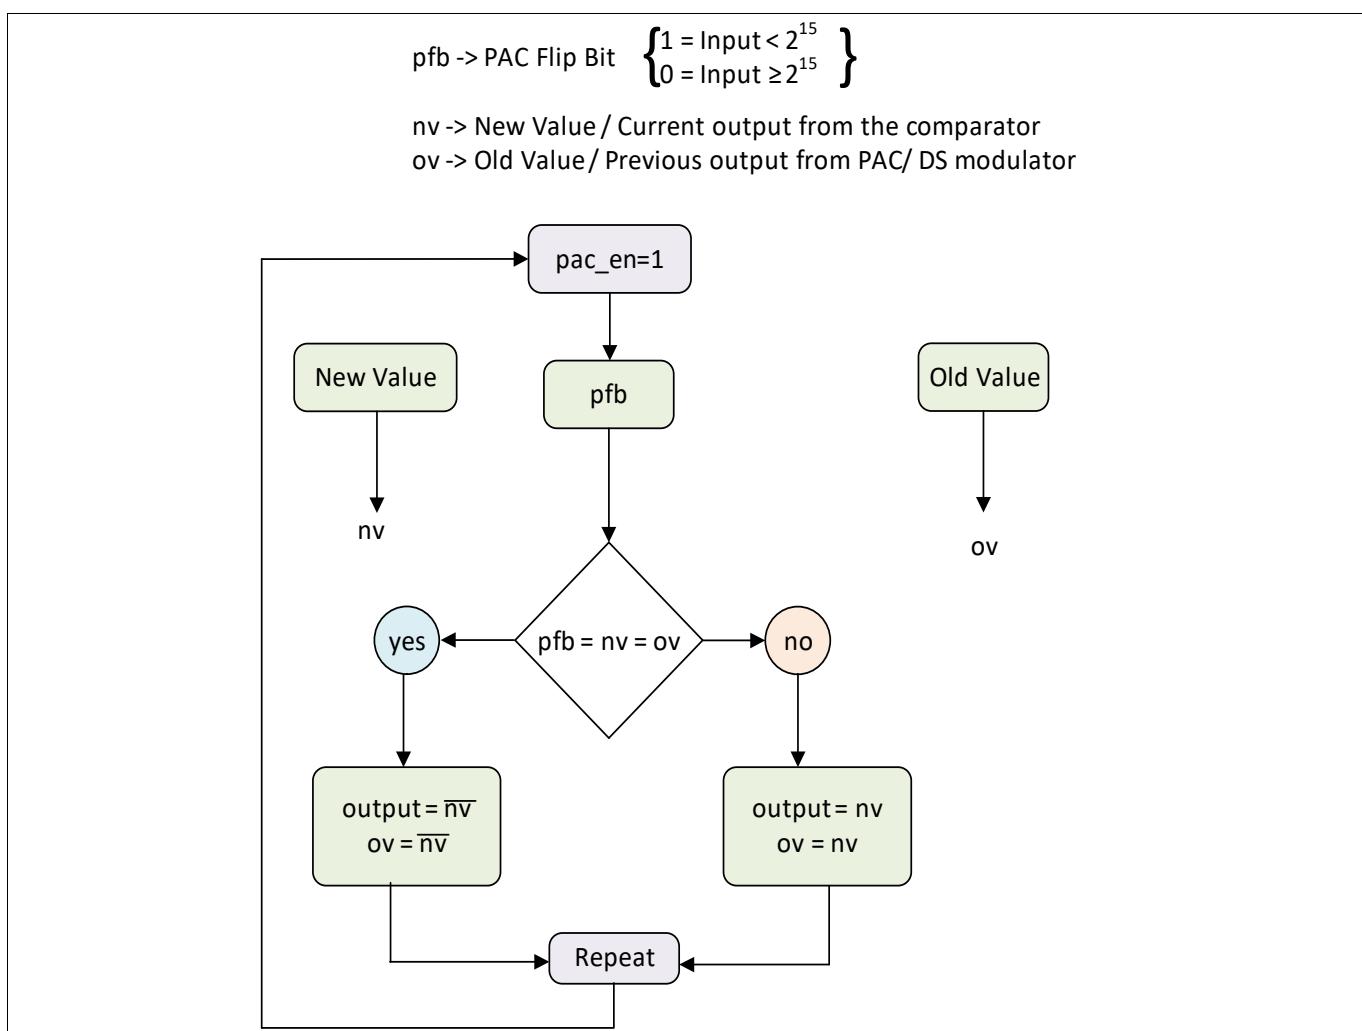

When the input is <2<sup>15</sup>, the PDM signal will have greater number of zeros than the number of ones and vice-versa for the input ≥ 2<sup>15</sup>. To increase the number of edges for the whole input range, PAC avoids the occurrence of two

## High Speed Pulse Density Modulation Module (HSPDM)

consecutive ones at the output of the Delta-sigma modulator for the input  $< 2^{15}$ , and occurrence of two consecutive zeros for the input  $\geq 2^{15}$ . Since the output value is fed back into the Delta-sigma loop, the loop corrects itself and maintains the pulse density of the signal. The PAC algorithm is explained in [Figure 334](#).

The PAC algorithm stores the previous output value (ov), which has the reset value '0'. When the PAC is enabled, the current output of the comparator (nv) is compared to the PAC flip bit (pfb) and ov. If these three values are the same then the negated nv value is pushed to the output and also stored as previous output value (ov). If the three compared values are not the same, then the output from the comparator is pushed to the output and the same value is stored as the old value, ov.

**Note:** *The user must not enable or disable the PAC during the run time. After the PAC is enabled or disabled, the Delta-sigma modulator must be restarted.*

**Figure 334** PAC algorithm

### 25.2.4 SRAM and Data Management

HSPDM has a 8KB in-built SRAM, which can store up to 4096 16-bit data points. The HSPDM RAM has an address space starting from  $F0280000_H$  to  $F0281FFF_H$  and the register address space starting from  $F0282000_H$  to  $F02820FF_H$  and support only word (32-bit) access. The SRAM and the RAM buffer manager (RAMBM) runs on the 100 MHz SPB (Serial Peripheral Bus) clock. The HSPDM supports two interface to the SPB, a Bus Peripheral Interface (BPI) for register access and a second slave interface SIF\_FPI to grant access to the SRAM [Figure 326](#).

## High Speed Pulse Density Modulation Module (HSPDM)

The SIF\_FPI interface supports burst mode for a fast upload of the SRAM. Although there are two interfaces to the SPB, the two interface can not be used in parallel.

Since the BSB0 and BSB1 are running on the other clock domain than the SRAM, there is a clock domain crossing from SRAM to bit-streaming blocks. Therefore, there is a synchronizing FIFO (sync FIFO) in between the SRAM and the bit-streaming blocks, which takes care of moving the 16-bit data from 100 MHz clock domain to bit-streaming block clock domain.

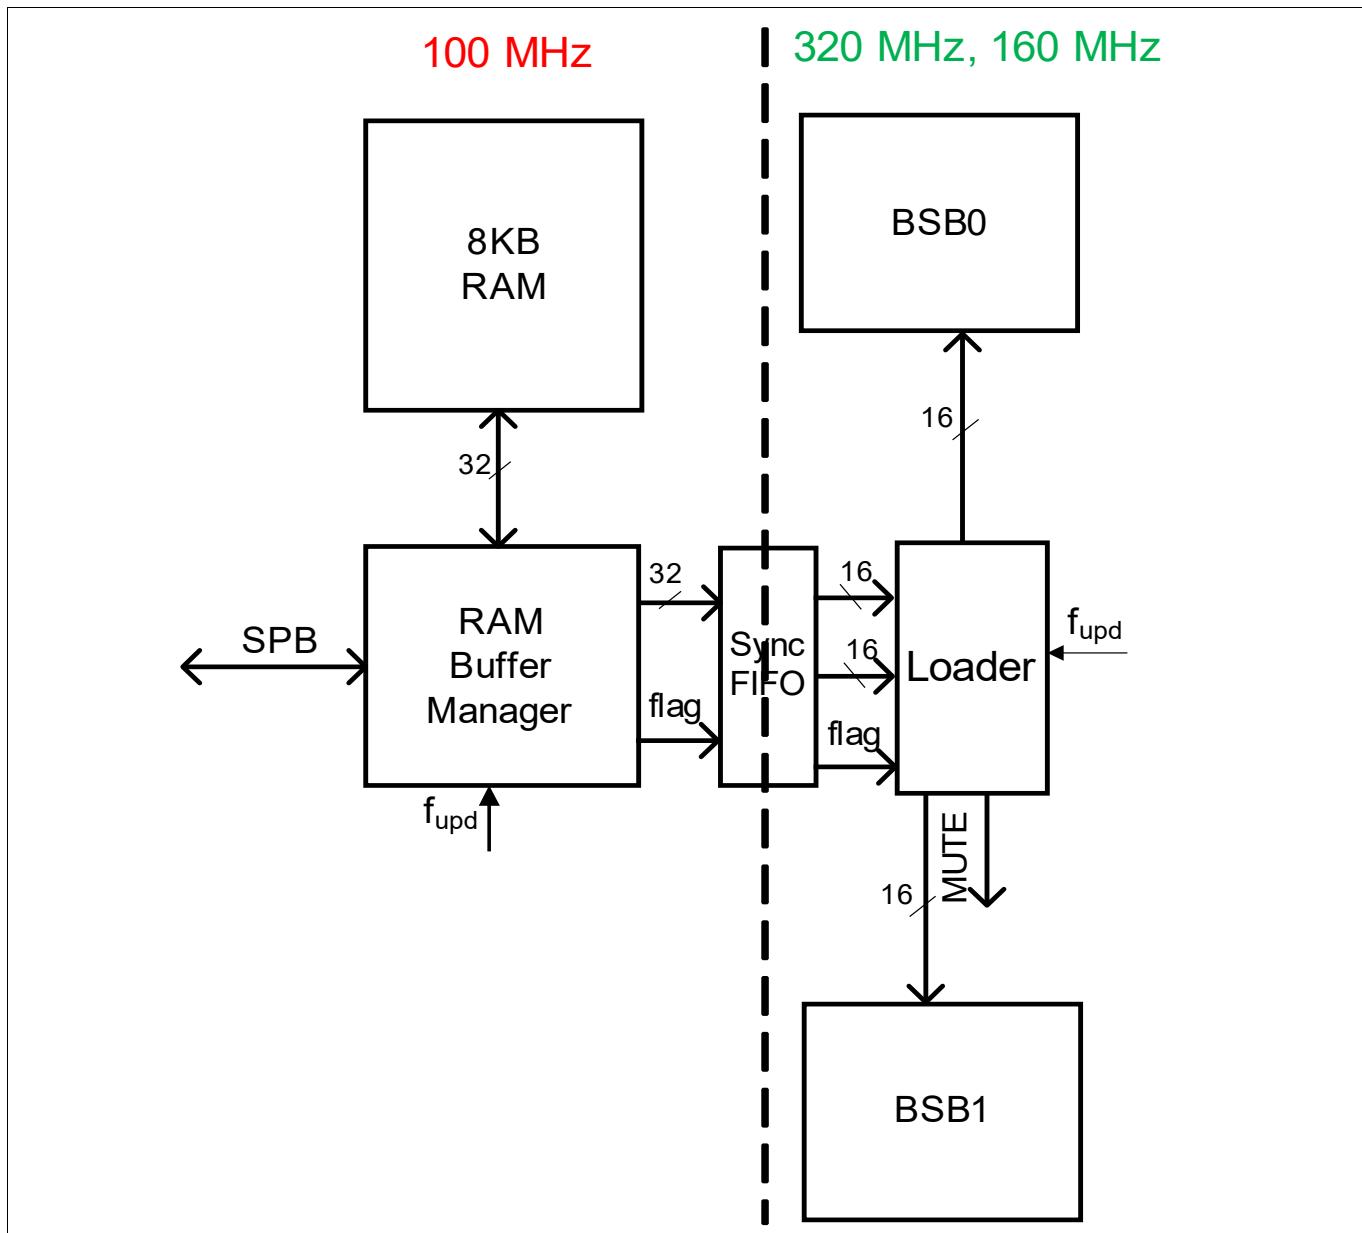

Figure 335 SRAM and data management

### 25.2.4.1 RAM Buffer Manager (RAMBM)

The RAM Buffer Manager, RAMBM, manages the following data tasks:

- Address generation for the RAM buffers that store the waveforms
- It defines two circular Buffers 'A' and 'B' with start and end addresses in the address space of the SRAM
- Manages switching between the Buffers 'A' and 'B'
- Transfers the data from the SRAM to the sync FIFO and manages to keep the sync FIFO constantly full

## High Speed Pulse Density Modulation Module (HSPDM)

- Controls the access to SRAM during the HSPDM run time
- Raise the flag on valid address matching between the address ranges stored in **MUTE0** and **MUTE1** and the current address which is fetched from the SRAM

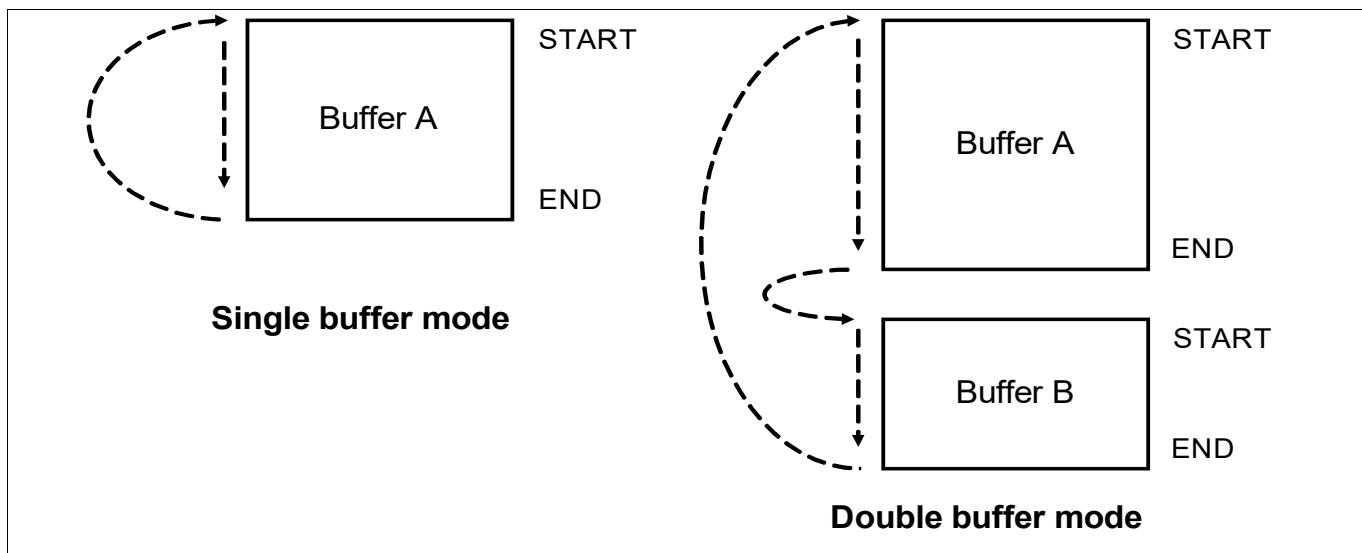

The registers **BUFA0** and **BUFB0** specifies the start and end address of Buffer A and Buffer B, respectively. **CURRAD** specify the current address being processed inside SRAM.

There are two modes of operation, single buffer mode (SBM) and double buffer mode (DBM). With **CON.MM** user can select between SBM and DBM. In SBM, only Buffer A is used, with automatic wrap around. In DBM, the streaming jumps between Buffer A and Buffer B in round robin. **CON.RUNS** (re)starts the bit-streaming from Buffer A start address. After reaching Buffer A end address, the address jumps to Buffer A start address or Buffer B start address, depending on the mode of operation: SBM or DBM, see [Figure 336](#) and [Figure 337](#).

The DBM also allows to switch between several waveforms stored in the RAM only by changing the start and end addresses of the two buffers.

If the start address and the end address of a buffer are equal and the mode is SBM, a constant value is streamed.

**Note:** *The software has the responsibility to program the start and end addresses correctly, such that, the end address is not lower than the start address. Also it is prohibited to change the mode during the run time. The mode, SBM or DBM must be configured at the start.*

**Figure 336 Single buffer mode and Double buffer mode**

### 25.2.4.2 MUTE Signal Generation

There are two registers, **MUTE0** and **MUTE1** that contain addresses to set and clear the signal MUTE. Both registers are completely interchangeable, meaning that the addresses defined in them are not associated in hardware to the start and the end of the two memory buffers in any way. The user has to take care that all the address settings fit such that the address range specified in **MUTE0** and **MUTE1** are non overlapping.

Each time the address counter in the RAMBM matches one of the two register values in **MUTE0** and **MUTE1**, the MUTE signal gets set or reset depending on the polarity bit field. MUTE signal can not be disabled but the polarity of the MUTE signal can be set using **CON.MPOL**. The content of the address defined in the registers **MUTE0** and **MUTE1** must match content of the address defines in the single buffer mode or double buffer mode. The status of the MUTE signal can be monitored by SW in the MUTE flag in the register **FLAGS**. The main purpose of this signal is to mark events with a defined time relation to the generated signal sequence see [Figure 338](#).

## High Speed Pulse Density Modulation Module (HSPDM)

Note: The MUTE signal is set and cleared when the content of the address defined in the registers **MUTE0** and **MUTE1** is loaded into the shift register or the Delta-sigma modulator. When the HSPDM is stopped and restarted again, the MUTE signal keeps its level, to reset the level of the MUTE signal, the HSPDM must be reset and then started.

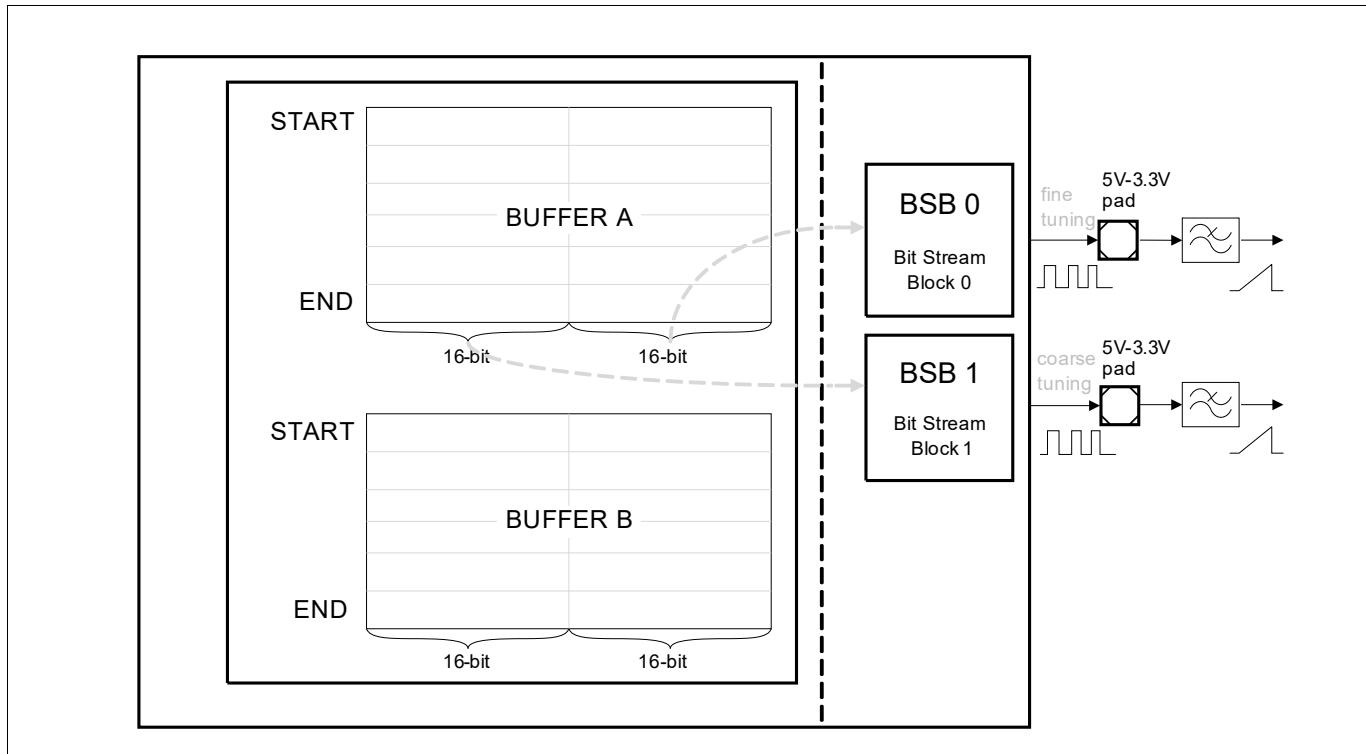

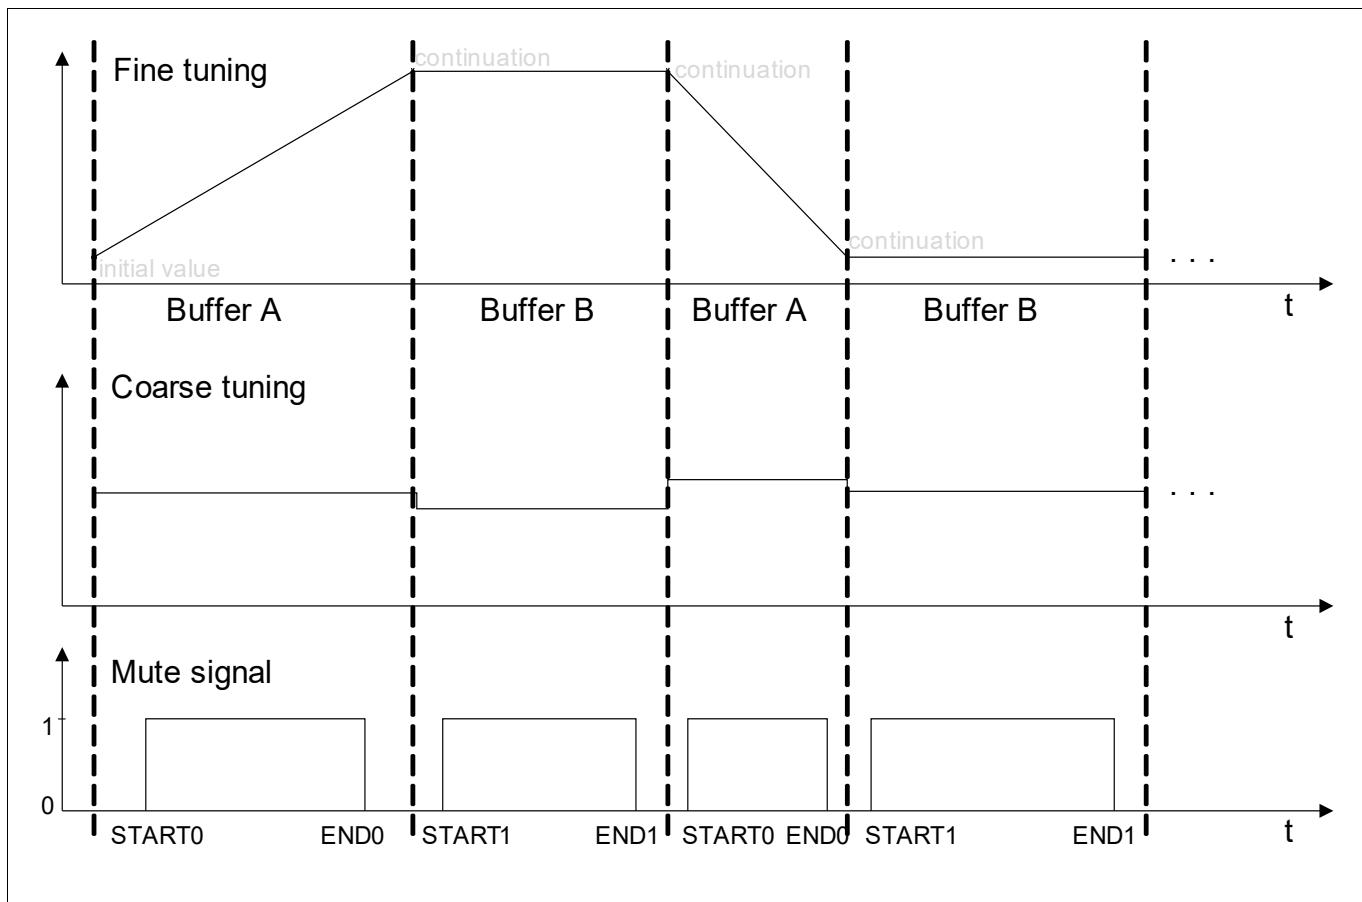

Figure 337 RAM storage of waveforms

## High Speed Pulse Density Modulation Module (HSPDM)

**Figure 338 Segmented Waveforms**

### 25.2.4.3 Interrupts

The HSPDM module generates the following interrupts:

- BFR, buffer interrupt, intended for triggering DMA transfers for filling the RAM
- MUTE, intended for notifying the CPU on certain events.
- Error interrupt, indicating RAM overflow.

BFR interrupt can be triggered by the buffer start and end events: BAS, BAE, BBS and BBE.

MUTE interrupt can be triggered by the MUTE Start and End events: M0S, M0E, M1S and M1E.

RAM overflow occurs if the last address of the RAM has been reached and a read from the next higher address has been attempted. It can occur if the start and the end addresses are wrongly configured (end less than start).

The register **FLAGS** contains the corresponding flags for these events. All events enabled in the register **FLAGSEN** trigger an interrupt. The flags can be cleared and set by software using the registers **FLAGSCLEAR** and **FLAGSSET**. Writing a '1' to a bit in the **FLAGSSET** register by software triggers the corresponding interrupt, if enabled.

### 25.2.4.4 Starting and Stopping the Bit-Streaming

HSPDM can be started or stopped by software or by hardware. The software can start the module by setting the RUN bit using **CON.RUNS** and the hardware by using the HWRUN signal. The status of the HSPDM can be monitored by reading the **CON.RUN** bit.

Each bit-stream block can be separately enabled or disabled by using the bits **CON.EN0** and **CON.EN1**. The user must not enable or disable the bit-stream block during the run. After changing the **CON.EN0** or **CON.EN1** bit, the HSPDM must be restarted. The user must avoid disabling both the bit-stream blocks. In such a use case user must

---

## High Speed Pulse Density Modulation Module (HSPDM)

stop the HSPDM. In the case of only one bit-streaming block enable, the SRAM operation remain the same as with the both bit-streaming blocks enabled. The upper or the lower 16-bits corresponding to the disabled bit-streaming block are ignored.

When a bit-streaming block is disabled or stopped, it drives 0 to the pad and all the internal states of the Delta-sigma modulator, the Shift register, the CIC filter and the compactor are reset to '0'.

### 25.2.4.5 Hardware Run Feature

The Hardware Run Feature allows starting the HSPDM with an edge of an external signal HWRUN. The software can select the type of the Active Edge (rising or falling) by using the bit **CON.HRAE**. Once started, the module runs independently of the signal HWRUN until the software clears the **CON.RUN** bit by using the bit **CON.RUNC**. After this the HWRUN signal can start the module again with new active edge.

If the bits RUNS and RUNC are erroneously both written with 1 at the same time by software, the RUN bit is cleared, meaning that RUNC has higher priority than RUNS. If the software wants to stop the module and the hardware to start the module, stopping the module via RUNC has higher priority.

---

## High Speed Pulse Density Modulation Module (HSPDM)

### 25.3 Registers

This section describes the kernel registers of the HSPDM module. All HSPDM kernel register names described in this section will be referenced in other parts by the module name prefix “HSPDM\_”.

All registers in the HSPDM address spaces are reset with the application reset.

The following tables give the overview of the HSPDM base addresses and registers.

HSPDM RAM takes 8KB, address space starting from  $F0280000_H$  to  $F0281FFF_H$ .

HSPDM register takes 256B, address space starting from  $F0282000_H$  to  $F02820FF_H$ .

## High Speed Pulse Density Modulation Module (HSPDM)

### 25.3.1 Kernel Registers

#### Module Identification Register

The Module Identification Register ID contains read-only information about the module version.

ID															
Module Identification Register (0008 <sub>H</sub> ) Application Reset Value: 00EB C0XX <sub>H</sub>															
31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16															
MODNUMBER															
r															
15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0															
MODTYPE								MODREV							
r															

Field	Bits	Type	Description
MODREV	7:0	r	<b>Module Revision Number</b> MODREV defines the module revision number. The value of a module revision starts with 01 <sub>H</sub> (first revision).
MODTYPE	15:8	r	<b>Module Type</b> This bit field is C0 <sub>H</sub> . It defines a 32-bit module.
MODNUMBER	31:16	r	<b>Module Number Value</b> This bit field together with MODTYPE uniquely identifies a module. The MODNUMBER for this module is 00EB <sub>H</sub>

#### RAM Buffer A Register 0

The RAM Buffer A Register 0 contains information about the start and the end address of buffer 'A'. This register is read and write enable.

BUFA0																							
RAM Buffer A Register 0 (0010 <sub>H</sub> ) Application Reset Value: 0000 0000 <sub>H</sub>																							
31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16																							
0								ENDA															
r

### 25.3.2 BPI\_FPI Registers

#### BPI\_FPI Registers Overview

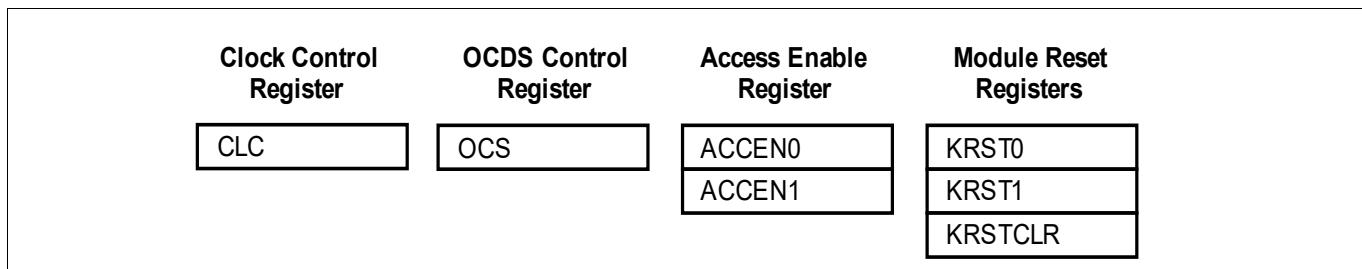

Figure 339 BPI\_FPI Registers

## High Speed Pulse Density Modulation Module (HSPDM)

**Figure 339** shows all registers associated with the BPI\_FPI module, configured for one kernel. The writes of the bus masters to the HSPDM module is controlled by Access Protection registers ACCENx.

The HSPDM implements two ACCENx registers, ACCEN0 and ACCEN1. The SRAM write access is also protected by Access Protection registers ACCENx.

The ACCENx registers are protected by Safety EndInit mechanism.

HSPDM must be stopped before entering the sleep mode and restarted after exiting the sleep mode. During the sleep mode, access to registers and SRAM is not allowed. It is not recommended to run HSPDM in sleep mode.

HSPDM does not support any soft suspend mode although there is a bit **OCS.SUS**. The **OCS.SUS** is not connected to any control of the HSPDM.

HSPDM supports hard suspend using **OCS.SUS**. In this mode, the clocks to the HSPDM are switched off, but registers are available for a read. During the hard suspend a read or a write performed on the HSPDM SRAM will result in a bus error. After the hard suspend, the user must make sure to reset the HSPDM. The behavior is undefined if there is no reset following the end of hard suspend.

### Clock Control Register

The Clock Control Register CLC allows the programmer to adapt the functionality and power consumption of the module to the requirements of the application. The description below shows the clock control register functionality which is implemented in the BPI\_FPI for the module. Where a module kernel is connected to the CLC clock control interface, CLC controls the module clock signal, sleep mode and disable mode for the module.

<b>CLC</b>

### OCDS Control and Status Register

The OCDS control and status register OCS controls the module's behavior in suspend mode (used for debugging).

## High Speed Pulse Density Modulation Module (HSPDM)

The OCDS control and status register is cleared by debug reset. The register can only be written when the OCDS is enabled. When OCDS is disabled the OCS suspend control is ineffective.

### Access Enable Register 0

The Access Enable Register 0 controls write access<sup>1)</sup> for transactions with the on chip bus master TAG ID 000000<sub>B</sub> to 011111<sub>B</sub>. The BPI\_FPI is prepared for a 6-bit TAG ID. The registers ACCENO / ACCEN1 are providing one enable bit for each possible 6-bit TAG ID encoding.

Mapping of TAG IDs to ACCENO.ENx: EN0 -> TAG ID 000000<sub>B</sub>, EN1 -> TAG ID 000001<sub>B</sub>, ..., EN31 -> TAG ID 011111<sub>B</sub>.

#### ACCENO

1) The BPI\_FPI Access Enable functionality controls only write transactions to the CLC, OCS, KRSTx and the kernel registers. Read transactions are not influenced. SW has to take care for destructive/modifying read functionality in kernel registers

## High Speed Pulse Density Modulation Module (HSPDM)

Field	Bits	Type	Description
0	31:0	r	<b>Reserved</b> Read as 0; should be written with 0.

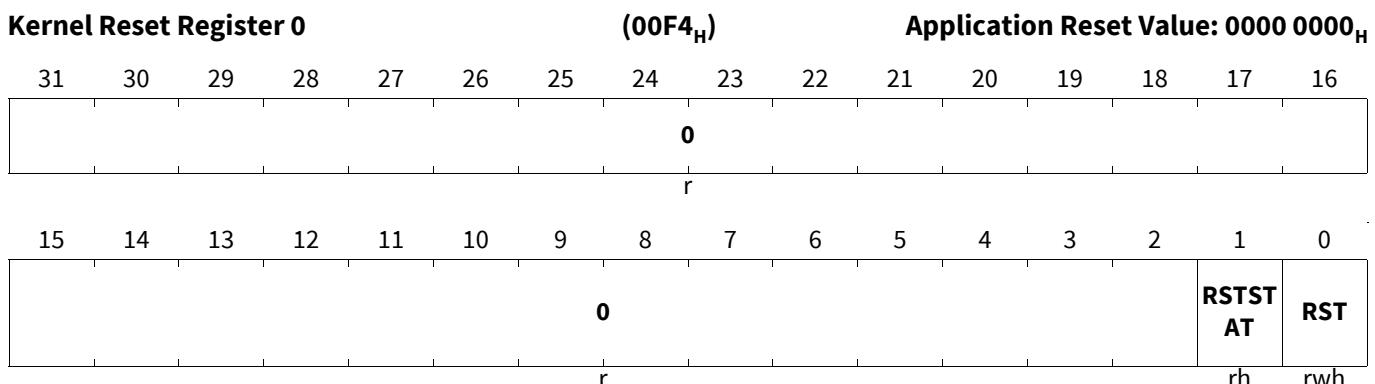

### Kernel Reset Register 0

The Kernel Reset Register 0 is used to reset the related module kernel. Kernel registers related to the Debug Reset (Class 1) are not influenced. To reset a module kernel it is necessary to set the RST bits by writing with '1' in both Kernel Reset Registers. The RST bit will be re-set by the BPI with the end of the BPI kernel reset sequence.

Kernel Reset Register 0 includes a kernel reset status bit that is set to '1' by the BPI\_FPI in the same clock cycle the RST bit is re-set by the BPI\_FPI. This bit can be used to detect that a kernel reset was processed. The bit can be re-set to '0' by writing '1' to the KRSTCLR.CLR register bit.

During the execution of the kernel reset until RSTSTAT is set, access to the kernel registers will result in an error acknowledge.

#### KRST0

Field	Bits	Type	Description
RST	0	rwh	<b>Kernel Reset</b> This reset bit can be used to request for a kernel reset. The kernel reset will be executed if the reset bits of both kernel registers are set. The RST bit will be cleared (re-set to '0') by the BPI_FPI after the kernel reset was executed. 0 <sub>B</sub> No kernel reset was requested 1 <sub>B</sub> A kernel reset was requested
RSTSTAT	1	rh	<b>Kernel Reset Status</b> This bit indicates whether a kernel reset was executed or not. This bit is set by the BPI_FPI after the execution of a kernel reset in the same clock cycle both reset bits. This bit can be cleared by writing with '1' to the CLR bit in the related KRSTCLR register. 0 <sub>B</sub> No kernel reset was executed 1 <sub>B</sub> Kernel reset was executed
0	31:2	r	<b>Reserved</b> Read as 0; should be written with 0.

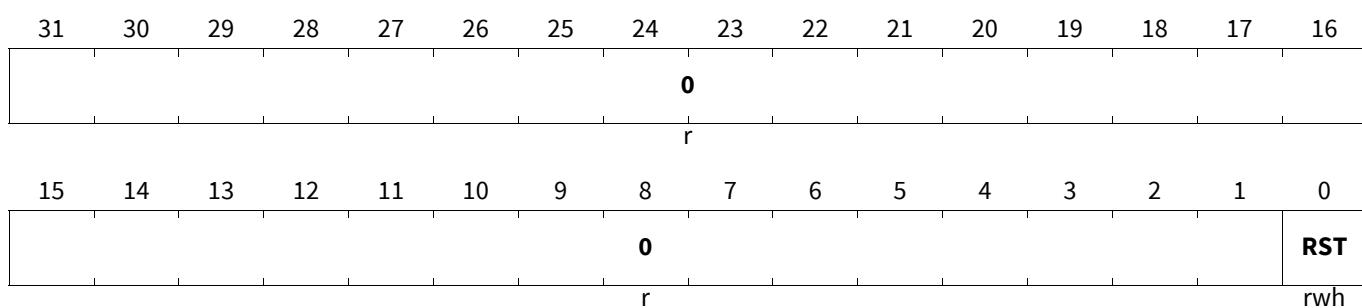

## High Speed Pulse Density Modulation Module (HSPDM)

### Kernel Reset Register 1

The Kernel Reset Register 1 is used to reset the related module kernel. Kernel registers related to the Debug Reset (Class 1) are not influenced. To reset a module kernel it is necessary to set the RST bits by writing with '1' in both Kernel Reset registers. The RST bit will be re-set by the BPI with the end of the BPI kernel reset sequence.

#### KRST1

##### Kernel Reset Register 1

## Camera and ADC Interface (CIF)

### 26 Camera and ADC Interface (CIF)

The Camera and ADC Interface Module (CIF) provides 16-bit wide parallel read interface that can be used to connect camera sensors and external Analog to Digital Converters (ADCs).

#### 26.1 Feature List

**The following list summarizes the CIF's features:**

- Throughput up to 96 MPixel/s
- 32-bit BBB slave programming interface
- BBB master interface
- ITU-R BT 601 compliant video interface supporting  $YC_bC_r$  and RAW data transfer
- ITU-R BT 656 compliant video interface supporting  $YC_bC_r$  and RAW data transfer
- Non line/frame aligned data transfer (data mode)
- 16-bit parallel camera and ADC interface
- $YC_bC_r$  4:2:2 processing
- Hardware JPEG encoder (supporting images up to a horizontal resolution of 1280 pixel) incl. JFIF1.02 stream generator and programmable quantization and Huffman tables
- Windowing and frame synchronization
- 1 Main and 5 Extra Image Cropping units allowing parallel transfer and position adjustment of up to 6 subregions
- Path from Main Image Stabilization or from one Extra Image Cropping unit to AGBT debug interface including a Metasymbol Generation unit inserting frame start and timing information into the stream
- Programmable watchdog timer to detect abortion/breaks in frame transmission
- Linear downscaling for the first extra path, supporting a mode for RGB Bayer Pattern
- Frame skip support for video (e.g. MPEG-4) encoding
- Macro block line, frame end, capture error, data loss interrupts and synchronization (h\_start, v\_start) interrupts
- Programmable polarity for synchronization signals
- Luminance/chrominance and chrominance blue/red swapping for  $YC_bC_r$  input signals
- Maximum input resolution of 4095x4095 pixels
- Buffer in EMEM organized as ring-buffer, supporting up to 2x8 Beat Bursts (2x32 Bytes)
- Buffer overflow protection for RAW data transfer and JPEG files
- Asynchronous reset input, software reset for the entire IP
- Support of planar, semi planar and interleaved storage format (main path)
- Power management by software controlled clock disabling of currently not needed sub-modules

#### 26.2 Overview

The following section provides overview of the architecture of the CIF module and its applications.

---

## Camera and ADC Interface (CIF)

### 26.2.1 Introduction

The Camera and ADC Interface (CIF) represents a complete video and still picture input interface transferring data from an image sensor into EMEM. Furthermore several hardware blocks - performing image processing operations on the incoming data - are provided.

#### 26.2.1.1 Camera and ADC Interface Functional Overview

Apart from providing the physical interfacing to various types of camera sensor modules, the CIF block implements image processing and encoding functionality. The integrated image processing unit supports image sensors with integrated  $Y\bar{C}_b\bar{C}_r$  processing. Additionally the CIF also supports transfer of RAW (e.g. Bayer Pattern) images and non frame synchronized data packets.

The CIF block features a 16 bit parallel interface.

All output data is transmitted via the memory interface to a BBB system using the master interface.

Programming of the CIF is done by register read/write transactions using a BBB slave interface.

#### 26.2.1.2 Camera and ADC Interface Block Diagram

[Figure 340](#) shows the \*\*\* 'Camera and ADC Interface Block Diagram' on page 2 \*\*\* (top level view).

The BBB interface is divided into a master and a slave interface with their own clock domains. These clock domains may be asynchronous to the CIF Module Clock. To avoid data loss the frequency of the BBB clocks need to fulfill the following requirements:

- BBB Interface Master Clock (DMA)  $\geq$  CIF Module Clock
- BBB Interface Master Clock (DMA)  $\leq 2 *$  CIF Module Clock
- CIF Module Clock  $\geq$  Pixel Clock (PCLK)

## Camera and ADC Interface (CIF)

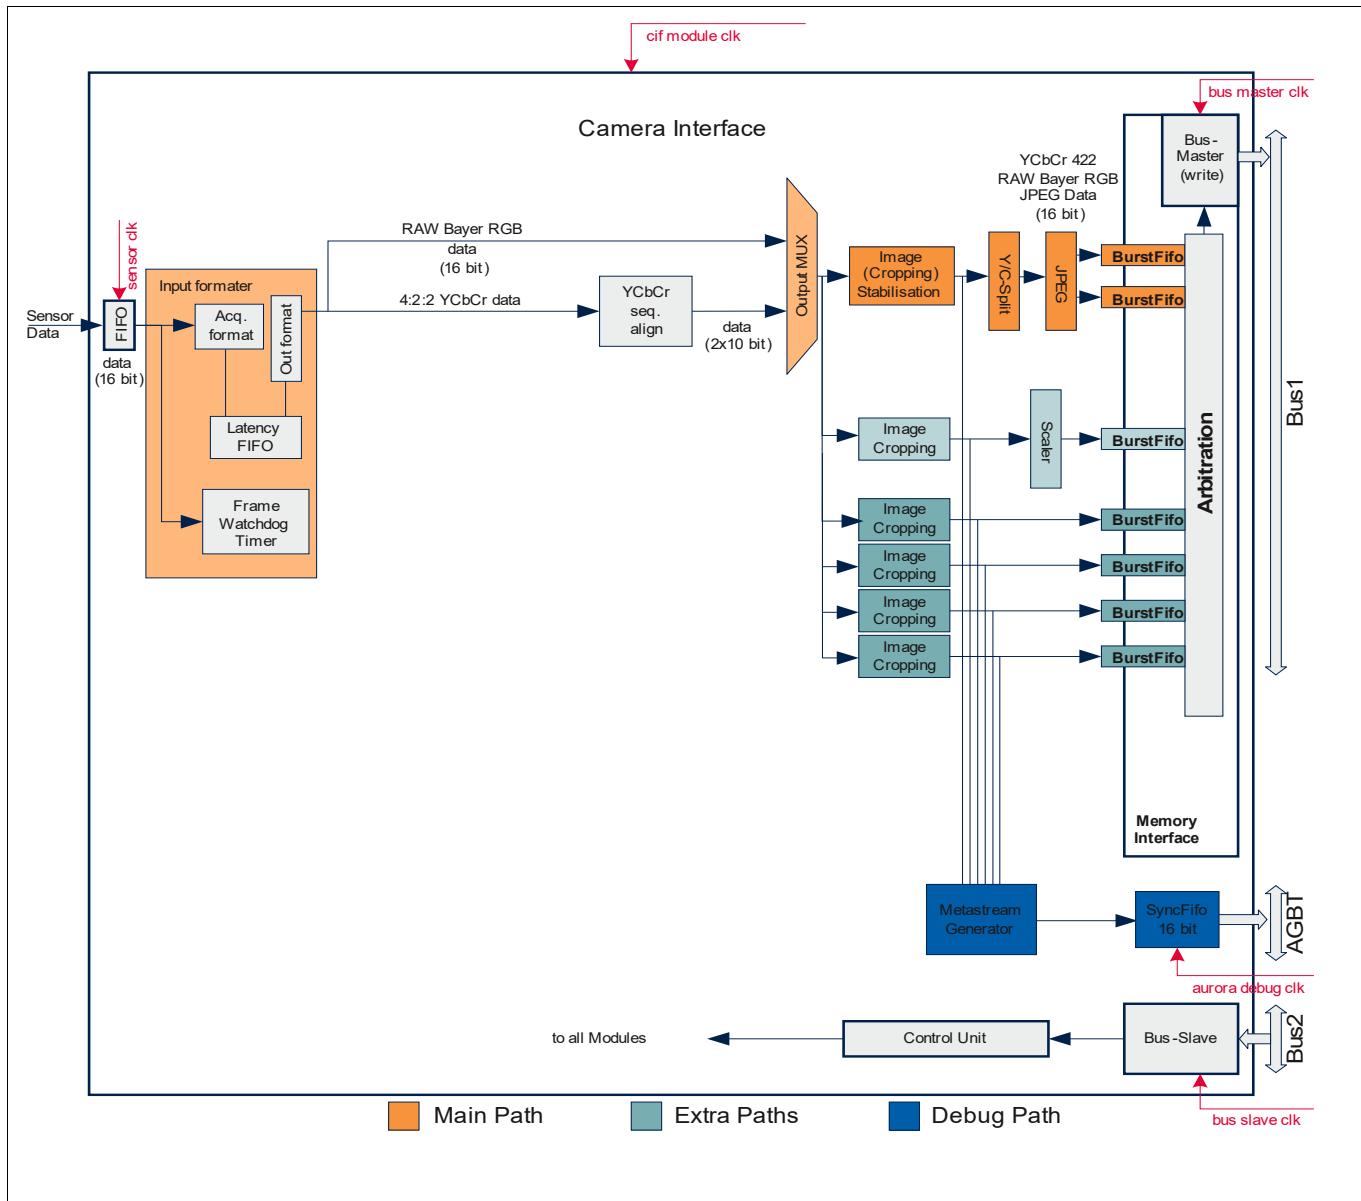

Figure 340 \*\*\* 'Camera and ADC Interface Block Diagram' on page 2 \*\*\*

### 26.2.2 Camera and ADC Interface Functional Specification

This chapter describes the CIF's functionality.

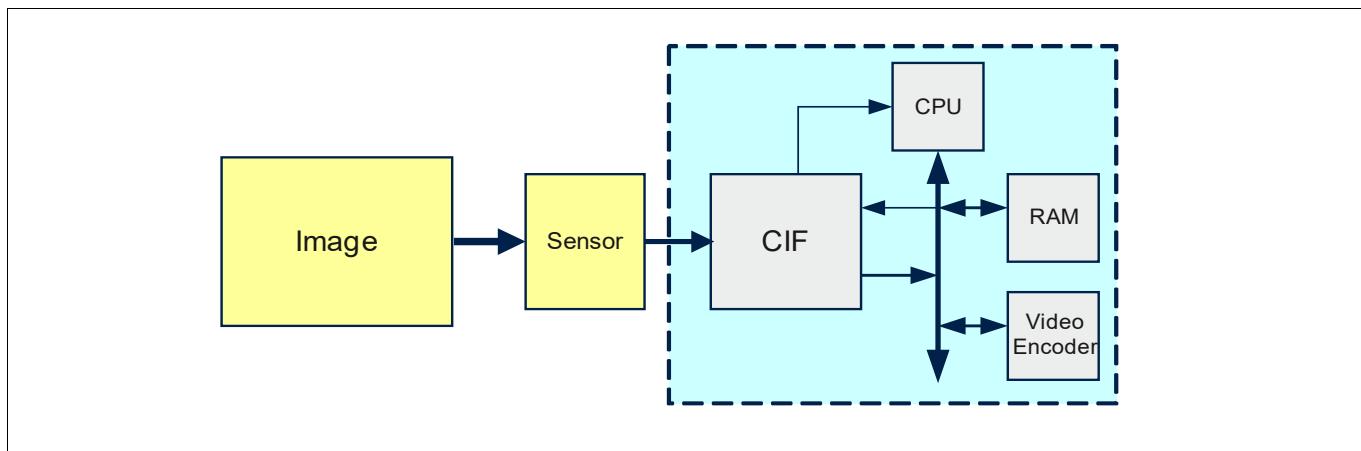

#### 26.2.2.1 Target Applications

The CIF is targeted on various applications requiring a mega pixel still image and/or video input (e.g.: mobile devices, automotive or industrial vision, ...).

##### 26.2.2.1.1 Camera Interface Example

A target application example is shown in [Figure 341](#).

## Camera and ADC Interface (CIF)

**Figure 341 Target application example**

The CIF provides a sensor/camera interface for a wide variety of video applications and it is optimized for high speed data transmission under terms of low power consumption.

**Table 1178 Available Signals for Sensor Interface**

Source	CIF I/O Name <sup>1)</sup>	Description
Sensor	PCLK	Pixel Clock from Sensor
Sensor	HSYNC	Horizontal Synchronisation Signal from Sensor
Sensor	VSYNC	Vertical Synchronisation Signal from Sensor
Sensor	D[15:0]	Data Bus from sensor (16 bit maximum)

1) See [Section 26.5, “IO Interfaces”](#)

This module is designed to be used for the following use cases:

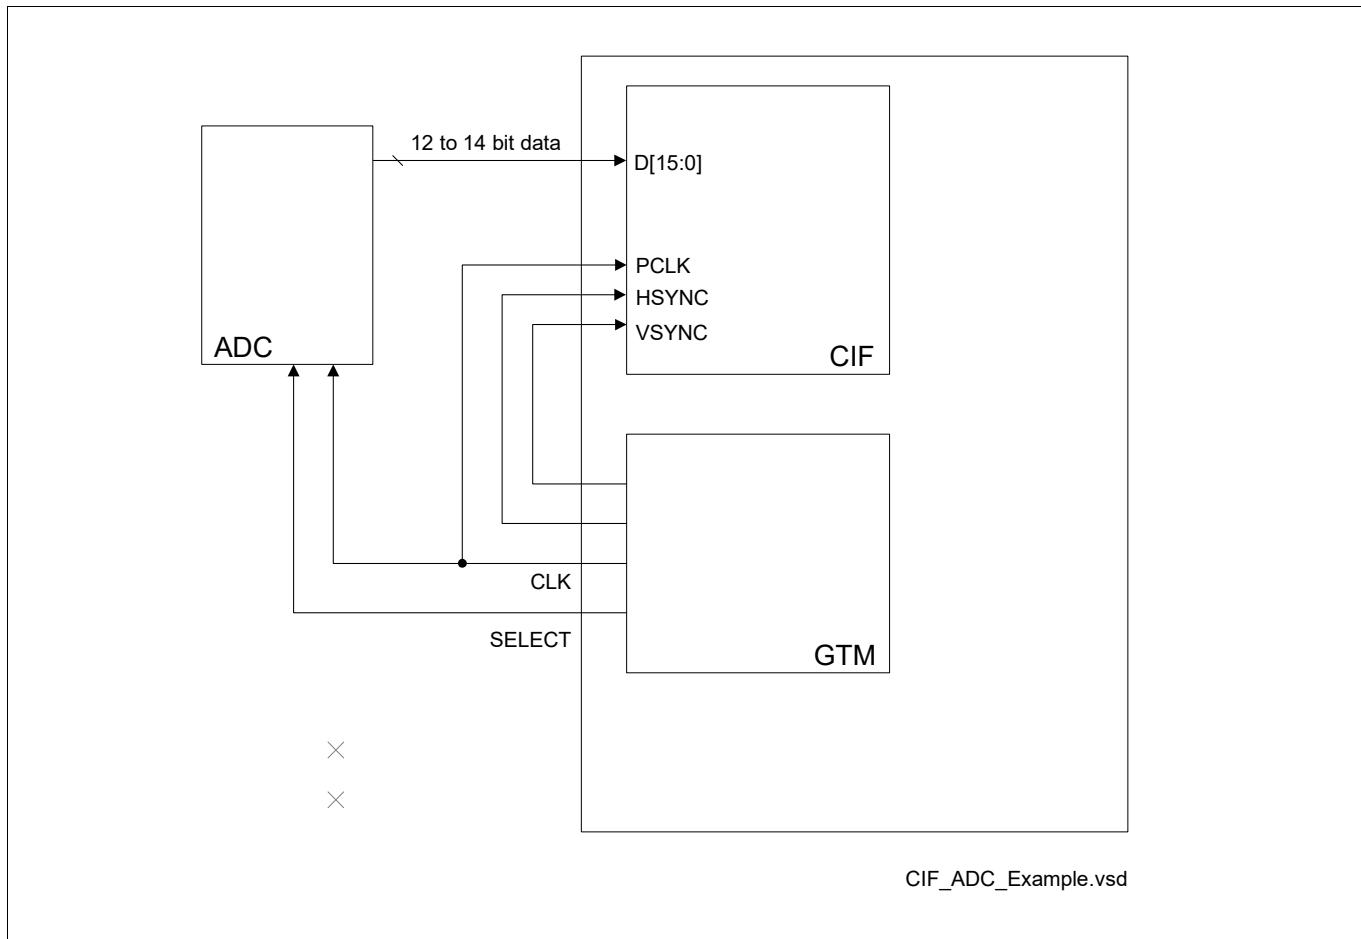

- Video capturing/encoding
- Still image capturing in  $YC_bC_r$  with on-the-fly JPEG encoding
- RAW frame data capturing
- Simple non line/frame aligned data reception (data mode) used for example for connecting to external ADCs

The CIF requires fast system memory for image storage in either planar/semi-planar/interleaved  $YC_bC_r$  or RAW planar format or as JPEG compressed data. The integrated JPEG encoding engine is able to generate a full JFIF 1.02 compliant JPEG file that can be displayed directly by any image viewer.

All important  $YC_bC_r$  formats - which are used for video compression (e.g. MPEG4) for instance - are supported. For on-the-fly encoding macro block line interrupts are generated to trigger video encoding.

### 26.2.2.1.2 Connecting External ADC

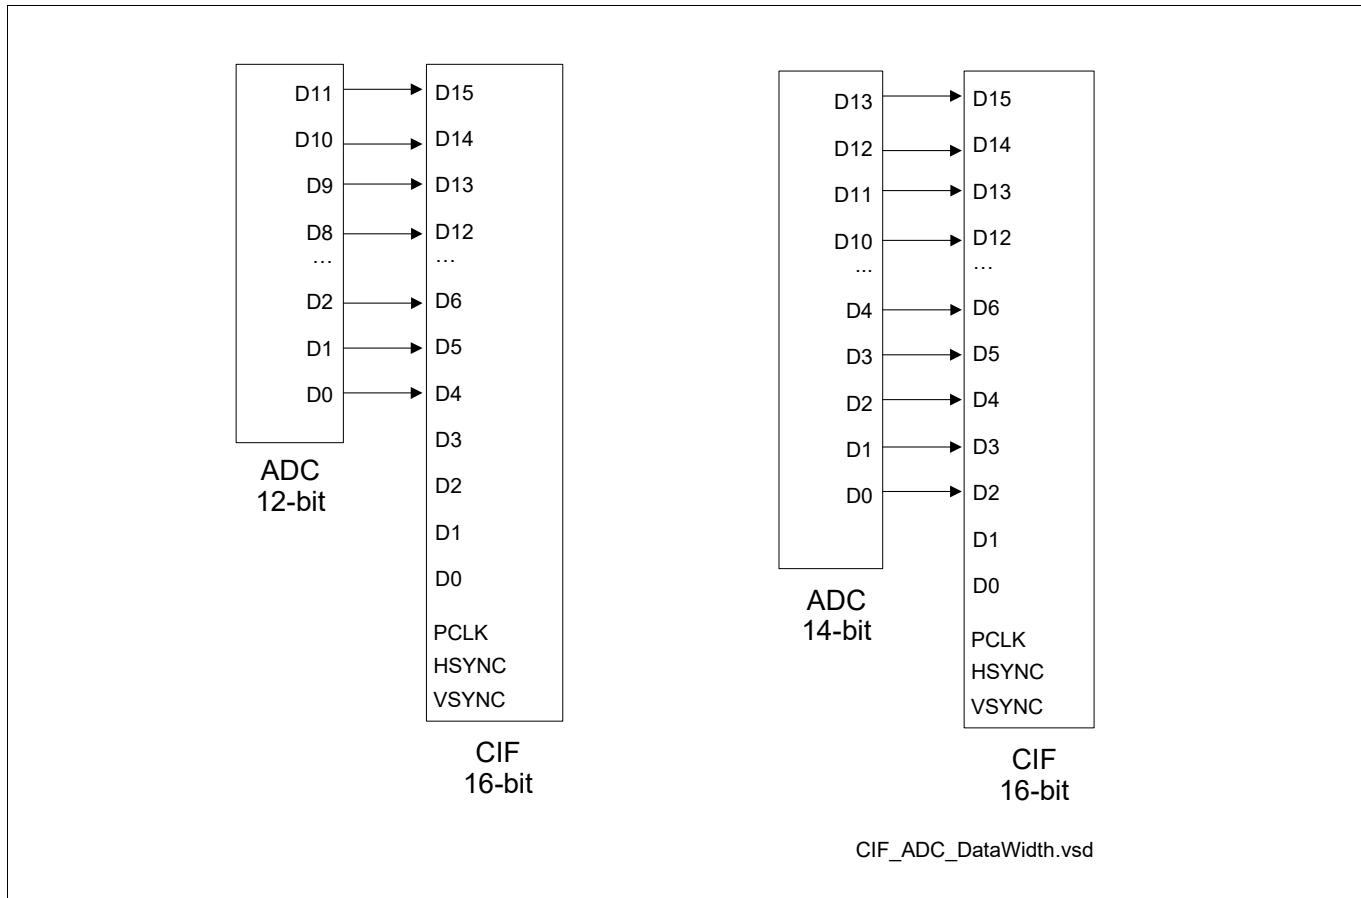

The CIF provides a parallel interface that can be used to connect external ADC converters. In order to connect to one or more external ADCs, the CIF module requires a timer module capable of generating the appropriate clock and select signals, like the Generic Timer Module (GTM). The [Figure 342](#) shows an example of a connection between a single ADC and the CIF module.

**Camera and ADC Interface (CIF)****Figure 342 Example of a Connection to an External ADC**

Connecting multiple ADCs to the CIF module may require an external multiplexer, and additional control signals to control it. Using twin or quad ADCs avoids the need for an external multiplexer.

## Camera and ADC Interface (CIF)

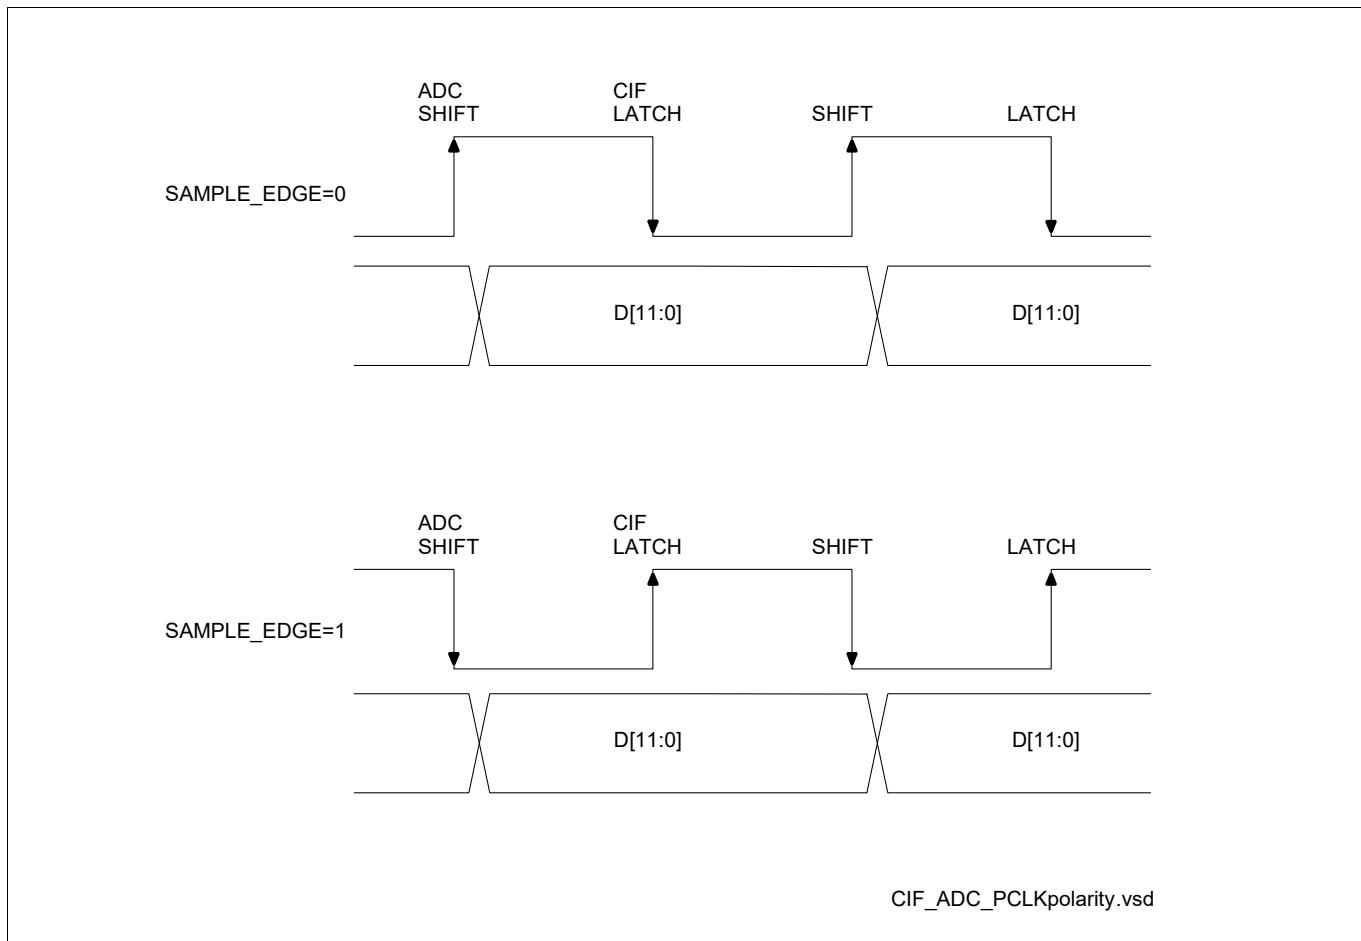

The ADC data has to be connected MSB aligned to the CIF input pins. The [Figure 343](#) shows examples of data connections between a 12-bit or 14-bit ADC and the CIF module.

**Figure 343 External ADC Data Alignment**

## Camera and ADC Interface (CIF)

The pixel clock PCLK controls the data transfer. The first edge of the clock signal can initiate the ADC to provide the data; the second edge can trigger the CIF to latch the data. In the **Figure 344** the providing of the next parallel data is referred to as “shifting”, which is what happens if the ADC has a data FIFO. The clock polarity can be programmed both in the GTM and in the CIF module. In the CIF module, the PCLK polarity is configured in by the bit field **ISP\_ACQ\_PROP.SAMPLE\_EDGE**.

**Figure 344 PCLK Clock Polarity and Data Transfer (12-bit ADC)**

The polarity of the signals HSYNC and VSYNC can also be configured by using the bit fields **ISP\_ACQ\_PROP.HSYNC\_POL** and **ISP\_ACQ\_PROP.VSYNC\_POL**.

## Camera and ADC Interface (CIF)

### 26.3 Functional Description

The CIF forms a complete video and still picture input interface solution for SoCs for various applications.

It is widely programmable and therefore very flexible to use. It supports input frame resolutions up to 4095x4095 pixels.

It consists of a Video Image Signal Processing unit (ISP), a Security Watchdog unit, luminance/chrominance splitter (Y/C Split), a linear downscaling unit, main and several extra cropping units, debug path, JPEG encoder, output unit, control unit (Ctrl) and a BBB slave interface for programming purposes.

All data transfer between EMEM and CIF is handled via the memory interface block.

For more information and a block diagram please refer to the sub module descriptions below and to [Section 26.2.1.1](#).

#### 26.3.1 Sub Module ISP

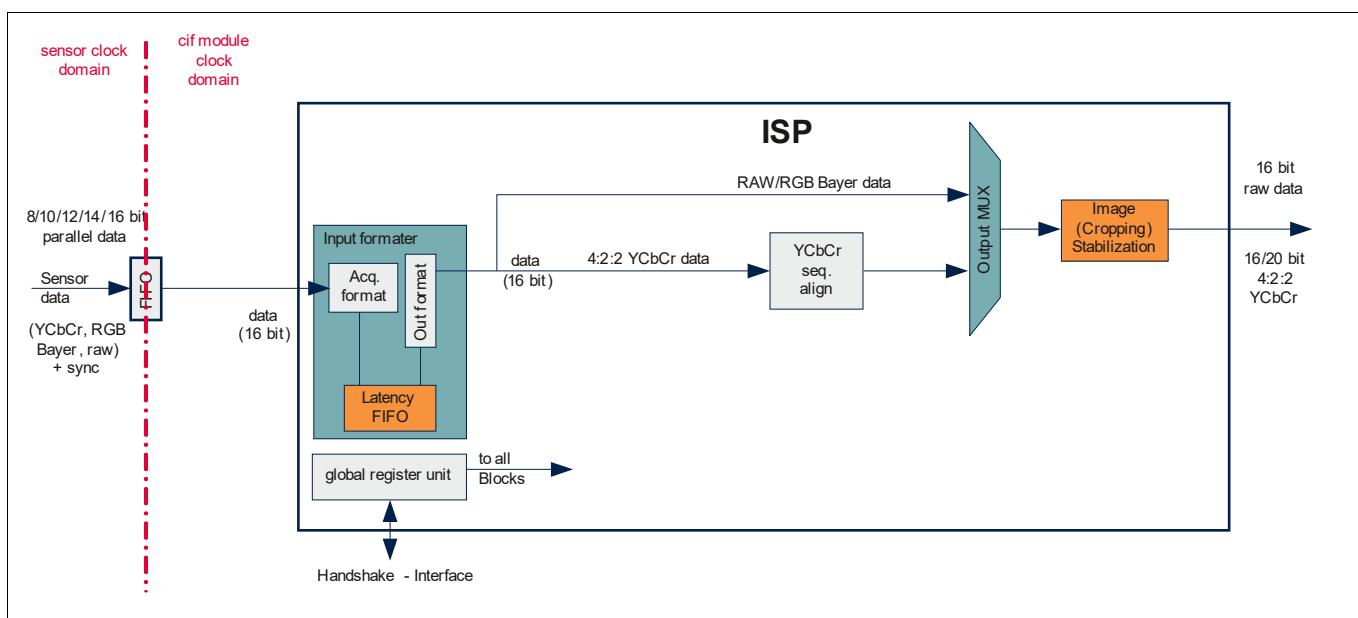

The ISP is the interface to the attached sensor device. It accepts either ITU-R BT.601 YCbCr or RAW RGB Bayer data, or ITU-R BT.656 YCbCr or RAW RGB Bayer data. Furthermore a so called “data mode” is supported which accepts non line or frame organized data. In this mode the states of the hsync and vsync hardware lines are considered as “enable” and “transfer indicator”. This mode allows connecting the CIF to any source delivering a parallel data stream (e.g. camera sensor including a JPEG encoder).

The input part of the ISP is fully programmable in terms of signal polarities, active video data positions, and luminance/chrominance order.

A handshake based mechanism is used for data qualification. As the sensor device can not be stopped from delivering data, a pipeline stall leads to an error if it occurs within an active video line.

The ISP also contains its own programming registers to be accessed by a 32 bit handshake interface.

The ISP can be configured to generate interrupts for multiple different conditions. All interrupts are mapped to the single physical request line ISP\_INT.

**Figure 345 Block Diagram of the ISP Sub Module**

The following features are implemented:

- CCIR656/601 compatible 16-bit video interface
- Input sampling on positive or negative sample clock

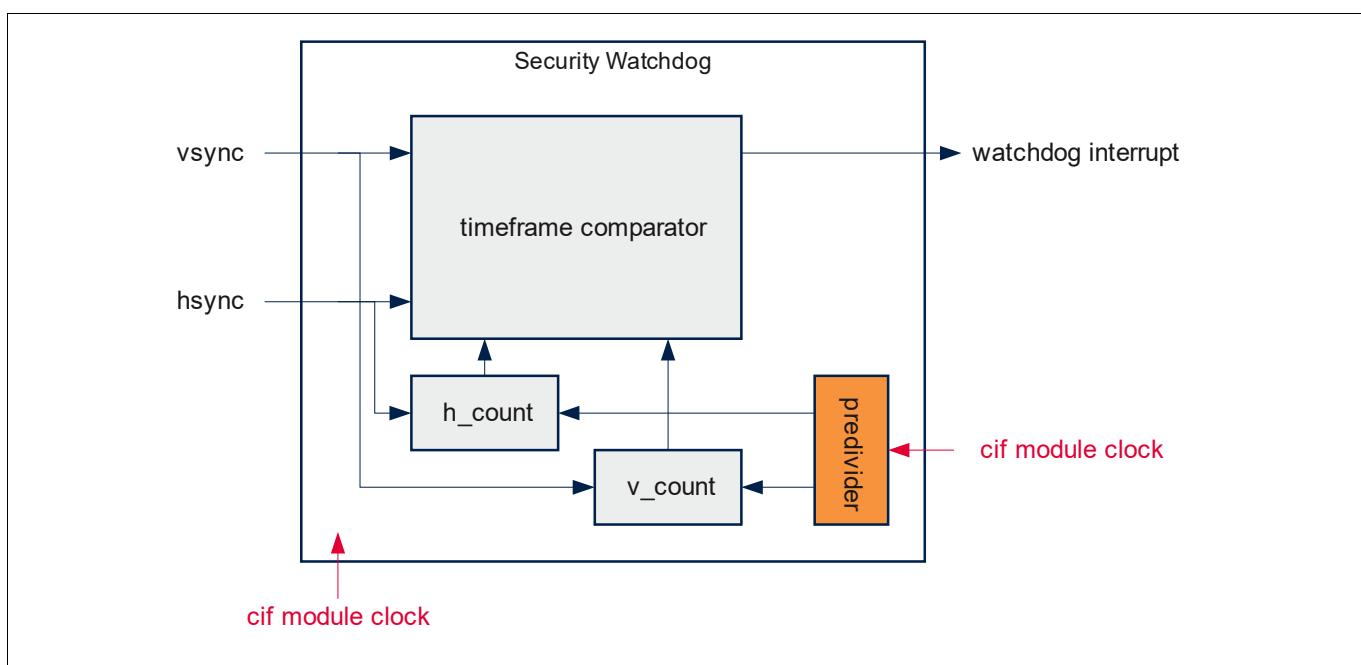

## Camera and ADC Interface (CIF)

- Cropping of the output picture (to crop interpolation artifacts), also used for windowing

### 26.3.2 Sub Module Security Watchdog

The Security Watchdog unit is used to monitor the incoming image data. Specifically it can be used to detect and report irregularities or interruptions in the data stream. To do so the horizontal and vertical synchronization signals in the input formatter unit are observed and are compared to programmable time-out frames. When a time-out frame gets violated an interrupt is generated to immediately report this event (routed to ISP\_INT).

The timing information is retrieved via 16 bit counters. There are two separate counters to measure horizontal and vertical timeframes in parallel. To enhance the configurability of the timing information an additional 16-bit prescaler controls the speed of the counter units, enabling a timing unit granularity from  $1*T_{cif\_clk}$  to  $216*T_{cif\_clk}$ .

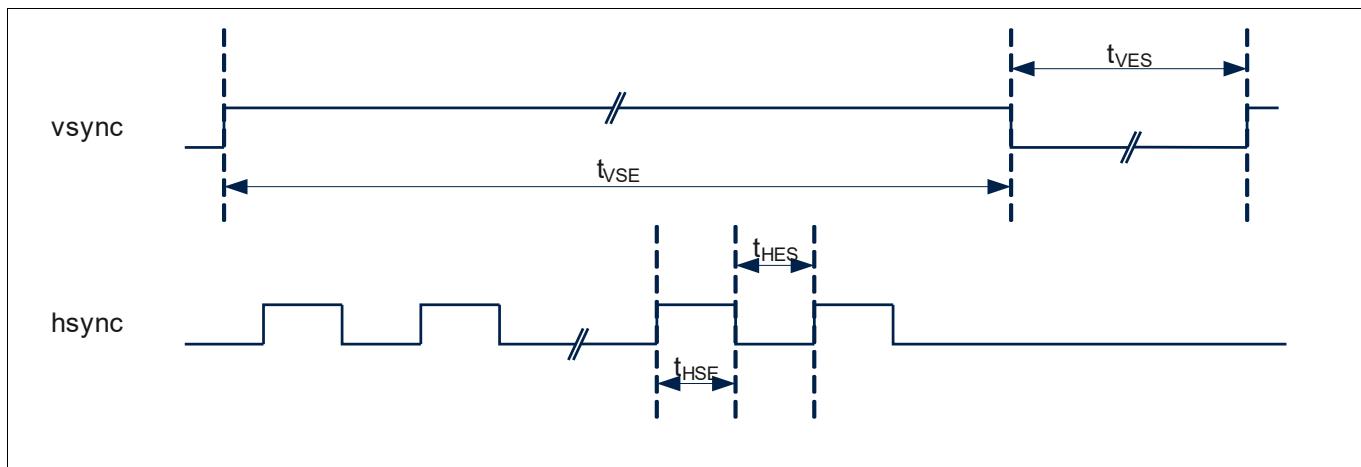

**Figure 346 Block diagram of the Security Watchdog sub module**

As can be seen in [Figure 347](#) there are four time frames of interest to be watched. The time between:

- Start and End of a frame (tVSE)
- End and Start of the next frame (tVES)
- Start and End of a line (tHSE)
- End and Start of the next line (tHES)

## Camera and ADC Interface (CIF)

**Figure 347 Programmable time-outs for the Security Watchdog**

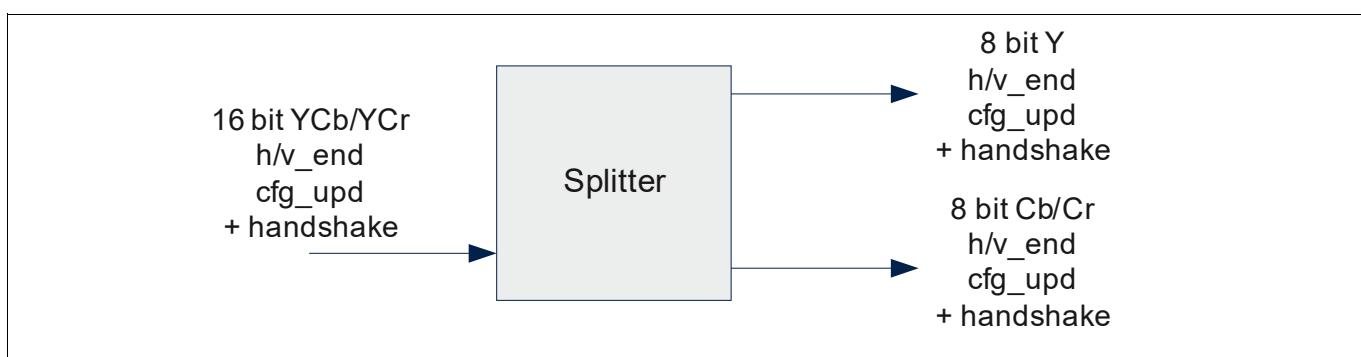

All those time-outs are programmable 16 bit values which can be set via the following registers: “[WD\\_V\\_TIMEOUT](#)” on Page 136 and “[WD\\_H\\_TIMEOUT](#)” on Page 136. So as soon as the corresponding counter reaches the programmed value an interrupt is triggered. A programmed value of zero means the time-out is not configured to trigger an event.

It is possible to completely disable the Security Watchdog unit by setting the corresponding bit of its (“[WD\\_CTRL](#)” on Page 135) or by disabling the clock of this sub module in the “[ICCL](#)” on Page 66.

### 26.3.3 Sub Module Y/C-Split

This module contains a data path splitter separating luminance (Y) and chrominance (C) information of a 16 bit YCbCr 4:2:2. Independent 8 bit Y and C channels are the result of this operation.

The Y/C Splitter must ensure that the output Y and C data streams are fully aligned, i.e. if Y data are processed in one clock cycle only, the C channel has to be stalled until the C component belonging to the processed Y component has been taken. [Figure 348](#) gives a coarse overview of the data flow from/to the sub-module.

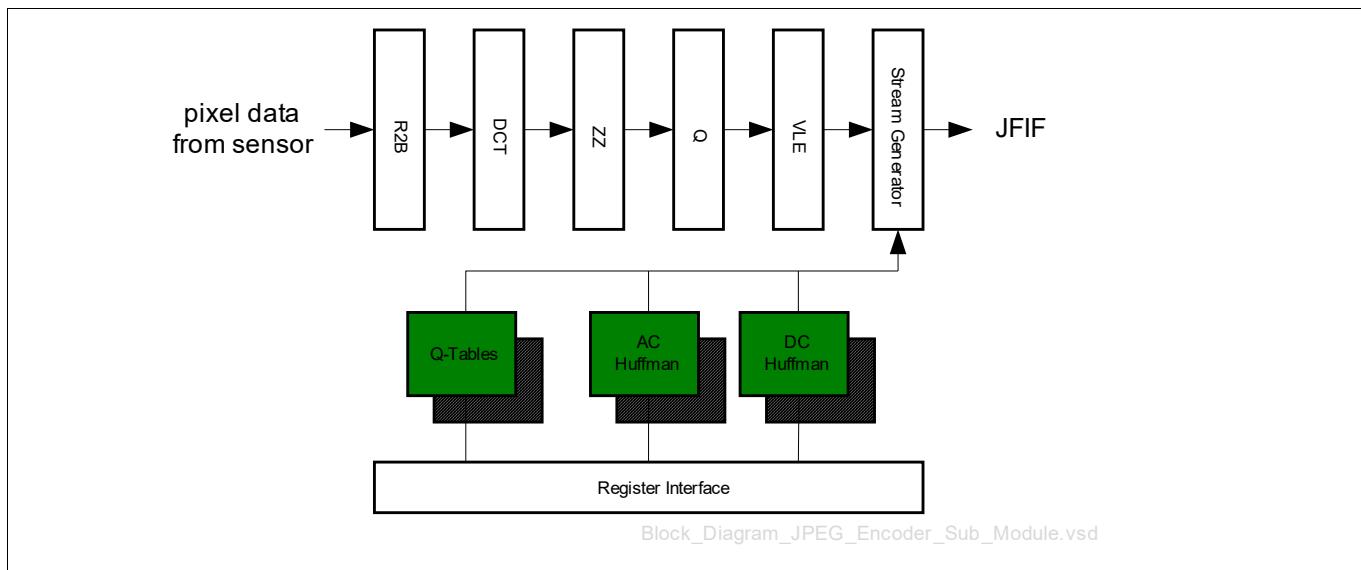

**Figure 348 Block Diagram of the Y/C-Splitting Sub Module**

### 26.3.4 Sub Module JPEG Encoder

The baseline JPEG encoder module consists of a JPEG encoder pipeline. The pipeline - which is shown in [Figure 349 “Block Diagram of the JPEG Encoder Sub Module” on Page 11](#) - is controlled by a register interface that is accessed via handshake interface. The following description gives an overview of the general functionality of the JPEG encoder.

## Camera and ADC Interface (CIF)

**Figure 349 Block Diagram of the JPEG Encoder Sub Module**

The encoding process starts with a raster to block conversion of the  $YC_bC_r$  4:2:2 pixel data provided e.g. by an imaging device. The incoming line oriented pixel data is reordered into 8x8 pixel blocks, one for each component. Every 8x8 pixel block undergoes a baseline DCT computation, a zigzag reordering, a quantization and a variable length encoding (Huffman based). Last encoding step is the generation of the JFIF 1.02 compliant data stream by inserting markers and tables.

The encoder needs two clock cycles per pixel for processing, if  $YC_bC_r$  4:2:2 data is used, which is the normal mode of the JPEG encoder.

The JPEG encoder can be configured to generate interrupts for several error conditions. All interrupts are routed to MJPEG\_INT.

### 26.3.5 Sub Module Linear Downscaler

The first extra path includes a simple scaling unit which allows to reduce the size of the transferred image by simply skipping lines and columns of a frame. The amount of horizontal (columns) and vertical (lines) data reduction can be programmed separately. The module supports four modes:

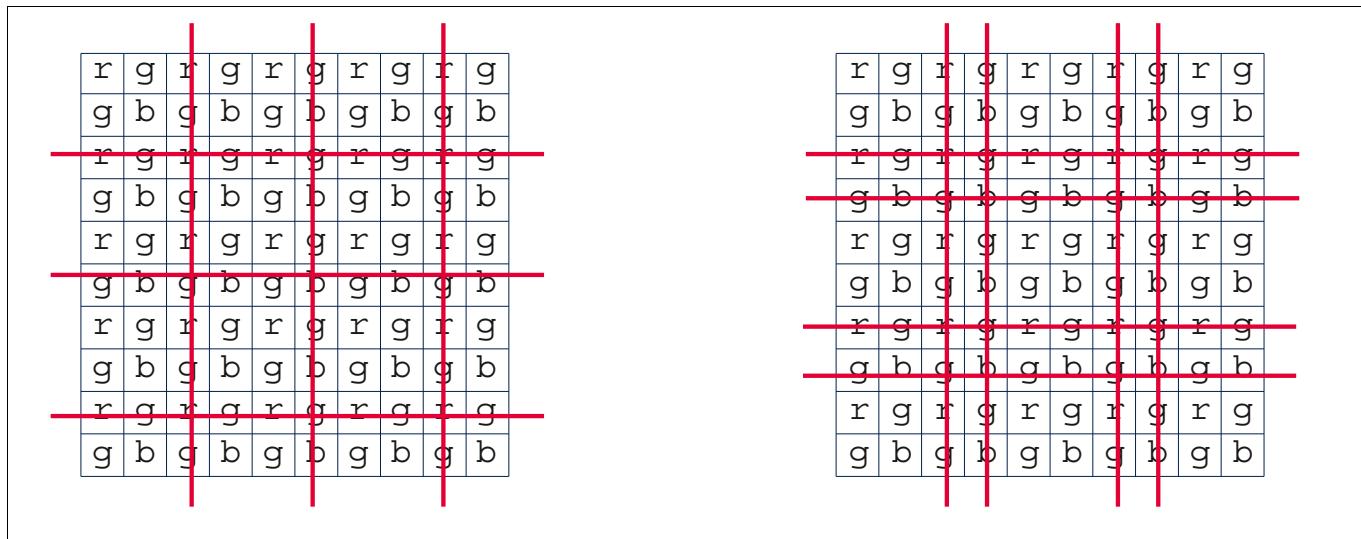

- Single skip
- Double or RGB Bayer skip
- Single pass
- Double pass

The single skip mode simply skips every nth line or column, but since this would destroy the integrity of a regular RGB Bayer pattern - see [Figure 350](#) - there is also the possibility to use the double skip mode which preserves the pattern.

Since skipping leads to a maximum data reduction of 50% at best there are corresponding pass modes to the skip modes. The difference of these modes is that only every nth pixel (or every nth two pixels) get(s) passed to the following processing unit, all other pixels get skipped. In other words: The pass mode can downscale the image data at rates  $\geq 50\%$ , whereas the skip mode allows scaling at rates  $\leq 50\%$ .

Regarding the single/double pass modes it is also important to mention that whether the bayer pattern stays preserved or not is here only dependant on the pass-value. Odd values of n will destroy the bayer pattern integrity, whereas even values will preserve it.

## Camera and ADC Interface (CIF)

**Figure 350 Single vs. RGB Bayer mode**

It's further worth mentioning that the linear downscaler - like any other image processing unit - can be set to a bypass mode where data is passed on unprocessed to the next module.

### 26.3.6 Sub Module Extra Path Units

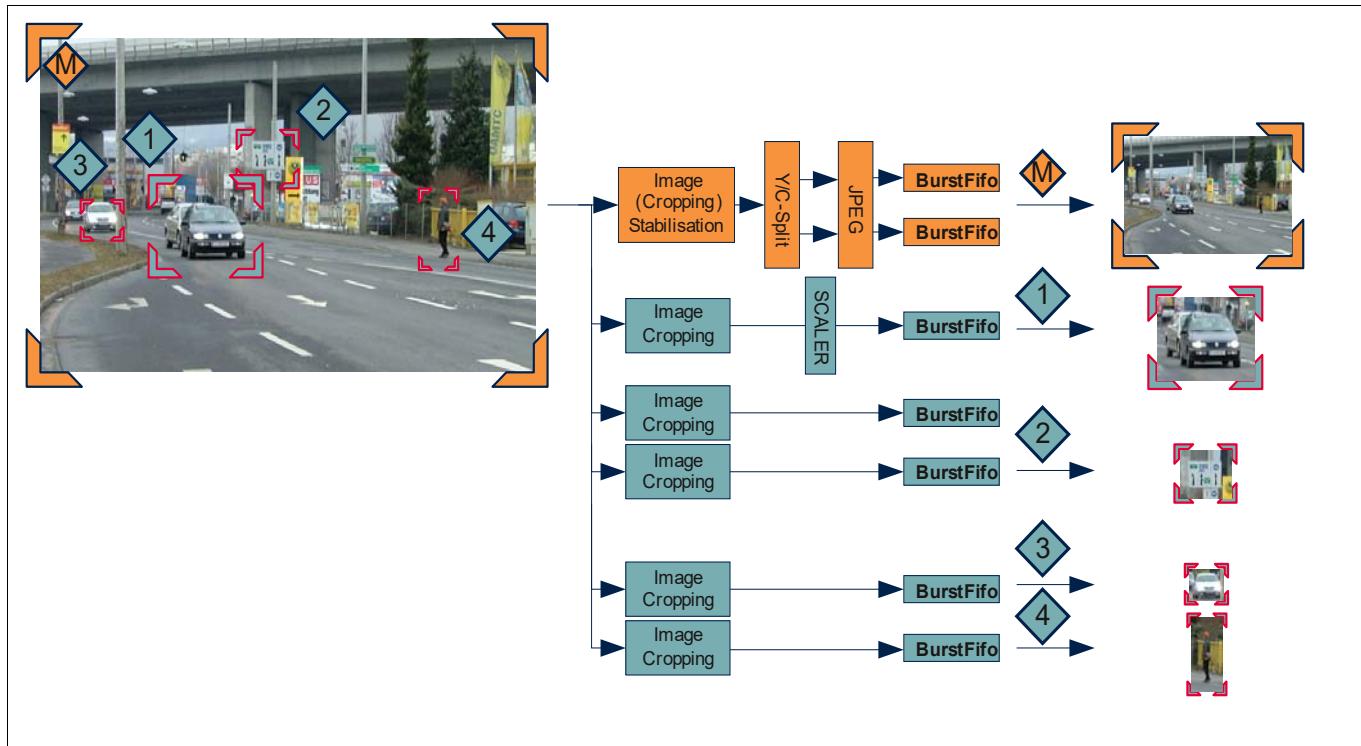

In addition to the main path, the CIF allows definition and transfer of up to 5 additional image regions into memory. Those extra paths all have their own image cropping unit<sup>1)</sup> which allows to crop a separate sub-region of the image. Furthermore it is possible to utilize the displacement and recenter functionality of the image cropping unit to adjust the position of the cropping window (e.g. tracking a moving object). For details about the functionality of the image stabilization unit see the corresponding section in the CIF Programmer's Manual.

**Figure 351** shows the function of the main and extra path units: The main path may capture the full incoming frame utilizing it's downscaling unit to keep the output size - and hence the computational effort for ongoing image processing by the system - low.

1) In the main path the Image Cropping unit is referred to as Image Stabilization unit, since in YCbCr video mode it may be used to compensate camera shakes.

## Camera and ADC Interface (CIF)

In parallel up to 5 (the example below shows four) sub images may be cropped from the same input image. Those images are stored and handled independent of the main path and also independent of each other.

**Figure 351 Example: Main and four active Extra Paths**

Since the Y/C-Split unit is not present in the extra paths, the following restriction is given:

- only one receive buffer (no support for planar/semi-planar storage)

Nevertheless every extra path has its own storage ring buffer and its own distinct interrupt generation unit for those. Those separate interrupts of the distinct extra paths are then again merged in a single multiple source interrupt register to a single separate extra path interrupt line (MIEP\_INT).

Only the first extra path has a downscaling unit, so for the other paths (including the main path) it is not possible to reduce the image dimension further after the cropping stages.

Every present extra path can be en/disabled via a programmable control register.

### Parallel use of several extra paths

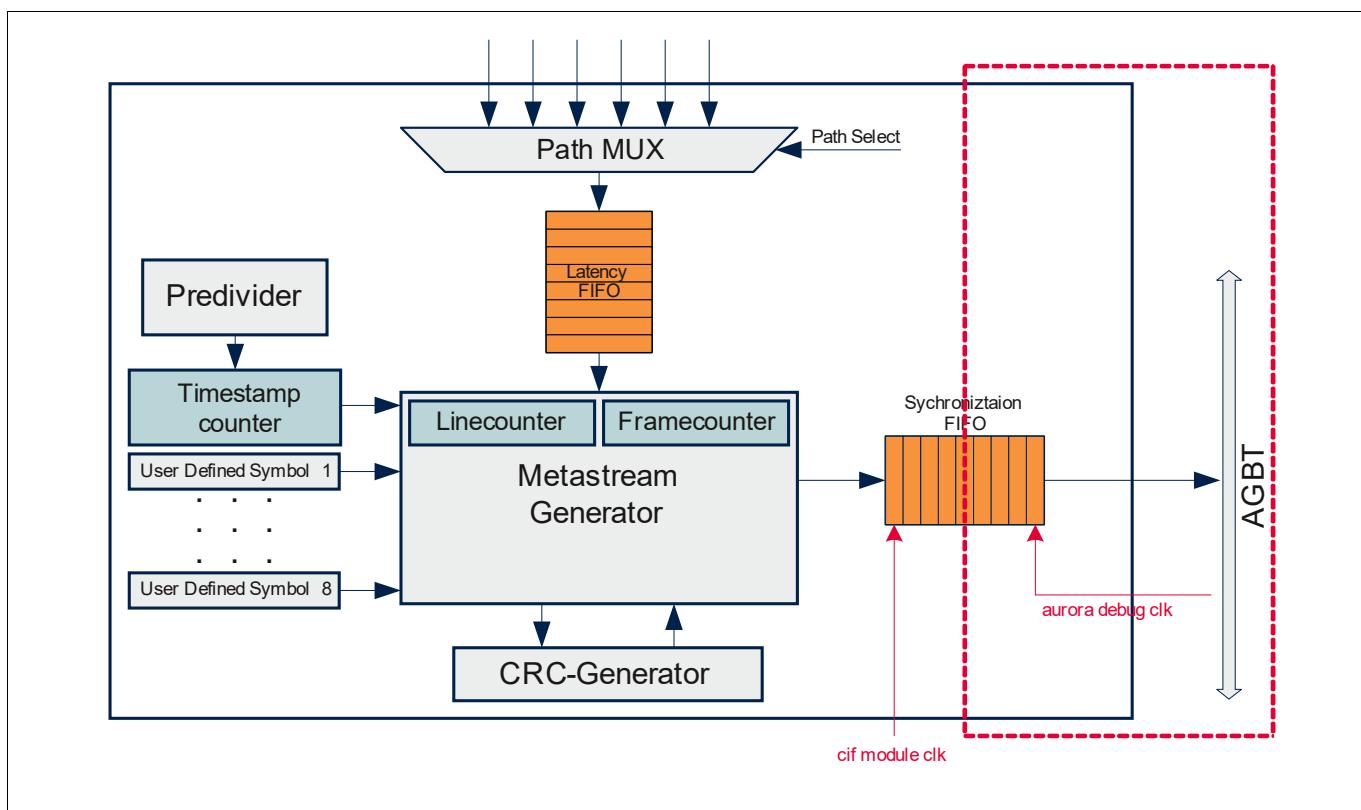

Using multiple overlapping or nested cropping windows leads to parallel activation of several extra paths generating bus load that could overload the memory interface and the back bone bus in case high baud rates are used. Use of more than two nested windows is not recommended. Extra care should be taken when using overlapped cropping windows to keep the peak BBB bus load low. For example, use cropping windows widths which are multiple of the burst size configured in the MI (Memory Interface) block. This allows the cropped regions to be transferred to memory using only bursts on the BBB bus, without a need for single moves to transfer the pixels at the end of a line that do not make a whole burst. For burst of four 32-bit moves, resulting in 16 bytes per burst, the optimal cropping window width is multiple of 16 pixels (1 byte per pixel). CIF single move takes 8 BBB clock cycles (0.5 bytes/clock cycle), burst of four 12 (1.33 bytes/clock cycle), and burst of eight 16 clock cycles (2 bytes/clock cycle). Burst of eight results in 200 Mbytes/sec for 100MHz BBB bus clock, which is the theoretical maximum if the CIF module is the only master on the BBB bus.

## Camera and ADC Interface (CIF)

### 26.3.7 Debug Path

The debug path is used to transfer data from one of the CIF paths (main or extra) to an Aurora Gigabit Trace (AGBT) debug interface. To do so the data from one of the paths - which may also still be passed on to the memory interface - is additionally routed to the debug unit. Despite simply passing this data on to the AGBT interface, the CIF debug path also inserts meta information and CRC checksums to the stream. This helps to ease, enhance and secure the analysis of the retrieved data.

As can be seen in the **Figure 352** it is possible to select - via a MUX - from which path the data to send via the Aurora interface is taken. The selected data is then transferred into a latency compensation FIFO. This is needed to let the Metastream Generator send several additional information symbols before the received data stream, which shall not block the transfer of this stream to memory meanwhile.

**Figure 352** Debug Path block diagram

Those additionally inserted symbols are:

- Metasymbol marker
- Metastream type information
- a 30-bit timestamp
- a Frame-/Linenumber
- up to eight 15-bit user defined symbols
- Payload length Information
- Header & Payload checksum

**Figure 353** shows an example of a pixel line as transferred over the debug interface. The pixel debug stream consists of 16-bit symbols, where the value  $FFFF_H$  shall be a reserved value - the so called Metasymbol marker - which distinctly marks the start of a debug frame. This leads to some obvious restrictions in other symbols. The general rule reads as follows: In every symbol despite the Metasymbol marker the highest bit (MSB) has to be  $0_B$ .

## Camera and ADC Interface (CIF)

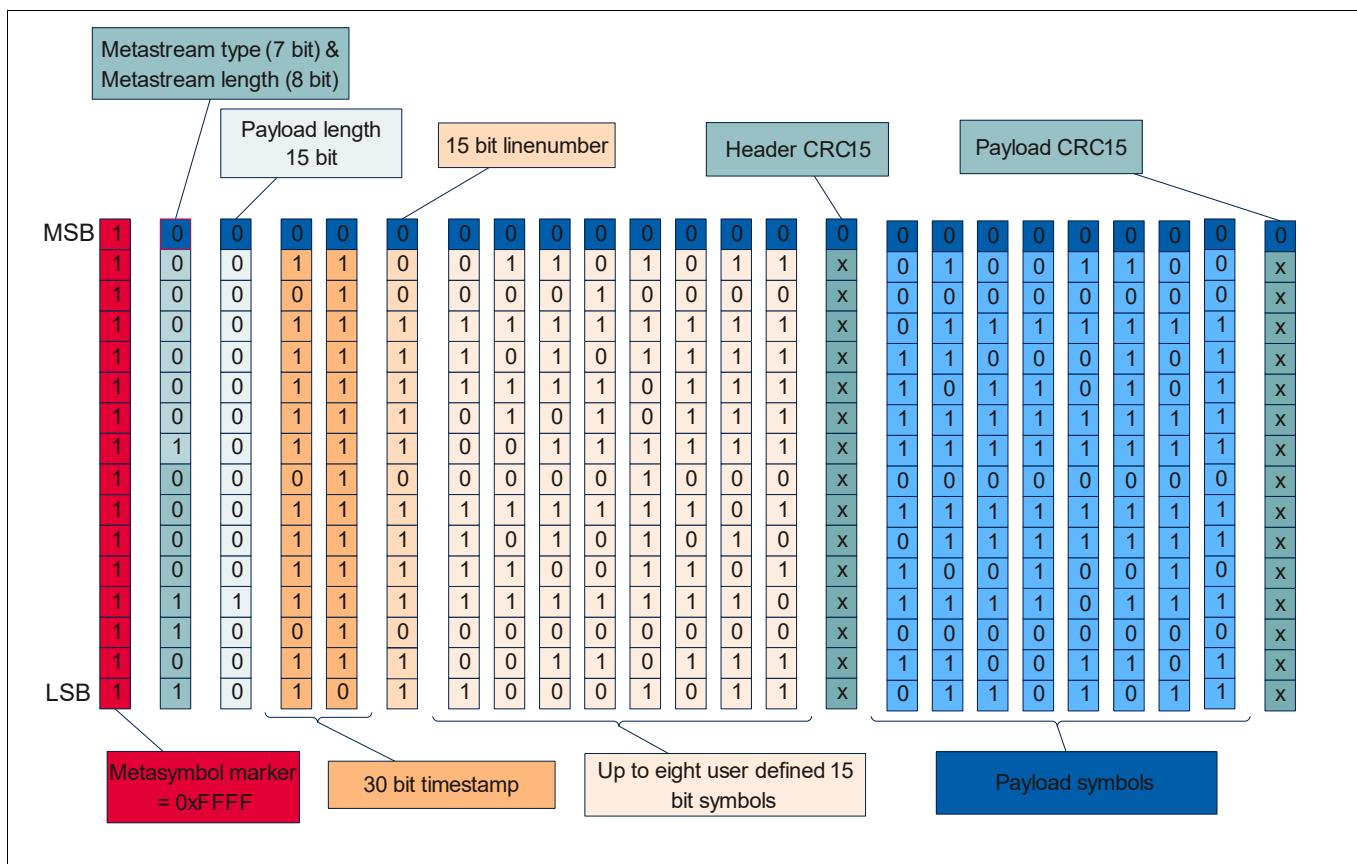

The currently supported Metastream types are:

- Start of Frame (SoF) Code  $00_H$
- Start of Line (SoL) Code  $01_H$

SoF is a simple Marker which only consists of the type and length information, timestamp, framenumber, user symbols and CRC. The SoF has no payload attached and hence no corresponding information like payload length or payload-CRC. Like the name suggests the SoF is sent only once at the beginning of an image frame. It has to be followed by - depending on the image size - several SoL packets.

**Figure 353** shows an example of a SoL packet. Basically it contains the same information like a SoF packet, just with a linenumber instead of a framenumber and additional payload information.

As can be also seen in the example the payload symbols - which are the image pixels of a line - are right shifted by one & stuffed with zero on the high significant end. In case of 16 bit data this means that the least significant bit of the payload gets lost. In 14 bit data mode, the data is right-shifted for 1 bit, but the two LSB bits are always zero, so there is no data loss. In YUV16 mode the module shifts right and the chrominance LSB is lost. In RAW16 mode the module does not shift and the LSB bit is lost.

**Figure 353** Line debug packet

The header length which is always included in a packet and the payload length which is additionally included in SoL packets can be used as additional security measures to quickly identify transmission gaps or similar issues. All given length information in the debug stream is referring to symbols. So in the example of **Figure 353** the payload length of 8 means that exactly 8 symbols of payload have to follow the header. The header length symbol gives the length of the header excluding the Metasymbol marker. For both values, header and payload - the CRC is not included.

The timestamp is a simple free running 30 bit counter and can be used to introduce quite accurate timing information to the stream. To enhance the flexibility of this counter a preceding prescaler unit is included which

## Camera and ADC Interface (CIF)

is clocked by the CIF module clock. This unit allows to configure the granularity of the timestamp to be between 1\*Tcif module clk to 232\*Tcif module clk.

User defined symbols are a way to insert/feedback software dependant information into the data stream. One possible application could be the insertion of coarse time/date information which supplements the internally generated timestamp.

The eight user defined symbols are freely programmable registers which can be included into the stream on a per symbol basis. Per default after reset no user defined symbols will be sent in the debug data stream.

Linenumber and framenumber are simple counters which can be reset by software at any time. The framenumber will run free and simply overflow starting again from zero, whereas the linenumber will be reset internally with every new SoF packet.

As CRC a 15 bit version using the same polynomial as the CAN-bus CRC is used. The input to this CRC is a full 16 bit symbol. The header CRC covers all symbols from the Metasymbol marker up to the last active user defined symbol. Whereas the payload CRC covers all payload symbols from the first after the header CRC up to the last.

If it is not needed it is possible to deactivate the whole debug path by disabling it's clock via the "["ICCL" on Page 66.](#)

**Note:** *The CIF module shifts the pixel data to the right when transferring via AGBT, in order to guarantee data symbol MSB of zero. Therefore, the LSB bit is lost in case the data is LSB aligned. This is valid for YUV data and 16-bit radar data. The raw RGB data is 14-bit MSB aligned and no LSB loss occurs.*

### Activating and Deactivating the AGBT Path

When activating the AGBT path, use the following sequence:

- first select CIF in the AGBT module then configure the AGBT registers in CIF and at the end enable the AGBT path in the CIF module

When deactivating the AGBT path, use the inverse sequence:

- first disable the AGBT path in the CIF module then deselect CIF in the AGBT module

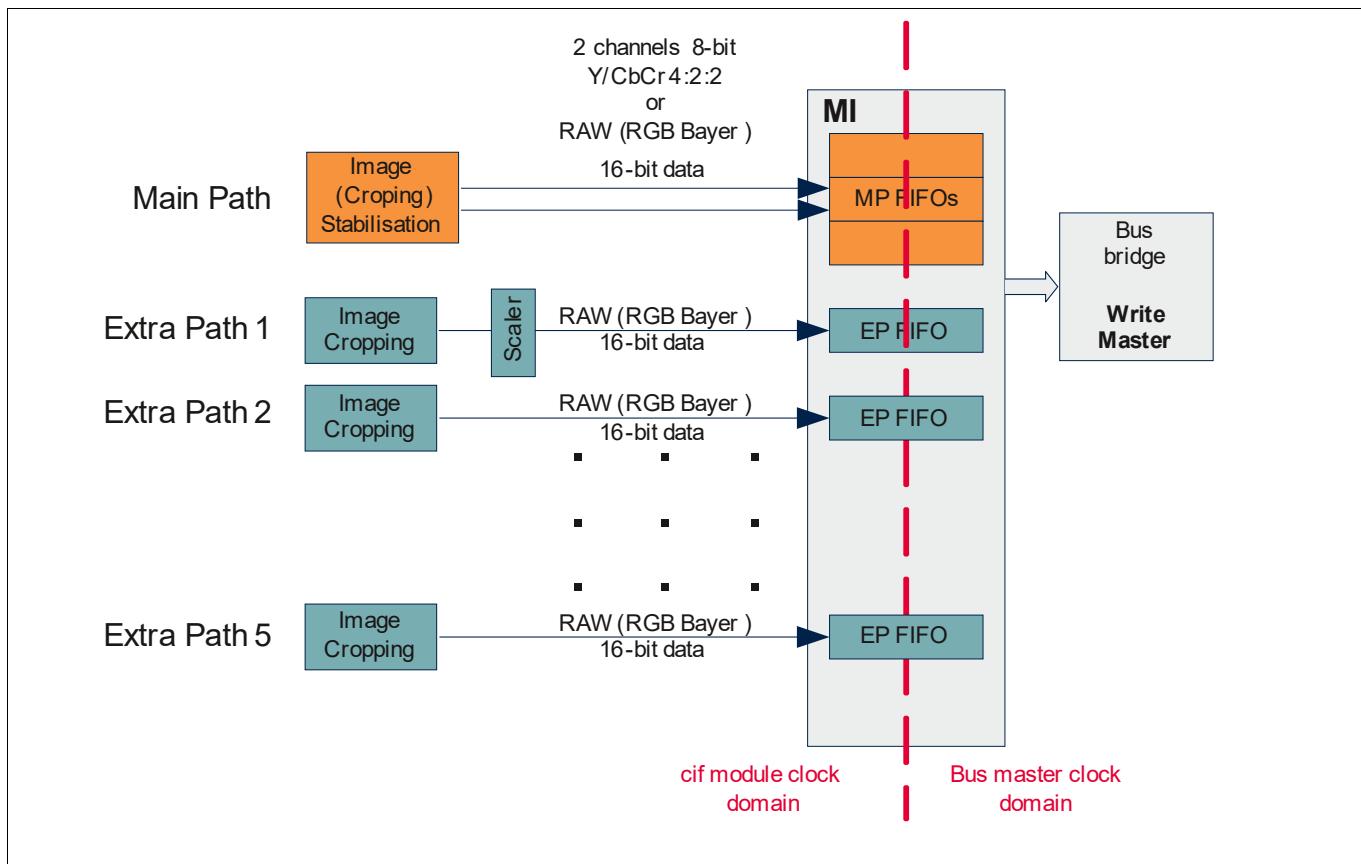

### 26.3.8 Sub Module Memory Interface (MI)

The Memory Interface module - shown as in [Figure 354](#) - has the following tasks:

- It collects the CIF internal data streams and writes them into the EMEM.
- It decouples the BBB master clock from the CIF module clock.

**Attention:** *In order to configure the CIF BBB master to access the EMEM, please refer to the system memory map.*

## Camera and ADC Interface (CIF)

**Figure 354 Overview Memory Interface connections**

The MI supports storage of main picture YCbCr, JPEG and RAW data (up to 16 bit). Y, Cb and Cr data is stored in EMEM supporting the following modes:

- separate buffers (planar)
- two buffers (semi planar)
- one buffer (interleaved)

**Figure 355** gives an overview of those three modes, but also shows the effect of the byte swapping option which effects the endianness of the output format.

All FIFOs used in MI are synchronization FIFOs which handle the task of decoupling the different clock domains.

## Camera and ADC Interface (CIF)

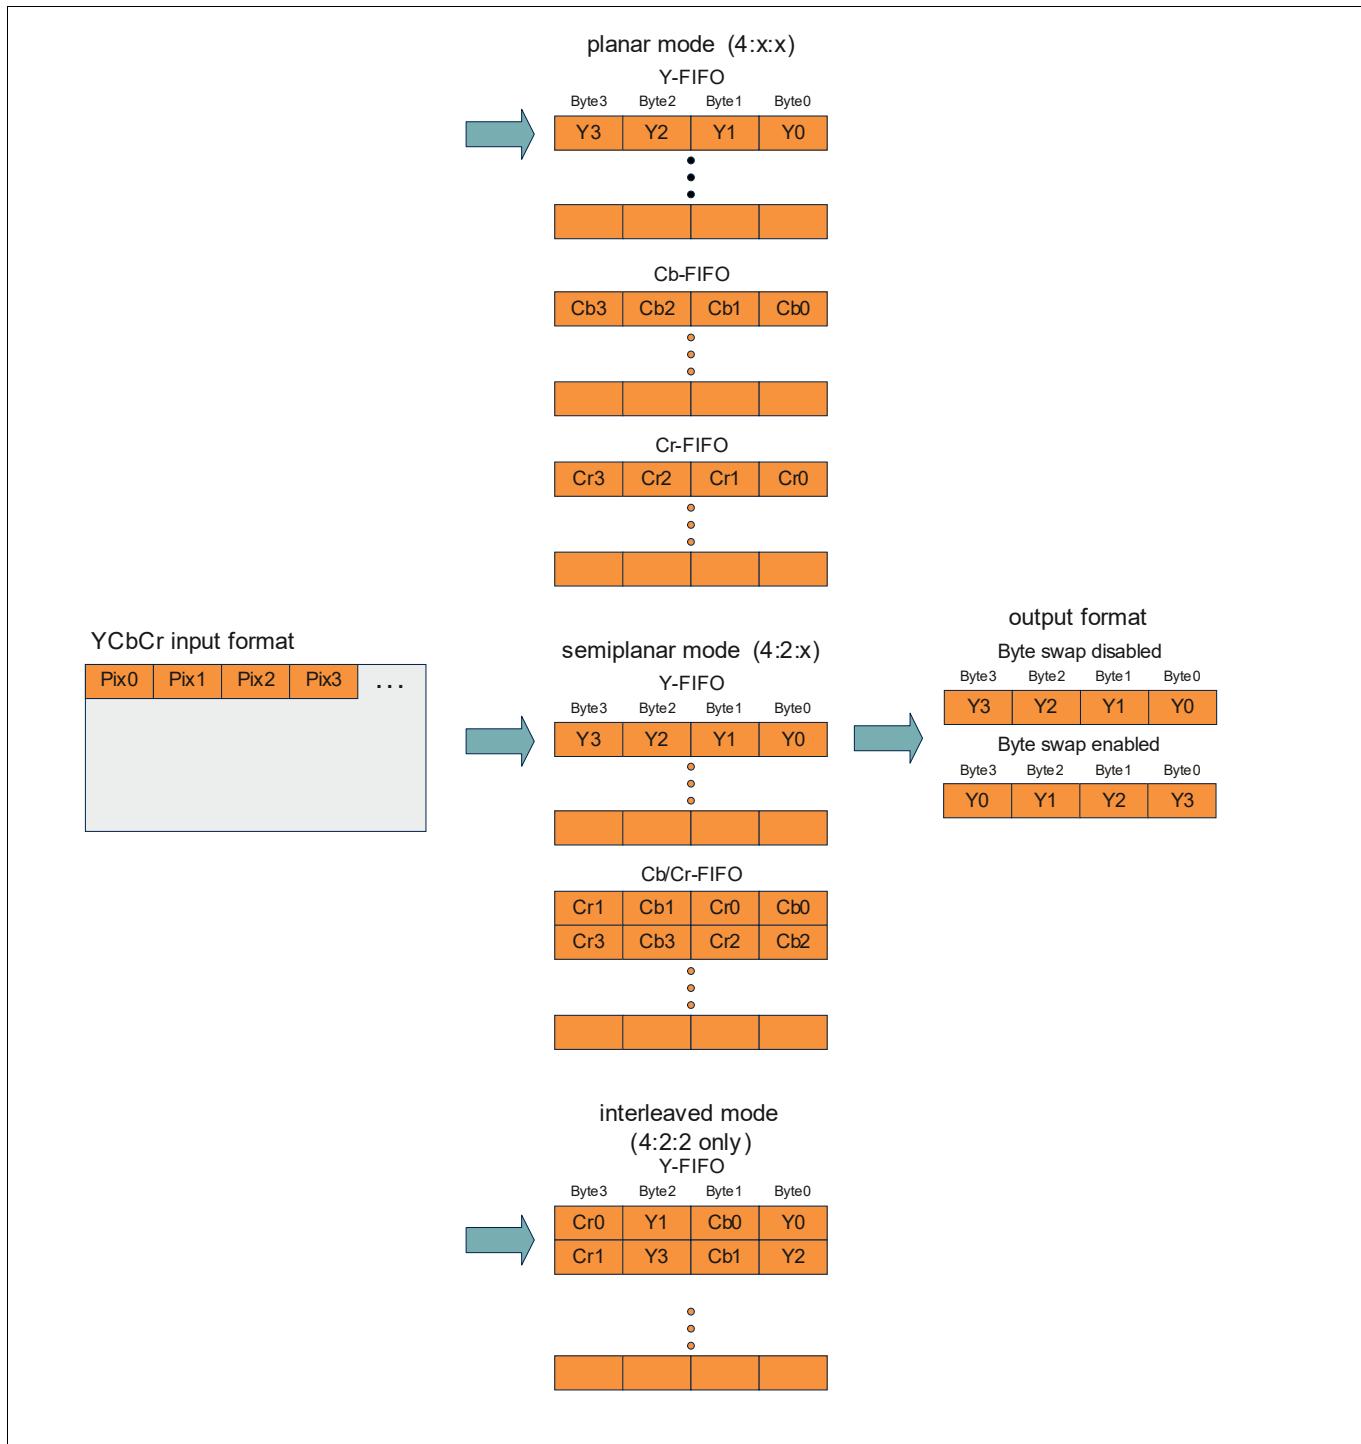

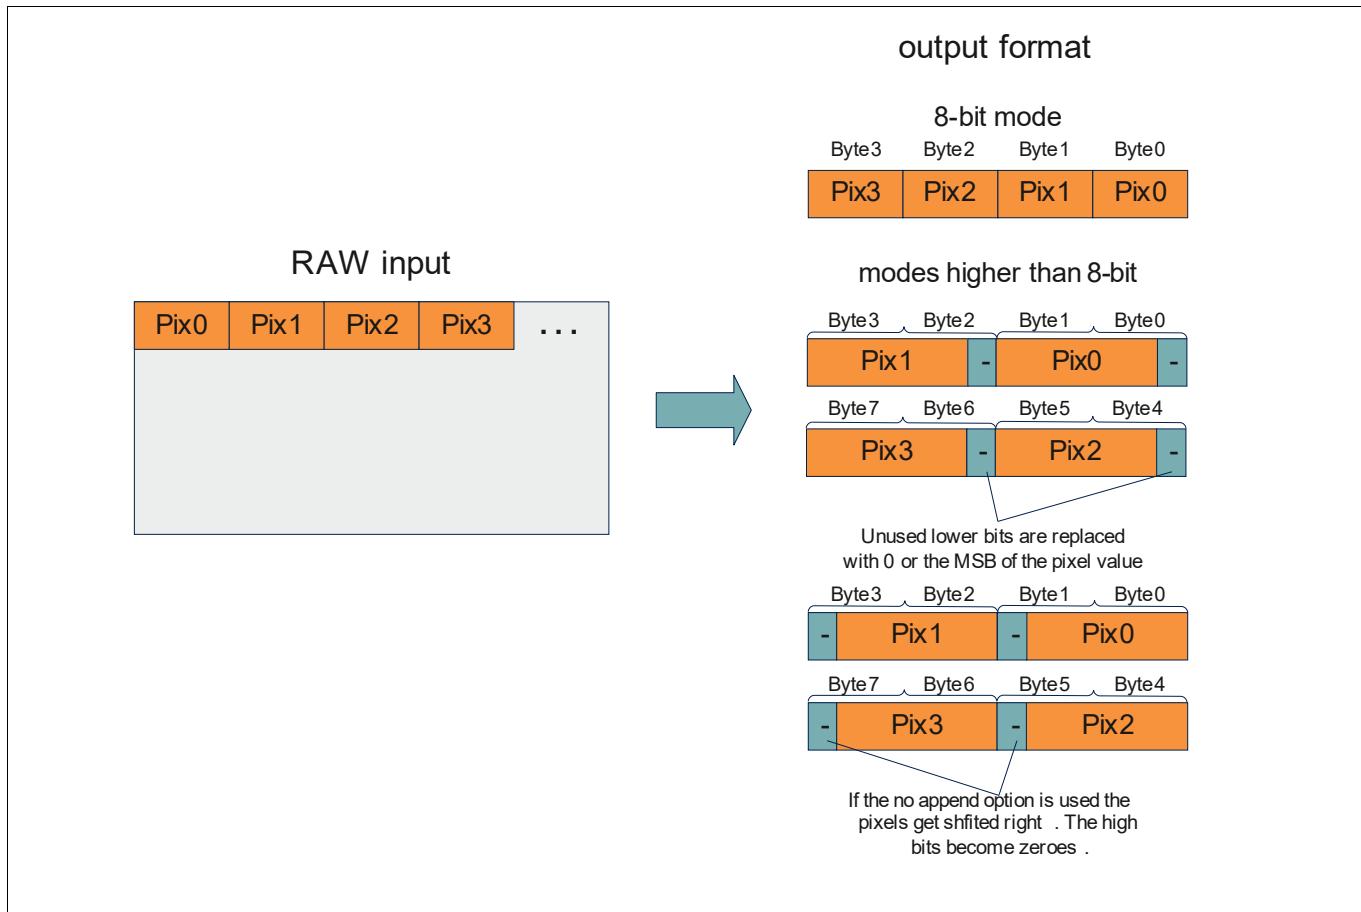

Figure 355 Storage scheme YCbCr in MI

For storage of RAW data only one FIFO buffer is supported/needed. If more than 8 bits data are required in RAW mode, then the data bits are stored as 16-bit words in memory. Usually these bits are stored MSB aligned, meaning the unused least significant bits remain zero or become a replica of the RAW data most significant bits (see “[INPUT\\_SELECTION](#)” on [Page 72](#)). It is also possible to disable this MSB alignment (“[INPUT\\_SELECTION\\_NO\\_APP](#)” on [Page 72](#)) leading to LSB aligned data values. This especially makes sense for non image RAW data (e.g. data mode). [Figure 356](#) visualizes the previously mentioned facts.

## Camera and ADC Interface (CIF)

**Figure 356 RAW data storage scheme in MI**

Unlike the main path the extra paths support interleaved storage mode only. This is given by the fact that extra paths only have a single component FIFO.

### 26.3.8.1 Write to EMEM

The following [Figure 357](#) shows the basic building blocks of the unit. As can be seen there are several input port handshake interfaces:

- 2 x 8 bit Y, Cb/Cr main picture data or up to 16 bit RAW data
- 64 bit JPEG data
- For every extra path 2 x 8 bit Y, Cb/Cr extra picture data<sup>1)</sup> or up to 16 bit RAW data

The following modes of operation are supported:

- image data only
- JPEG data only
- RAW data only

The interface to the EMEM is a simple handshake oriented protocol, which is connected to the BBB master via a bridge. Three kinds of bus accesses are supported, 8-beat bursts, 4-beat bursts and single transfers, all with a data width of 32 bit. The storage areas, which are located in the EMEM, are organized as ring buffers.

Interrupts are generated for the following events:

- picture end of frame

1) YCbCr data is handled interleaved as 16 bit data extra paths.

## Camera and ADC Interface (CIF)

- macro block line (16 lines of Y data and 8 lines of Cb and Cr data of the picture are written to the EMEM)
- programmed fill level of picture Y data reached
- wrap around of the programmed address range separately for Y, Cb and Cr of the picture
- BBB write error propagated by the handshake target interface

Interrupts are mapped onto a single, physical request line MI\_INT for the main path and interrupts associated with the extra paths are mapped to MIEP\_INT.

Each FIFO can store at least two 8-beat bursts.

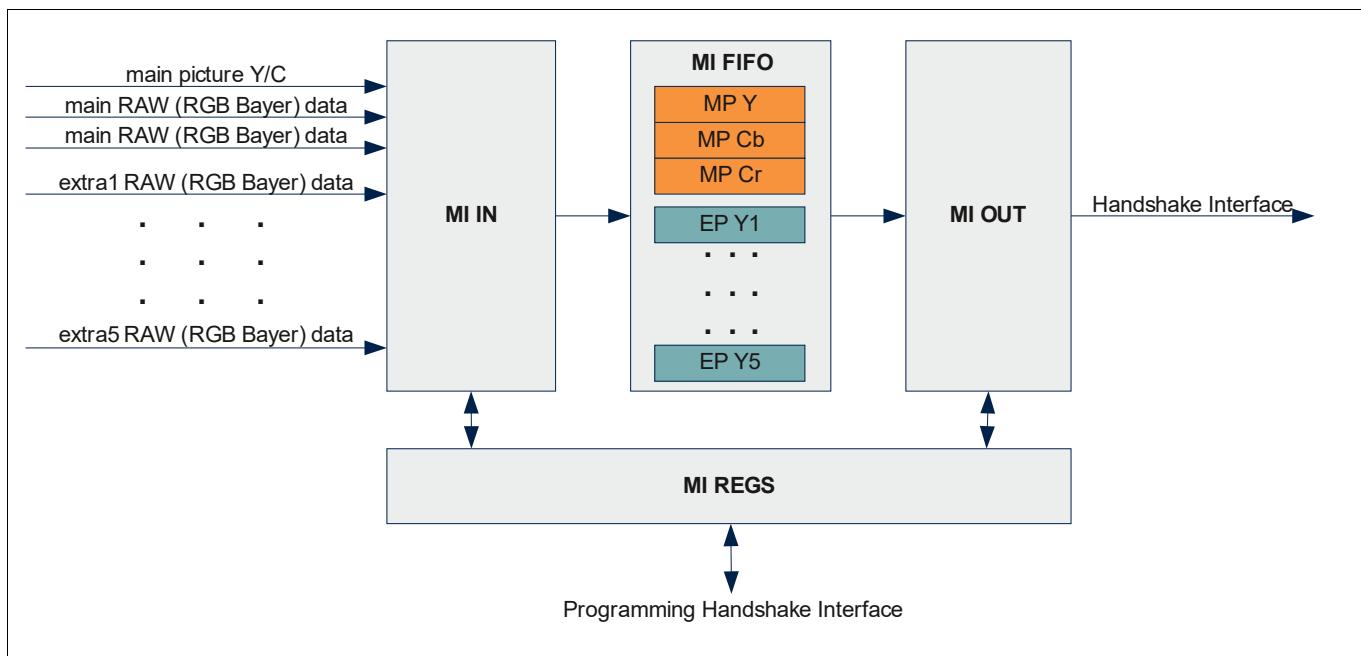

Figure 357 Block Diagram of the Memory Interface write path

### 26.3.9 BBB Master Interface

The BBB Master Interface connects the Memory Interface to the BBB.

- Unique TAG
- Word Access only
- Priority relative to CPU access via EMEM
- Bandwidth on bus
- RAM arbitration inside EMEM
- Reset behavior
- Bus error handling

## Camera and ADC Interface (CIF)

### 26.3.10 BBB Slave Interface

The BBB Slave Interface connects the Control Unit to the BBB system. Internally it represents an AHB-Slave-to-handshake-Initiator block, while from the BBB a standard SPB\_BPI is used.

- No safety features.
- No OCDS functionality.
- No ENDINIT/OEN/... protection
- Standard CLC register.
- Allowed access width is 32-bit only.  
8-bit and 16-bit accesses are treated as 32-bit and the content of all 32 data signals of the bus is written to the register.
- Error handling - no notification of read and write accesses to reserved locations

### 26.3.11 Control Unit

The Control Unit serves two purposes:

- Interface from BBB Slave Interface to the local configuration register blocks of the other modules
- Clock and reset control registers for the CIF

The Control Unit has one 32 bit handshake input interface, three 16 bit handshake output interfaces, and two 32 bit handshake output interfaces.

As all transfers from the handshake input interface are 32 bit wide, these accesses have to be mapped accordingly to the 16 bit handshake interfaces, e.g. ignoring the upper 16 bits or filling them with zeros respectively.

Each block inside the CIF uses a dedicated clock signal that can be controlled by a programmable register inside the Control Unit.

Existing software resets in the CIF blocks can also be controlled by a programmable register inside the Control Unit. An asynchronous reset for the sensor clock domain has to be generated from the system reset. A soft reset for all registers in the CIF is provided. It behaves like the asynchronous hardware reset.

**Attention:** *When resetting the whole CIF module, use the [BBB\\_KRST0](#) register for the whole module, and not the partial resets from the register [IRCL](#).*

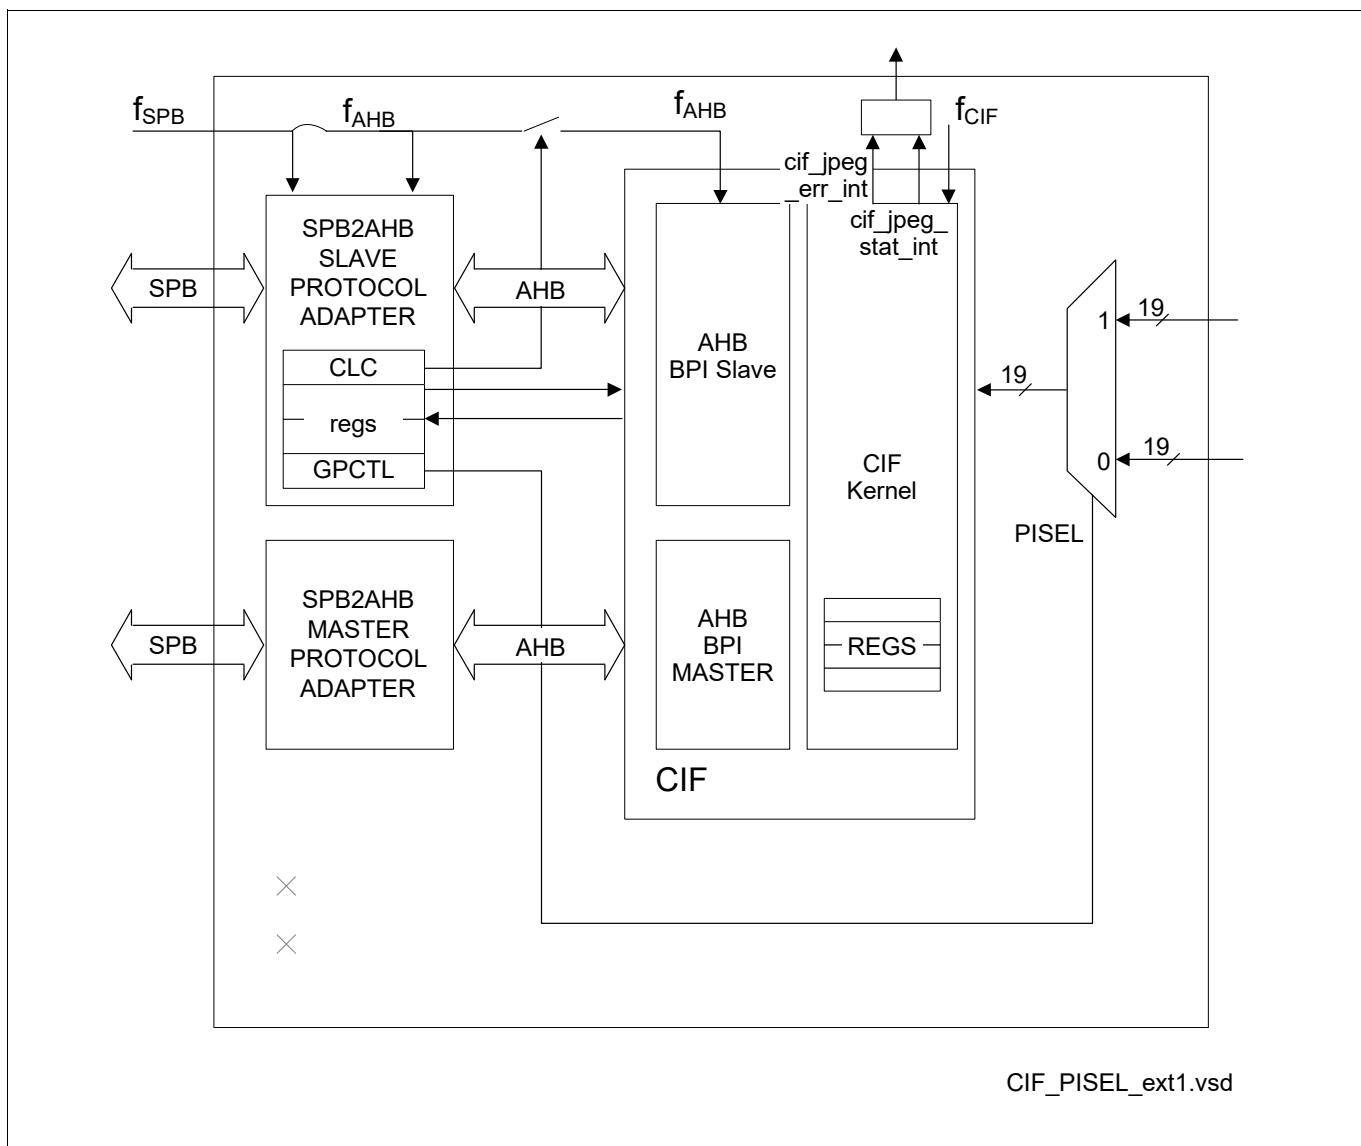

### 26.3.12 Shadow Registers

A distinctive feature of the local configuration registers is the implementation of “shadow registers”. Because it can not be ensured that the complete re-programming of the CIF can be done during the vertical blanking period between two frames shadow registers have been introduced. These shadow registers hold the configuration values that are actually used for processing and are only updated with the latest written configuration values after a special update signal is triggered. This update signal may be generated after a frame has ended but in order to allow a fast configuration it may also be forced to trigger immediately.

## Camera and ADC Interface (CIF)

### 26.3.13 CIF Module Integration and BPI Adapter

This section describes the implementation and integration details of the CIF module.

**Figure 358 Overview of the SPB2AHB adapter**

**Note:** Normally only one pin mapping of CIF signals to pins is available, selected by **BBB\_GPCTL**. PISEL default value of 0. The second selection is tied to low.

#### 26.3.13.1 BPI\_SPB Module Registers

This section describes the registers implemented in the slave (SPB2AHB) adapter component.

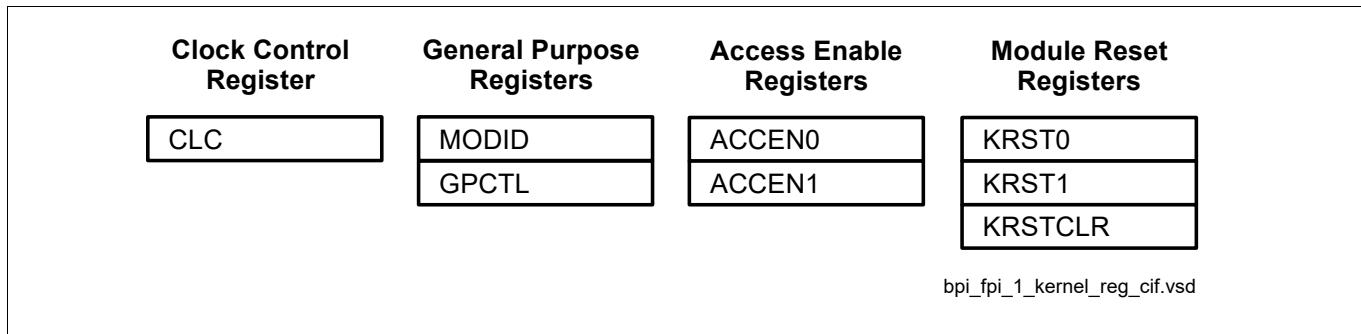

In this specification release it is assumed that the BPI\_SPB registers will use reserved addresses in the module address space, and not separate address page. This issue is subject of discussion and may change.

## Camera and ADC Interface (CIF)

### 26.3.13.1.1 System Registers

**Figure 359** shows all registers associated with the BPI\_SPB module, configured for one kernel. The Offset Address in the following BPI\_SPB register table and in the BPI\_SPB register descriptions are proposals. In a standard 32 bit peripheral the CLC is mapped to offset address 00h, module ID to 08h.

#### BPI\_SPB Registers Overview

**Figure 359 BPI\_SPB Registers**

#### Standard Registers

The adapter will implement the following standard registers as defined in the specification for the SPB BPI:

- MODID, Module ID<sup>1)</sup>
- CLC, Clock Control
- ACCEN0, Access Enable 0
- ACCEN1, Access Enable 1
- KRST0, Kernel Reset 0
- KRST1, Kernel Reset 1
- KRSTCLR, Kernel Reset Clear
- GPCTL Register

Instantiation of the CLC register is controlled by a VHDL generic. Instantiation of the KRST0, KRST1, and KRSTCLR registers is controlled by a second VHDL generic. The MODID, ACCEN0 and ACCEN1 registers will always be present.

If a particular register is not instantiated then any associated output ports on the adapter entity will be driven to a constant logic value.

#### Kernel Reset

If a kernel reset is requested, the adapter will synchronously assert the internal kernel reset output and error any ongoing accesses on the SPB bus not addressed to the adapter's internal SFRs.

The method of using the kernel reset output from the adapter to initialise the associated AHB module is module specific and outside the scope of this specification.

Any AHB accesses in progress will be synchronously terminated.

1) It is possible to set the fields of the module ID register without altering the adapter RTL by setting VHDL generics on the adapter instantiation

## Camera and ADC Interface (CIF)

### GPCTL

There is a single adapter specific SFR implemented in the adaptor.

The SFR contains 32 general purpose read/write control bits without ENDINIT protection. All the bits are connected to output ports on the SPB2AHB entity. The SFR will implement no safety requirements and is not suitable for controlling hardware related to safety functions. The SFR supports, byte, half word and word transactions only. All other transactions are rejected with an SPB error termination.

*Note:* In the CIF module, this register is reserved.

### Principle of Operation

When the controlling state machine detects an SPB access, it compares the address to the address of the SFR. This address is configurable via VHDL generic when instantiating the adaptor. In the case that the address matches the SFR address, the normal state machine transitions are interrupted and the access is not passed to the AHB bus.

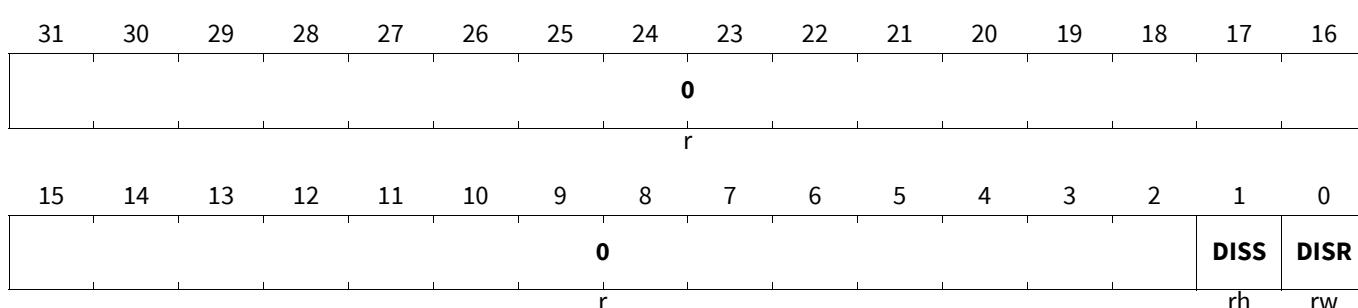

If the access opcode is not SDTB, SDTH or SDTW, then the access is terminated with an SPB error. If the opcode is supported, the SFR data will be returned on the SPB bus if the transaction is a read or the appropriate bits of the register will be updated if the access is a write.

### Clock Control Register

The Clock Control Register, CLC, acts globally and allows the complete AHB module to be disabled to reduce power consumption when the module is not required. When the module is disabled ( $\text{DISS}=1_B$ ), only register accesses to the adapter register address space are permitted. All other accesses to the module address space will be errored.

#### BBB\_CLC

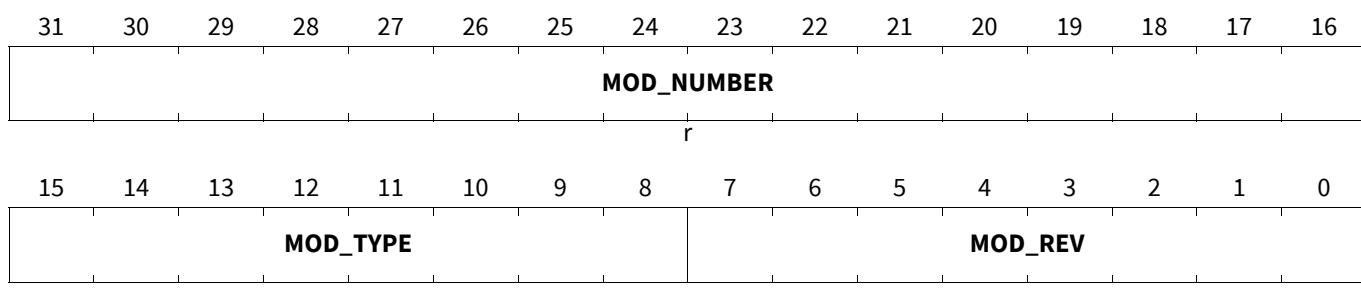

**Clock Control Register** (0000<sub>H</sub>) Application Reset Value: 0000 0003<sub>H</sub>

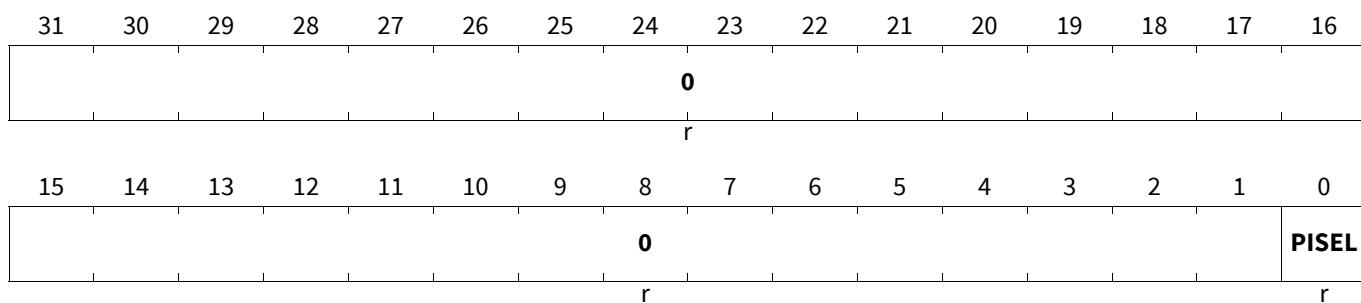

Field	Bits	Type	Description
<b>DISR</b>	0	rw	<b>Module Disable Request Bit</b> Used for enable/disable control of the module.
<b>DISS</b>	1	rh	<b>Module Disable Status Bit</b> Bit indicates the current status of the module.
<b>0</b>	31:2	r	<b>Reserved</b> Read as 0; should be written with 0.

### Module Identification Register

The identification register allows the programmer version-tracking of the module. The table below shows the identification register which is implemented in the DMA module.

**Camera and ADC Interface (CIF)****BBB\_MODID****Module Identification Register**(0004<sub>H</sub>)Application Reset Value: 00B3 C0XX<sub>H</sub>

Field	Bits	Type	Description
MOD_REV	7:0	r	<b>Module Revision Number</b> This bit field defines the module revision number. The value of a module revision starts with 01H (first revision).
MOD_TYPE	15:8	r	<b>Module Type</b> The bit field is set to C0H which defines the module as a 32-bit module.
MOD_NUMBE R	31:16	r	<b>Module Number Value</b> This bit field defines a module identification number.

**General Purpose Control Register****BBB\_GPCTL****General Purpose Control Register**(0008<sub>H</sub>)Application Reset Value: 0000 0000<sub>H</sub>

Field	Bits	Type	Description
PISEL	0	r	<b>Port Input Select Bit</b> Selects between two pin mappings of the CIF interface. 0 <sub>B</sub> pin mapping 0 selected (default) 1 <sub>B</sub> pin mapping 1 selected
0	31:1	r	<b>reserved</b> Reads 0. Should be written with 0.

**Access Enable Register 0**

The Access Enable Register 0 controls write access for transactions to registers with the on chip bus master TAG ID 000000<sub>B</sub> to 011111<sub>B</sub> (see On Chip Bus chapter for the products TAG ID <-> master peripheral mapping). The

## Camera and ADC Interface (CIF)

adapter is prepared for a 6 bit TAG ID. The registers ACCEN0 / ACCEN1 provide one enable bit for each possible 6 bit TAG ID encoding.

Mapping of TAG IDs to ACCEN0.ENx: EN0 -> TAG ID 000000B, EN1 -> TAG ID 000001B, ..., EN31 -> TAG ID 011111B.

### **BBB\_ACCENO**

Field	Bits	Type	Description
RES	31:0	r	<b>Reserved</b> Read as 0; should be written with 0.

### **Kernel Reset Register 0**

The Kernel Reset function is used to synchronously reset the AHB module. To activate the kernel reset, it is necessary to set the RST bits by writing with 1<sub>B</sub> in both Kernel Reset Registers. The RST bit will be re-set by the adapter with the end of the adapter kernel reset sequence.

## Camera and ADC Interface (CIF)

Kernel Reset Register 0 includes a kernel reset status bit that is set to  $1_B$  in the same clock cycle the RST bit is reset. This bit can be used to detect that a kernel reset was processed. The bit can be re-set to '0' by writing '1' to the KRSTCLE.CLR register bit.

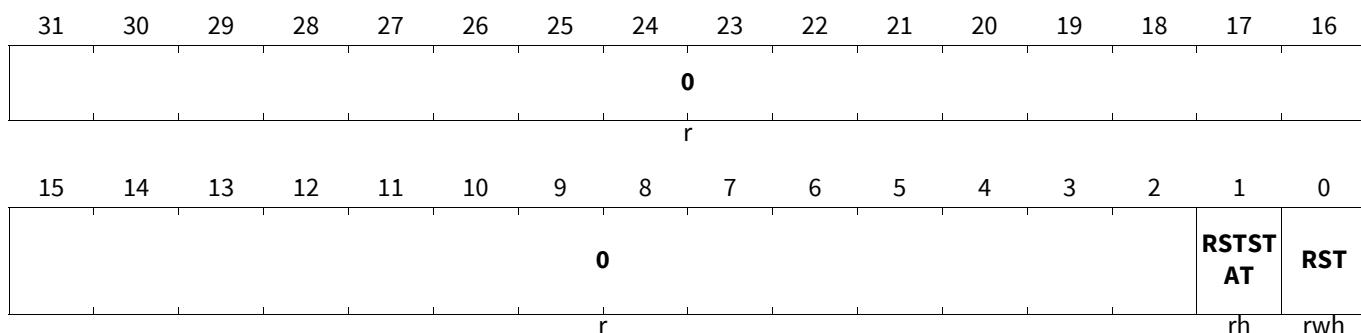

During the execution of the kernel reset until RSTSTAT is set, write accesses to the module registers will result in an error acknowledge. Adapter registers can still be accessed.

### **BBB\_KRST0**

#### **Kernel Reset Register 0**

(0014<sub>H</sub>)

**Application Reset Value: 0000 0000<sub>H</sub>**

Field	Bits	Type	Description
<b>RST</b>	0	rwh	<b>Kernel Reset</b> This reset bit can be used to request for a kernel reset. The kernel reset will be executed if the reset bits of both kernel registers are set. The RST bit will be cleared (reset to $0_B$ ) after the kernel reset was executed. $0_B$ No kernel reset was requested $1_B$ A kernel reset was requested
<b>RSTSTAT</b>	1	rh	<b>Kernel Reset Status</b> This bit indicates whether a kernel reset was executed or not. This bit is set after the execution of a kernel reset in the same clock cycle both reset bits. This bit can be cleared by writing with '1' to the CLR bit in the related KRSTCLR register. $0_B$ No kernel reset was executed $1_B$ Kernel reset was executed
<b>0</b>	31:2	r	<b>Reserved</b> Read as 0; should be written with 0.

### **Kernel Reset Register 1**

The Kernel Reset Register 1 is used to reset the related module kernel. Kernel registers related to the Debug Reset (Class 1) are not influenced. To reset a module kernel it is necessary to set the RST bits by writing with '1' in both Kernel Reset registers. The RST bit will be re-set by the BPI with the end of the BPI kernel reset sequence.

**Camera and ADC Interface (CIF)****BBB\_KRST1****Kernel Reset Register 1**(0018<sub>H</sub>)**Application Reset Value: 0000 0000<sub>H</sub>**

## Camera and ADC Interface (CIF)

### 26.3.14 CIF Programming Hints

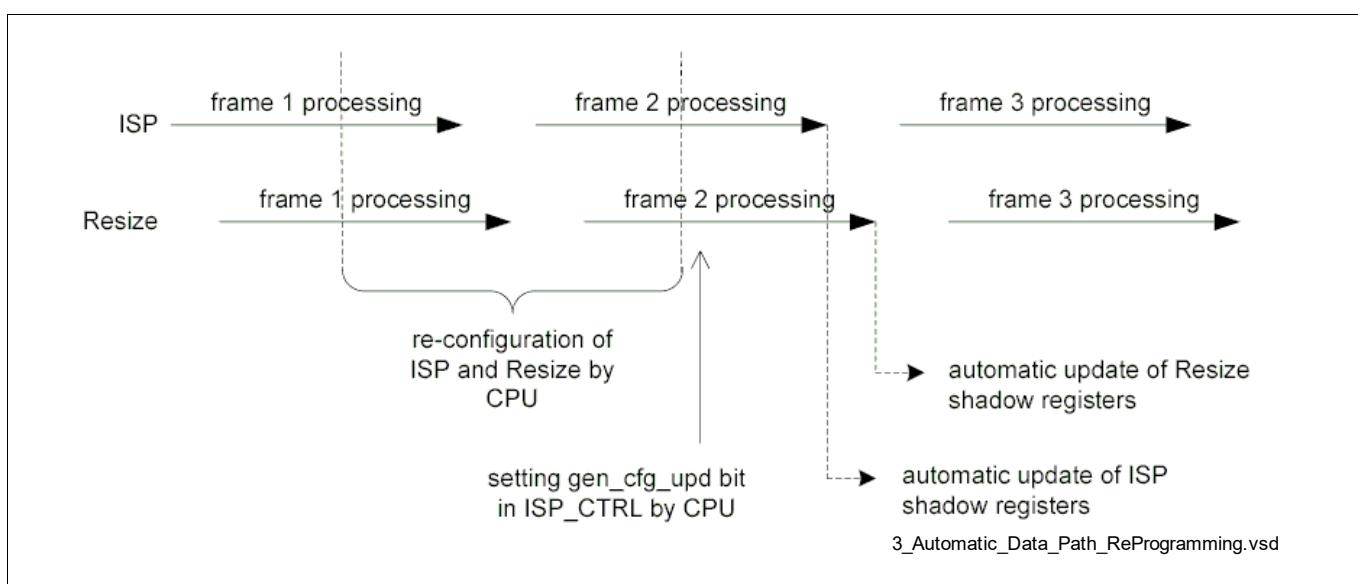

#### 26.3.14.1 Configuration and Shadow Registers

Most of the configuration registers inside the CIF hold static programming information (e.g. horizontal and vertical synchronization polarities at the sensor interface). But, in some cases it is required to dynamically re-program the active processing data path with new parameters (e.g. for zooming by re-defining the window). All of these new parameters must not be changed during the processing of a frame, but between frames or at the end of a frame.

Re-programming is done by a CPU attached to the Bus slave interface. Because it can not be ensured that the complete re-programming can be done during the vertical blanking period between two frames shadow registers have been introduced. These shadow registers hold the configuration values that are actually used for processing. Their corresponding configuration registers (e.g. ISP\_OUT\_H\_OFFSET\_SHD and ISP\_OUT\_H\_OFFSET) store the new values until the configuration update is triggered.

For initial programming after reset or for complete re-programming of the CIF (e.g. changing from viewfinder mode to snapshot mode and vice versa) there exists a cfg\_upd trigger bit in the main control register of each sub-module making use of shadow registers. Writing a 1 into this field copies the configuration register value into the shadow register. Mostly the main control register also has a shadow register. Other control bits set during the same write transfer as the cfg\_upd bit are also copied to the shadow register.

Another method of shadow register update is used for dynamically re-programming the data path (see [Figure 360 “Automatic Data Path Re-Programming” on Page 29](#)). In this case the ISP, which is always the first part of the pipeline, triggers the configuration update for the whole pipeline by setting the gen\_cfg\_upd bit in the ISP main control register ISP\_CTRL. This causes a configuration update pulse to be sent through the pipeline together with the last pixel of a frame. Each sub-module of the active processing pipeline updates its shadow registers after processing the last pixel of a frame and sends the configuration update pulse to the next stage of the pipeline.

**Figure 360 Automatic Data Path Re-Programming**

Some configuration registers exist that can be changed during processing without use of shadow registers. These are for example adjustment registers in the ISP or the color processing unit which have immediate influence of

## Camera and ADC Interface (CIF)

the processing in terms of pixel calculations. But, no processing errors or unknown formats will result in re-programming of these register. So it is safe to modify them at any time.

### 26.3.14.2 General Setup for Operation

The basic configuration of the CIF must be done in idle mode. This mode can be entered by either:

- Applying the asynchronous system reset
- Software reset which is combined with the asynchronous system reset
- Applying software resets to all CIF sub-modules (refer to VI\_IRCL register)
- Disabling the ISP by setting `isp_en` in `ISP_CTRL` to 0 and waiting for “`isp_off`” IRQ

In idle mode the following sub-modules must be configured: ISP, memory interface and control unit for image capturing to memory.

The configuration steps, which are performed by register accesses via the Bus slave interface, are the following:

- Set CIF to idle state
- Image acquisition configuration:
  - Set the input acquisition window depending on the attached camera device (`ISP_ACQ_H_OFFSET`, `ISP_ACQ_V_OFFSET`, `ISP_ACQ_H_SIZE`, `ISP_ACQ_V_SIZE`)
  - Define synchronization signal mode and polarity, data sample edge referring to the sensor clock (`ISP_ACQ_PROP`), and number of frames to be captured (`ISP_NR_FRAMES`)
- Image windowing setup:
  - Define the ISP output window (`ISP_OUT_H_OFFSET`, `ISP_OUT_V_OFFSET`, `ISP_OUT_H_SIZE`, `ISP_OUT_V_SIZE`)
- Immediate ISP configuration update (`cfg_upd = 1` in `ISP_CTRL`)
- Data path configuration:
  - Depending on the use case the data path must be configured for the desired operation (`VI_DPCL`)
- Main picture memory buffer configuration:
  - Define luminance (Y) buffer base address and size in system memory (`MI_MP_Y_BASE_ADDR`, `MI_MP_Y_SIZE`)
  - Define Y data start offset relative to the Y buffer (`MI_MP_Y_OFFSET`)
  - Define chrominance blue ( $C_B$ ) buffer base address and size in system memory (`MI_MP_CB_BASE_ADDR`, `MI_MP_CB_SIZE`)
  - Define  $C_B$  data start offset relative to the  $C_B$  buffer (`MI_MP_CB_OFFSET`)
  - Define chrominance red ( $C_R$ ) buffer base address and size in system memory (`MI_MP_CR_BASE_ADDR`, `MI_MP_CR_SIZE`)
  - Define  $C_R$  data start offset relative to the  $C_R$  buffer (`MI_MP_CR_OFFSET`)
- Immediate memory interface configuration update:
  - Define to update base and offset shadow registers(`init_base = 1` and `init_offset = 1` in `MI_INIT`)
  - Update shadow registers for video (in) and Bus part (out) (`cfg_upd_mi_in = 1` and `cfg_upd_mi_out = 1` in `MI_CTRL`)
- Enable/disable interrupts (`ISP_IMSC`, `MI_IMSC`)

Now the basic setup of all necessary registers is done.

For programming a specific use case the data path needs to be configured in the right way (please refer to chapter “[Use Case Description” on Page 47](#)). Additionally not active sub-modules can be switched off as described in chapter “[Power Management” on Page 51](#).

## Camera and ADC Interface (CIF)

### 26.3.14.3 Start-Stop Programming

#### 26.3.14.3.1 Data capturing controlled by the ISP

Data capturing is controlled by the ISP only. All the other sub-modules in the processing pipeline automatically stop processing if no video data is available.

The CIF starts and stops video data capturing in a frame synchronized way. So the time of enabling data capturing is not important as the ISP waits for the beginning of a frame before sampling data. The same applies for stopping video data capturing. Regardless of the current pixel position in the frame or outside the frame the current frame is always captured completely before disabling the ISP.

The ISP contains an input acquisition and an output formatting unit. Both units are able to start and stop video processing frame synchronously. For video capturing both units must be enabled, but for disabling capturing at least one of them must be switched off.

**Note:** *It is highly recommended to use the output formatter of the ISP for controlling video processing, because this unit is able to generate an “isp off” interrupt based on the ISP output frame after windowing.*

Additionally it is possible to specify the number of frames to be captured by writing this number into ISP\_NR\_FRAMES. Continuous capturing is enabled by writing a 0 into this register.

So to enable the ISP input\_en in ISP\_CTRL must be set to 1 first. At this point the ISP starts capturing data but does not provide them at its output interface. The output interface is part of the output formatter which also does the output windowing. It is enabled setting isp\_en in ISP\_CTRL to 1.

To stop video capturing it is sufficient to disable the ISP output formatter by setting isp\_en in ISP\_CTRL to 0, or if a certain number of frames to be captured have been specified, the ISP automatically disables its output formatter. Then the “isp off” interrupt is generated after putting out the last pixel of the last frame.

**Note:** *After stopping data capturing at the ISP the processing pipeline is still working for a while because of the pipeline delay of some pixel lines. This delay depends on the mode of operation. The maximum delay is about 11 lines.*

The pipeline is clean after either applying the software reset to the involved sub-modules (resulting in loss of data in memory), or it must be waited until the complete frame has been written into system memory. The latter is done by waiting for the “frame end” interrupt of the output unit.

### 26.3.14.4 Abort of Processing

Complete abort of processing can be either done by applying the asynchronous system reset to the CIF, the software reset for the entire CIF or by applying the software resets to all involved sub-modules which is the preferred method.

#### 26.3.14.4.1 Frame Skip

For the main picture data path another way of discarding pixel data exist: frame skipping. This can be used if e.g. the video encoding device can not keep up with the frame rate provided by the CIF. In this case the system controller has to set the skip bit in the MI\_INIT register of the memory interface.

For frame skipping the memory interface discards all remaining pixels of the current frame at its main picture input ports. It only completes the current burst transfer and flushes all main picture internal data FIFOs. Resetting of the related offset data pointers for the buffers depends on the value of init\_offset in MI\_CTRL. If init\_offset is

## Camera and ADC Interface (CIF)

set to 1 the buffer offset counters are reset to the programmed values in MI\_MP\_Y/CB/CR\_OFFSETS. If init\_offset is set to 0 the offset counters for all buffers are set to the beginning of the current (skipped) frame.

Frame skipping does not affect “frame end” interrupt generation.

### 26.3.14.4.2 Handling Picture Size Error

Aborting the ISP processing becomes necessary, if an input picture size violation is detected by the hardware. In this case the interrupt PIC\_SIZE\_ERR is raised, and the ISP does not generate a frame end interrupt, even if the picture size is corrected. To recover from this condition, a software reset of the ISP is necessary. After a reset the picture size needs to be programmed to the appropriate values and processing can be started again.

To find the reason behind the picture size error the register ISP\_ERR might be helpful. This register provides the information about where exactly the size error occurred.

### 26.3.14.5 Interrupt Handling

The CIF provides two programmable level active interrupt outputs driven by the ISP and memory interface sub-modules. Interrupt control and status registers are located locally in their originating sub-modules. All sub-module masked interrupts are ORed together to drive the interrupt line.

Five interrupt registers are provided for each interrupt line per block able to generate interrupts:

- Interrupt mask register (IMSC)
- Raw interrupt status register (RIS)
- Masked interrupt status register (MIS)
- Interrupt clear register (ICR)
- Interrupt set register (ISR)

The IMSC register defines if the events actually generate an interrupt. If a mask bit is set, the corresponding event is allowed to generate an interrupt. Per default all mask bits are set to 0 to prevent interrupt generation.

The RIS register shows the status of all sub-module internal events without effect of the mask register IMSC.

The MIS register shows the status of the events allowed to trigger an interrupt (MIS = RIS AND IMSC). If an interrupt has been thrown the MIS register must be read for locating the accountable event.

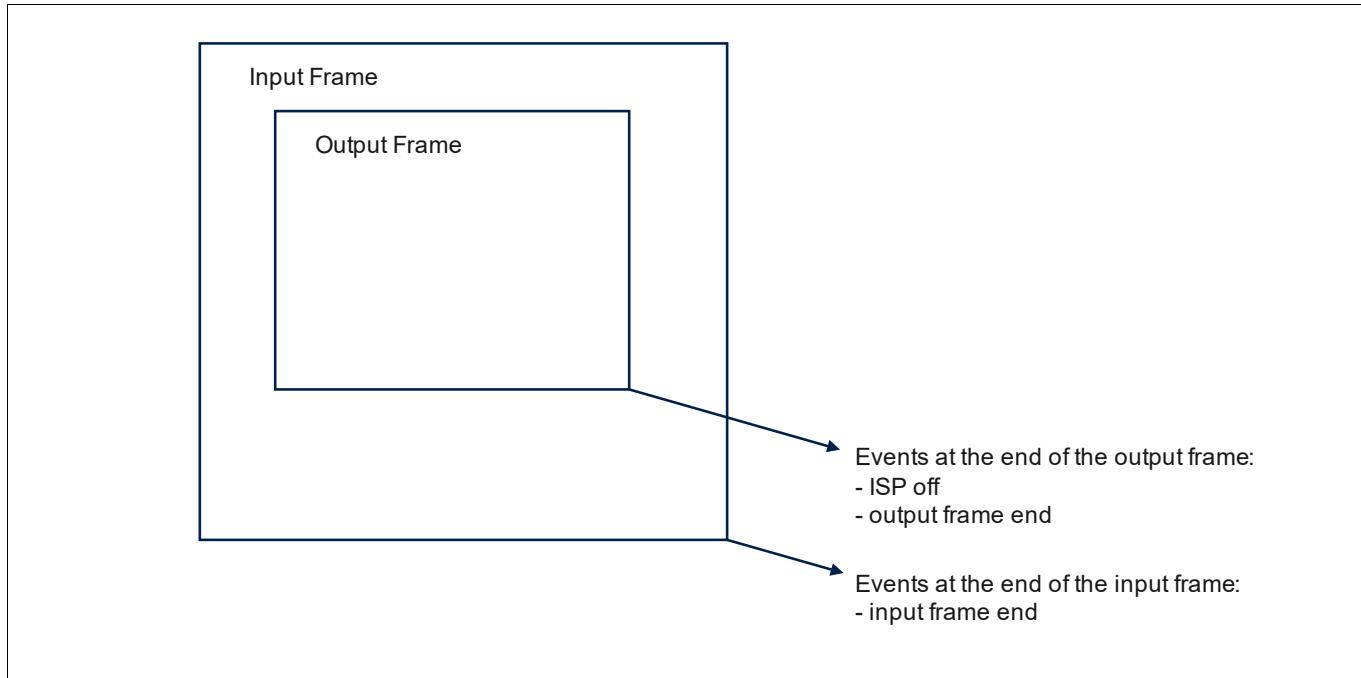

The ICR register is used for clearing interrupts by resetting the event. Writing a 1 into a interrupt bit resets the respective event. Reading of this register always returns “ $00_H$ ”.

The ISR register is used to trigger events for debug and test purposes. Writing a 1 into an interrupt bit activates the associated event and an interrupt will be thrown if the mask register is set accordingly. Reading this register always returns “ $00_H$ ”.

### 26.3.14.5.1 ISP Events

The ISP generates events at several positions during input and output data formatting. [Figure 361](#) shows the trigger points for the following events:

- ISP returns to idle state (isp\_off)
- Output frame end reached (out\_frame\_end)
- Input frame end reached (in\_frame\_end)

**Camera and ADC Interface (CIF)****Figure 361 Frame Based ISP Events**

Additionally the following error events may be generated:

- Input picture size violation detected (pic\_err)
- Loss of data detected during an active (data\_loss)

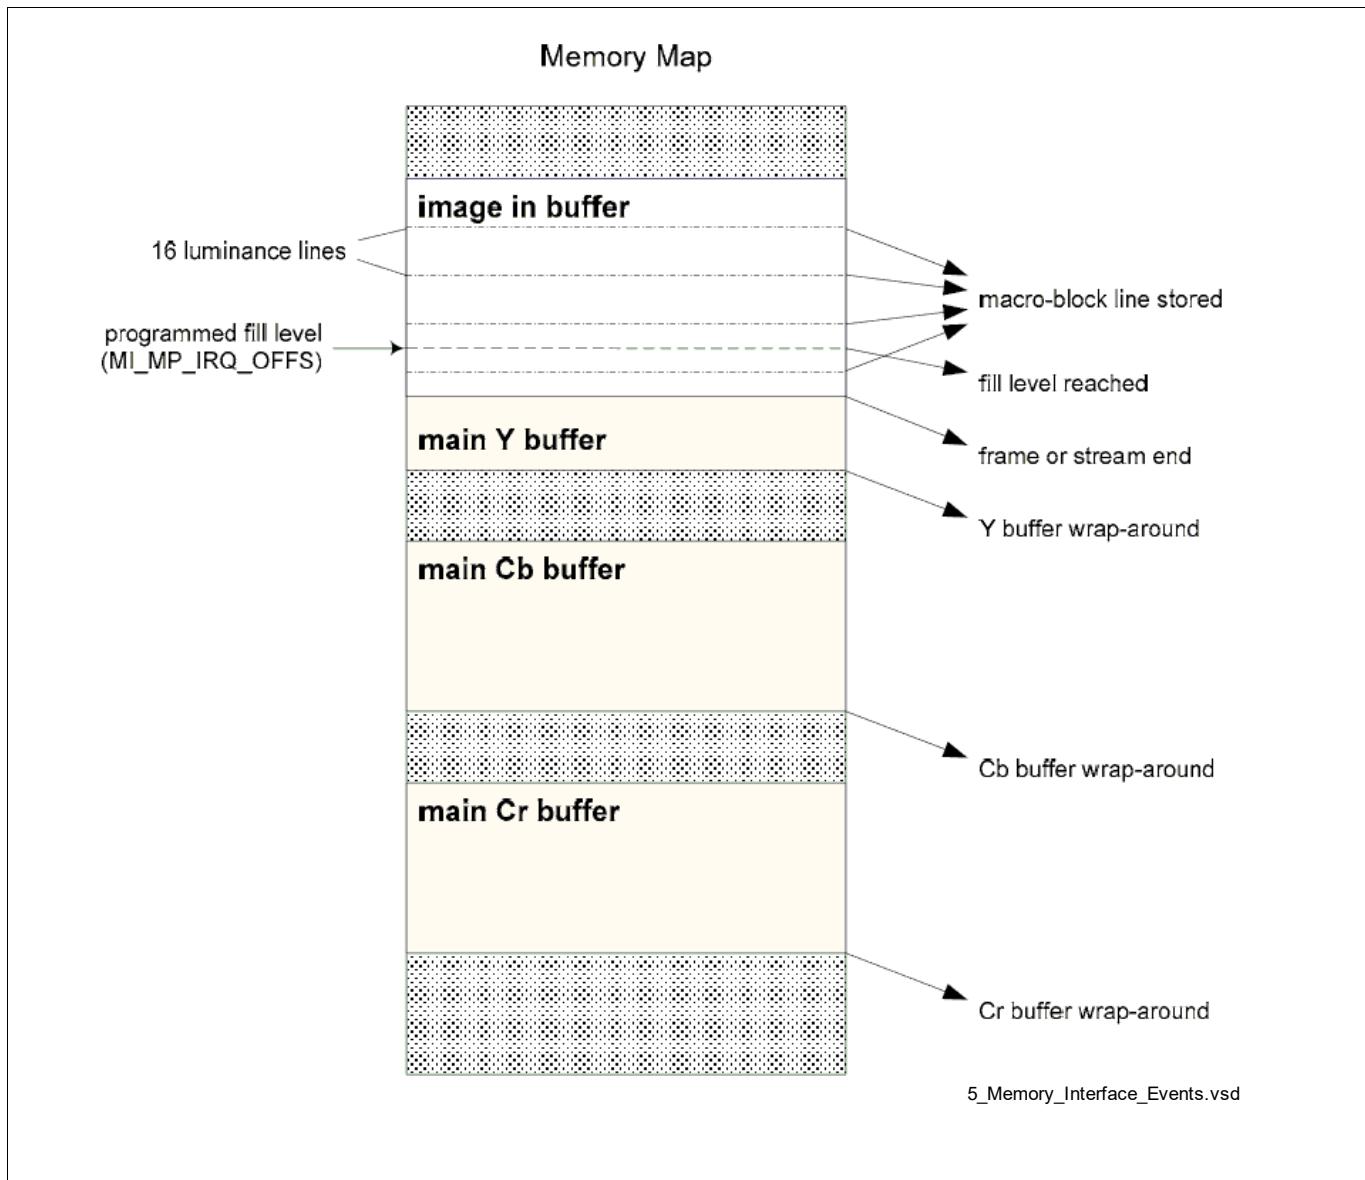

These two events are immediately triggered as they occur. For more information on ISP events please refer to chapter "[“ISP Programming” on Page 35](#).

## Camera and ADC Interface (CIF)

### 26.3.14.5.2 Memory Interface (MI) Events

The MI provides events from several internal sources (see [Figure 362 “Memory Interface Events” on Page 34](#)) supporting video encoding as well as signalling error and transfer end conditions:

- Bus write error detected (write\_err)
- Main picture buffer wrap-around occurred for Y, C<sub>b</sub>, C<sub>r</sub> buffers (wrp\_m\_y, wrp\_m\_cb, wrp\_m\_cr)
- Programmed fill level reached in main Y buffer (fill\_m\_y)
- Next macro-block line stored (mblk\_line)
- Last pixel of image or RAW data stream is written into memory (frame\_end)

**Figure 362 Memory Interface Events**

The “macro block line” and “frame end” events not only depend on the Y buffer, but also on C<sub>b</sub> and C<sub>r</sub> buffers because all pixel components have to be written to memory before triggering the appropriate event. For “frame end” this synchronization works for all supported YC<sub>b</sub>C<sub>r</sub> formats (4:2:2, 4:2:0). The “macro-block line” event relies on 16 luminance and 8 chrominance lines, which are in YC<sub>b</sub>C<sub>r</sub> 4:2:0 format.

## Camera and ADC Interface (CIF)

For better debugging in MI an additional status register is implemented. The MI shows status information of the FIFOs in the MI\_STATUS register and if a read or write Bus error occurred. This registers can be cleared with the according MI\_STATUS\_CLR register. Usage of this register should be as follows: If an error interrupt was triggered from the sensor FIFO of the ISP (DATA\_LOSS interrupt), then the MI\_STATUS register should be checked to find out the reason for the error. One reason could be the latency of the Bus bus, which results in FIFO full bits set in the MI\_STATUS register.

### 26.3.14.6 Reset Handling

Three types of resets are supported by the CIF:

- Asynchronous system reset
- Software reset for the entire CIF
- Independent software resets for each sub-module

The asynchronous reset is a low active system reset for resetting all flip-flops inside the CIF. After an asynchronous reset no processing, status, or configuration information is kept.

The same behaviour as for “asynchronous system reset” is true for the software reset bit of the entire CIF. All status and configuration register information is reset. After applying this reset the software must wait at least 10 module clock cycles before the CIF can be reprogrammed.

The independent software resets for each sub-module are meant for just resetting processing and status information, but not configuration register content. So, the software reset is first choice if a processing error occurs and the system should be re-initialized without need to fully re-program the device. It is triggered by single bits for all CIF sub-modules in VI\_IRCL.

### 26.3.14.7 Programming Guide

This chapter gives a detailed overview about programming of the particular CIF sub-modules.

#### 26.3.14.7.1 ISP Programming

The ISP sub-module contains input acquisition, output formatting, as well as status and error interrupt generation.

An overview of the internal processing blocks of the ISP is given in the figure [“Block Diagram of the ISP Sub Module” on Page 8](#).

#### Error Handling

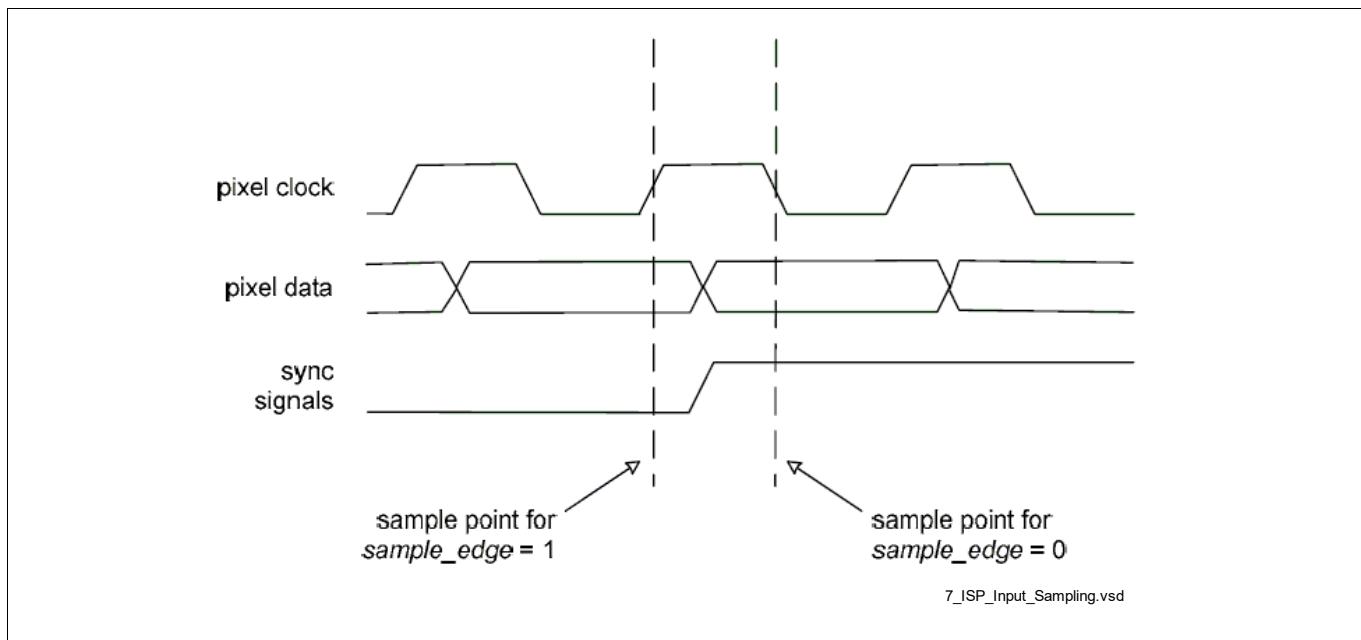

If an input picture size violation was detected and reported (interrupt) by the ISP, then the ISP needs to be reseted (soft-reset) in order to do the processing of the following frames. Without reset the frame end interrupt will not work correctly for the following frames, even if the picture size is correct then.

#### Input Acquisition

The input formatter is responsible for sampling data from the sensor device and providing it to the other blocks in the processing pipelines.

As the clock provided by the image sensor is used for data sampling, the sample edge can be selected depending on the phase shift between data and pixel clock. If sample\_edge in ISP\_ACQ\_PROP is set to 1 the rising edge of the pixel clock is used, otherwise the falling edge. The sample edge selection depends on the phase relationship between pixel clock and image data.

## Camera and ADC Interface (CIF)

**Figure 363 ISP Input Sampling**

The input acquisition has to be adapted to the specifics of the attached sensor device in terms of image resolution, color space format, black pixel regions, etc.

In addition please make sure that the sensor device delivers at least 2 lines of vertical blanking and at least 5 pixels horizontal blanking in its video timing. This is needed for the CIF ISP to function properly.

The input acquisition window has to be defined using the registers

ISP\_ACQ\_H\_OFFSET,  
ISP\_ACQ\_V\_OFFSET,  
ISP\_ACQ\_H\_SIZE,  
ISP\_ACQ\_V\_SIZE.

In addition the sample window can be further cropped for the following processing chains by the registers

ISP\_OUT\_H\_OFFSET,  
ISP\_OUT\_V\_OFFSET,  
ISP\_OUT\_H\_SIZE,  
ISP\_OUT\_V\_SIZE.

This is necessary, because processing blocks must not be fed with images containing black pixel areas. These areas have to be cut off before the image data is transferred to the CIF's ISP.

Furthermore the polarity of the horizontal and vertical synchronization signals in ITU-R BT.601 mode have to be defined using hsync\_pol and vsync\_pol in ISP\_ACQ\_PROP.

Limited support for capturing of interlaced video is available. So either odd or even, or both fields can be sampled (field\_sel in ISP\_ACQ\_PROP).

In the ISP\_CTRL programming register the operating mode for the ISP must be selected with isp\_mode (also refer to the following chapters).

Input formatter enabling and disabling is described in chapter [“Start-Stop Programming” on Page 31](#).

### Output Formatting and Image Stabilization

At the output of the ISP sub module the image data may be cropped a third time by using the registers

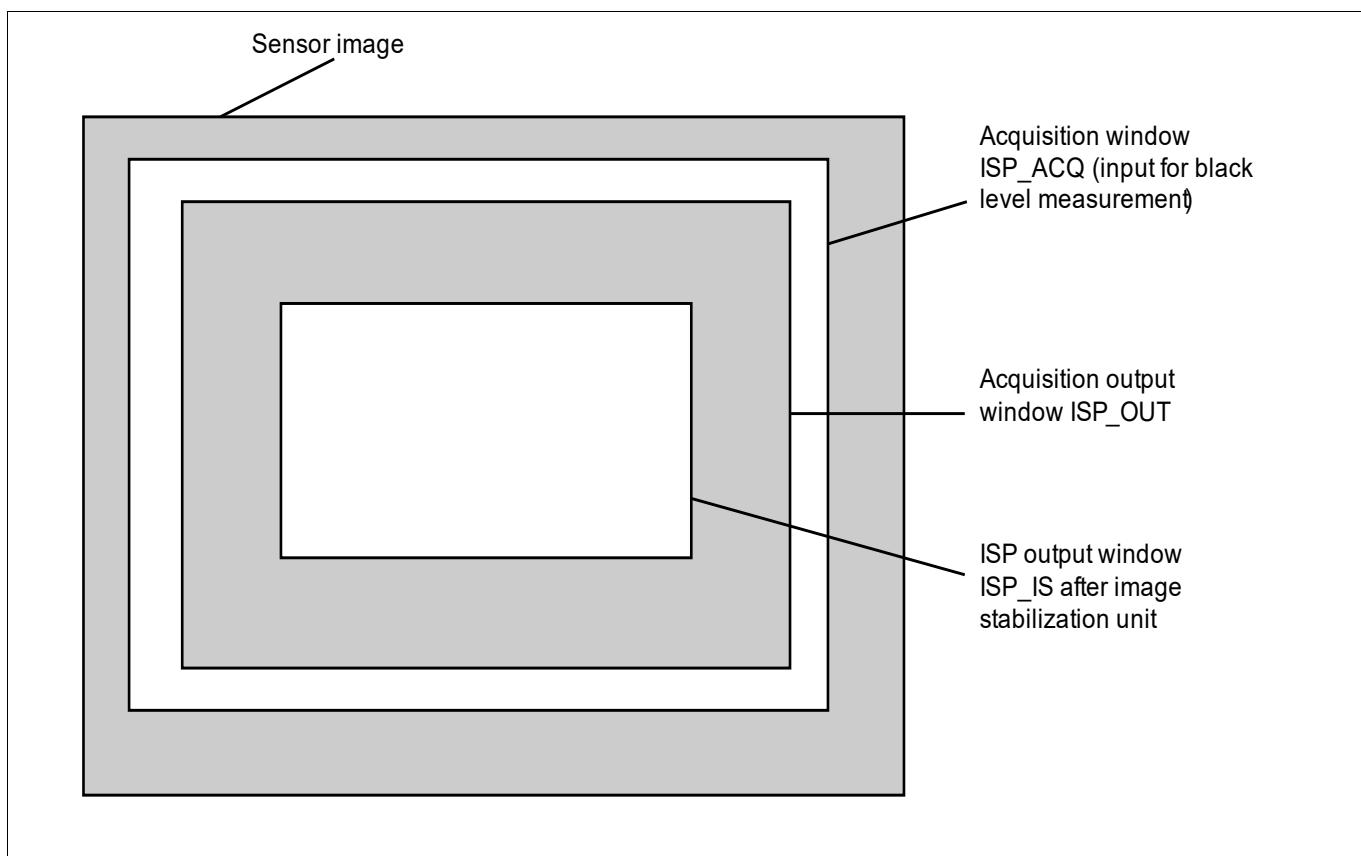

ISP\_IS\_H\_OFFSET,

## Camera and ADC Interface (CIF)

ISP\_IS\_V\_OFFSET,  
ISP\_IS\_H\_SIZE,  
ISP\_IS\_V\_SIZE.

These registers should be used, if digital zoom features shall be implemented in the system software.

**Figure 364** illustrates the different possible regions which can be defined by the corresponding register settings. Some of these regions may have the same size and offset (settings), if a differentiation is not needed.

**Figure 364 Possible cropping regions of ISP**

In addition the output cropping module is designed to support image stabilization features for video capturing. For image stabilization a sub frame must be chosen from the input frame, because a certain border around the output image is needed to have some margin for correcting the position of the image. Based on externally generated camera global motion data, image stabilization offers the functionality to compensate for that camera motion by moving the chosen sub frame across the input frame according to the signalled camera motion. The information source for global motion may be a motion sensor or extracted from the image content by a video encoder. The global motion vector has to be written into the configuration register ISP\_IS\_DISPLACE by software for each frame. To prevent the sub frame from running out of the input frame, the sub frame is re-centered at a programmable rate that is proportional to its distance from the center of the input frame. The rate is programmed by setting the register ISP\_IS\_RECENTER with appropriate values.

In addition, the maximum allowed displacement of the sub window is programmable by using ISP\_IS\_MAX\_DX and ISP\_IS\_MAX\_DY registers. The output picture size is using shadow registers. If the programmed size can't be reached due to incorrect register programming or wrong input formats, a picture size error interrupt is triggered.

In standard mode (image stabilization switched off: is\_en=0 in ISP\_IS\_CTRL), the registers ISP\_IS\_H\_OFFSET, ISP\_IS\_V\_OFFSET, ISP\_IS\_H\_SIZE, and ISP\_IS\_V\_SIZE are used to cut a programmable sub frame out of the input frame as described above.

## Camera and ADC Interface (CIF)

If image stabilization is switched on, the horizontal and vertical offset of the chosen sub frame is automatically updated. This automatic update according to camera displacements dx and dy programmed to the ISP\_IS\_DISPLACE register is implemented as described below.

Instead of using the values programmed to the configuration registers ISP\_IS\_H\_OFFSETS and ISP\_IS\_V\_OFFSETS, (which are now used to configure the initial position of the chosen sub frame) two new internal registers cur\_h\_offs and cur\_v\_offs are used to dynamically choose the sub frame sent to the output interface. These are updated with each frame in the following way:

```

if IS_RECENTER != 0
    cur_h_offs = (cur_h_offs - dx) - ((cur_h_offs - IS_H_OFFSETS) / 2IS_RECENTER)
else
    cur_h_offs = (cur_h_offs - dx)

cur_h_offs is clipped to the range
[IS_H_OFFSETS - IS_MAX_DX ... IS_H_OFFSETS + IS_MAX_DX].

```

The system software has to ensure that IS\_H\_OFFSETS is greater or equal IS\_MAX\_DX and that IS\_H\_SIZE + IS\_H\_OFFSETS + IS\_MAX\_DX does not exceed the horizontal size of the input frame. Recommended value for IS\_MAX\_DX is equal to IS\_H\_OFFSETS.

```

if IS_RECENTER != 0
    cur_v_offs = (cur_v_offs - dy) - ((cur_v_offs - IS_V_OFFSETS) / 2IS_RECENTER)
else
    cur_v_offs = (cur_v_offs - dy)

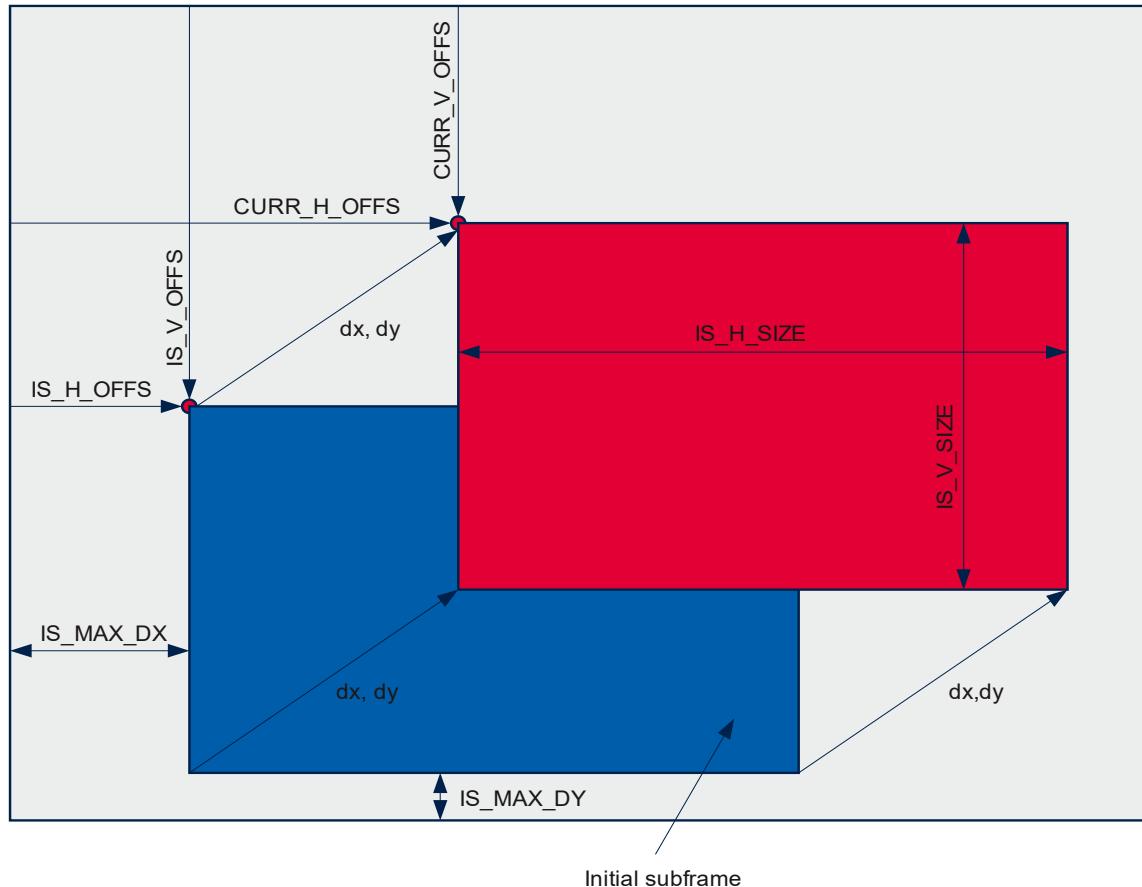

cur_v_offs is clipped to the range
[IS_V_OFFSETS - IS_MAX_DY ... IS_V_OFFSETS + IS_MAX_DY].

```

The system software has to ensure that IS\_V\_OFFSETS is greater or equal IS\_MAX\_DY and that IS\_V\_SIZE + IS\_V\_OFFSETS + IS\_MAX\_DY does not exceed the vertical size of the input frame. Recommended value for IS\_MAX\_DY is equal to IS\_V\_OFFSETS.

The system software has to ensure that the dx and dy values in ISP\_IS\_DISPLACE register are always up to date. Especially when no movement was detected the values have to be set to zero.

## Camera and ADC Interface (CIF)

**Figure 365 Illustration of image stabilization parameters**

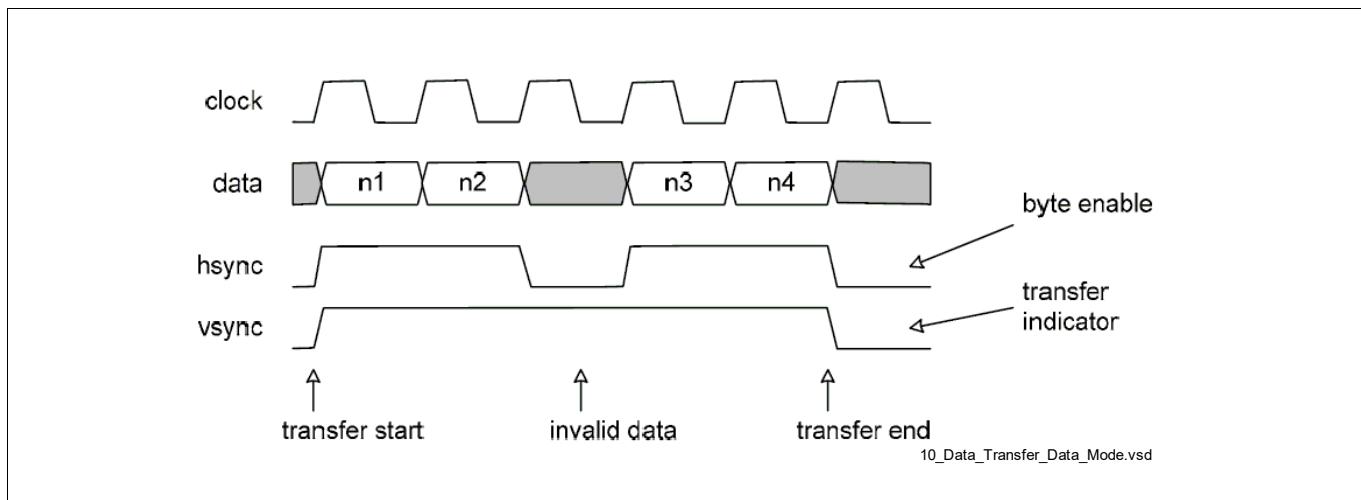

### Data Mode

In data mode all input data are considered as bytes. No line or frame organization is expected any more, so the states of the hsync and vsync hardware lines are considered as "byte enable" and "transfer indicator". This mode allows connecting the CIF to any source delivering a data stream (e.g. camera sensor including a JPEG encoder). This mode is selected by programming a "4" into the `isp_mode` field of `ISP_CTRL`. In this mode no limitation for the amount of data exists. The data will be stored in system memory in the region "main Y buffer".

As the synchronization signal polarities are programmable, the same applies to byte enable and transfer indicator as well. Also the sample edge can be selected by programming the register `ISP_ACQ_PROP` accordingly.

To start a transfer sequence, the transfer indicator (vsync) and byte enable (hsync) may be asserted (driven to an active level, usually low) at the same time or one after another in the following order: first assert vsync, then assert hsync. The transfer end condition is detected by the CIF when these signals are de-asserted as shown in **Figure 366**. Detecting the transfer end condition will lead to a main-path frame-end interrupt as soon as the last byte of this transfer is written to the system memory. During a transfer sequence, sampling of the input data can be paused by de-asserting the hsync for the desired amount of clock cycles.

## Camera and ADC Interface (CIF)

**Figure 366 Data Transfer in Data Mode with Active High Level**

Note that because there are no line and frame structures in the data mode any more, there is also no frame synchronized start mechanism as described above. Thus, the time of enabling the ISP is important here, because if the transfer indicator line is asserted at the moment of enabling the ISP, data capturing would start right away. If the entire amount of bytes of a transfer sequence is to be captured, the ISP must be enabled while the transfer indicator is de-asserted.

In situations with periodically repeated transfer sequences, the suggested strategy of capturing one entire sequence is as follows:

- Setup the complete processing chain including input acquisition, data path and output buffer size and address.
- Setup the memory interface to skip the next incoming frame (i.e. suppress the actual writing in system memory)
- Start the ISP for one frame only and wait for the frame-end interrupt. Because starting the ISP was done unsynchronized with the transfer sequence repetition, the CIF usually will not sample the entire number of bytes of this sequence. But this is not important, because we have suppressed writing to memory anyway, and are only interested in the frame-end-notification interrupt.
- As soon as the frame-end interrupt occurs, we know for sure that the last transfer sequence has just been completed. Now re-program the output buffer address, start the ISP for another single frame, and wait again for the frame-end notification.
- Upon occurrence of the frame-end interrupt, the entire number of data bytes from the last transfer sequence can be found in the output buffer.

In data mode, the values of the registers ISP\_ACQ\_V\_OFF, ISP\_ACQ\_H\_OFF, ISP\_ACQ\_H\_SIZE and ISP\_ACQ\_V\_SIZE are irrelevant.

### RAW Picture Mode

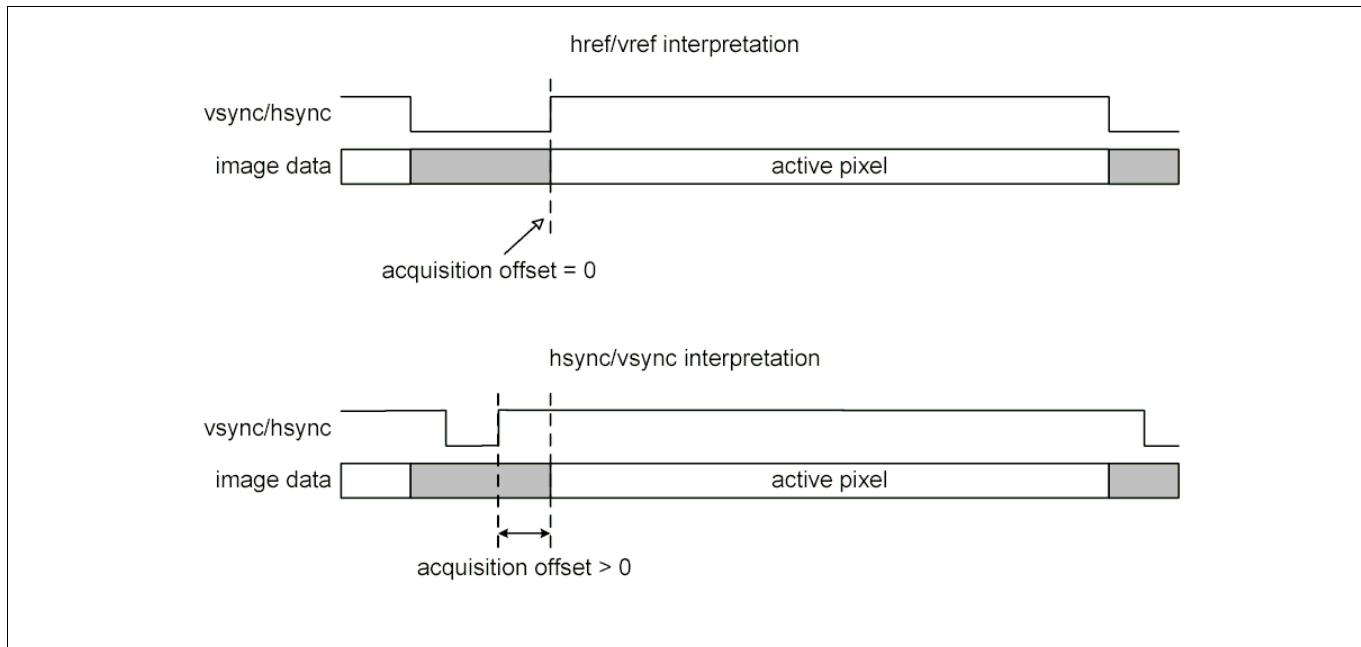

RAW picture mode allows sampling of the input image according to the setting of the BT.601 sync signals and providing it directly at the output of the ISP. No data processing is done at all allowing to store the 8 up to 16-bit data samples from the sensor device directly in system memory. No luminance/chrominance separation and re-ordering are done. After writing a 0 into the isp\_mode field of ISP\_CTRL the ISP is set to RAW picture mode.

The maximum size of data is limited by the offset and size counters. This means a maximum of 4095x4095 bytes are possible. The image data will be stored in the main Y buffer. In case of more than 8 bits data, the data bits are stored in 16-bit words in memory. The bits are stored MSB aligned.

### ITU-R BT 601/656 YC<sub>b</sub>C<sub>r</sub>4:2:2 Mode

## Camera and ADC Interface (CIF)

This ITU-R BT 601/656 mode allows the connection of an image sensor with integrated ISP functionality. In this case  $YC_bC_r$  data is expected at the sensor interface. In ITU-R BT 656 mode the synchronization signals are not considered as all timing reference data are encoded into the data stream (SAV and EAV codes). For ITU-R BT 601 mode the vertical and horizontal synchronization signals are sampled together with the image data. The synchronization signals can be interpreted as synchronization pulses, or as reference signals to be seen in the following figure.

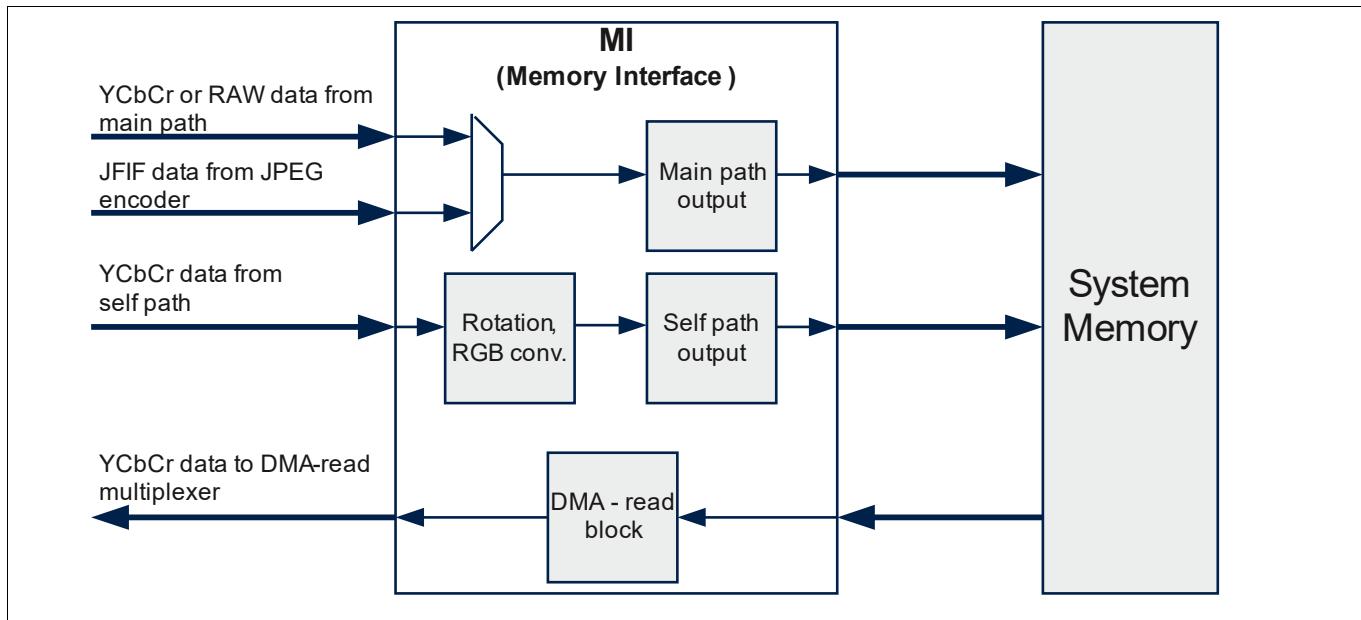

**Figure 367 Reference and Synchronization Signals for ITU-R BT 601 Mode**

### 26.3.14.7.2 Memory Interface Programming

The CIF memory interface unit (MI) is responsible for reading/writing image data from/to the system memory. As shown in Figure “[Memory Interface Unit overview](#)” on Page 42, the MI has three main tasks, which can operate independently:

- Take image data from the main path, either in YCbCr or RAW format and write it into certain data buffers located in the system memory.

## Camera and ADC Interface (CIF)

**Figure 368 Memory Interface Unit overview**

### External Output Buffers

Depending on which paths are enabled and which output format is selected, the MI unit can simultaneously output image data to up to 6 independent buffers. The buffers are named according to their relation to the main data path and their usage in the (most common) YCbCr planar output format: main-Y-buffer, main-Cb-buffer, main-Cr-buffer.

The buffers itself are not part of the CIF IP; they are system memory areas accessible from the bus that is also connected to the CIF. One can think of the MI as a kind of DMA controller, which writes to the configured memory locations without any CPU assistance. To configure the memory locations, each of the buffers mentioned earlier has a set of registers assigned to it.

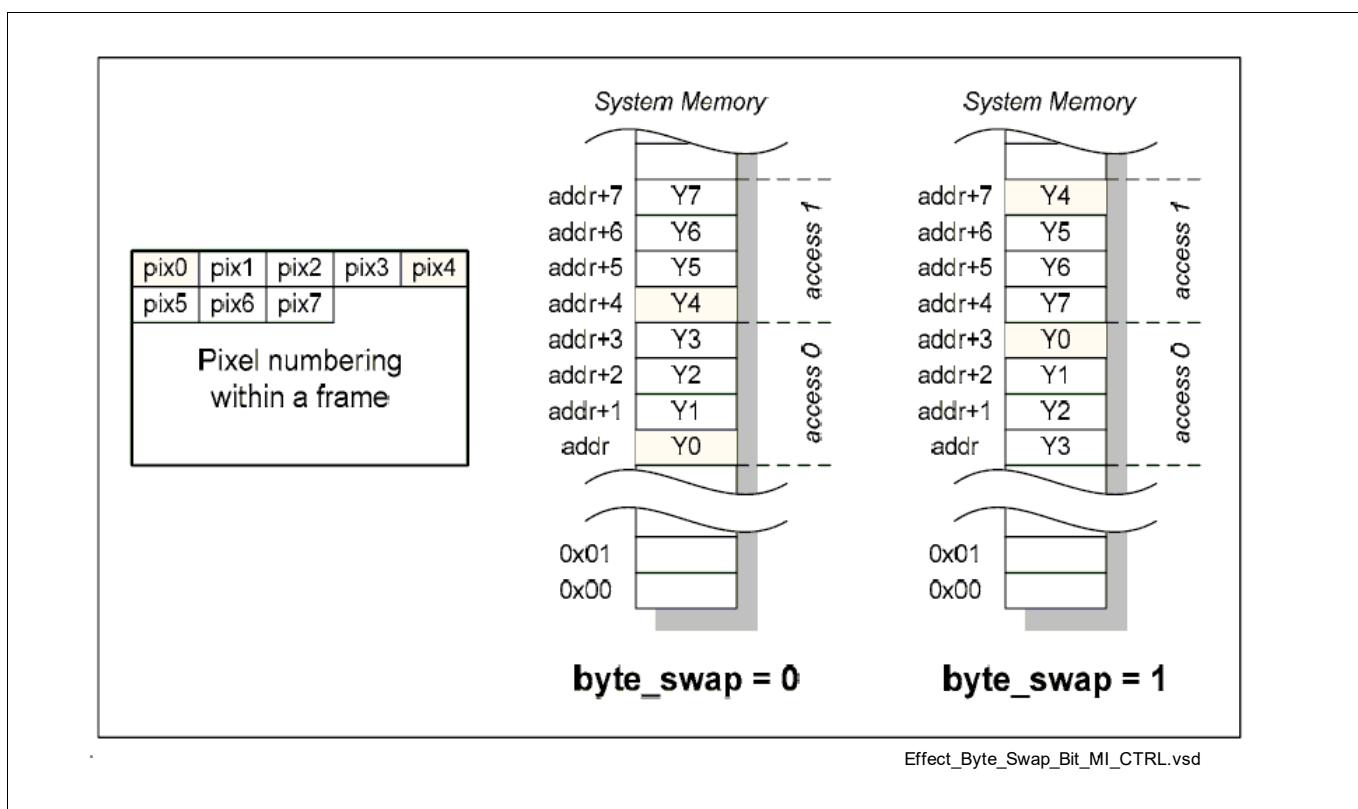

- MI\_xx\_xx\_BASE\_AD\_INIT
  - This is the base address of the memory area to use for that buffer. (e.g. the lowest address of that buffer)  
Note that buffer base addresses must be 4-byte-aligned. In case the target system uses some kind of PMMU, the physical address must be specified, because virtual-to-physical translation is not possible for this kind of DMA-like transfer.
- MI\_xx\_xx\_SIZE\_INIT
  - This is the size of the memory area in bytes. Note that the size is also required to be a multiple of 4. It is ensured that for write operations in this particular buffer, the MI will only write to memory locations from the base address to the base address + the size - 1. If the MI reaches the end of the memory area while continuously writing data, the buffer "wraps around" and it proceeds to write starting from the base address again. This wrap around event can also be used to trigger an interrupt. See the MI\_RIS register for details.
- MI\_xx\_xx\_OFFSET\_CNT\_INIT
  - This is the initial offset (in bytes) for writing to the buffer after e.g. a soft reset. Usually, to write to the buffer from the very beginning, an offset of zero is to be programmed into this register.
- MI\_xx\_xx\_OFFSET\_CNT\_START
  - This is a read-only register, which holds the offset at which the MI had written the last processed frame. This register is updated at frame end, so at any given time, it contains always the starting offset of the last completely processed frame.

## Camera and ADC Interface (CIF)

One of the buffers, the main-Y-buffer, is additionally able to trigger an interrupt as soon as a particular filling level is reached. This level can be configured in terms of an offset count (in bytes) from the base address using the MI\_MP\_Y\_IRQ\_OFFSET\_INIT register.

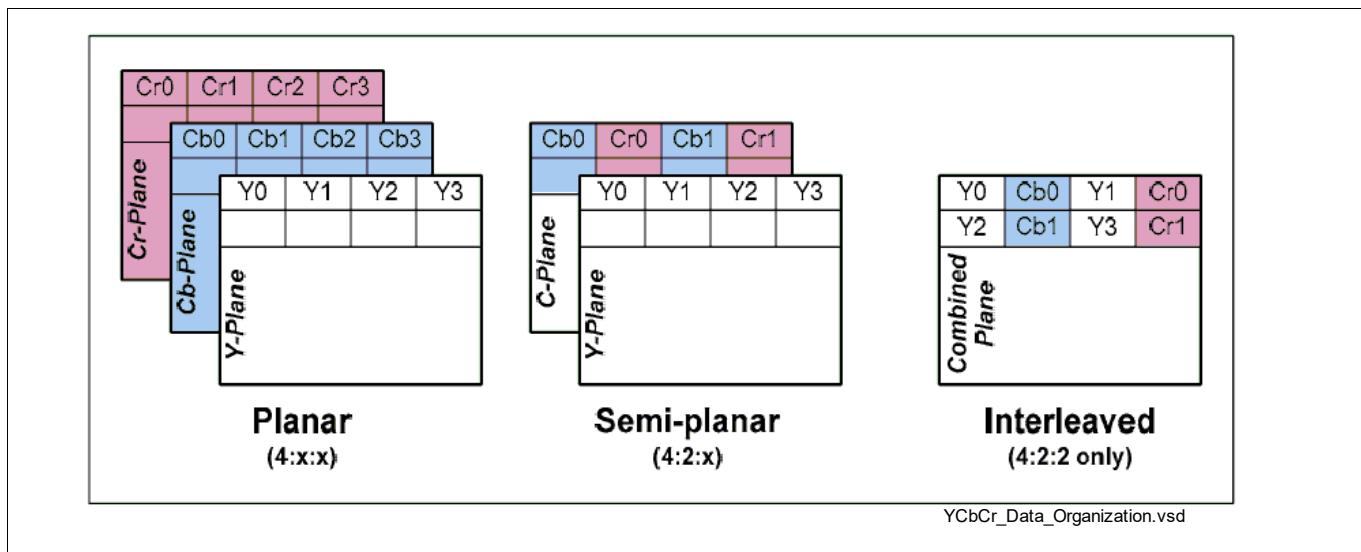

Further, the MI supports updating the buffer configuration seamlessly between two consecutive frames without dropping a frame by using the shadow register concept described in chapter [“Configuration and Shadow Registers” on Page 29](#). Two bits in the MI\_CTRL register (init\_offset\_en and init\_base\_en) can be used to select whether the base address and size, or the offset counters, or both are being updated at the next configuration update pulse. It should be noted that it is only possible to update the selected parts of all the buffers at once. It is not possible to re-configure only specific buffers and leave the others left untouched.

As mentioned earlier, there are some restrictions permitting only 4-byte-alignment buffer base addresses, and both sizes and offsets also need to be a multiple of 4. This is because the MI writes the data to the memory areas in 4-byte-accesses. It is possible to change the endianess of these accesses with the byte\_swap bit in the MI\_CTRL register. [Figure 369](#) illustrates this with the example use case of writing 8-bit Y-samples from a frame with a width of 5 pixels. The setting of the byte\_swap bit affects the write accesses to all buffers regardless of whether YCbCr or RAW data is to be written. Note that "addr" is a 4-byte aligned address in this example. For all other output schemes illustrated and discussed in this chapter, a setting of byte\_swap = 0 is assumed.

**Figure 369 Effect of the byte\_swap bit in MI\_CTRL**

## Camera and ADC Interface (CIF)

**Figure 370** YCbCr Data organization

### Main Path output programming

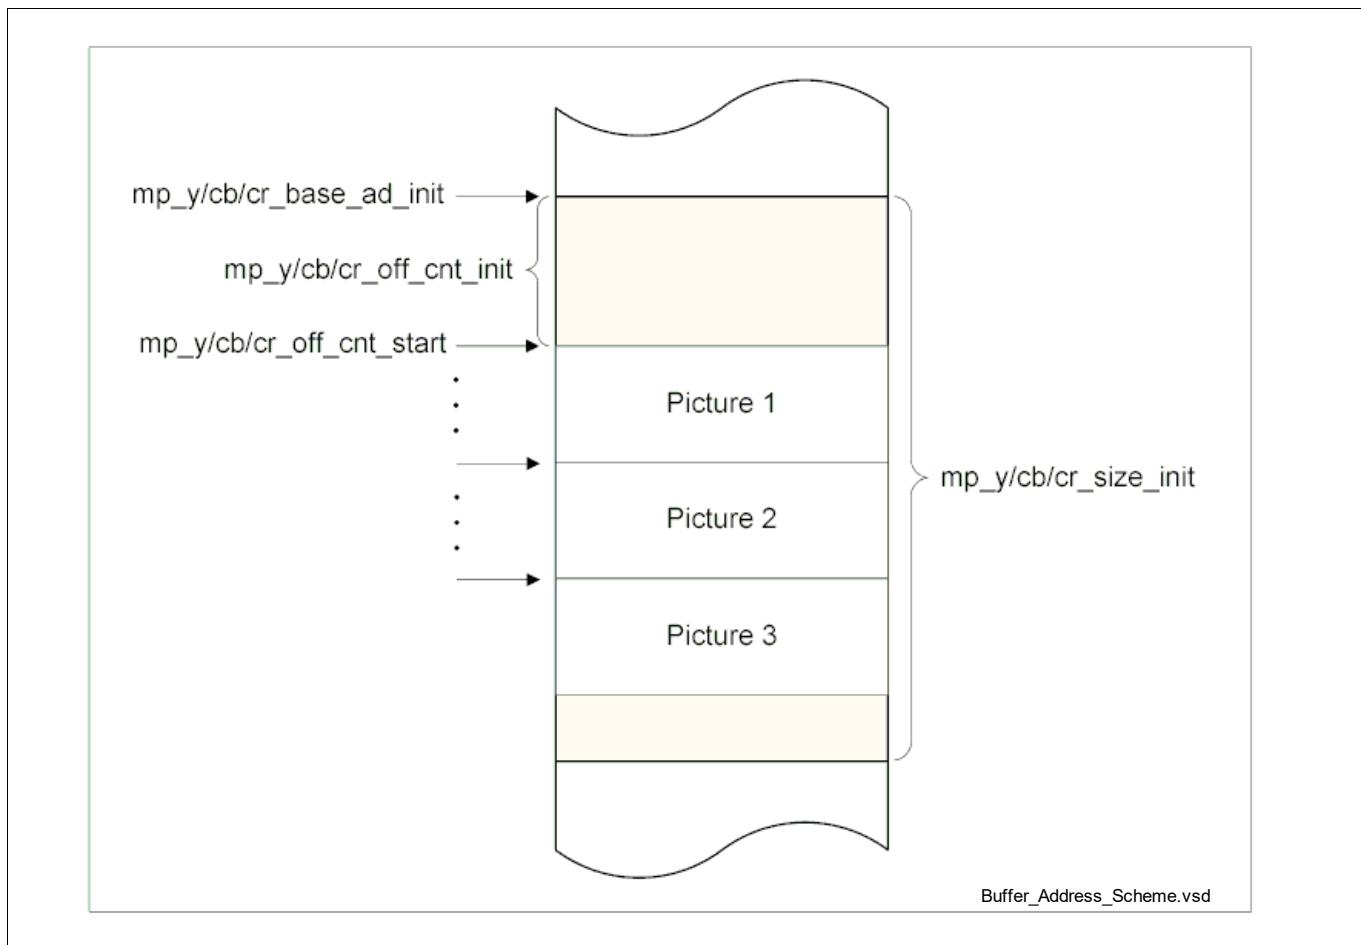

The main path output sub-module of the MI is intended to be used for video stream generation (YCbCr for further compressing via software encoders), or high resolution still image snapshot. To achieve this, it can be configured to output one out of the following data sources:

- YCbCr data from the main path scaler
  - To enable this, bit mp\_enable in the MI\_CTRL register is to be set. The data can be output in planar, semi-planar or interleaved format, as shown in [Figure 370](#). The selection is done with the bits mp\_write\_format in the MI\_CTRL register. In semi-planar mode, the main-Cb-buffer is used for the multiplexed Cb/Cr values and the main-Cr-buffer remains unused. In interleaved mode, only the main-Y-buffer is used for all the multiplexed values.
- RAW data from the main path scaler.
  - This mode is enabled by setting the bit raw\_enable in the MI\_CTRL register. RAW data is assumed to be received via the same way as YCbCr data, but is written to the main-Y-buffer only. In RAW mode, the mp\_write\_format bits of the MI\_CTRL register are used to select between 8-bit mode (which will write only the 8 most significant bits of every sample) up to 16-bit mode (which will e.g. write the full 16-bit msb-aligned into 2 bytes of the output buffer). This implies that for the higher than 8-bit modes, a buffer size twice as much is necessary as for the 8-bit mode, and the least significant bits of every 16-bit value are unused and remain zero.

In some RAW data modes the actual number of bytes to write per frame depends on the input signal and/or the compression ratio, and is not known in advance. Thus, this number is given in the read-only MI\_BYTE\_CNT register, which is updated at frame end only. So this register always shows the number of bytes written to the main-Y-buffer for last completely processed frame.

It is assumed that all the sub-modules within the CIF's processing chain located in front of the MI are configured in a way that the input data to the MI main path corresponds to what it is configured for. If this is not the case, the behavior of the MI is not predictable.

## **Camera and ADC Interface (CIF)**

**Figure 371 Buffer address scheme, valid for main picture buffers**

### **26.3.14.7.3 Getting Started - First steps for startup**

This chapter describes the first steps to startup the CIF in YCbCr mode. The procedure and the register contents are presented. Generally, all sub modules (like MI, EP, LDS) within CIF can be configured in arbitrary order but the ISP sub module must be enabled last.

## General Hints

Activity of the input port (data and sync lines) can be observed through register ISP\_FLAGS\_SHD.

## Recipe 1: YCbCr Bypass Mode

In YCbCr Bypass mode the image sensor is expected to deliver pre-processed image data in YCbCr format at its parallel output port. Because of the pre-processing, most of the CIF's ISP functionality can be bypassed, so only a small number of registers must be programmed to put this mode into operation. The Main Scaler unit will also be bypassed, so that the incoming data will be presented almost unmodified at the output. All that's left to do in the processing chain is YC-sequence reordering.

## Requirements / Preconditions

In this example, we assume a sensor delivering VGA-sized (640x480) frames continuously using YCbCr data format with 4:2:2 color sub sampling. Synchronization is assumed to be done according to ITU.BT601 (i.e. using separate wires carrying hsync and vsync signals, both active high in this example).

## Camera and ADC Interface (CIF)

It is further assumed that the sensor is already up and running and that it is configured to the mode described above. Its pixel clock is running and meets the CIF's AC-requirements, and the sync signals and image sensor data bus are routed to the CIF's input ports.

### Basic Initialization

1. Enable the main clock in VI\_CCL  $VI\_CCL = 0000\ 0000_H$
2. Enable all clocks of all sub-modules  $VI\_ICCL = FFFF\ FFFF_H$
3. Trigger the asynchronous system reset of the CIF

Typically the asynchronous reset line is connected to a central module of your SOC, handling resets for all components. Usually there is one bit reserved for this purpose.

There may be some delay required in the software before the following access to the CIF (time until the central module clears reset, time until the reset signal is synchronized to the sensor clock domain of the CIF).

### ISP input acquisition

1. Switch to ITU.BT601 compatible mode (ISP still disabled yet)  $ISP\_CTRL = 0000\ 0004_H$
2. Set the input acquisition properties according to what is delivered by the sensor: sampling at falling edge of pixel clock; h- and v-sync high active; sample sequence Y-Cb-Y-Cr; don't care about odd or even fields; 8-bit data interface.  
 $ISP\_ACQ\_PROP = 0000\ 0300_H$
3. Set the input acquisition window according to what is delivered by the sensor.(here, we assume no delay between the sync signals and the active pixel data, that's why the offset values can remain zero. Horizontal size is twice the image width, because for every 2 incoming pixels, there are also 2 chrominance values):

$ISP\_ACQ\_H\_SIZE = 0000\ 0500_H$  ( $2 * 640 = 1280$ )

$ISP\_ACQ\_H\_OFS = 0$

$ISP\_ACQ\_V\_SIZE = 0000\ 01E0_H$  (480)

$ISP\_ACQ\_V\_OFS = 0$

### ISP output formatter

1. We want to output the complete incoming frame from the sensor (no cropping) so the whole sensor resolution need to be programmed in the output window

$ISP\_OUT\_H\_SIZE = 0000\ 0280_H$  (640)

$ISP\_OUT\_V\_SIZE = 0000\ 01E0_H$  (480)

$ISP\_OUT\_H\_OFFS = 0$   $ISP\_OUT\_V\_OFFS = 0$

### Data Path

1. Select parallel interface and main data path, enable output of main data path

$VI\_DPCL = 0000\ 0001_H$   $MI\_CTRL = 0000\ 0001_H$

### Memory Interface

1. Set Y, Cb and Cr buffer position and size (32bit aligned). Update shadow registers with next configuration update:
  - a)  $MI\_MP\_Y\_BASE\_AD\_INIT = <Y\ base\ address>$
  - b)  $MI\_MP\_Y\_SIZE\_INIT = <sizeY>$
  - c)  $MI\_MP\_CB\_BASE\_AD\_INIT = <Cb\ base\ address>$
  - d)  $MI\_MP\_CB\_SIZE\_INIT = <sizeC>$
  - e)  $MI\_MP\_CR\_BASE\_AD\_INIT = <Cr\ base\ address>$

## Camera and ADC Interface (CIF)

f) MI\_MP\_CR\_SIZE\_INIT = <sizeC>

Set to main picture data mode (do not swap bytes, do not mirror) and update shadow register immediately. (This also transfers the base address and the size to their respective shadow registers).

MI\_CTRL = 0030 0001<sub>H</sub>      MI\_INIT = 0000 0010<sub>H</sub>

### Interrupt Processing

1. Setup interrupt service routines, clear and enable interrupts if needed, e.g. frame end interrupt of memory interface:

a) MI\_ICR = 0000 0001<sub>H</sub> MI\_IMSC = 0000 0001<sub>H</sub>

### Start the CIF

1. Enable input acquisition and output formatter (to start the output formatter there is no configuration update necessary). As soon as the CIF is started the lower two bits of ISP\_FLAGS\_SHD are set.

ISP\_CTRL = ISP\_CTRL | 00000011<sub>H</sub> With the initialization sequence above, the CIF is set to sample all incoming frames and presents them at the output. If this is not the desired use case and e.g. a single frame is to be captured instead, this can be configured using the input acquisition register ISP\_ACQ\_NR\_FRAM. If this register is nonzero, only the given number of frames is being captured after the CIF has been started.

### 26.3.14.8 Use Case Description

The CIF is designed to support for example the following mobile phone use cases:

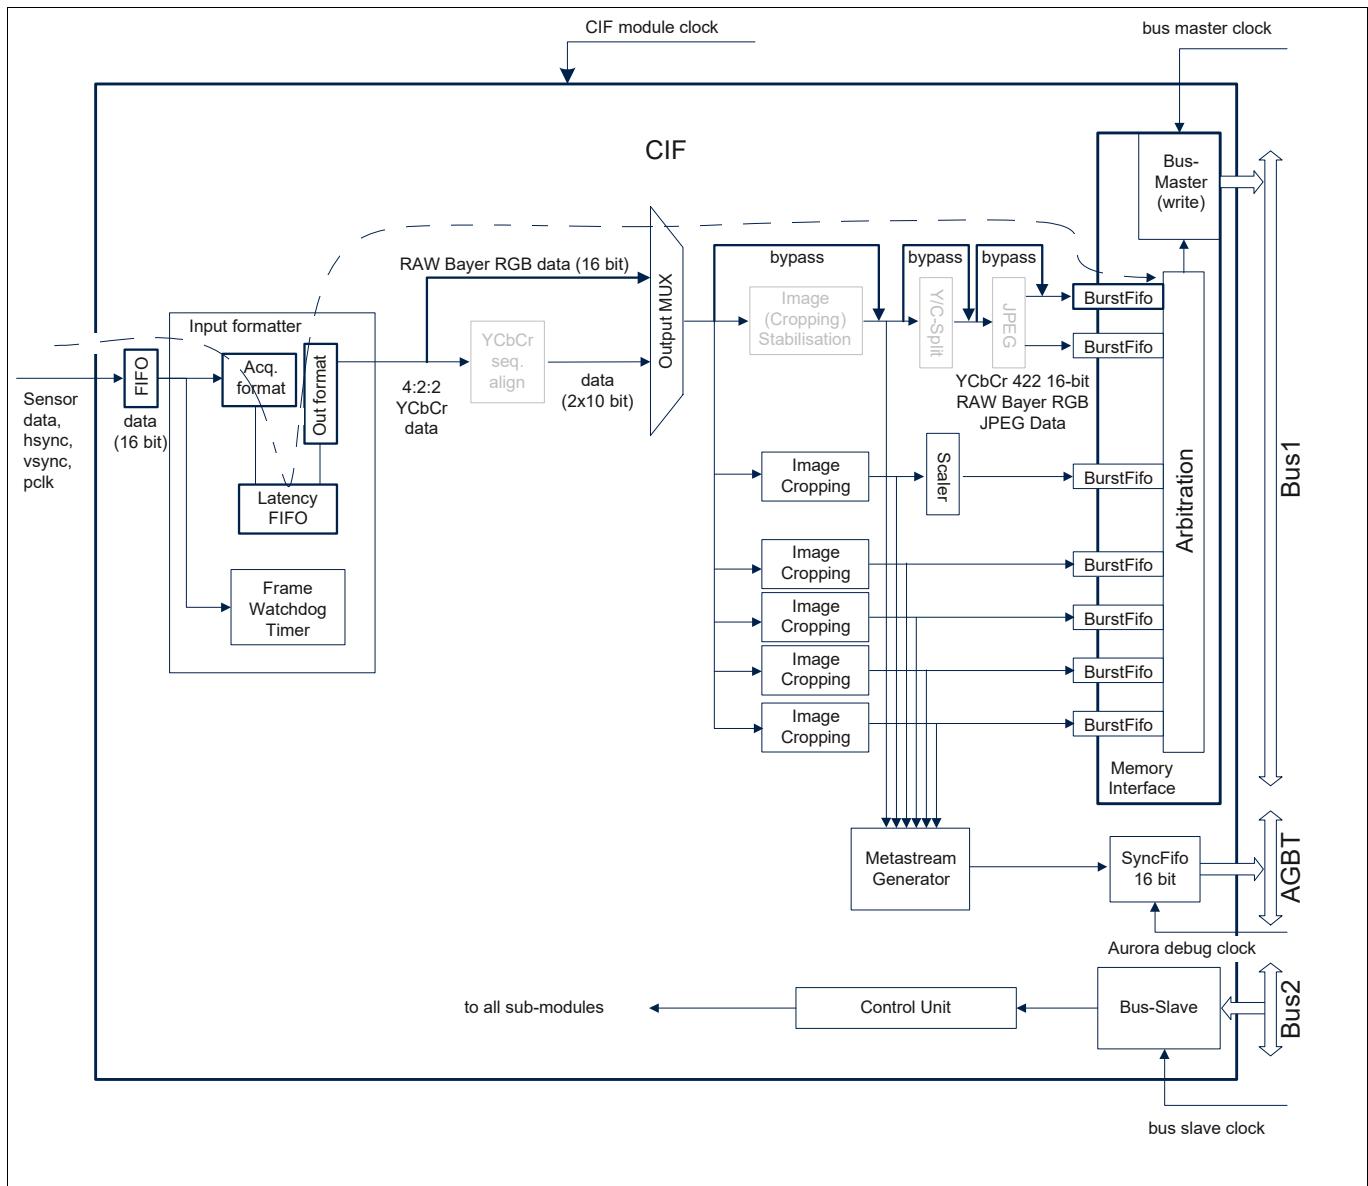

- Data transfer from external devices into system memory
- Viewfinder mode for still image capture
- Still image capture
- Video encoding

The above mentioned use cases are described in detail in the following chapters. Furthermore information about power management and configuration accesses are also given in this section.

## Camera and ADC Interface (CIF)

### 26.3.14.8.1 Data Transfer

This use case transfers byte data, like JPEG compressed data from a camera sensor with integrated JPEG encoder, into system memory (main Y buffer). Further processing must not be done as these data are no plain image or video data. The [Figure 372](#) shows the blocks active during data transfer. The inactive blocks are bypassed or disabled.

**Figure 372 Active Blocks for Use Case Data Transfer**

A transfer indicator and a byte valid signal (refer to [Figure 366](#)) are used to identify transfer start and stop as well as to identify valid data bytes. The ISP has to be set to data mode (mode field in ISP\_CTRL), all other functions (e.g. offset and size registers) are not used. The data path must be switched to 8 bit data/Raw data mode (VI\_DPCL).

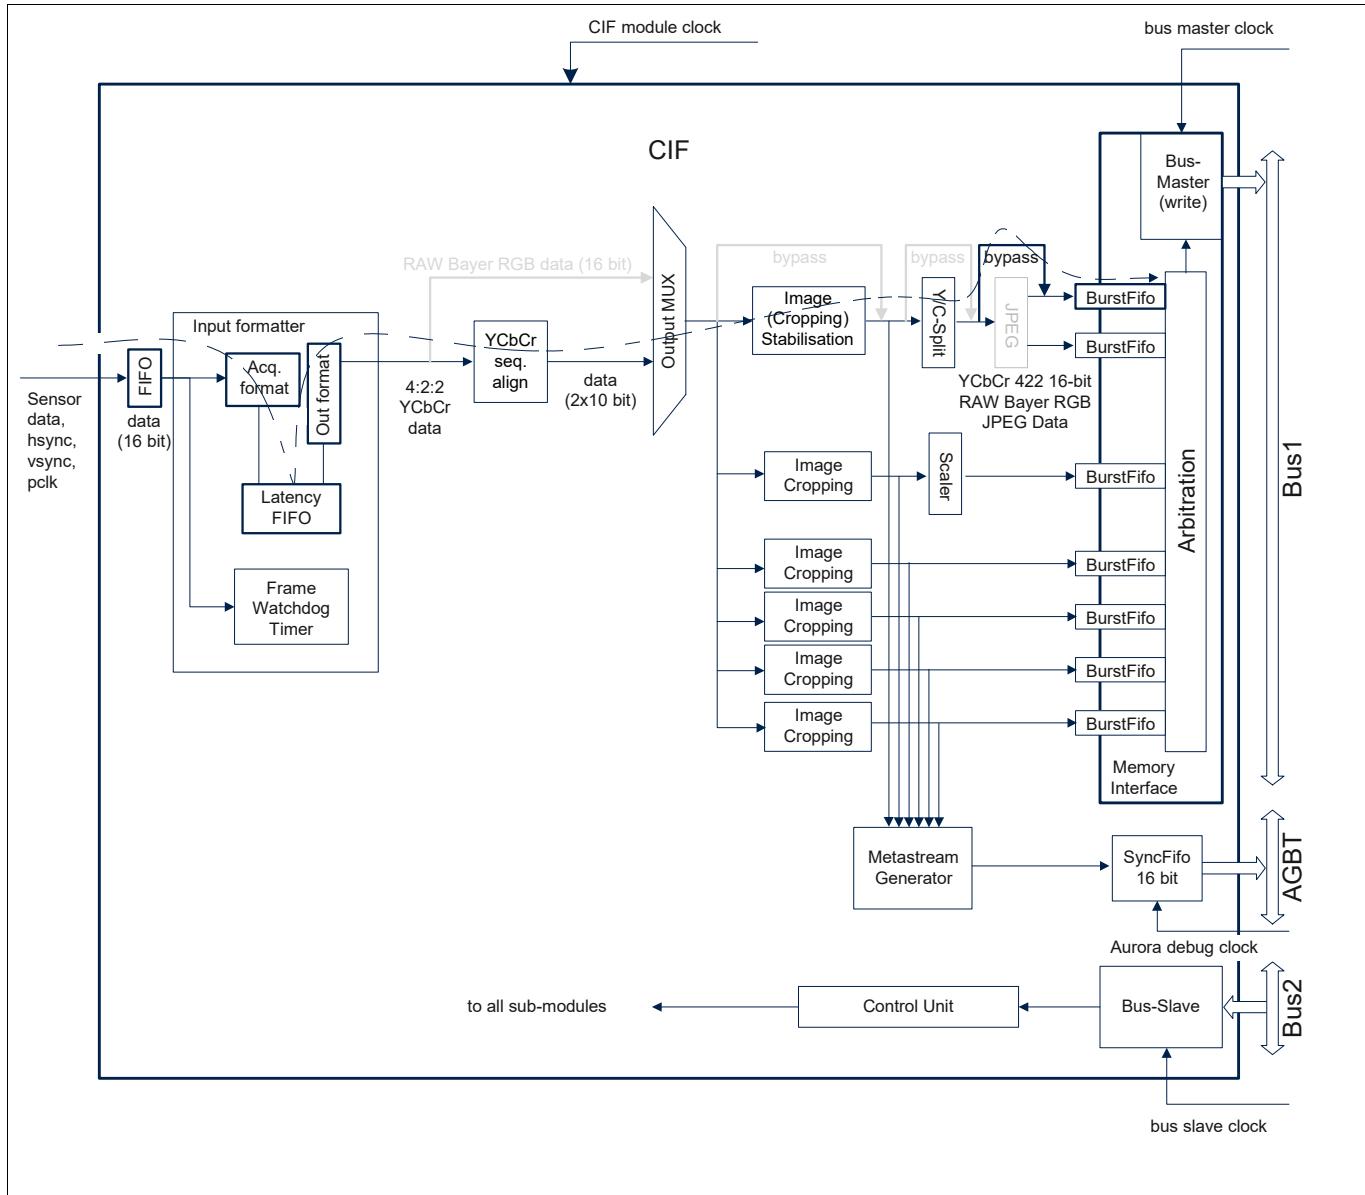

At the memory interface the Y buffer must be defined (MI\_MP\_Y\_BASE\_ADR, MI\_MP\_Y\_SIZE) and the RAW data port must be enabled (raw\_data\_en in MI\_CTRL).

After transfer being indicated by the “frame end” interrupt of the memory interface the number of transferred bytes can be read from MI\_BYTE\_CNT.

## Camera and ADC Interface (CIF)

### 26.3.14.8.2 Viewfinder Mode

This use case is to be used for displaying a video stream at an attached LCD. The CIF is responsible for capturing the video data at the sensor interface and transferring a continuous image data stream to the system memory.

**Figure 373 Active Blocks for Use Case Viewfinder**

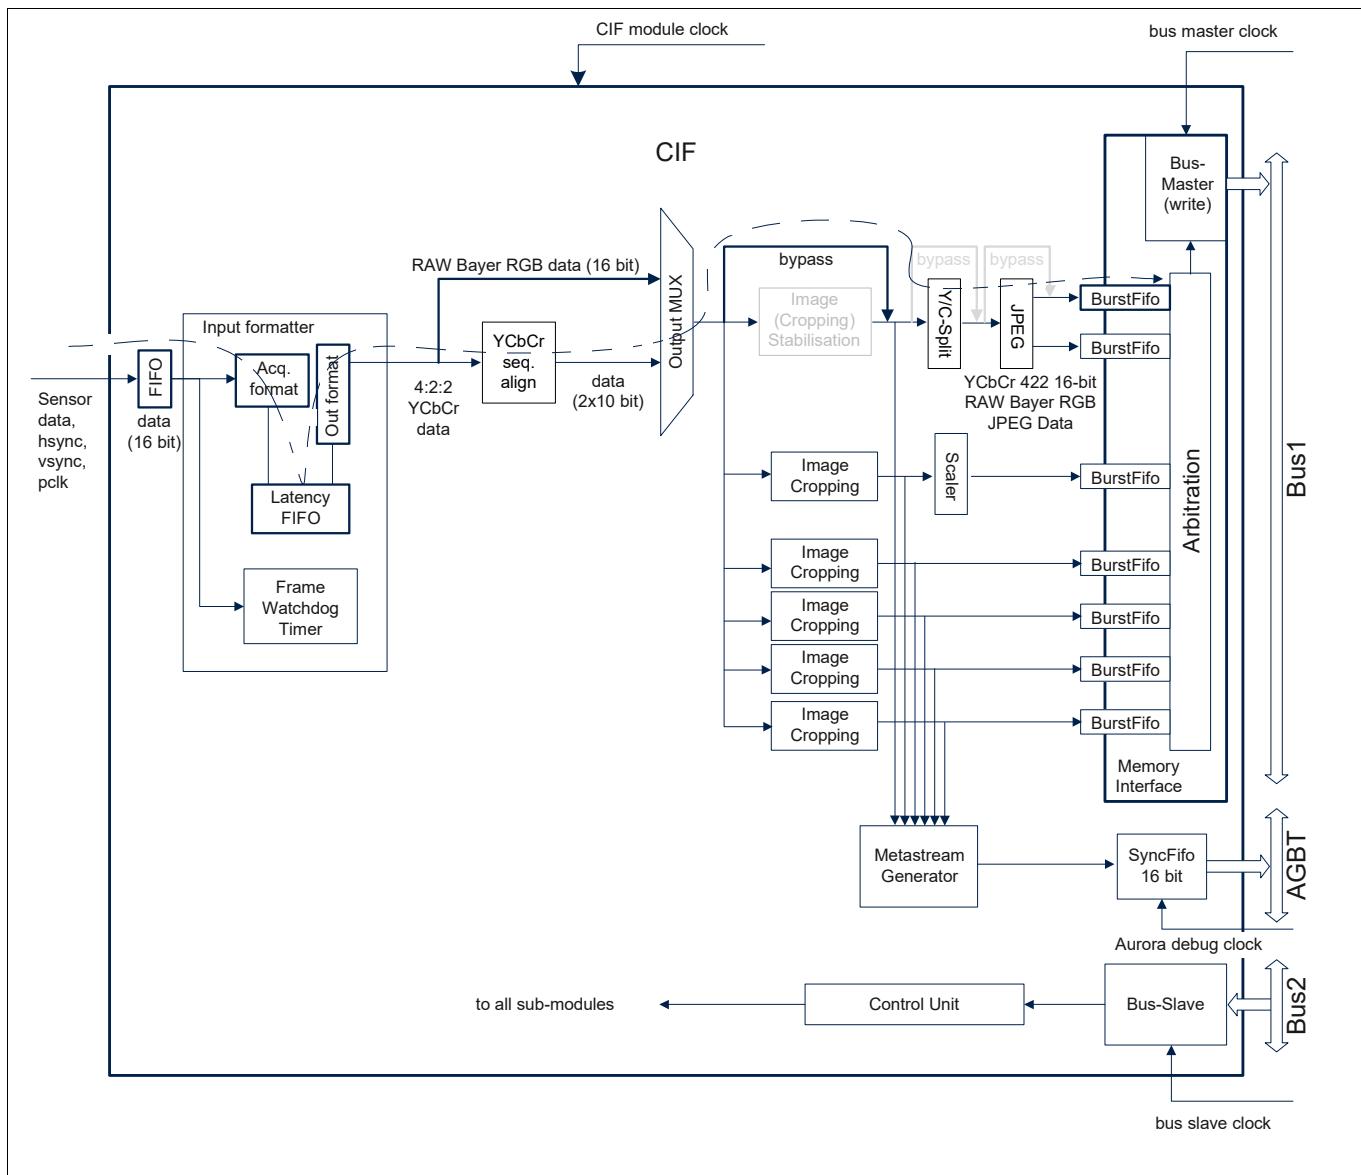

Image data are captured at the ISP. The mode depends on the camera sensor being used and can be YCbCr 4:2:2 with embedded timing control signals or external synchronization signals (selected by the `isp_mode` field in `ISP_CTRL`).

## Camera and ADC Interface (CIF)

### 26.3.14.8.3 Still Image Capture

This use case is meant for capturing a still image.

The use case viewfinder always precedes the capturing use case.

**Figure 374 Active Blocks for Use Case Still Image Capture**

In this use case the ISP samples the image and color processing can be done. The data path must be set to main 8bit luminance and chrominance processing format.

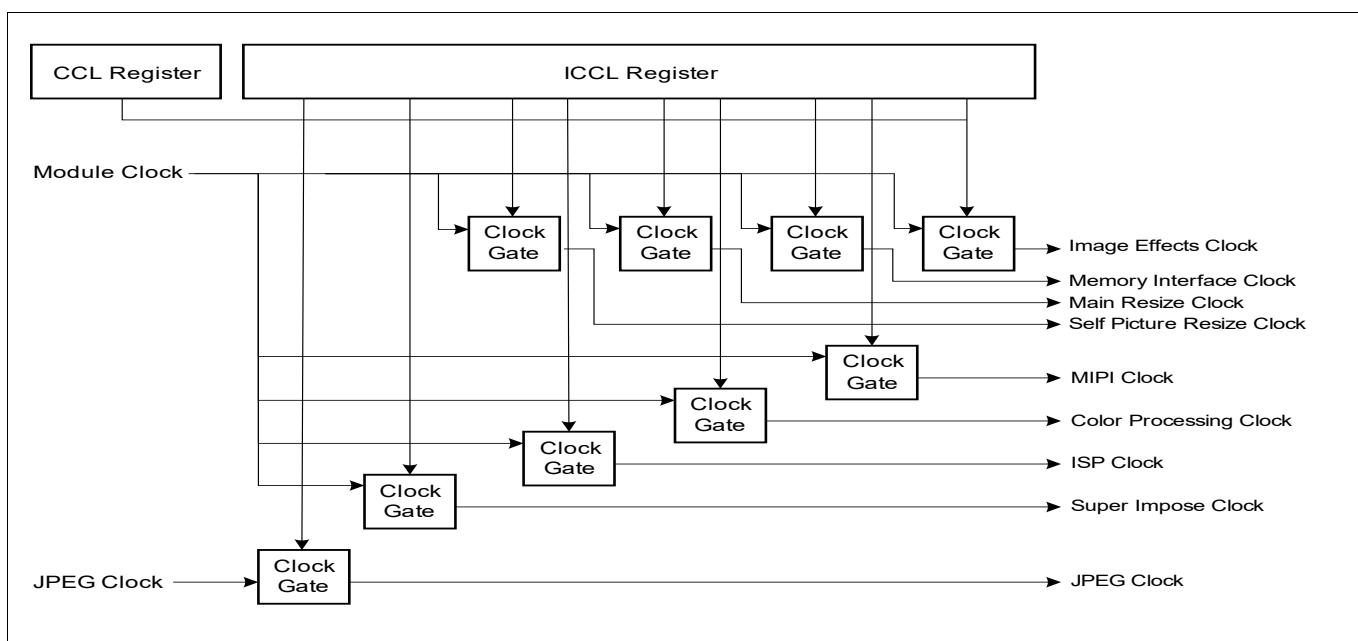

## Camera and ADC Interface (CIF)

### 26.3.14.9 Power Management

There are two main power modes for the CIF: running and switched-off. In running mode the master clock provided at the Bus interface is passed to the CIF blocks. In switched-off mode the master clock is disabled (gated) in the CIF control unit. So only register accesses are possible, but no processing. Controlling the main power modes is done using the VI\_CCL configuration register.

In running mode a further method exists to minimize power consumption of the CIF. Separate clock gating exists for all blocks inside the CIF (except the Y/C-splitter). This is controlled by the VI\_ICCL configuration register. For each module that is not needed for the actual processing (bypassed or disabled) the module clock can be disabled by clock gating as shown in Figure “[Clock Gating Scheme for the CIF](#)” on Page 51.

Clock gating for static configuration registers is handled automatically. Their clocks are enabled during read or write accesses via the Bus slave interface only, otherwise they are switched off.

**Figure 375 Clock Gating Scheme for the CIF**

### 26.3.14.10 Basics on Configuration Access

Configuration accesses are done by using the Bus slave interface. Single beat transactions with a data width of 32 bits are supported.

Each CIF sub-module contains its own local configuration registers. For optimized power consumption these registers are clocked during read/write data transfers only. This clock gating is handled automatically by the control unit and is fully transparent to the application.

---

**Camera and ADC Interface (CIF)**

## 26.4 Registers

The following section describes the CIF registers on bit level.

## Camera and ADC Interface (CIF)

### 26.4.1 CIF Control Registers

The communication and control flow to and from the CIF module is realized via internal registers. Access to the registers will be provided via an BBB slave interface. Each access is 32 bit aligned.

The CIF uses a distributed configuration register scheme. So there is no central unit containing all programming registers, but all CIF sub-modules contain their own programming registers.

**Note:** *Write accesses to reserved access locations are ignored. Read access deliver all zeros. No traps are triggered. Accesses of bus masters not enabled with the ACCENx registers cause acknowledge error.*

The register set is divided into the following register types:

- Control registers
- Configuration setting registers
- Shadow configuration setting registers
- Interrupt registers

Shadow registers are used to support dynamic data path re-programming. The next programming values are written into the configuration setting registers of a local configuration unit of a CIF internal block. Shadow registers are used for the processing part of the sub-modules to keep the current values for processing. Updating of these shadow registers can be triggered by either the configuration update bits in the sub-module control registers in terms of immediate update, or by triggering the “generate configuration update” bit in the ISP control register to automatically update all shadow registers in the whole data processing pipeline after the last pixel of a processed frame.

**Camera and ADC Interface (CIF)**

The registers are addressed wordwise.

**Table 1180 Registers Access Types**

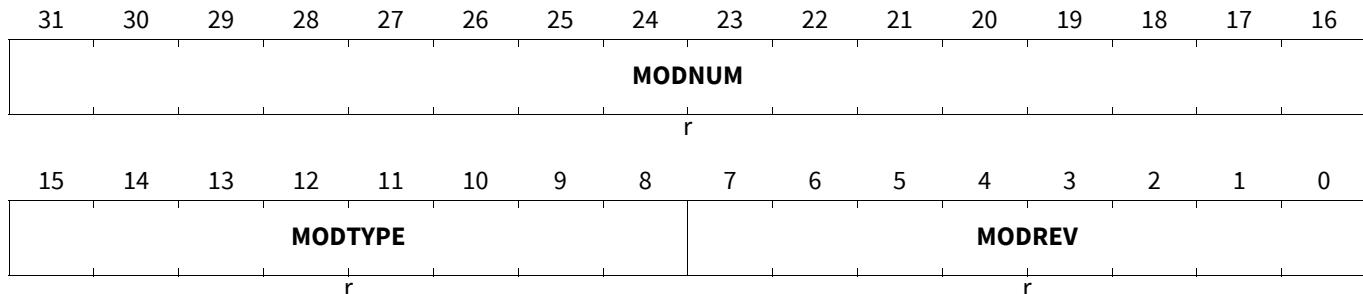

Mode	Symbol	Description Hardware (HW)	Description Software (SW)
<b>Basic Access Types</b>			
read/write	rw	Register is used as input for the HW	Register is read and writable by SW
read	r	Register is written by HW (register between input and output -> one cycle delay)	Value written by SW is ignored by HW; that is, SW may write any value to this field without affecting HW behavior
write	w	Register is written by software and affects hardware behavior with every write by software.	Register is writable by SW. When read, the register does not return the value that has been written previously, but some constant value instead.

**26.4.1.1 CIF Clock Control Registers****Clock Control Register**

Field	Bits	Type	Description
<b>CIF_CCLDISS</b>	1	r	<b>Status of cif_ccl[2] bit</b> (copy of cif_ccl[2])
<b>CIF_CCLFDIS</b>	2	rw	<b>Clock Control Logic disable</b> 0 <sub>B</sub> processing/cfg-clocks for all CIF sub modules enabled 1 <sub>B</sub> processing/cfg-clocks for all CIF sub modules disabled w/o access to ID and CIF_CCL register
<b>0</b>	0, 31:3	r	<b>Reserved</b> Read as 0, should be written with 0.

## Camera and ADC Interface (CIF)

## 26.4.2.5 Miscellaneous ISP Registers

## ISP Error Register

## ISP\_ERR

## ISP Error Register

(073C<sub>H</sub>)Application Reset Value: 0000 0000<sub>H</sub>

Field	Bits	Type	Description
INFORM_SIZE_ERR	0	r	Size error is generated in inform submodule
IS_SIZE_ERR	1	r	Size error is generated in image stabilization submodule
OUTFORM_SIZE_ERR	2	r	Size error is generated in outmux submodule
0	31:3	r	Reserved Read as 0.

## Camera and ADC Interface (CIF)

### ISP\_ERR and ISP\_ERR\_CLR

For debug purposes the **ISP\_ERR** and **ISP\_ERR\_CLR** are implemented. In the case a PIC\_SIZE\_ERR interrupt is signalled the SW is able to see in which submodule this error was generated. Writing to the **ISP\_ERR\_CLR** register clears this bit.

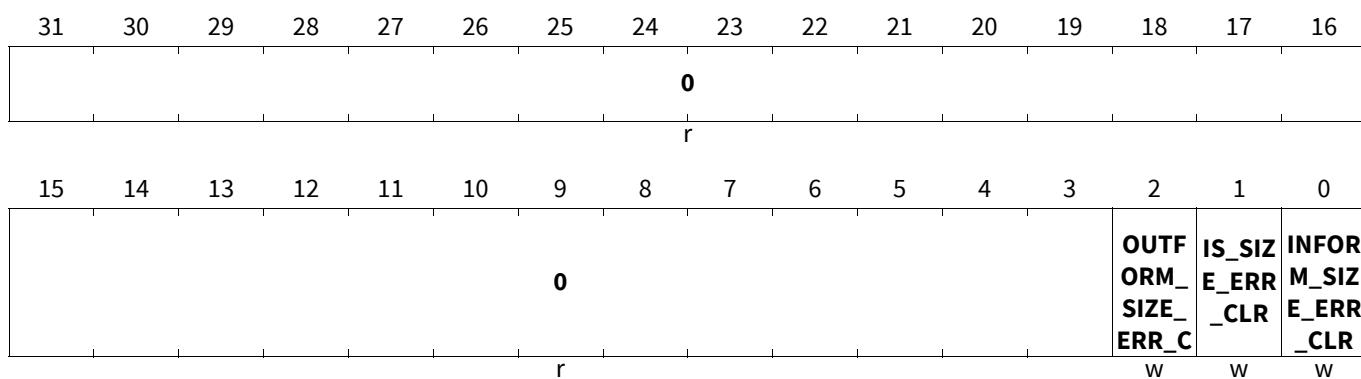

#### ISP Error Clear Register

##### ISP\_ERR\_CLR

##### ISP Error Clear Register

(0740<sub>H</sub>)

Application Reset Value: 0000 0000<sub>H</sub>

Field	Bits	Type	Description
INFORM_SIZE_ERR_CLR	0	w	<b>Size error is cleared</b>
IS_SIZE_ERR_CLR	1	w	<b>Size error is cleared</b>
OUTFORM_SIZE_ERR_CLR	2	w	<b>Size error is cleared</b>
0	31:3	r	<b>Reserved</b> Read as 0, should be written with 0.

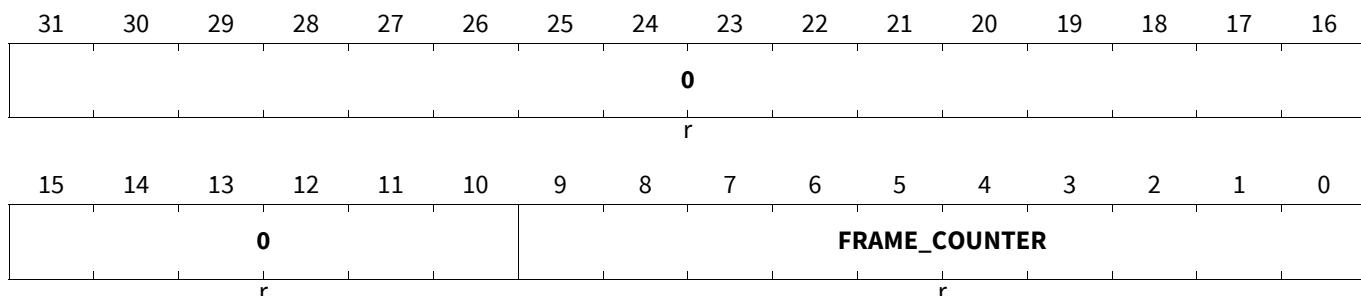

#### ISP Frame Counter Register

##### ISP\_FRAME\_COUNT

##### ISP Frame Counter Register

(0744<sub>H</sub>)

Application Reset Value: 0000 0000<sub>H</sub>

**Camera and ADC Interface (CIF)**

Field	Bits	Type	Description
<b>FRAME_COUN TER</b>	9:0	r	<p><b>Current Frame Count of Processing</b></p> <p>In the ISP_FRAME_COUNT register the number of processed frames are displayed. For example: If a 8 is programmed into the ISP_ACQ_NR_FRAMES register, a read access to the ISP_FRAME_COUNT register during processing of the first picture shows a 7. After the entire frames are processed the ISP_OFF interrupt is generated and the ISP_FRAME_COUNT has the count zero. In case a '0' is programmed into the ISP_ACQ_NR_FRAMES register (continues mode) the ISP_FRAME_COUNT register keeps the value '0'.</p>
<b>0</b>	31:10	r	<p><b>Reserved</b></p> <p>Read as 0.</p>

## Camera and ADC Interface (CIF)

## 26.4.3 Linear Downscaler Programming Registers

The address of each CIF Linear Downscaler register is evaluated as CIF\_LIN\_DSSCALE\_BASE + Offset.

## 26.4.3.1 Linear Downscaler Configuration Registers

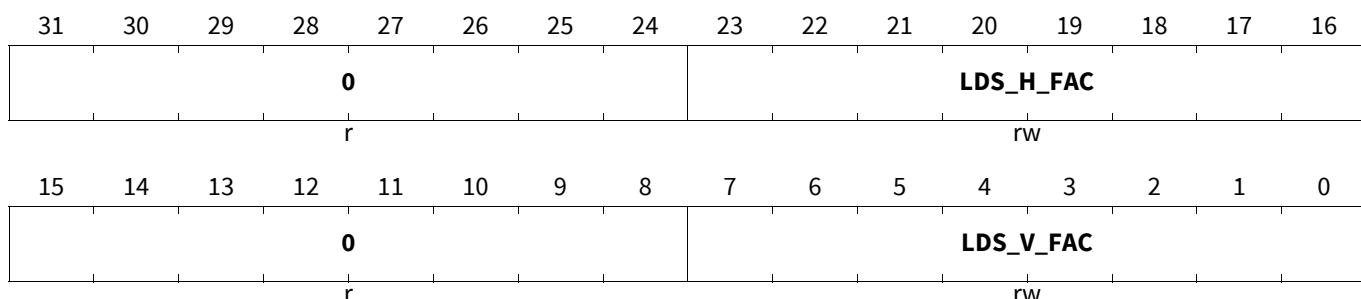

## Linear Downscaler Control Register

## LDS\_CTRL

Linear Downscaler Control Register (2600<sub>H</sub>) Application Reset Value: 0000 0000<sub>H</sub>

## Camera and ADC Interface (CIF)

### 26.4.4 Memory Interface Programming Registers

The address of each CIF memory interface register is evaluated as CIF\_MI\_BASE + Offset.

#### 26.4.4.1 Memory Interface Control Registers

##### Memory Interface Global Control Register

Note: *In order to select the appropriate mode, set one bit from RAW\_ENABLE, JPEG\_ENABLE and MP\_ENABLE to 1, and set the others to 0.*

##### MI\_CTRL

**Memory Interface Global Control Register (1500<sub>H</sub>) Application Reset Value: 0000 0000<sub>H</sub>**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
								MP_WRITE_FORMAT	INIT_OFFSET_EN	INIT_BASE_N	0	BURST_LEN_CHROM	0	BURST_LEN_LUM	
				0					r	rw	rw	r	rw	r	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
								BYTE_SWAP		0		RAW_ENABLE	JPEG_ENABLE	0	MP_ENABLE
				0					r	rw	r	rw	rw	r	rw

Field	Bits	Type	Description
<b>MP_ENABLE</b>	0	rw	<b>Enables main picture data path, YCbCr mode</b> Programmed value becomes effective (visible in control shadow register) after a soft reset, a forced software update or an automatic config update. Affects MI_IN and MI_OUT module.
<b>JPEG_ENABLE</b>	2	rw	<b>Enables JPEG mode</b> Programmed value becomes effective (visible in control shadow register) after a soft reset or a forced software. Affects MI_IN and MI_OUT module.
<b>RAW_ENABLE</b>	3	rw	<b>Enables RAW mode</b> Programmed value becomes effective (visible in control shadow register) after a soft reset or a forced software update. Affects MI_IN and MI_OUT module.
<b>BYTE_SWAP</b>	7	rw	<b>Byte Swap Enable</b> Enables change of byte order of the 32 bit output word at write port.  Note: <i>Programmed value becomes effective immediately. So write to the register only if no picture data is sent.</i>  0 <sub>B</sub> no byte mirroring 1 <sub>B</sub> byte order is mirrored but the bit order within one byte doesn't change

## Camera and ADC Interface (CIF)

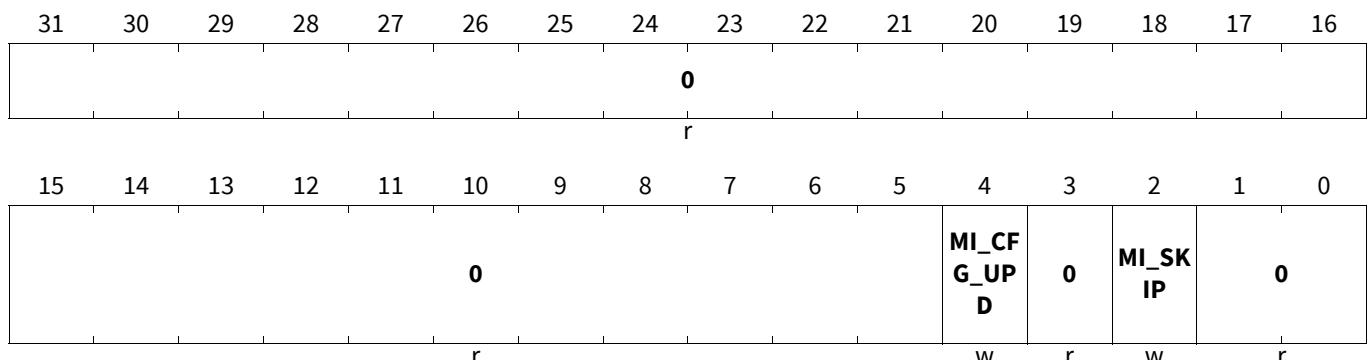

Field	Bits	Type	Description
<b>BURST_LEN_LUM</b>	16	rw	<p><b>Luminance Burst Length</b>            Burst length for Y, JPEG, or RAW data affecting write port.            Ignored if 8-beat bursts not supported.            This burst configuration is also applied to the Extra Paths.</p> <p><i>Note:</i> Programmed value becomes effective immediately. So write to the register only if no picture data is sent.</p> <p>0<sub>B</sub> 4-beat bursts            1<sub>B</sub> 8-beat bursts</p>
<b>BURST_LEN_CHROM</b>	18	rw	<p><b>Chrominance Burst Length</b>            Burst length for Cb or Cr data affecting write port.            Ignored if 8-beat bursts not supported.</p> <p><i>Note:</i> Programmed value becomes effective immediately. So write to the register only if no picture data is sent.</p> <p>0<sub>B</sub> 4-beat bursts            1<sub>B</sub> 8-beat bursts</p>
<b>INIT_BASE_EN</b>	20	rw	<p><b>Init Base Address Enable</b>            Enables updating of the base address and buffer size shadow registers for picture to the programmed register init values.</p> <p>MI_MP_Y/CB/CR_BASE_AD_INIT            -&gt; MI_MP_Y/CB/CR_BASE_AD_SHD            MI_MP_Y/CB/CR_SIZE_INIT            -&gt; MI_MP_Y/CB/CR_SIZE_SHD</p> <p>The update will be executed either when a forced software update occurs (in register MI_INIT bit cfg_upd = 1) or when an automatic config update signal arrives at the MI input port. So only the corresponding shadow registers are affected.</p>
<b>INIT_OFFSET_EN</b>	21	rw	<p><b>Init Offset Counter Enable</b>            Enables updating of the offset counters shadow registers for picture to the programmed register init values.</p> <p>MI_MP_Y/CB/CR_OFFSET_CNT_INIT            -&gt; MI_MP_Y/CB/CR_OFFSET_CNT_SHD</p> <p>The update will be executed either when a forced software update occurs (in register MI_INIT bit cfg_upd = 1) or when an automatic config update signal arrives at the MI input port. So only the corresponding shadow registers are affected.</p> <p>After a picture skip has been performed init_offset_en selects between skip restart and skip init mode (see bit skip in register MI_INIT).</p>

**Camera and ADC Interface (CIF)**

Field	Bits	Type	Description
<b>MP_WRITE_FORMAT</b>	23:22	rw	<p><b>Main Picture YCbCr Write Format</b>  Defines how YCbCr main picture data is written to memory.  Ignored if JPEG data is chosen.</p> <p>The description listed first in the table below indicates the write format as used in YCbCr mode, the second one is valid for RAW data mode only.</p> <p><i>Note:</i> Programmed value becomes effective immediately. So write to the register only if no picture data is sent to the path.</p> <ul style="list-style-type: none"> <li>00<sub>B</sub> planar (YCbCr mode) / RAW &amp; data mode (8 bit)</li> <li>01<sub>B</sub> semi-planar for YCbCr 4:2:x / RAW 8 bit</li> <li>10<sub>B</sub> interleaved_combined for YCbCr 4:2:2 only / RAW &amp; data mode (greater 8 up to 16 bit)</li> <li>11<sub>B</sub> reserved / RAW greater 8 up to 16 bit</li> </ul>
<b>0</b>	1, 6:4, 15:8, 17, 19, 31:24	r	<p><b>Reserved</b>  Read as 0, should be written with 0.</p>

**Memory Interface Control Register For Address Init And Skip Function Register****MI\_INIT**

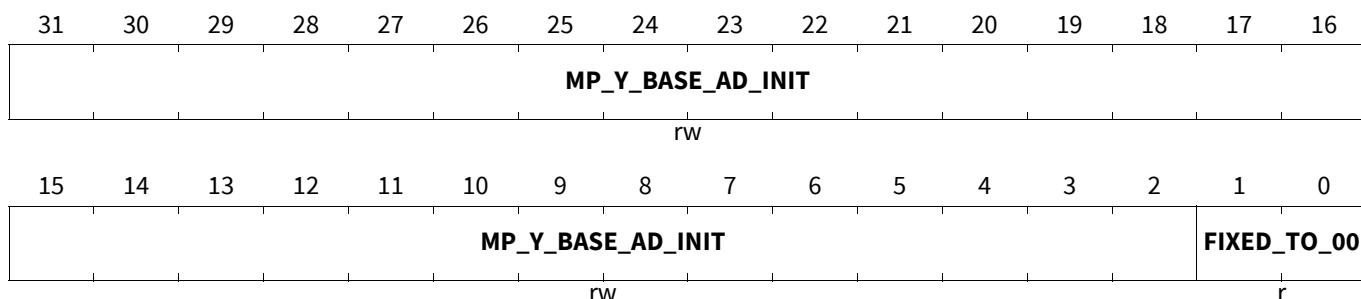

**Memory Interface Control Register For Address Init And Skip Function Register(1504<sub>H</sub>) Application Reset Value: 0000 0000<sub>H</sub>**

## Camera and ADC Interface (CIF)

Field	Bits	Type	Description
<b>MI_SKIP</b>	2	w	<p><b>Skip Picture</b></p> <p>Skip of current or next starting main picture: Aborts writing of main picture image data of the current frame to RAM (after the current burst transmission has been completed). Further main picture data up to the end of the current frame are discarded.No further macroblock line interrupt (_line), no wrap around interrupt for main picture (wrap_mp_y/cb/cr) and no fill level interrupt (fill_mp_y) are generated.Skip does not affect the generation of the main path frame end interrupt (mp_frame_end).The byte counter (register MI_BYTE_CNT) is not affected. It produces the correct number of JPEG or RAW data bytes at the end of the current (skipped) frame.After a skip has been performed the offset counter for the main picture at the start of the following frame are set depending on the bit init_offset_en in register MI_CTRL:</p> <p>A) Skip restart mode (init_offset_en = 0) The offset counters of the main picture are restarted at the old start value of the previous skipped frame.</p> <p>B) Skip init mode (init_offset_en = 1) The offset counters of the main picture are initialized with the register contents of the offset counter init registers without any additional forced software update or automatic config update.</p>
<b>MI_CFG_UPD</b>	4	w	<p><b>Forced Configuration Update</b></p> <p>Leads to an immediate update of the shadow registers. Depending on the two init enable bits in the MI_CTRL register (init_offset_en and init_base_en) the offset counter, base address and buffer size shadow registers are also updated.</p>
0	1:0, 3, 31:5	r	<p><b>Reserved</b></p> <p>Read as 0, should be written with 0.</p>

Field	Bits	Type	Description
FIXED_TO_00	1:0	r	Bits [1:0] are set to “00” (word aligned value).

## Camera and ADC Interface (CIF)

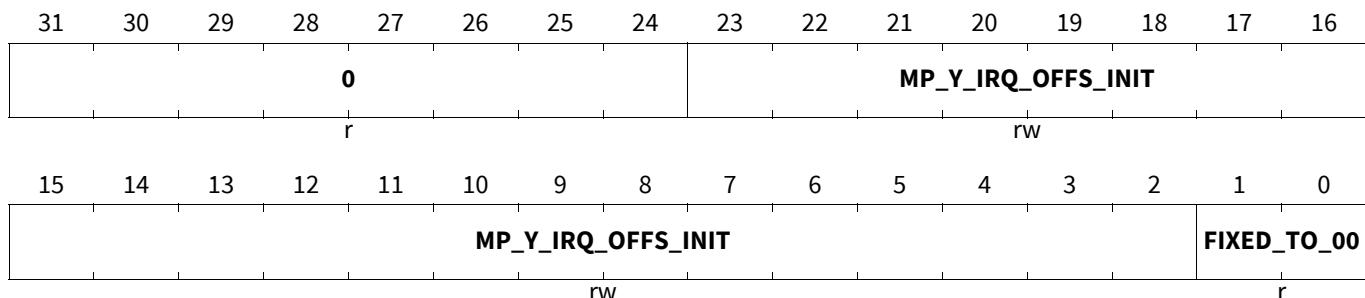

Field	Bits	Type	Description
<b>MP_Y_OFFSET_C</b>	23:2	r	<b>Main Picture Y Offset Counter Start</b> Offset counter value which points to the start address of the previously processed picture (main picture Y component, JPEG or RAW data). Updated at frame end. Note: A soft reset resets the contents to the reset value.
<b>0</b>	31:24	r	<b>Reserved</b> Read as 0.

**Memory Interface Fill Level Interrupt Offset Value For Main Picture Y, JPEG or RAW Data Register**

Register 236

**MI\_MP\_Y\_IRQ\_OFFSET\_INIT****Memory Interface Fill Level Interrupt Offset Value For Main Picture Y, JPEG or RAW Data Register(1518H)**

Application Reset Value: 0000 0000H

Field	Bits	Type	Description
<b>FIXED_TO_00</b>	1:0	r	<b>Bits [1:0] are set to “00” (word aligned value).</b>
<b>MP_Y_IRQ_OF</b>	23:2	rw	<b>Main Picture Y IRQ Offset Init</b> Reaching this programmed value by the current offset counter for addressing main picture Y component, JPEG or RAW data leads to generation of fill level interrupt fill_mp_y. Programmed value becomes effective (visible in corresponding shadow register) after a soft reset, a forced software update or an automatic config update.
<b>0</b>	31:24	r	<b>Reserved</b> Read as 0, should be written with 0.

**Camera and ADC Interface (CIF)****Memory Interface Base Address For Main Picture Cb Component Ring Buffer Register****MI\_MP\_CB\_BASE\_AD\_INIT****Memory Interface Base Address For Main Picture Cb Component Ring Buffer Register(151C<sub>H</sub>) Application****Reset Value: 0000 0000<sub>H</sub>**

## Camera and ADC Interface (CIF)

## 26.4.5 JPEG Encoder Programming Registers

The address of each CIF JPEG encoder register is evaluated as CIF\_JPE\_BASE + Offset.

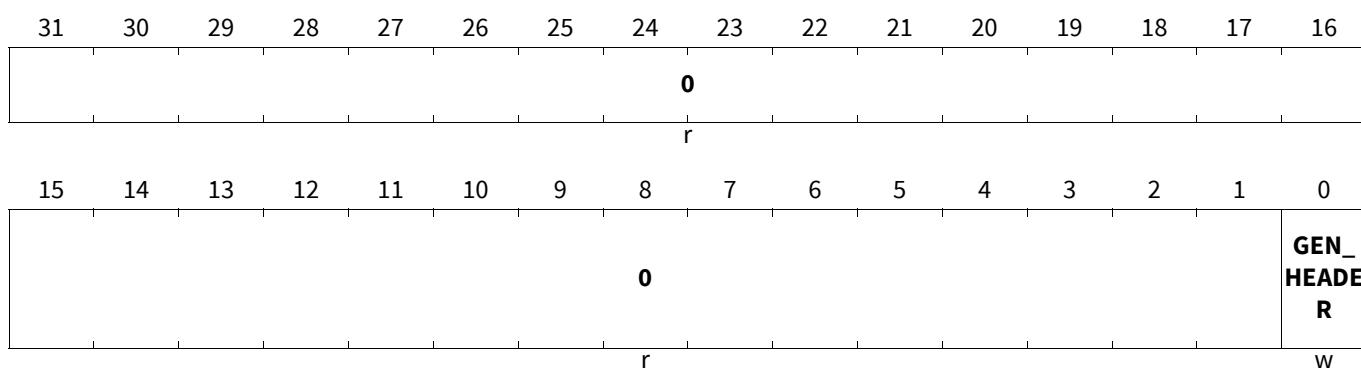

## 26.4.5.1 JPEG Encoder Control Registers

## JPE Command To Start Stream Header Generation Register

Register 305

## JPE\_GEN\_HEADER

JPE Command To Start Stream Header Generation Register( $1900_{H}$ ) Application Reset Value:  $0000\ 0000_{H}$

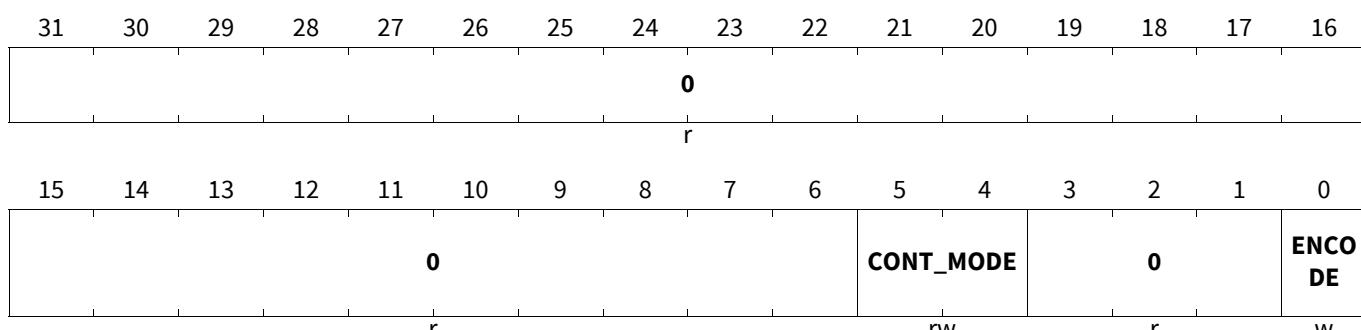

Field	Bits	Type	Description
GEN_HEADER	0	w	<b>Generate Header</b> $1_B$ Start command to generate stream header; auto reset to zero after one clock cycle
0	31:1	r	<b>Reserved</b> Read as 0, should be written with 0.

## JPE Start Command To Start JFIF Stream Encoding Register

## JPE\_ENCODE

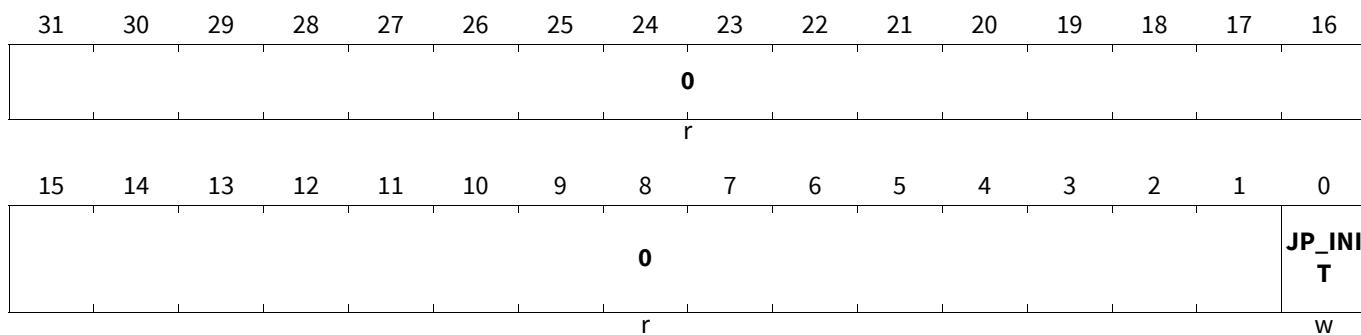

JPE Start Command To Start JFIF Stream Encoding Register( $1904_{H}$ ) Application Reset Value:  $0000\ 0000_{H}$

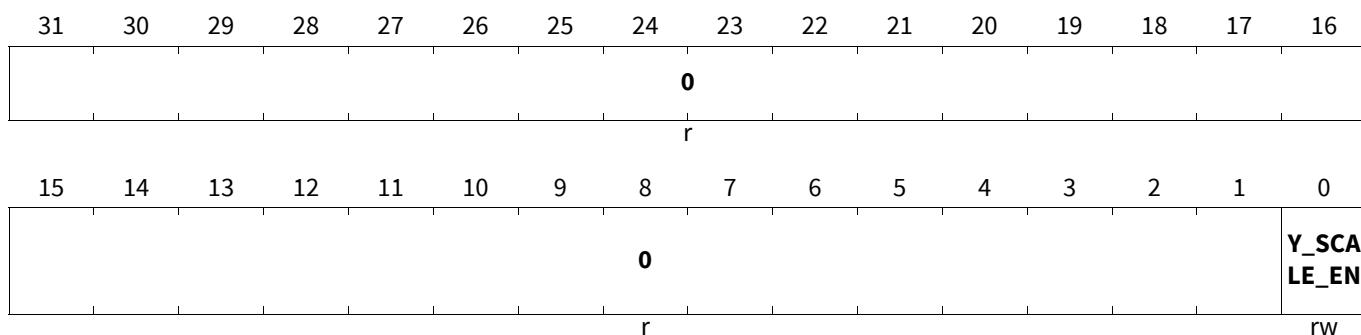

Field	Bits	Type	Description
ENCODE	0	w	<b>Encode</b> $1_B$ Start command to start JFIF stream encoding; auto reset to zero after one clock cycle

**Camera and ADC Interface (CIF)**

Field	Bits	Type	Description
<b>CONT_MODE</b>	5:4	rw	<b>Encoder continuous mode</b> "00": encoder stops at frame end (corresponds to former behavior) "01": encoder starts automatically to encode the next frame "10": unused "11": encoder first generates next header and then encodes automatically the next frame These settings are checked after encoding one frame. They are not auto-reset by hardware.
<b>0</b>	31:1, 31:6	r	<b>Reserved</b> Read as 0, should be written with 0.

**JPE Automatic Configuration Update Register****JPE\_INIT****JPE Automatic Configuration Update Register (1908<sub>H</sub>)****Application Reset Value: 0000 0000<sub>H</sub>**

Field	Bits	Type	Description
<b>JP_INIT</b>	0	w	<b>JPEG Init</b> This bit has to be set after "Encode" to start the JPEG encoder. The "Encode" command becomes active either with JP_INIT or with the input signal "CFG_UPD" auto reset to zero after one clock cycle !!! <sub>1_B</sub> Immediate start of JPEG encoder.
<b>0</b>	31:1	r	<b>Reserved</b> Read as 0, should be written with 0.

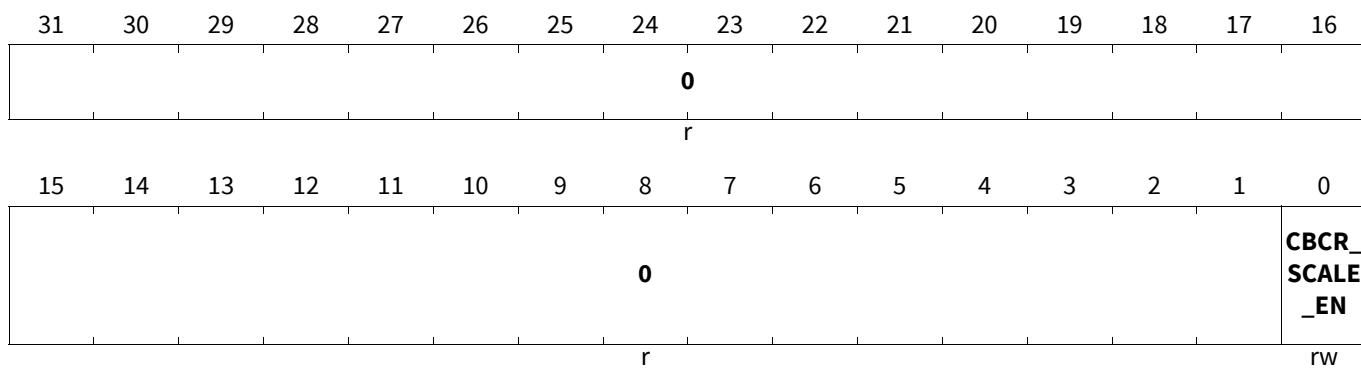

**JPE Y Value Scaling Control Register****JPE\_Y\_SCALE\_EN****JPE Y Value Scaling Control Register****(190C<sub>H</sub>)****Application Reset Value: 0000 0000<sub>H</sub>**

## Camera and ADC Interface (CIF)

Field	Bits	Type	Description
<b>Y_SCALE_EN</b>	0	rw	<b>Y scale flag</b> $0_B$ no Y input scaling $1_B$ scaling Y input from [16..235] to [0..255]
<b>0</b>	31:1	r	<b>Reserved</b> Read as 0, should be written with 0.

## JPE Cb/Cr Value Scaling Control Register

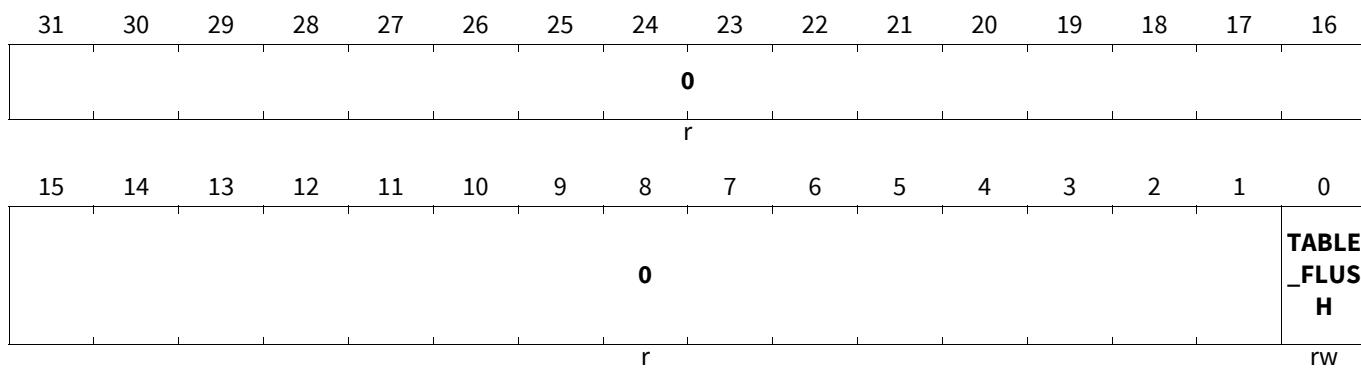

## JPE\_CBCR\_SCALE\_EN

JPE Cb/Cr Value Scaling Control Register (1910<sub>H</sub>) Application Reset Value: 0000 0000<sub>H</sub>

Field	Bits	Type	Description
<b>CBCR_SCALE_EN</b>	0	rw	<b>Cb/Cr scale flag</b> $0_B$ no Cb/Cr input scaling $1_B$ scaling Cb/Cr input from [16..240] to [0..255]
<b>0</b>	31:1	r	<b>Reserved</b> Read as 0, should be written with 0.

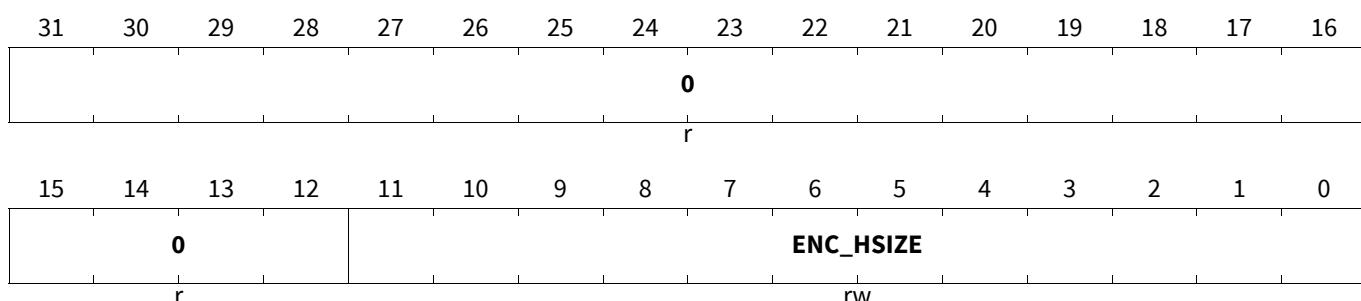

## JPE Header Generation Debug Register

## JPE\_TABLE\_FLUSH

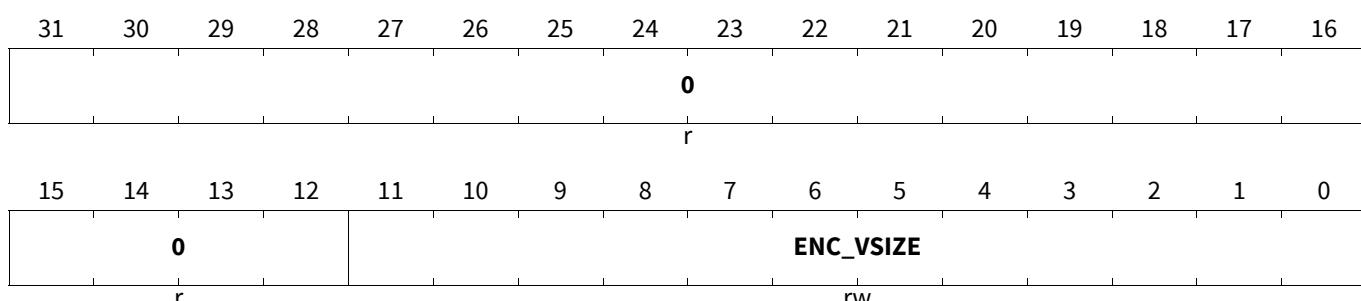

JPE Header Generation Debug Register (1914<sub>H</sub>) Application Reset Value: 0000 0000<sub>H</sub>

**Camera and ADC Interface (CIF)**

Field	Bits	Type	Description
<b>TABLE_FLUSH</b>	0	rw	<b>Header generation debug control flag</b> (controls transmission of last header bytes if the 64 bit output buffer is not completely filled) 0 <sub>B</sub> wait for encoded image data to fill output buffer 1 <sub>B</sub> immediately transmit last header bytes
<b>0</b>	31:1	r	<b>Reserved</b> Read as 0, should be written with 0.

**JPEG Codec Horizontal Image Size For Encoding Register****JPE\_ENC\_HSIZE****JPEG Codec Horizontal Image Size For Encoding Register(1918<sub>H</sub>)****Application Reset Value: 0000 0000<sub>H</sub>**

Field	Bits	Type	Description
<b>ENC_HSIZE</b>	11:0	rw	<b>Horizontal Size</b> JPEG codec horizontal image size for R2B and SGEN blocks
<b>0</b>	31:12	r	<b>Reserved</b> Read as 0, should be written with 0.

**JPEG Codec Vertical Image Size For Encoding Register****JPE\_ENC\_VSIZE****JPEG Codec Vertical Image Size For Encoding Register(191C<sub>H</sub>)****Application Reset Value: 0000 0000<sub>H</sub>**

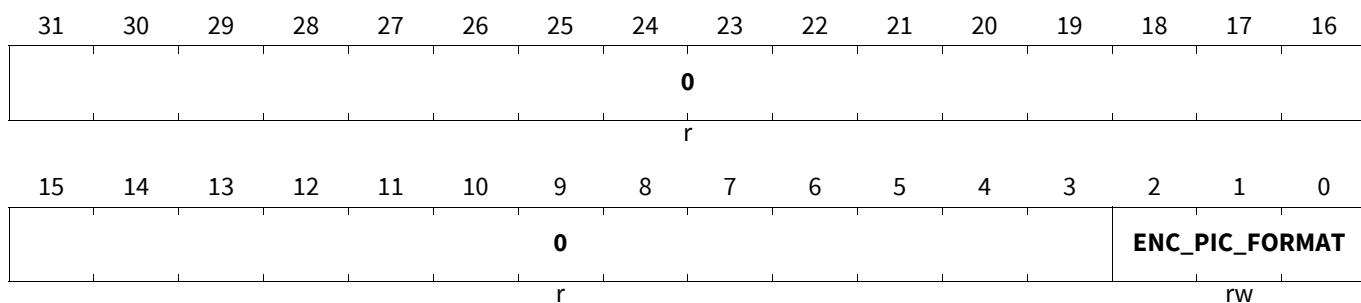

Field	Bits	Type	Description
<b>ENC_VSIZE</b>	11:0	rw	<b>Vertical Size</b> JPEG codec vertical image size for R2B and SGEN blocks

**Camera and ADC Interface (CIF)**

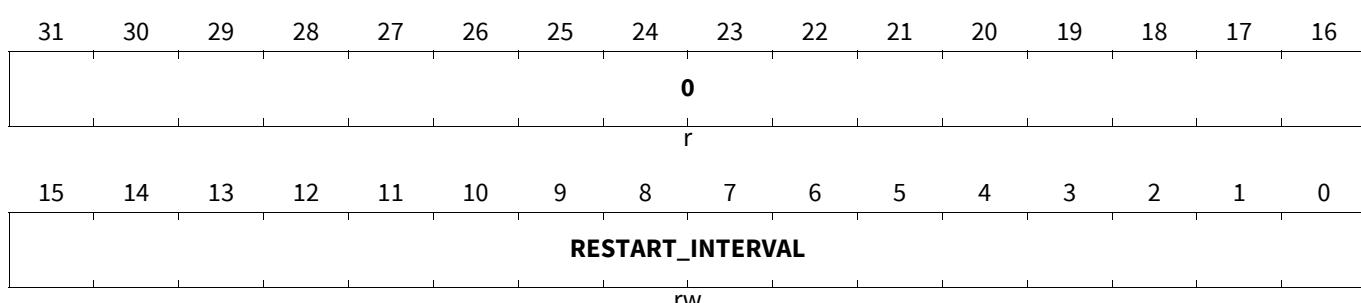

Field	Bits	Type	Description
0	31:12	r	<b>Reserved</b> Read as 0, should be written with 0.

**JPEG Picture Encoding Format Register**

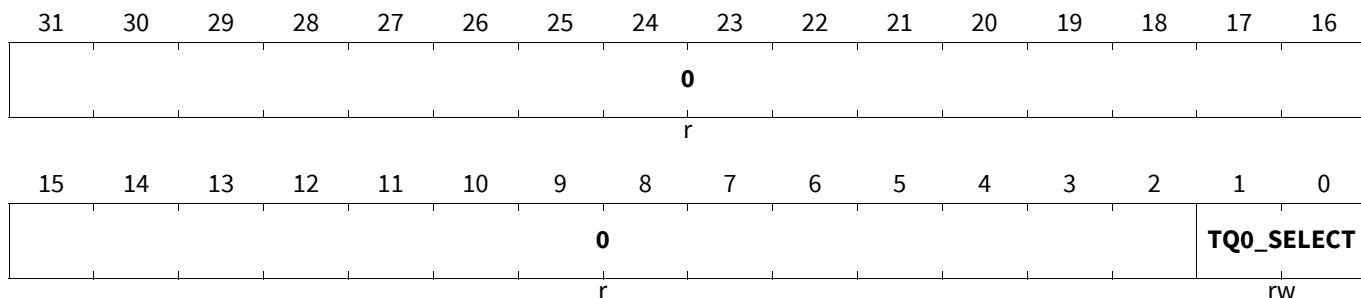

Register 313

**JPE\_PIC\_FORMAT****JPEG Picture Encoding Format Register (1920<sub>H</sub>) Application Reset Value: 0000 0001<sub>H</sub>**

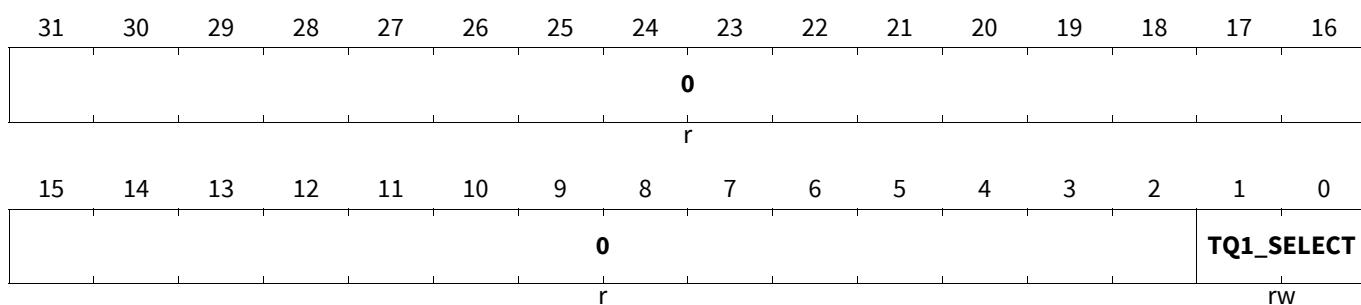

Field	Bits	Type	Description
ENC_PIC_FORMAT	2:0	rw	<b>Picture Encoding Format</b> $001_B$ 4:2:2 format $100_B$ 4:0:0 format ... $111_B$ 4:0:0 format
0	31:3	r	<b>Reserved</b> Read as 0, should be written with 0.

**JPE Restart Marker Insertion Register****JPE\_RESTART\_INTERVAL****JPE Restart Marker Insertion Register (1924<sub>H</sub>) Application Reset Value: 0000 0000<sub>H</sub>**

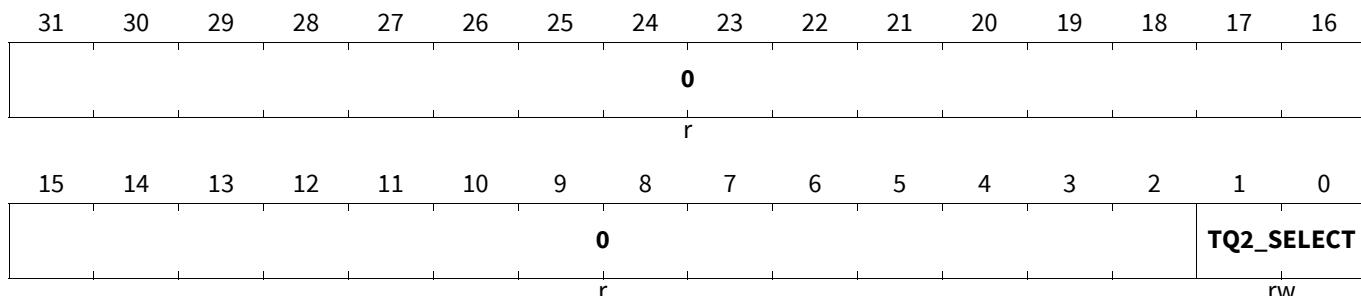

Field	Bits	Type	Description
RESTART_INTERVAL	15:0	rw	<b>Restart Interval</b> No of MCU in reset interval via host
0	31:16	r	<b>Reserved</b> Read as 0, should be written with 0.

**Camera and ADC Interface (CIF)****Q-table Selector 0, Quant. Table For Y Component****JPE\_TQ\_Y\_SELECT****Q-table Selector 0, Quant. Table For Y Component( $1928_H$ )****Application Reset Value: 0000 0000<sub>H</sub>**

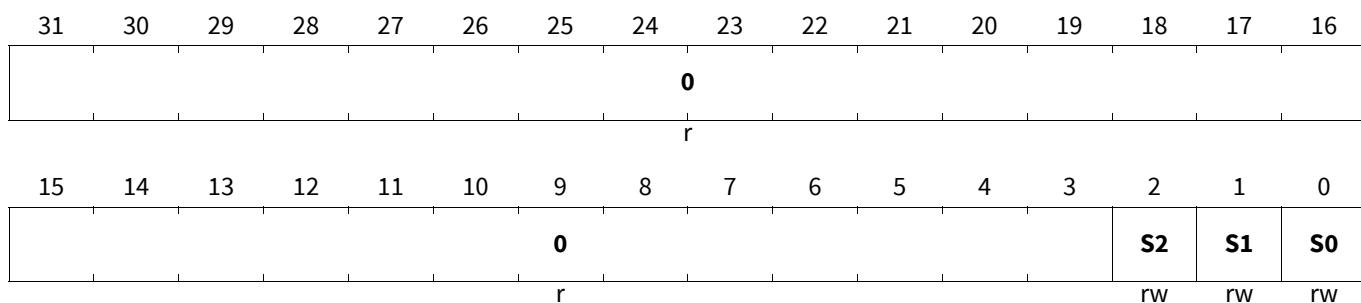

Field	Bits	Type	Description
TQ0_SELECT	1:0	rw	<b>Q-Table Selector Y</b> Q-table selector 0, Quant. For Y component. $00_B$ Q-Table 0 $01_B$ Q-Table 1 $10_B$ Q-Table 2 $11_B$ Q-Table 3
0	31:2	r	<b>Reserved</b> Read as 0, should be written with 0.

**Q-table Selector 1, Quant. Table For U Component****JPE\_TQ\_U\_SELECT****Q-table Selector 1, Quant. Table For U Component( $192C_H$ )****Application Reset Value: 0000 0001<sub>H</sub>**

Field	Bits	Type	Description
TQ1_SELECT	1:0	rw	<b>Q-Table Selector U</b> Q-table selector 1, Quant. For U component. $00_B$ Q-Table 0 $01_B$ Q-Table 1 $10_B$ Q-Table 2 $11_B$ Q-Table 3
0	31:2	r	<b>Reserved</b> Read as 0, should be written with 0.

**Camera and ADC Interface (CIF)****Q-table Selector 2 Quant Table For V Component****JPE\_TQ\_V\_SELECT****Q-table Selector 2 Quant Table For V Component( $1930_H$ )****Application Reset Value: 0000 0001<sub>H</sub>**

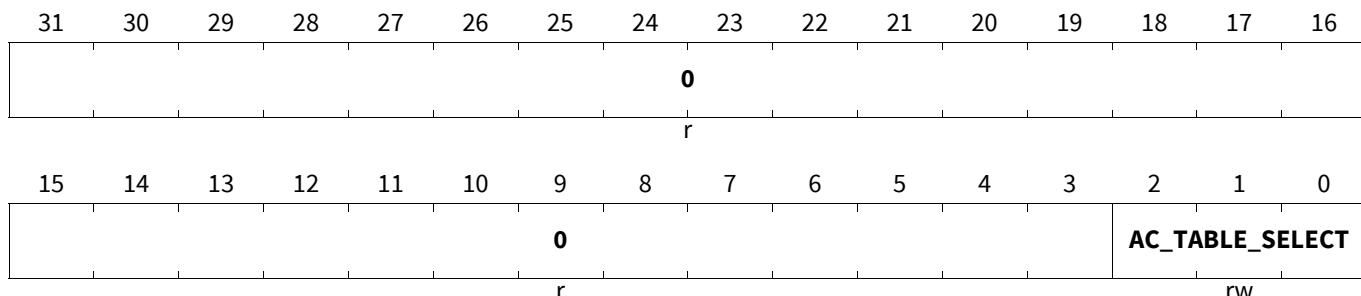

Field	Bits	Type	Description
<b>TQ2_SELECT</b>	1:0	rw	<b>Q-Table Selector V</b> Q-table selector 2, Quant. For V component. 00 <sub>B</sub> Q-Table 0 01 <sub>B</sub> Q-Table 1 10 <sub>B</sub> Q-Table 2 11 <sub>B</sub> Q-Table 3
<b>0</b>	31:2	r	<b>Reserved</b> Read as 0, should be written with 0.

**JPE Huffman Table Selector For DC Values Register****JPE\_DC\_TABLE\_SELECT****JPE Huffman Table Selector For DC Values Register( $1934_H$ )****Application Reset Value: 0000 0006<sub>H</sub>**

Field	Bits	Type	Description
<b>S0</b>	0	rw	<b>DC Table Selector</b> 0 <sub>B</sub> dc table 0; component 0 1 <sub>B</sub> dc table 1; component 0
<b>S1</b>	1	rw	<b>DC Table Selector</b> 0 <sub>B</sub> dc table 0; component 1 1 <sub>B</sub> dc table 1; component 1
<b>S2</b>	2	rw	<b>DC Table Selector</b> 0 <sub>B</sub> dc table 0; component 2 1 <sub>B</sub> dc table 1; component 2

**Camera and ADC Interface (CIF)**

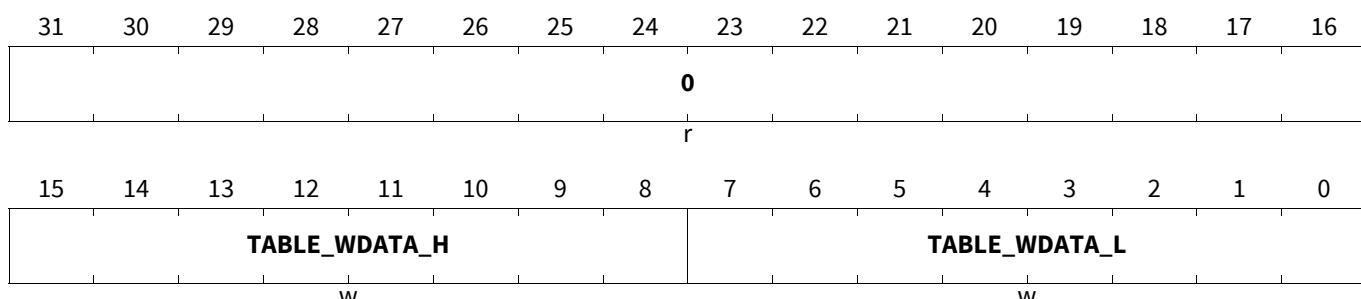

Field	Bits	Type	Description
<b>0</b>	31:3	r	<b>Reserved</b> Read as 0, should be written with 0.

**JPE Huffman Table Selector For AC Values Register****JPE\_AC\_TABLE\_SELECT**JPE Huffman Table Selector For AC Values Register( $1938_{\text{H}}$ )Application Reset Value:  $0000\ 0006_{\text{H}}$ 

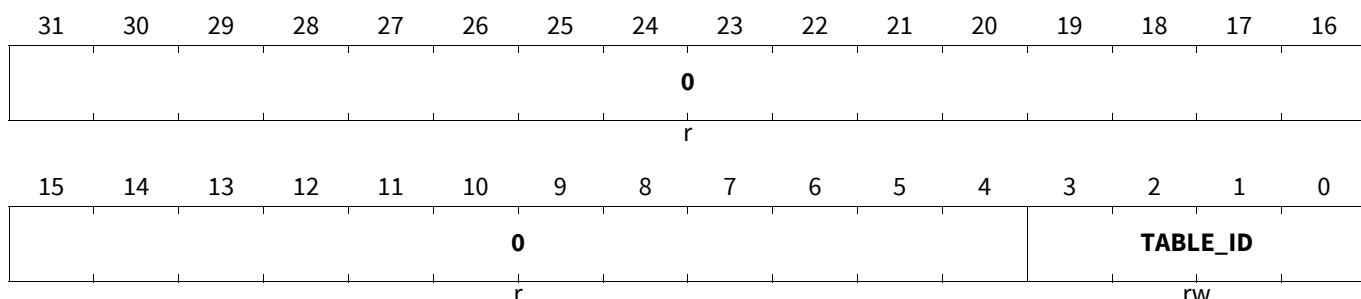

Field	Bits	Type	Description
<b>AC_TABLE_SELECT</b>	2:0	rw	<b>AC Table Selector</b> “xx0” = dc table 0; component 0 “x1x” = dc table 1; component 0 “x0x” = dc table 0; component 1 “x1x” = dc table 1; component 1 “0xx” = dc table 0; component 2 “1xx” = dc table 1; component 2
<b>0</b>	31:3	r	<b>Reserved</b> Read as 0, should be written with 0.

**JPE Table Programming Register****JPE\_TABLE\_DATA**

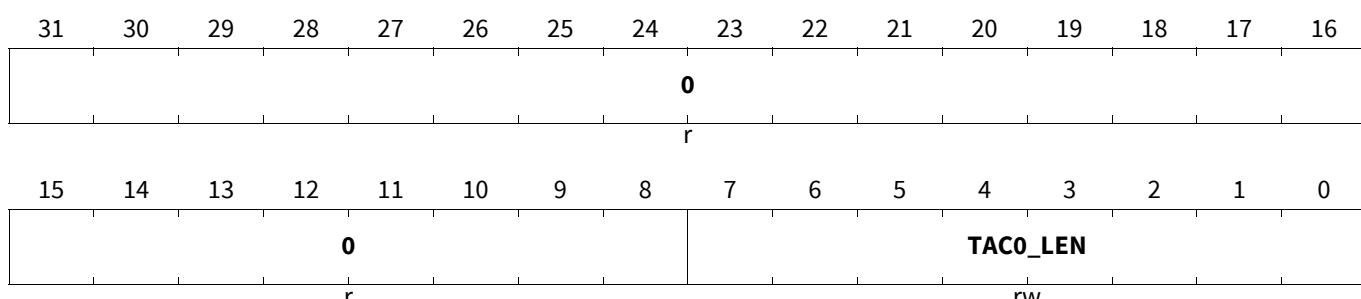

JPE Table Programming Register

 $(193C_{\text{H}})$ Application Reset Value:  $0000\ 0000_{\text{H}}$ 

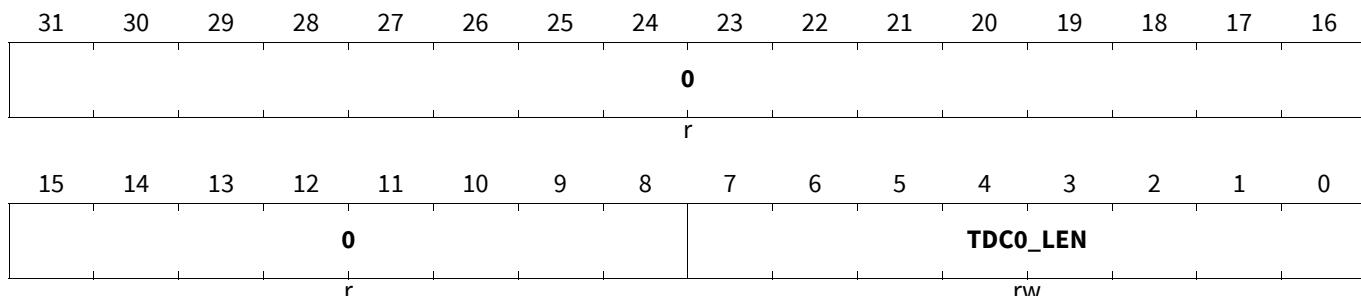

Field	Bits	Type	Description
<b>TABLE_WDAT_A_L</b>	7:0	w	<b>Table data LSB</b>
<b>TABLE_WDAT_A_H</b>	15:8	w	<b>Table data MSB</b>
<b>0</b>	31:16	r	<b>Reserved</b> Read as 0, should be written with 0.

**Camera and ADC Interface (CIF)****JPE Table Programming Select Register****JPE\_TABLE\_ID**
**JPE Table Programming Select Register (1940<sub>H</sub>) Application Reset Value: 0000 0000<sub>H</sub>**

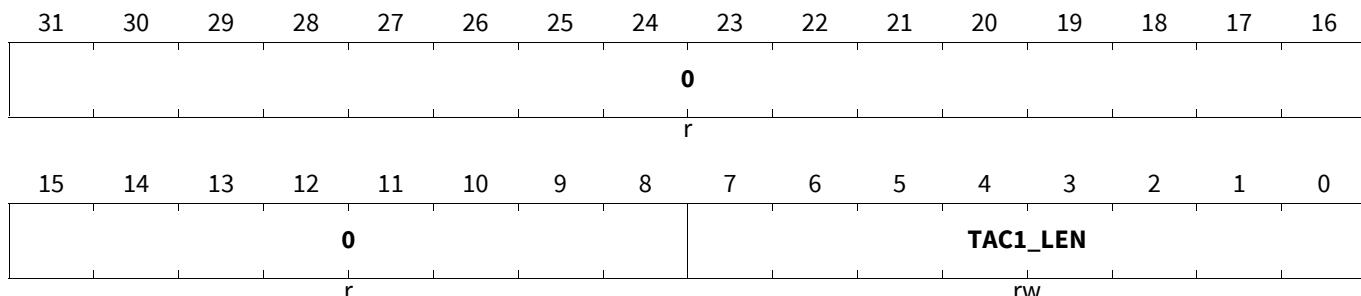

Field	Bits	Type	Description																
<b>TABLE_ID</b>	3:0	rw	<p><b>JPE Table ID</b>  Select table according to the following list. Values 8<sub>H</sub> through F<sub>H</sub> are reserved for debug purposes.</p> <table> <tr><td>0<sub>H</sub></td><td>Q-Table 0</td></tr> <tr><td>1<sub>H</sub></td><td>Q-Table 1</td></tr> <tr><td>2<sub>H</sub></td><td>Q-Table 2</td></tr> <tr><td>3<sub>H</sub></td><td>Q-Table 3</td></tr> <tr><td>4<sub>H</sub></td><td>VLC DC Table 0</td></tr> <tr><td>5<sub>H</sub></td><td>VLC AC Table 0</td></tr> <tr><td>6<sub>H</sub></td><td>VLC DC Table 1</td></tr> <tr><td>7<sub>H</sub></td><td>VLC AC Table 1</td></tr> </table>	0 <sub>H</sub>	Q-Table 0	1 <sub>H</sub>	Q-Table 1	2 <sub>H</sub>	Q-Table 2	3 <sub>H</sub>	Q-Table 3	4 <sub>H</sub>	VLC DC Table 0	5 <sub>H</sub>	VLC AC Table 0	6 <sub>H</sub>	VLC DC Table 1	7 <sub>H</sub>	VLC AC Table 1
0 <sub>H</sub>	Q-Table 0																		
1 <sub>H</sub>	Q-Table 1																		
2 <sub>H</sub>	Q-Table 2																		
3 <sub>H</sub>	Q-Table 3																		
4 <sub>H</sub>	VLC DC Table 0																		
5 <sub>H</sub>	VLC AC Table 0																		
6 <sub>H</sub>	VLC DC Table 1																		
7 <sub>H</sub>	VLC AC Table 1																		
<b>0</b>	31:4	r	<p><b>Reserved</b>  Read as 0, should be written with 0.</p>																

**JPE Huffman AC Table 0 Length Register****JPE\_TAC0\_LEN**
**JPE Huffman AC Table 0 Length Register (1944<sub>H</sub>) Application Reset Value: 0000 00B2<sub>H</sub>**

Field	Bits	Type	Description
<b>TAC0_LEN</b>	7:0	rw	<p><b>AC Table 0 Length</b>  Huffman table length for ac0 table</p>
<b>0</b>	31:8	r	<p><b>Reserved</b>  Read as 0, should be written with 0.</p>

**Camera and ADC Interface (CIF)****JPE Huffman DC Table 0 Length Register****JPE\_TDC0\_LEN****JPE Huffman DC Table 0 Length Register (1948<sub>H</sub>) Application Reset Value: 0000 001C<sub>H</sub>**

Field	Bits	Type	Description
<b>TDC0_LEN</b>	7:0	rw	<b>DC Table 0 Length</b> Huffman table length for dc0 table
<b>0</b>	31:8	r	<b>Reserved</b> Read as 0, should be written with 0.

**JPE Huffman AC Table 1 Length Register****JPE\_TAC1\_LEN****JPE Huffman AC Table 1 Length Register (194C<sub>H</sub>) Application Reset Value: 0000 00B2<sub>H</sub>**

Field	Bits	Type	Description
<b>TAC1_LEN</b>	7:0	rw	<b>AC Table 1 Length</b> Huffman table length for ac1 table
<b>0</b>	31:8	r	<b>Reserved</b> Read as 0, should be written with 0.

**Camera and ADC Interface (CIF)****JPE Huffman DC Table 1 Length Register****JPE\_TDC1\_LEN****JPE Huffman DC Table 1 Length Register (1950<sub>H</sub>) Application Reset Value: 0000 001C<sub>H</sub>**

<b>DEB_VLC_TAB</b> <b>LE_BUSY</b>	5	r	<b>Debug VLC Table Busy</b> Debug signal only (vlc access to huff-tables) Unit will initialize huff tables internally, busy for ~400 cycles after reset.
<b>DEB_BAD_TA</b> <b>BLE_ACCESS</b>	8	r	<b>Debug Bad Table Access</b> Debug signal only (set if an access to the TABLE_DATA or to the TABLE_ID register is performed, when the JPEG_ENCODER is busy. In this case a default handshake acknowledge is generated. Thus the configuration bus is not blocked)
<b>0</b>	1:0, 7:6, 31:9	r	<b>Reserved</b> Read as 0.

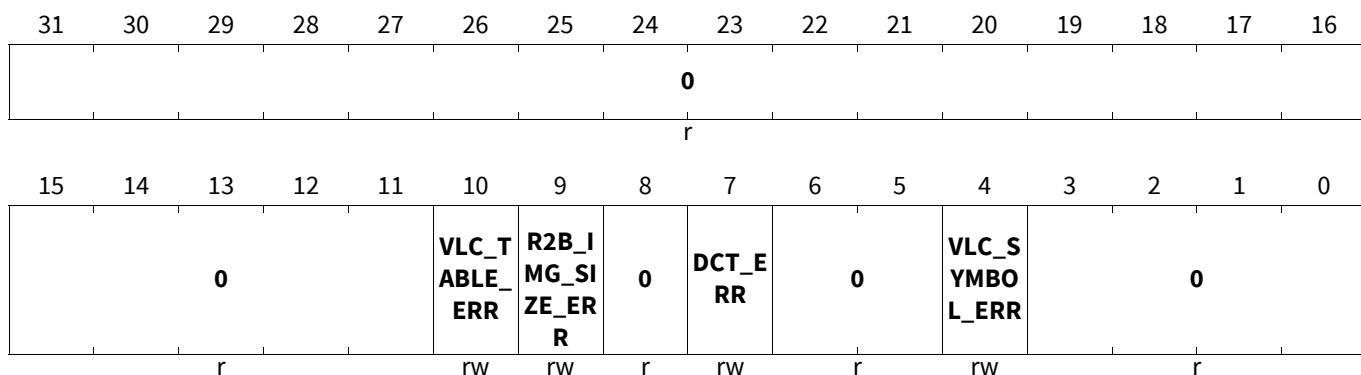

## Camera and ADC Interface (CIF)

## 26.4.5.2 JPEG Encoder Interrupt Registers

## JPE Error Interrupt Mask Register

JPE\_ERROR\_IMR

JPE Error Interrupt Mask Register

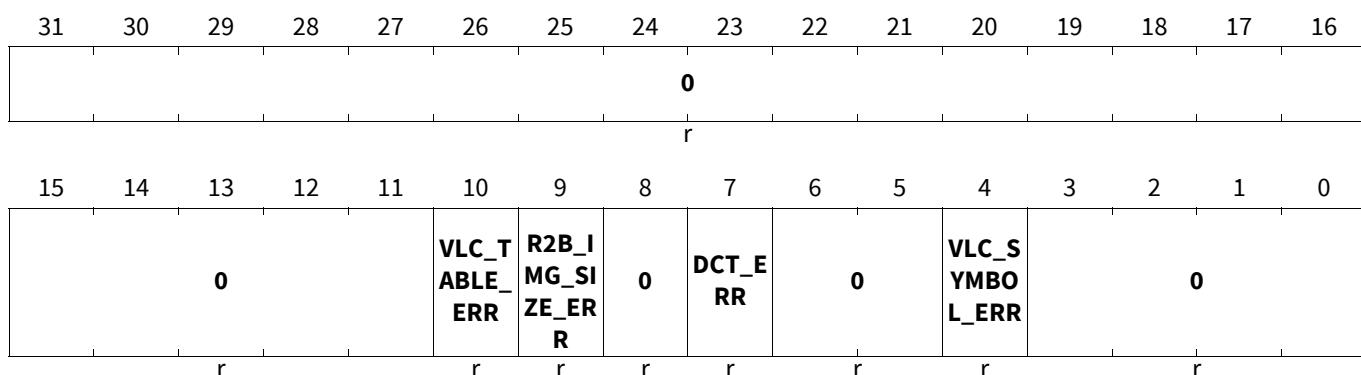

(1968<sub>H</sub>)Application Reset Value: 0000 0000<sub>H</sub>

Field	Bits	Type	Description
VLC_SYMBOL_ERR	4	rw	<b>VLC Symbol Error</b> 1 <sub>B</sub> interrupt is activated (masked in)
DCT_ERR	7	rw	<b>DC Table Error</b> 1 <sub>B</sub> interrupt is activated (masked in)
R2B_IMG_SIZE_ERR	9	rw	<b>R2B Image Size Error</b> 1 <sub>B</sub> interrupt is activated (masked in)
VLC_TABLE_ERR	10	rw	<b>VLC Table Error</b> 1 <sub>B</sub> interrupt is activated (masked in)
0	3:0, 6:5, 8, 31:11	r	<b>Reserved</b> Read as 0, should be written with 0.

## JPE Error Raw Interrupt Status Register

JPE\_ERROR\_RIS

JPE Error Raw Interrupt Status Register

(196C<sub>H</sub>)Application Reset Value: 0000 0000<sub>H</sub>

## Camera and ADC Interface (CIF)

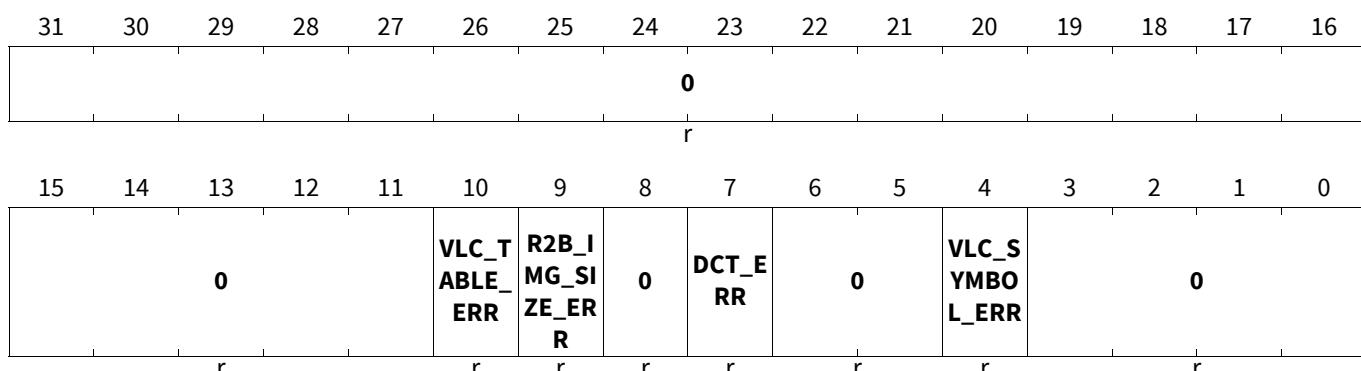

Field	Bits	Type	Description
<b>VLC_SYMBOL_ERR</b>	4	r	<b>VLC Symbol Error</b> 1 <sub>B</sub> illegal symbol detected (encoding)
<b>DCT_ERR</b>	7	r	<b>DC Table Error</b> 1 <sub>B</sub> block start mismatch
<b>R2B_IMG_SIZE_ERR</b>	9	r	<b>R2B Image Size Error</b> 1 <sub>B</sub> mismatch of predefined h_size and v_size values with calculated values (encode mode)
<b>VLC_TABLE_E_RR</b>	10	r	<b>VLC Table Error</b> 1 <sub>B</sub> illegal table detected
0	3:0, 6:5, 8, 31:11	r	<b>Reserved</b> Read as 0

### JPE Error Masked Interrupt Status Register

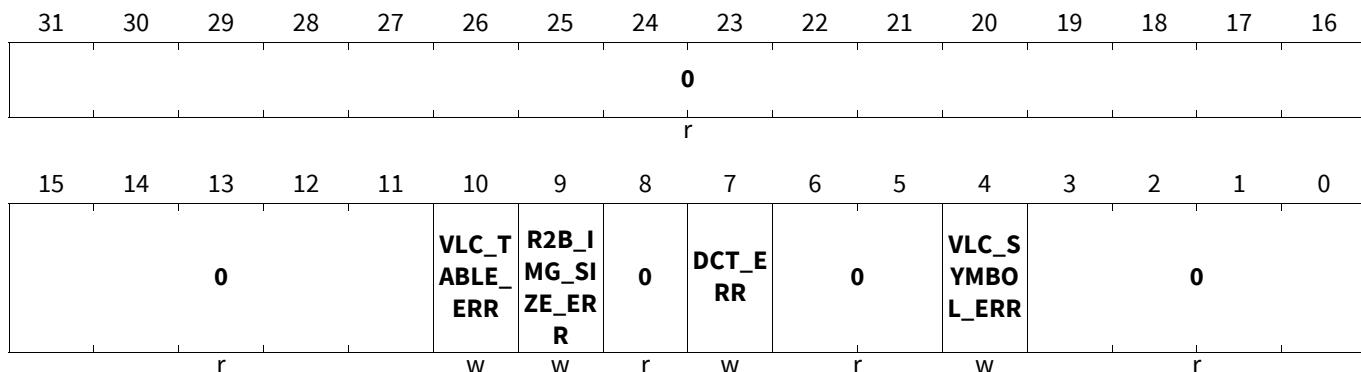

#### JPE\_ERROR\_MIS

JPE Error Masked Interrupt Status Register (1970<sub>H</sub>)

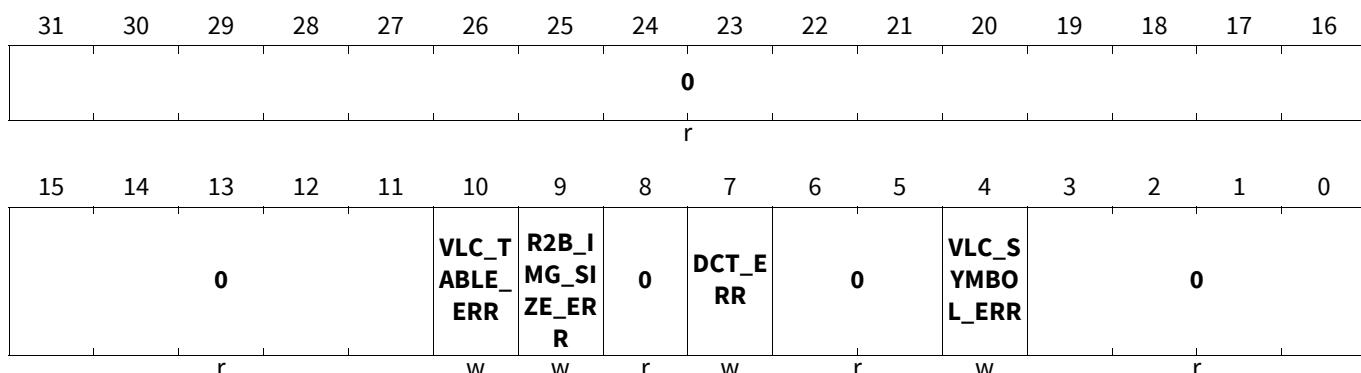

Application Reset Value: 0000 0000<sub>H</sub>

Field	Bits	Type	Description
<b>VLC_SYMBOL_ERR</b>	4	r	<b>VLC Symbol Error</b> 1 <sub>B</sub> illegal symbol detected (encoding)
<b>DCT_ERR</b>	7	r	<b>DC Table Error</b> 1 <sub>B</sub> block start mismatch
<b>R2B_IMG_SIZE_ERR</b>	9	r	<b>R2B Image Size Error</b> 1 <sub>B</sub> mismatch of predefined h_size and v_size values with calculated values (encode mode)
<b>VLC_TABLE_E_RR</b>	10	r	<b>VLC Table Error</b> 1 <sub>B</sub> illegal table detected
0	3:0, 6:5, 8, 31:11	r	<b>Reserved</b> Read as 0.

**Camera and ADC Interface (CIF)****JPE Error Interrupt Set Register****JPE\_ERROR\_ISR****JPE Error Interrupt Set Register**(1978<sub>H</sub>)Application Reset Value: 0000 0000<sub>H</sub>

Field	Bits	Type	Description
VLC_SYMBOL_ERR	4	w	<b>VLC Symbol Error</b> 1 <sub>B</sub> set error bit, bit is reset to zero after 1 clk
DCT_ERR	7	w	<b>DC Table Error</b> 1 <sub>B</sub> set error bit, bit is reset to zero after 1 clk
R2B_IMG_SIZE_ERR	9	w	<b>R2B Image Size Error</b> 1 <sub>B</sub> set error bit, bit is reset to zero after 1 clk

**Camera and ADC Interface (CIF)****26.4.6 Security Watchdog Programming Registers**

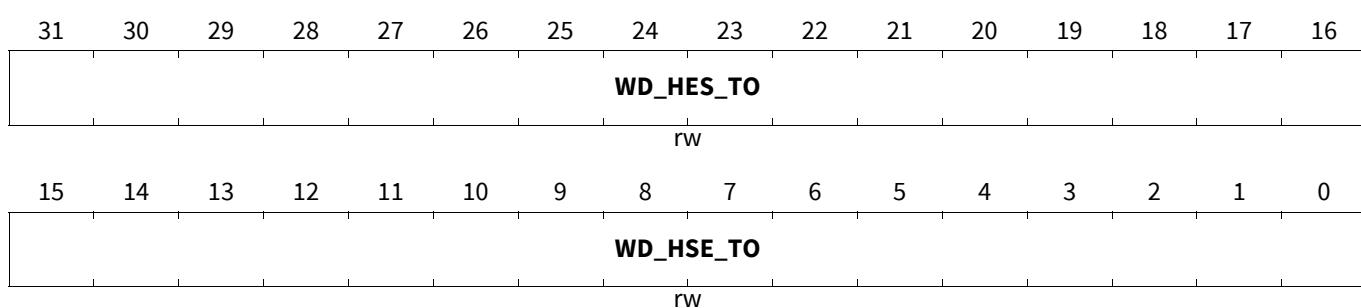

The address of each CIF Security Watchdog register is evaluated as CIF\_WATCHDOG\_BASE + Offset.

**26.4.6.1 Watchdog Configuration Registers****Watchdog Control Register****WD\_CTRL**

Field	Bits	Type	Description
<b>WD_EN</b>	0	rw	<b>Enable Security Watchdog</b> 0 <sub>B</sub> unit is disabled 1 <sub>B</sub> enables the watchdog unit
<b>RST_H_CNT</b>	1	w	<b>Reset Horizontal Counter</b> 0 <sub>B</sub> nothing happens 1 <sub>B</sub> reset counter
<b>RST_V_CNT</b>	2	w	<b>Reset Vertical Counter</b> 0 <sub>B</sub> nothing happens 1 <sub>B</sub> reset counter
<b>RST_PD_CNT</b>	3	w	<b>Reset Predivider Counter</b> 0 <sub>B</sub> nothing happens 1 <sub>B</sub> reset counter
<b>WD_PREDIV</b>	31:16	rw	<b>Watchdog Counter Predivider</b> A value of 0 means that the Watchdog Counters are increased with every CIF clock cycle. Every other value N leads to an increment at every N+1th cycle.
<b>0</b>	15:4	r	<b>Reserved</b> Read as 0, should be written with 0.

**Camera and ADC Interface (CIF)****Watchdog Vertical Timeout Register****WD\_V\_TIMEOUT****Watchdog Vertical Timeout Register**(2504<sub>H</sub>)Application Reset Value: 0000 0000<sub>H</sub>

Field	Bits	Type	Description
<b>WD_VSE_TO</b>	15:0	rw	<b>Watchdog Vertical Start End Timeout</b> A value of 0 means that the Timeout is disabled. Every other value leads to an interrupt trigger when the vertical counter reaches the value in the vertical Start End phase.
<b>WD_VES_TO</b>	31:16	rw	<b>Watchdog Vertical End Start Timeout</b> A value of 0 means that the Timeout is disabled. Every other value leads to an interrupt trigger when the vertical counter reaches the value in the vertical End Start phase.

**Watchdog Horizontal Timeout Register****WD\_H\_TIMEOUT****Watchdog Horizontal Timeout Register**(2508<sub>H</sub>)Application Reset Value: 0000 0000<sub>H</sub>

Field	Bits	Type	Description
<b>WD_HSE_TO</b>	15:0	rw	<b>Watchdog Horizontal Start End Timeout</b> A value of 0 means that the Timeout is disabled. Every other value leads to an interrupt trigger when the horizontal counter reaches the value in the horizontal Start End phase.
<b>WD_HES_TO</b>	31:16	rw	<b>Watchdog Horizontal End Start Timeout</b> A value of 0 means that the Timeout is disabled. Every other value leads to an interrupt trigger when the horizontal counter reaches the value in the horizontal End Start phase.

## Camera and ADC Interface (CIF)

## 26.4.6.2 Watchdog Interrupt Registers

## Watchdog Interrupt Mask Register

## Watchdog Interrupt Clear Register

(2518)<sub>H</sub>

**Application Reset Value: 0000 0000<sub>H</sub>**

The figure consists of two horizontal bar charts. The top chart has a horizontal axis labeled 'r' with tick marks at integer intervals from 31 to 16. Above each tick mark is a numerical value: 31, 30, 29, 28, 27, 26, 25, 24, 23, 22, 21, 20, 19, 18, 17, and 16. A central tick mark is labeled '0'. The bottom chart has a similar horizontal axis labeled 'r' with tick marks at integer intervals from 15 to 0. Above each tick mark is a numerical value: 15, 14, 13, 12, 11, 10, 9, 8, 7, 6, 5, 4, 3, 2, 1, and 0. A central tick mark is labeled '0'. Both charts have a light gray background with white bars.

## 26.4.8.3 Memory Interface Extra Path Control Registers

## Memory Interface Extra Path j Control Register

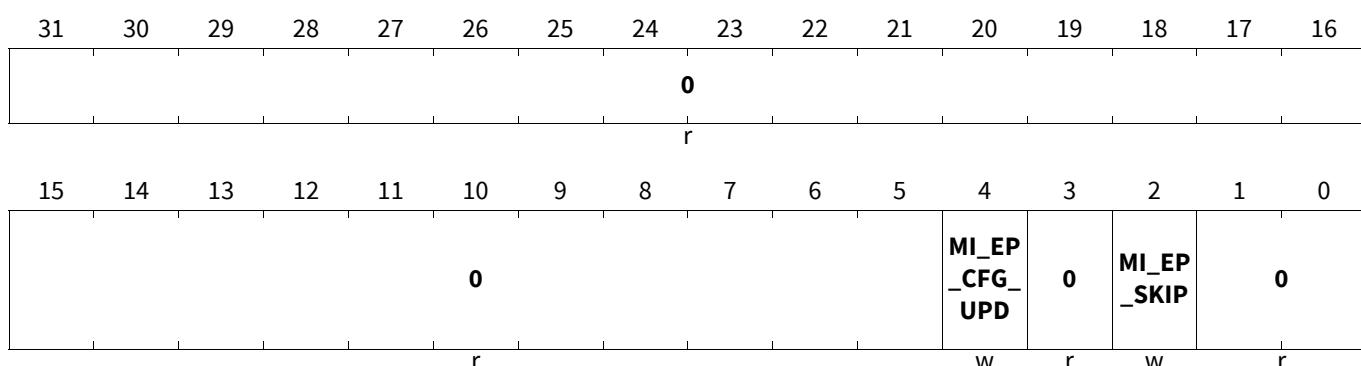

## MIEP\_j\_CTRL (j=0-4)

Memory Interface Extra Path j Control Register( $3600_H+j*100_H$ )Application Reset Value: 0000 0000<sub>H</sub>

Field	Bits	Type	Description
<b>EP_ENABLE</b>	0	rw	<b>Enables enable ep picture data path</b> Programmed value becomes effective (visible in control shadow register) after a soft reset, a forced software update or an automatic config update. Affects MI_IN and MI_OUT module.

## Camera and ADC Interface (CIF)

Field	Bits	Type	Description
BYTE_SWAP	7	rw	<p><b>Byte Swap Enable</b>            Enables change of byte order of the 32 bit output word at write port.</p> <p><i>Note:</i> Programmed value becomes effective immediately. So write to the register only if no picture data is sent.</p> <p><math>0_B</math> no byte mirroring  <math>1_B</math> byte order is mirrored but the bit order within one byte doesn't change</p>
INIT_BASE_EN	20	rw	<p><b>Init Base Address Enable</b>            Enables updating of the base address and buffer size shadow registers for picture to the programmed register init values.</p> <p>MI_EP_BASE_AD_INIT            -&gt; MI_EP_BASE_AD_SHD            MI_EP_SIZE_INIT            -&gt; MI_EP_SIZE_SHD</p> <p>The update will be executed either when a forced software update occurs (in register MI_EP_n_INIT bit cfg_upd = 1) or when an automatic config update signal arrives at the MI input port. So only the corresponding shadow registers are affected.</p>
INIT_OFFSET_EN	21	rw	<p><b>Init Offset Counter Enable</b>            Enables updating of the offset counters shadow registers for Extra Path to the programmed register init values.</p> <p>MI_EP_OFFS_CNT_INIT            -&gt; MI_EP_OFFS_CNT_SHD</p> <p>The update will be executed either when a forced software update occurs (in register MI_EP_n_INIT bit cfg_upd = 1) or when an automatic config update signal arrives at the MI input port. So only the corresponding shadow registers are affected.</p> <p>After a picture skip has been performed init_offset_en selects between skip restart and skip init mode (see bit skip in register MI_EP_INIT).</p>
EP_WRITE_FORMAT	23:22	rw	<p><b>Extra Path Write Format</b>            Defines how Extra Path data is written to memory.</p> <p><i>Note:</i> Programmed value becomes effective immediately. So write to the register only if no picture data is sent to the path.</p> <p><math>00_B</math> RAW &amp; data mode (8 bit)  <math>01_B</math> RAW 8 bit  <math>10_B</math> RAW &amp; data mode (greater 8 up to 16 bit)  <math>11_B</math> YCbCr 16 bit; YCbCr data is handled interleaved as 16 bit data in extra paths.</p>
0	6:1, 19:8, 31:24	r	<p><b>Reserved</b>            Read as 0, should be written with 0.</p>

**Camera and ADC Interface (CIF)****Memory Interface Extra Path j Control Register For Address Init And Skip Function Register****MIEP\_j\_INIT (j=0-4)****Memory Interface Extra Path j Control Register For Address Init And Skip Function Register(3604<sub>H</sub>+j\*100<sub>H</sub>)****Application Reset Value: 0000 0000<sub>H</sub>**

Field	Bits	Type	Description
<b>MI_EP_SKIP</b>	2	w	<p><b>Skip Picture</b>  Skip of current or next starting main picture:  Aborts writing of main picture image data of the current frame to RAM  (after the current burst transmission has been completed). Further  picture data up to the end of the current frame are discarded.No further  macroblock line interrupt (mblk_line), no wrap around interrupt for  picture (wrap_ep_n) and no fill level interrupt (fill_ep_n) are  generated.Skip does not affect the generation of the extra path frame  end interrupt (ep_frame_end).The byte counter (register  MI_EP_BYTE_CNT) is not affected. It produces the correct number of  RAW data bytes at the end of the current (skipped) frame.After a skip has  been performed the offset counter for the main picture at the start of the  following frame are set depending on the bit init_offset_en in register  MI_CTRL:</p> <p><b>A)</b> Skip restart mode (init_offset_en = 0)  The offset counters of the Extra Path are restarted at the old start value  of the previous skipped frame.</p> <p><b>B)</b> Skip init mode (init_offset_en = 1)  The offset counters of the Extra Path are initialized with the register  contents of the offset counter init registers without any additional forced  software update or automatic config update.</p>
<b>MI_EP_CFG_U PD</b>	4	w	<p><b>Forced Configuration Update</b>  Leads to an immediate update of the shadow registers. Depending on  the two init enable bits in the MI_EP_n_CTRL register (init_offset_en and  init_base_en) the offset counter, base address and buffer size shadow  registers are also updated.</p>

**Debug Path Predivider Control Register****DP\_PDIV\_CTRL****Debug Path Predivider Control Register**(2804<sub>H</sub>)Application Reset Value: 0000 0000<sub>H</sub>

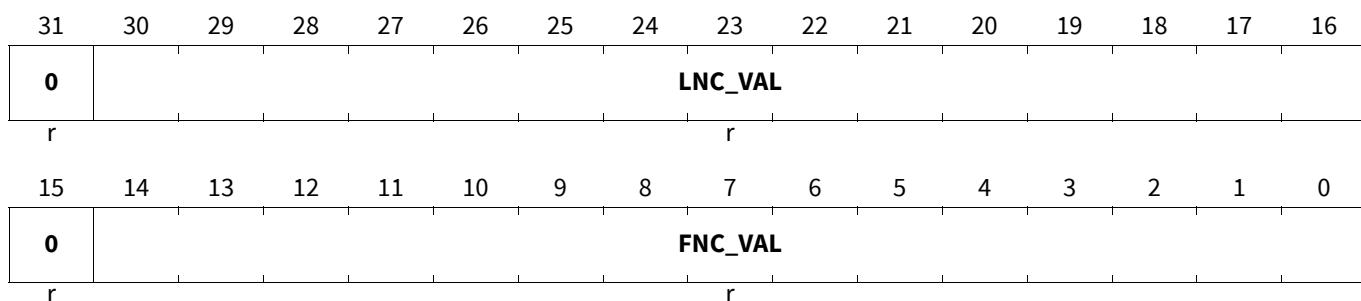

## Camera and ADC Interface (CIF)

Field	Bits	Type	Description
PDIV_VAL	31:0	rw	If the Debug Path and the Timestamp Counter are enabled, the timestamp counter will be increased with every pdiv_val+1 CIF module clock cycle.

## 26.4.9.2 Debug Path Status Registers

## Debug Path Frame/Line Counter Status Register

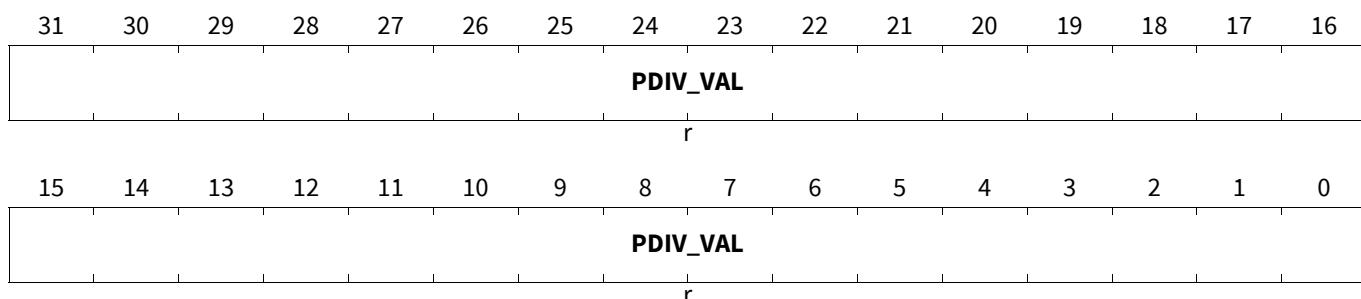

## DP\_FLC\_STAT

Debug Path Frame/Line Counter Status Register(2808<sub>H</sub>)Application Reset Value: 0000 0000<sub>H</sub>

Field	Bits	Type	Description
FNC_VAL	14:0	r	Returns the current value of the Frame Number Counter
LNC_VAL	30:16	r	Returns the current value of the Line Number Counter
0	15, 31	r	Reserved Read as 0.

## Debug Path Predivider Counter Status Register

## DP\_PDIV\_STAT

Debug Path Predivider Counter Status Register (280C<sub>H</sub>)Application Reset Value: 0000 0000<sub>H</sub>

Field	Bits	Type	Description
PDIV_VAL	31:0	r	Returns the current value of the Predivider Counter.

**Camera and ADC Interface (CIF)****Debug Path Timestamp Counter Status Register****DP\_TSC\_STAT****Debug Path Timestamp Counter Status Register(2810<sub>H</sub>)****Application Reset Value: 0000 0000<sub>H</sub>**

0	UDS														
r	rw														

Field	Bits	Type	Description
UDS	14:0	rw	User Defined Symbol which may be inserted into debug stream
0	31:15	r	<b>Reserved</b> Read 0, should be written with 0.

**26.5 IO Interfaces****Table 1181 List of CIF Interface Signals**

Interface Signals	I/O	Description
MI_INT	out	<b>CIF MI Service Request</b>
MIEP_INT	out	<b>CIF MI EP Service Request</b>

## Camera and ADC Interface (CIF)

**Table 1181 List of CIF Interface Signals (cont'd)**

Interface Signals	I/O	Description
ISP_INT	out	<b>CIF ISP Service Request</b>
MJPEG_INT	out	<b>CIF MJPEG Service Request</b>
PCLK	in	<b>Sensor Pixel Clock input</b>
D(15:0)	in	<b>sensor pixel data input</b>
Hsync	in	<b>horizontal synchronization signal input</b>
Vsync	in	<b>vertical synchronization signal input</b>

## 26.6 Revision History

**Table 1182 Revision History**

Reference	Change to Previous Version	Comment
<b>V1.4.7</b>	- Translation of the chapter to new documentation format.	
<b>V1.4.8</b>	- Document adjusted to the structure of 6 top-level sub-chapters.  Page 178 <b>Revision History</b> , format reworked. - First-level heading structure adjusted.	
<b>V1.4.9</b>	- Update of document to new template to correct reported problem with page numbering after User Manual build process.  Page 3 <b>Section 26.2.2.1.1, “Camera Interface Example”</b> . New table added for I/O signals  Page 177 <b>Section 26.5, “IO Interfaces”</b> . Updated to align names with chapter text  Page 19 <b>Section 26.3.8.1, “Write to EMEM”</b> . Description of interrupts updated to include name of physical request.  Page 8 <b>Section 26.3.1, “Sub Module ISP”</b> . Details of interrupt connection added  Page 9 <b>Section 26.3.2, “Sub Module Security Watchdog”</b> . Details of interrupt connection added  Page 10 <b>Section 26.3.4, “Sub Module JPEG Encoder”</b> . Details of interrupt connection added  Page 19 <b>Section 26.3.8.1, “Write to EMEM”</b> . Details of interrupt connection added	
<b>V1.4.10</b>	Page 137 <b>Section 26.4.6.2, “Watchdog Interrupt Registers”</b> . Bitfield ordering corrected.  Page 12 <b>Section 26.3.6, “Sub Module Extra Path Units”</b> . Several corrections to grammar and spelling  Page 21 <b>Section 26.3.10, “BBB Slave Interface”</b> . Corrections to spelling and removal of spurious text.	

**Camera and ADC Interface (CIF)****Table 1182 Revision History (cont'd)**

<b>Reference</b>	<b>Change to Previous Version</b>	<b>Comment</b>
Page 21	<b>Section 26.3.12, “Shadow Registers”.</b> Grammar of first sentence improved	
Page 35	<b>Section 26.3.14.7.1, “ISP Programming”</b> , subsection “Data Mode”. Incorrectly inserted paragraph break removed after “if the transfer indicator line”.	

**V1.4.11**

Page 21	<b>Section 26.3.10, “BBB Slave Interface”.</b> Spelling mistake. “ENDINT” corrected to “ENDINIT”.	
All	Cosmetic Update of Tables. No customer relevant updates.	

**V1.4.12**

Page 52	<b>Section 26.4.</b> Register summary table updated to add 32 bit access restriction to each register
